Asset pricing under optimal contracts

Jakša Cvitanić (Caltech)

joint work with

Hao Xing (LSE)

Thera Stochastics - A Mathematics Conference in Honor of Ioannis Karatzas
Motivation and overview

- Existing literature:
  - Prices are fixed, optimal contract is found
  - Contract is fixed, prices are found in equilibrium
- An exception: Buffa-Vayanos-Woolley 2014 [BVW 14]
- However, [BVW 14] still severely restrict the set of admissible contracts
- We allow more general contracts and explore equilibrium implications
Literature

- **Fixed contracts:**
  - Brennan (1993)
  - Cuoco-Kaniel (2011)
  - He-Krishnamurthy (2011)
  - Lioui and Poncet (2013)
  - Basak-Pavlova (2013)

- **Fixed prices:**
  - Sung (1995)
  - Cadenillas, Cvitanić and Zapatero (2007)
  - Leung (2014)
  - Cvitanić, Possamai and Touzi, CPT (2016, 2017)
Optimal contract is obtained within the class

\[
\text{compensation rate} = \phi \times \text{portfolio return} - \chi \times \text{index return}.
\]

Our questions:

1. What is the optimal contract when investors are allowed to optimize in a larger class of contracts?
   (Linear contract is optimal in [Holmstrom-Milgrom 1987])

2. What are the equilibrium properties?
The optimal contract depends on the output, its **quadratic variation**, the contractible sources of risk (if any), and the **cross-variations** between the output and the risk sources.
Our results

- Computing the optimal contract and equilibrium prices

- Optimal contract rewards Agent for taking specific risks and not only the systematic risk

- Stocks in large supply have high risk premia, while stocks in low supply have low risk premia

- Equilibrium asset prices distorted to a lesser extent:

  Second order sensitivity to agency frictions compared to the first order sensitivity in [BVW 14].
Outline

Introduction

Model [BVW 14]

Main results

Mathematical tools
Assets

Riskless asset has an exogenous constant risk-free rate $r$.

Prices of $N$ risky assets will be determined in equilibrium.

Dividend of asset $i$ is given by

$$D_{it} = a_i p_t + e_{it},$$

where $p$ and $e_i$ follow Ornstein-Uhlenbeck processes

$$dp_t = \kappa^p (\bar{p} - p_t)dt + \sigma_p dB^p_t,$$

$$de_{it} = \kappa_i^e (\bar{e}_i - e_{it})dt + \sigma_{e_i} dB^e_{it}.$$

Vector of asset excess returns per share

$$dR_t = D_t dt + dS_t - rS_t dt.$$

The excess return of index

$$l_t = \eta' R_t,$$

where $\eta = (\eta_1, \ldots, \eta_N)'$ are the numbers of shares of assets in the market.
Available shares

Number of shares available to trade:
\[ \theta = (\theta_1, \ldots, \theta_N)' \]
(Some assets may be held by buy-and-hold investors.)

We assume that \( \eta \) and \( \theta \) are not linearly dependent. (Manager provides value to Investor.)
Portfolio manager

Portfolio manager’s wealth process follows

\[ d\tilde{W}_t = r\tilde{W}_t dt + (bm_t - \bar{c}_t)dt + dF_t, \]

- \( \bar{c}_t \) is Manager’s consumption rate
- \( F_t \) is the cumulative compensation paid by Investor
- \( bm_t \) is the private benefit from his shirking action \( m_t \), \( b \in [0, 1] \), [DeMarzo-Sannikov 2006]
- No private investment
- Chooses portfolio \( Y \) for Investor
Investor

The reported portfolio value process:

\[ G = \int_0^\cdot (Y_s' dR_s - m_s ds). \]

Investor observes only \( G \) and \( I \).

Her wealth process follows

\[ dW_t = rW_t dt + dG_t + y_t dl_t - c_t dt - dF_t, \]

- \( Y_t \) is the vector of the numbers of shares chosen by Manager
- \( y_t \) is the number of shares of index chosen by Investor
- \( c_t \) is Investor’s consumption rate
- \( m_t \) is Manager’s shirking action, assumed to be nonnegative
Manager’s optimization problem

Manager maximizes utility over intertemporal consumption:

\[
\bar{V} = \max_{\bar{c}, m, Y} \mathbb{E} \left[ \int_0^{\infty} e^{-\delta t} u_A(\bar{c}_t) dt \right],
\]

- \( \bar{\delta} \) is Manager’s discounting rate

- \( u_A(\bar{c}) = -\frac{1}{\bar{\rho}} e^{-\bar{\rho} \bar{c}} \)
Manager’s optimization problem

Manager maximizes utility over intertemporal consumption:

$$\bar{V} = \max_{\bar{c}, m, Y} \mathbb{E} \left[ \int_0^\infty e^{-\bar{\delta} t} u_A(\bar{c}_t) dt \right],$$

- $\bar{\delta}$ is Manager’s discounting rate
- $u_A(\bar{c}) = -\frac{1}{\bar{\rho}} e^{-\bar{\rho} \bar{c}}$

If Manager is not employed by Investor, he maximizes

$$\bar{V}^u = \max_{\bar{c}^u, Y^u} \mathbb{E} \left[ \int_0^\infty e^{-\bar{\delta} t} u_A(\bar{c}_t^u) dt \right]$$

subject to budget constraint

$$d\bar{W}_t = r\bar{W}_t + Y^u_t dR_t - \bar{c}_t^u dt.$$

Manager takes the contact if $\bar{V} \geq \bar{V}^u$. 
Investor’s maximization problem

Investor maximizes utility over intertemporal consumption:

\[ V = \max_{c,F,y} \mathbb{E} \left[ \int_0^\infty e^{-\delta t} u_P(c_t) dt \right], \]

- \( \delta \) is Investor’s discounting rate
- \( u_P(c) = -\frac{1}{\rho} e^{-\rho c} \)
Investor’s maximization problem

Investor maximizes utility over intertemporal consumption:

\[
V = \max_{c,F,y} \mathbb{E} \left[ \int_0^\infty e^{-\delta t} u_P(c_t) dt \right],
\]

- \( \delta \) is Investor’s discounting rate
- \( u_P(c) = -\frac{1}{\rho} e^{-\rho c} \)

If Investor does not hire Manager, she maximizes

\[
V^u = \max_{c^u,y^u} \mathbb{E} \left[ \int_0^\infty e^{-\delta t} u_P(c^u_t) dt \right]
\]

subject to budget constraint

\[
dW_t = rW_t + y^u_t dl_t - c^u_t dt.
\]

Investor hires Manager if \( V \geq V^u \).
Equilibrium

A price process $S$, a contract $F$ in a class of contracts $\mathcal{F}$, and an index investment $y$, form an equilibrium if

1. Given $S$, $(F, \mathcal{F})$, and $y$, Manager takes the contract, and $Y = \theta - y \eta$ solves Manager’s optimization problem.

2. Given $S$, Investor hires Manager, and $(F, y)$ solves Investor’s optimization problem, and $F$ is the optimal contract in $\mathcal{F}$. 
Outline

Introduction

Model [BVW 14]

Main results

Mathematical tools
Asset prices

There exists an equilibrium with asset prices $S_{it} = a_{0i} + a_{pi} p_t + a_{ei} e_{it}$ (assuming $\theta$ and $\eta$ are not linearly dependent.)

Setting $a_p = (a_{p1}, \ldots, a_{pN})'$ and $a_e = \text{diag}\{a_{e1}, \ldots, a_{eN}\}$, we have

$$a_{pi} = \frac{a_i}{r + \kappa_p}, \quad a_{ei} = \frac{1}{r + \kappa_i^e}, \quad i = 1, \ldots, N,$$

(assuming the matrix $\Sigma_R = a_p \sigma_p^2 a_p' + a_e \sigma_e^2 a_e$ is invertible.)
There exists an equilibrium with asset prices $S_{it} = a_{0i} + a_{pi}p_t + a_{ei}e_{it}$ (assuming $\theta$ and $\eta$ are not linearly dependent.)

Setting $a_p = (a_{p1}, \ldots, a_{pN})'$ and $a_e = \text{diag}\{a_{e1}, \ldots, a_{eN}\}$, we have

$$a_{pi} = \frac{a_{i}}{r + \kappa_p}, \quad a_{ei} = \frac{1}{r + \kappa_i^e}, \quad i = 1, \ldots, N,$$

(assuming the matrix $\Sigma_R = a_p\sigma_p^2a_p' + a_e\sigma_E^2a_e$ is invertible.)

Notation:

$$\begin{align*}
\text{Var}^\eta &= \eta'\Sigma_R\eta, \\
\text{Covar}^{\theta,\eta} &= \eta'\Sigma_R\theta,
\end{align*}$$

CAPM beta of the fund portfolio: $\beta^\theta = \frac{\text{Covar}^{\theta,\eta}}{\text{Var}^\eta}.$
Asset Returns

Asset excess returns are

\[ \mu - r = r \frac{\rho \bar{\rho}}{\rho + \bar{\rho}} \Sigma R \theta + r D_b \Sigma R (\theta - \beta^\theta \eta), \]

where

\[ D_b = (\rho + \bar{\rho}) \left( b - \frac{\rho}{\rho + \bar{\rho}} \right)^2. \]

- When \( b \in [0, \frac{\rho}{\rho + \bar{\rho}}] \), the first best is obtained.

- When \( \frac{\theta_i}{\eta_i} > \beta^\theta \), risk premium of asset \( i \) increases with \( b \).

- When \( \frac{\theta_i}{\eta_i} < \beta^\theta \), risk premium of asset \( i \) decreases with \( b \).
Asset prices/returns

In [BVW 14], $\mathcal{D}_b$ is replaced by

$$\mathcal{D}_b^{BVW} = \bar{\rho} \left( b - \frac{\rho}{\rho + \bar{\rho}} \right)^+.$$ 

Note that

$$\mathcal{D}_b < \mathcal{D}_b^{BVW}, \quad \text{for any } b \in (0, 1).$$

**Figure:** Solid lines: our result; Dashed lines: [BVW 14].
Index and portfolio returns

Excess return of the index

\[
\eta'(\mu - r) = r \frac{\rho \bar{\rho}}{\rho + \bar{\rho}} \text{Covar}^{\theta,\eta}. 
\]

Excess return of Manager’s portfolio

\[
\theta'(\mu - r) = r \frac{\rho \bar{\rho}}{\rho + \bar{\rho}} \text{Var}^{\theta} + r \mathcal{D}_b \left( \text{Var}^{\theta} - \frac{(\text{Covar}^{\theta,\eta})^2}{\text{Var}^{\eta}} \right). 
\]

Figure: Solid line: our result, Dashed line: [BVW 14]
**Optimal contract**

\[ dF_t = Cdt + \frac{\rho}{\rho + \bar{\rho}} dG_t + \xi (dG_t - \beta^0 dl_t) + \frac{r}{2} \zeta d\langle G - \beta^0 l, G - \beta^0 l \rangle_t \]

- **Optimality in a large class of contracts**
- **Conjecture:** It is optimal in general.

- \( \xi = (b - \frac{\rho}{\rho + \bar{\rho}})_+, \ zeta = (\rho + \bar{\rho})(b + \xi)(1 - b - \xi)\xi \)

- When \( b \leq \frac{\rho}{\rho + \bar{\rho}} \), \( \xi = \zeta = 0 \), only the first two terms show up. The return of the fund is shared between investor and portfolio manager with ratio \( \frac{\rho}{\rho + \bar{\rho}} \).

**BVW 14** contract corresponds to the two terms in the middle.

- The quadratic variation term is new.

- The term \( \langle G - \beta^0 l, G - \beta^0 l \rangle \) rewards Manager to take the specific risk of individual stocks, and not only the systematic risk of the index.
Optimal strategy

Manager’s vector of optimal holdings is given by

\[ Y^* = \frac{1}{r} \frac{1}{C_b} \Sigma_R^{-1} (\mu - r) + \frac{1}{r} \left( \frac{\rho + \bar{\rho}}{\rho \bar{\rho}} \frac{D_b}{C_b} \right) \frac{\eta'(\mu - r)}{\text{Var}\eta} \eta, \]  

(1)

where

\[ D_b = (\rho + \bar{\rho})(b - \frac{\rho}{\rho + \bar{\rho}})^2, \]  

(2)

\[ C_b = \frac{\rho \bar{\rho}}{\rho + \bar{\rho}} + D_b. \]
Optimal contract

When \( b \geq \frac{\rho}{\rho + \bar{\rho}} \),

\( \xi \) is increasing in \( b \), so as to make Manager to not employ the shirking action.

Dependence of \( \zeta \) on \( b \):
New contract improves Investor’s value

For the asset price in [BVW 14], Investor’s value is improved by using the new contract.

Figure: Solid line: our contract, Dashed line: [BVW 14]
Admissible contracts: motivation

For any Manager’s admissible strategy \( \Xi = (\bar{c}, Y, m) \), consider
\[
\Xi^t = \{ \hat{\Xi} \text{ admissible} \mid \hat{\Xi}_s = \Xi_s, s \in [0, t] \}.
\]

Define Manager’s continuation value process \( \bar{V}(\Xi) \) as
\[
\bar{V}_t(\Xi) = \text{ess sup}_{\Xi^t} E_t \left[ \int_t^\infty e^{-\bar{\delta}(s-t)} u_A(\bar{c}_s) ds \right], \quad t \geq 0.
\]
Admissible contracts: motivation

For any Manager’s admissible strategy \( \Xi = (\bar{c}, Y, m) \), consider

\[
\Xi^t = \{ \hat{\Xi} \text{ admissible} \mid \hat{\Xi}_s = \Xi_s, s \in [0, t] \}.
\]

Define Manager’s *continuation value process* \( \tilde{V}(\Xi) \) as

\[
\tilde{V}_t(\Xi) = \text{ess sup}_{\Xi^t} \mathbb{E}_t \left[ \int_{t}^{\infty} e^{-\delta(s-t)} u_A(\bar{c}_s) ds \right], \quad t \geq 0.
\]

(i) \( \partial_{\tilde{W}_t} \tilde{V}_t(\Xi) = -r \bar{\rho} \tilde{V}_t(\Xi); \)

(ii) Transversality condition: \( \lim_{t \to \infty} \mathbb{E} \left[ e^{-\delta t} \tilde{V}_t(\Xi) \right] = 0; \)

(iii) Martingale principle:

\[
\tilde{V}_t(\Xi) = e^{-\delta t} \tilde{V}_t(\Xi) + \int_{0}^{t} e^{-\delta s} u_A(\bar{c}_s) ds,
\]

is a supermartingale for arbitrary admissible strategy \( \Xi \), and is a martingale for the optimal strategy \( \Xi^* \).
Admissible contracts: definition
(Motivated by CPT (2016), (2017))

A contract $F$ is admissible if

1. there exists a constant $\bar{V}_0$,
2. for any Agent’s strategy there exist $\mathbb{F}^{G,I}$-adapted processes $Z, U, \Gamma^G, \Gamma^I, \Gamma^{GI}$ such that the process $\bar{V}(\Xi)$, defined via

$$d\bar{V}_t(\Xi) = X_t[(bm_t - \bar{c}_t)dt + Z_t dG_t + U_t dI_t$$

$$+ \frac{1}{2} \Gamma_t^G d\langle G, G \rangle_t + \frac{1}{2} \Gamma_t^I d\langle I, I \rangle_t + \Gamma_t^{GI} d\langle G, I \rangle_t]$$

$$+ \delta \bar{V}_t(\Xi)dt - H_t dt, \quad \bar{V}_0(\Xi) = \bar{V}_0,$$

where $X_t = -r\bar{\rho}\bar{V}_t(\Xi)$ and $H$ is the Hamiltonian

$$H = \sup_{\bar{c}, m \geq 0, \gamma} \left\{ u_A(\bar{c}) + X \left[ bm - \bar{c} - Zm + ZY'(\mu - r) + U\eta'(\mu - r) \right. \right.$$

$$+ \frac{1}{2} \Gamma^G Y'\Sigma_R Y + \frac{1}{2} \Gamma^I \eta' \Sigma_R \eta + \Gamma^{GI} Y' \Sigma_R \eta \left. \right\},$$

satisfies $\lim_{t \to \infty} \mathbb{E}[e^{-\delta t} \bar{V}_t(\Xi)] = 0.$
Manager’s optimal strategy

Lemma

Given an admissible contract with

\[ X > 0, \quad Z \geq b, \quad \text{and} \quad \Gamma^G < 0, \]

the Manager’s optimal strategy is the one maximizing the Hamiltonian,

\[ \bar{c}^* = (u'_A)^{-1}(X), \quad m^* = 0, \]

\[ Y^* + y\eta = -\frac{Z}{\Gamma^G} \sum_{R}^{-1}(\mu - r) - \frac{\Gamma^{Gl}}{\Gamma^G} \eta, \]

and we have

\[ \bar{V}(\Xi) = \hat{V}(\Xi). \]
Do we lose on generality?

[CPT 2016, 2016] considered the finite horizon case,

\[d\tilde{V}_t = X_t \left[ b m_t dt + Z_t dG_t + U_t dl_t + \frac{1}{2} \Gamma^G_t d\langle G, G \rangle_t + \frac{1}{2} \Gamma^I_t d\langle I, I \rangle_t + \Gamma^G_I t d\langle G, I \rangle_t \right] - H_t dt.\]

\(\tilde{V}_T = C_T\) is the lump-sum compensation paid.

They showed the set of \(C\) that can be represented as \(\tilde{V}_T\) is dense in the set of all (reasonable) contracts. Hence, there is no loss of generality in their framework.

Their proof is based on the 2BSDE theory, e.g., [Soner-Touzi-Zhang 2011,12,13].

**Conjecture:** A similar result holds for the infinite horizon case. (Work in progress by Lin, Ren, and Touzi.)
Representation of admissible contracts

Lemma

An admissible contract $F$ can be represented as

$$
\begin{align*}
\dF_t &= Z_t \dG_t + U_t \dl_t + \frac{1}{2} \Gamma^G_t \d\langle G, G \rangle_t + \frac{1}{2} \Gamma^I_t \d\langle I, I \rangle_t + \Gamma^G_{t} \d\langle G, I \rangle_t \\
&\quad + \frac{1}{2} r \bar{\rho} \d\langle Z \cdot G + U \cdot I, Z \cdot G + U \cdot I \rangle_t - \left( \frac{\delta}{r \bar{\rho}} + \bar{H}_t \right) \dt,
\end{align*}
$$

where $Z \cdot G = \int_0^t Z_s \dG_s$ and

$$
\bar{H}_t = \frac{1}{\bar{\rho}} \log(-r \bar{\rho} \bar{V}_0) - \frac{1}{\bar{\rho}} + (Z_t Y^*_t + U_t \eta)'(\mu_t - r) \\
+ \frac{1}{2} \Gamma^G_t (Y^*_t)' \Sigma R Y^*_t + \frac{1}{2} \Gamma^I_t \eta' \Sigma R \eta + \Gamma^G_{t} (Y^*_t)' \Sigma R \eta.
$$

In particular, $F$ is adapted to $\mathbb{F}^{G, I}$ (as it should be).
Investor’s problem

1. Guess Investor’s value function

\[ V(w) = K e^{-r \rho w}, \]

2. Treat \( Z, U, \Gamma^G, \Gamma^G \) as Investor’s control variables.

3. Work the with HJB equation satisfied by \( V \).
Conclusion

- We find an asset pricing equilibrium with the contract optimal in a large class. (Maybe the largest.)

- Price/return distortion less sensitive to agency frictions.

- The contract also based on the second order variations.

Future work:

- Square root, CIR dividend processes
Happy birthday Yannis!
