EIGENVARIEITIES FOR REDUCTIVE GROUPS

ERIC URBAN

Abstract. We develop the theory of overconvergent cohomology introduced by G. Stevens and we use it to give a construction of Eigenvarieties associated to any reductive group $G$ over $\mathbb{Q}$ such that $G(\mathbb{R})$ has discrete series. We prove that the so-called Eigenvarieties are equidimensional and flat over the weight space.

0. Introduction

The theory of $p$-adic families of automorphic forms has known many developments since the original breakthrough of H. Hida in the early eighties who constructed $p$-adic families of ordinary modular cusp eigenforms. His results were further extended to finite slope modular forms by Coleman using the $p$-adic spectral theory of the Atkin $U_p$ operator and the construction by Coleman-Mazur of the Eigencurve brought a more geometric and global aspect to the theory.

Although Hida’s original approach as well as Coleman’s strategy were built on Katz’ theory of $p$-adic and overconvergent modular forms, the cohomological method, whose idea is originally due to Shimura, using cohomology of arithmetic subgroups to study congruences between Hecke eigenvalues led several authors following H. Hida in the ordinary case and G. Stevens in the finite slope case to construct families of Hecke eigensystems for reductive groups $G$ over $\mathbb{Q}$ whose archimedean part $G(\mathbb{R})$ is compact modulo center. For example, see [Bu04, Ch04, Em06]. However, the extension of these techniques for more general reductive group were hindered by the difficulty to handle the torsion of the cohomology of the corresponding arithmetic subgroups.

In this paper, we by-pass this difficulty for groups $G$ such that $G^{der}(\mathbb{R})$ satisfy the Harish-Chandra condition\(^2\) (i.e. containing a compact Cartan subgroup) and construct $p$-adic families of automorphic (cuspidal) representations for $G$. In particular, we construct Eigenvarieties associated to such

---

During the preparation of this work, the author was supported by grants from the National Science Foundation and by a fellowship from the Guggenheim Foundation.

\(^1\)The original geometric approach has also been also generalized by Hida to all Shimura varieties of PEL type and also in some non-ordinary case by other authors. See for example [K04, K06, KL05, SU06b].

\(^2\)For example it applies to any unitary or symplectic groups over a totally real field.
groups whose points are in bijection with automorphic representations having non trivial Euler-Poincaré characteristic and we prove that it is equidi-
mensional of the expected dimension. The main difference between our
approach and other authors’ strategy is to work with the total cohomol-
ogy instead of studying the cohomology separately in each degree. More
precisely, we work with some kind of “perfect complex” that computes the
cohomology of the corresponding arithmetic groups with coefficients in a
family of certain $p$-adic distribution spaces. Moreover, instead of trying to
construct a universal module that interpolates the cohomology when the
weight of the system of coefficients varies, we rather make a $p$-adic analytic
interpolation of the trace of the Hecke operators acting on the total coho-
mology. Our approach is somehow similar to Wiles’ idea of constructing
families of Galois representations by the use of pseudo-representations. We
give two applications of the $p$-adic analyticity property with respect to the
weight of these traces. One concerns the construction of Eigenvarieties and
therefore of $p$-adic families of automorphic representations. We give actu-
ally an axiomatic treatment of the construction of Eigenvarieties from the
existence of $p$-adic analytic families of traces of Hecke operators. The other
one is to derive a $p$-adic trace formula in geometric terms very similar to the
one by Arthur-Selberg.

For groups $G$ such that $G(\mathbb{R})$ do not satisfy Harish-Chandra condition,
like $GL_n$ with $n > 2$, our method provides evidences that the reason of the
presence of torsion is related to the vanishing of the Euler-Poincaré charac-
teristic of the $\pi$-isotypical component of the cohomology when $\pi$ is a cuspidal
representation of $G(\mathbb{A})$. In fact, for $GL_3/\mathbb{Q}$, Ash and Stevens have noticed
that certain cuspidal representations do not lie in a $p$-adic family and came
up with a conjecture that says vaguely that a cuspidal representation can be
deformed $p$-adically in a family of classical cuspidal representations if and
only if it is essentially self-dual. According to Langlands’ philosophy, all such
representations should come from orthogonal or symplectic groups, and the
“if” part of this conjecture would follow from our result applied to these
classical groups. Surprisingly, it turns out that our method can be modi-
fied in order to give a proof of this without assuming Langlands’transfer
principle (see section 5.6).

After I gave several lectures on this work, I learned that M. Koike and L.
Clozel had worked on a somehow similar approach in the past, similar in
the sense that they also proved some continuity statement w.r.t the weight
of the trace of the Hecke operators (see Clozel’s unpublished manuscript
[Cl93] and Koike’s papers [Ko75, Ko76]) by using the explicit form of the

---

3For $G = GL(2)/K$ with $K$ imaginary quadratic, Calegari and Mazur have remarked
the same phenomena.

4I am grateful to D. Vogan for drawing my attention to the fact that the twisted Euler
characteristic by a Cartan type involution is non trivial for most of the cohomological
representations.
Selberg trace formula. Our approach differs from theirs in two ways. Firstly, we don’t use an explicit form of the trace formula to prove the analyticity statement and we use $p$-adic spectral theory on the Banach spaces defined by the locally analytic induction of $p$-adic characters. Secondly, our trace is a trace of a compact operator acting on a complex of $p$-adic Banach spaces although theirs is the usual classical trace computed by Arthur-Selberg. As a by-product, we have obtained a $p$-adic trace formula. We hope to give some applications of it in the future.

To illustrate our work, we now give a description of a special case of our main result on the existence of $p$-adic families of automorphic representations. We want to stress upon the fact that we have constructed here deformations of automorphic representations rather than deformations of automorphic forms as it is done usually in the literature. It has especially the advantage to give a better control of the informations at the ramified places. This fact is very useful for applications like in [SU06a, SU06b].

We fix $G$ a reductive group such that $G(\mathbb{R})$ has discrete series. Let $S_G(K)$ be the locally symmetric space associated to $G$ and a neat open subgroup $K$ of the finite adelic points of $G$. Let $\pi$ be an automorphic representation of $G(\mathbb{A})$ occurring in the cohomology of $S_G(K)$ with the system of coefficient $\mathcal{F}_{\lambda^{alg}}(\mathbb{C})$ the dual of the irreducible algebraic representation of highest weight $\lambda^{alg}$ with respect to some Borel pair. Such a representation will be called automorphic and cohomological of weight $\lambda^{alg}$. It can be seen (and we will see such a representation in this way) as a representation of the Hecke algebra of the $\mathbb{Q}$-valued locally constant functions on $G(\mathbb{A})$ with compact support that we denote $C^{\infty}_c(G(\mathbb{A}), \mathbb{Q})$.

We now fix a prime $p$. For simplicity let us assume in this introduction that $G$ splits over $\mathbb{Q}_p$ and fix a Borel pair $(B, T)$. Let $R^+$ be the set of the corresponding positive roots. We denote by $I$ an Iwahori subgroup of $G(\mathbb{Q}_p)$ in good position w.r.t. $(B, T)$. More generally, we denote $I_m$ the Iwahori subgroup of depth $m$ defined by

$$I_m := \{g \in G(\mathbb{Z}_p) | g \pmod{p^m} \in B(\mathbb{Z}/p^m\mathbb{Z})\}$$

We consider the semi-group

$$T^- := \{t \in T(\mathbb{Q}_p) | |\alpha(t)|_p \leq 1 \forall \alpha \in R^+\}$$

and we denote $T^- \subset T^-$ the sub-monoid of elements $t$ such that the inequalities in the above definition are strict. Then put $\Delta^- := I.T^- . I$ and $\Delta^- := I.T^- . I$. We consider $\mathcal{U}_p$ the local Hecke algebra\(^5\) at $p$ generated over $\mathbb{Z}_p$ by the characteristic function of the double classes $u_t := I_m u I_m$. Let $K^p \subset G(\mathbb{A})$ be an open compact subgroup of the finite adelic points of $G$

----

\(^5\)It is an easy fact that the structure of this algebra does not depend upon $m$. Hence we have dropped $m$ from the notation.
away from $p$. We now consider
\[ \mathcal{H}_p(K^p) := C^\infty_c(K^p \backslash G(\mathbb{A}^p)/K^p, \mathbb{Q}_p) \otimes \mathcal{U}_p \subset C^\infty_c(G(\mathbb{A}_f), \mathbb{Q}_p) \]
where the left hand side of the tensor product denotes the the locally constant function on $G(\mathbb{A}_f)$ with compact support which are bi-invariant by $K^p$. We call \textbf{finite slope representations} of $G$ of level $K^p$, the finite dimensional representations of $\mathcal{H}_p(K^p)$ over a complete field extension of $\mathbb{Q}_p$ such that for each $t \in T^-$, the double class $u_t$ acts as an invertible automorphism. In particular, if such a representation is irreducible, the $u_t$'s act by multiplication by non zero scalars.

Let $\pi$ be a cohomological automorphic representation. Let us choose $K^p \subset G(\mathbb{A}_f^p)$ and some sufficiently deep pro-$p$-Iwahori subgroup $I'_m$ such that $\pi_f^{K^p, I'_m} \neq 0$. We consider the action of $I_m/I'_m \cong T(\mathbb{Z}/p^m\mathbb{Z})$ on this subspace and choose a character $\epsilon$ of this group such that the $\epsilon$-isotypical component of $\pi_f^{K^p, I'_m}$ is non trivial. Then we have an action of $\mathcal{H}_p(K^p)$ on $\pi_f^{K^p, I'_m} \otimes \epsilon^{-1}$. An irreducible constituent of the representation of $\mathcal{H}_p(K^p)$ acting on this space will be called a $p$-\textbf{stabilization} of $\pi$. The finite slope irreducible representations of $\mathcal{H}_p(K^p)$ obtained in this way will be called \textbf{finite slope classical automorphic} representations of weight $\lambda = \lambda_{alg} + \epsilon$ that we consider as a $p$-adic valued continuous character of $T(\mathbb{Z}_p)$. If the original $\pi$ is cuspidal, a $p$-stabilization of it will be called cuspidal too.

Fix $S$ a finite set of primes such that the open subgroup $K^p \subset G(\mathbb{A}_f^p)$ is maximal hyperspecial away from $S$. Then consider $R_{S,p}$ the abstract Hecke algebra defined as the sub-algebra of $\mathcal{H}_p(K^p)$ of $\mathbb{Z}_p$-valued locally constant functions with compact support contained in $G(\mathbb{A}_f^{S \cup \{p\}}, \Delta)$. Note that $R_{S,p}$ is contained in the center of $\mathcal{H}_p(K^p)$. Therefore the action of $R_{S,p}$ on a finite slope representation $\sigma$ of $\mathcal{H}_p(K^p)$ is given by multiplication by a character $\theta_\sigma$ of $R_{S,p}$.

Let $\pi_0$ be a finite slope irreducible cuspidal representation of $G(\mathbb{A})$ of weight $\lambda_0$. We normalize this action so that the double class $u_t$ acts by multiplying the usual standard action by $|\lambda_0(t)|_p^{-1}$ and we denote $\theta_0$ the corresponding character of $R_{S,p}$.

We say that $\theta_0$ is not critical with respect to $\lambda_0$ if for some $t \in T^-$ we have
\[ v_p(\theta_0(u_t)) < (\lambda_0(H_\alpha) + 1)v_p(\alpha(t)) \]
for each simple root $\alpha$, with $H_\alpha$ denotes the corresponding co-root.

Finally, we introduce the weight space. Let $Z_p = Z_p(K^p)$ be the $p$-adic closure of the image of $Z(\mathbb{Q}) \cap K^p.T(\mathbb{Z}_p)$ in $T(\mathbb{Z}_p)$ for some $K^p$ neat and hyperspecial maximal away from $S$. It easy to see that $Z_p$ does not depend of $K^p$ but only of $S$. If $G$ is $\mathbb{Q}$-split, then $Z_p$ is trivial; otherwise, its rank is related to the rank of some units and also some Leopoldt defect. Our weight space is the rigid analytic space $X = X_{K^p}$ defined over $\mathbb{Q}_p$ such that
\( \chi(\mathbb{Q}_p) = \text{Hom}_{\text{cont}}(T(\mathbb{Z}_p)/\mathbb{Z}_p, \mathbb{Q}_p^\times) \). Then we have the following theorem (See subsection 5.4.3).

**Theorem:** Assume that \( \theta_0 \) is not critical with respect to \( \lambda_0 \) and that the algebraic part of \( \lambda_0 \) is dominant regular. Then, there exists

1. an affinoid open neighborhood \( \mathcal{U} \subset \mathcal{X} \) of \( \lambda_0 \),
2. a generically flat finite cover \( \mathcal{V} \) of \( \mathcal{U} \) with structural morphism \( w \),
3. a homomorphism \( \theta_{\mathcal{V}} \) from \( R_{S,p} \) to the ring \( \mathcal{O}(\mathcal{V}) \) of analytic functions on \( \mathcal{V} \),
4. a distribution character \( I_{\mathcal{V}} : H_p(K_p) \rightarrow \mathcal{O}(\mathcal{V}) \),
5. a point \( y_0 \in \mathcal{V}(\mathbb{Q}_p) \) above \( \lambda_0 \),
6. a Zariski dense subset \( \Sigma \subset \mathcal{V}(\mathbb{Q}_p) \) such that \( w(y) \) is algebraic regular dominant \( \forall y \in \Sigma \),
7. for each \( y \in \Sigma \), a non empty set \( \Pi_y \) of finite slope irreducible automorphic representation of weight \( \lambda_y = w(y) = \lambda_{alg}^{\Pi_y} \epsilon_y \),

satisfying the following:

i. The specialization of \( \theta_{\mathcal{V}} \) at \( y_0 \) is equal to \( \theta_0 \),
ii. For any \( y \in \Sigma \), the specialization \( \theta_y \) of \( \theta_{\mathcal{V}} \) at \( y \) is a character occurring in the representation of \( R_{S,p} \) in \( \pi^{I_{\mathcal{V}}}_{i=0} \) for all \( \pi \in \Pi_y \).
iii. For each \( y \in \Sigma \), the specialization \( I_y \) of \( I_{\mathcal{V}} \) at \( y \) satisfies:

\[
I_y(f) = \sum_{\pi \in \Pi_y} m(\pi, \lambda) I_{\pi}(f)
\]

for all \( f \in H_p(K_p) \) where \( m(\pi, \lambda) \) is the Euler-Poincaré characteristic of \( \pi \) in \( H^*(\tilde{S}_G, \mathcal{V}_\lambda^\vee) \) defined as

\[
m(\pi, \lambda) := \sum_{i} (-1)^i \dim \text{Hom}_{H_p(K_p)}(\pi^{K_p I_m}, H^i_{\text{cusp}}(\tilde{S}_G(K_p I_m), \mathcal{V}_\lambda^\vee))
\]

where \( f \mapsto I_{\pi}(f) \) is the trace distribution \( f \mapsto \text{tr}(\pi(f)) \) defined on \( H_p(K_p) \).

Moreover, the distribution character \( I_{\mathcal{V}} \) can be chosen such that \( \Pi_y \) be a singleton for a Zariski dense subset of \( \Sigma \).

In a recent preprint, Ash-Stevens have constructed\(^6\) all we need to construct the total Eigenvariety for any reductive group (see [AS06]). By total, we mean that the points occurring in that Eigenvariety are in bijections with systems of Hecke eigenvalues of finite slope occurring in the cohomology with coefficients in a Banach space of \( p \)-adic distributions (and not only those having a non trivial Euler-Poincaré characteristic). However, their result does not give any informations about the dimension of the irreducible

\(^6\)They have actually constructed local pieces of the total Eigenvariety. A global construction has been recently carried out by Z. Xiang in [Xi10].
components. Our construction gives a complete description of the components of the Eigenvariety having the same dimension as weight space. When the group is anisotropic, it is exactly the set of Hecke eigensystems having a non trivial Euler-Poincaré characteristic. In general, we describe it as a union of cuspidal and various Eisenstein components. In section 5.4 of the present paper, we present a conjecture for the dimension of the irreducible component passing through a given point of the Eigenvariety in terms of the multiplicities of the corresponding system of Hecke eigenvalues in the various degrees of the cohomology. It is also worth noticing that these components do not always\textsuperscript{7} contain a Zariski dense subset of classical points (i.e attached to a classical automorphic representation). I hope this paper will convince the reader that the good framework to study $p$-adic automorphic representations and their families is the one of derived category.

We now give a brief description of the content of the different sections. In section 1, we introduce the basic notations and we give a brief account of the cohomology of arithmetic groups with algebraic coefficients. Especially, we recall the main important results of Borel-Wallach, Saper, Li-Schwermer and Franke. In section 2, we introduce some formalism of derived category of complex of Banach spaces and the spectral theory of compact operators acting on them. In the section 3, we define the locally $p$-adic analytic induction spaces “à la Ash-Stevens-Hida” that will be used to define what we have called the “overconvergent cohomology”. In section 4, we study this cohomology and we prove that the trace of the compact operators $u_t$ acting on it is an analytic function of the weight $\lambda \in \mathcal{X}(\mathbb{Q}_p)$. We also introduce the notion of effective finite slope character distribution which is a linear functional on the Hecke algebras $\mathcal{H}_p(K^p)$ that behaves like the trace of compact operator acting on a $p$-adic Banach space. In section 5, we make an axiomatic construction of Eigenvariety associated to analytic families of effective finite slope distribution and we apply it to the analytic families of finite slope distribution constructed in the previous chapter. In section 6, we establish some $p$-adic trace formulae interpolating Arthur’s and Franke’s trace formulae.

\textbf{Acknowledgments.} It will be obvious to the reader that this work is much influenced by the works of Ash-Stevens, Coleman-Mazur and Hida. But it is especially my pleasure to thank H. Hida for many inspiring conversations all over the years and also for pointing out a few inaccuracies in an early version of this paper. I would also like to thank A. Ash, L. Clozel, M. Harris, B. Mazur, C. Skinner, G. Stevens, J. Tilouine and D. Vogan for useful conversations during the preparation of this work. I am also grateful to the organizers of the Eigenvarieties semester at Harvard in the spring 2006 for giving me the opportunity to think about these questions again. I would

1. Cohomology of arithmetic groups

1.1. Notations and conventions.

1.1.1. General notations. We denote respectively by \( \mathbb{Q} \), \( \mathbb{R} \) and \( \mathbb{C} \) the fields of rational, real and complex numbers. For any prime \( p \), \( \mathbb{Q}_p \) is the field of \( p \)-adic numbers and we denote by \( \mathbb{C}_p \) the closure of an algebraic closure \( \overline{\mathbb{Q}}_p \) of \( \mathbb{Q}_p \). Throughout this paper, we fix \( \overline{\mathbb{Q}} \) an algebraic closure of \( \mathbb{Q} \) and embeddings \( \iota_\infty \) and \( \iota_p \) of \( \overline{\mathbb{Q}} \) into \( \mathbb{C} \) and \( \mathbb{C}_p \). Any number field \( M \) will be considered as a subfield of \( \overline{\mathbb{Q}} \).

We denote by \( |\cdot|_p \) the non-archimedean norm of \( \mathbb{C}_p \) normalized by \( |p|_p = p^{-1} \). We denote by \( \mathbb{A} \) the ad` ele ring over \( \mathbb{Q} \) and we fix a decomposition \( \mathbb{A} = \mathbb{A}_f \times \mathbb{R} \). If \( M \) is a number field, we will denote also \( \mathbb{A}_M = \mathbb{A} \otimes M \) and for each place \( v \) of \( M \), we write \( M_v \) for the completion of \( M \) at \( v \).

Sometimes we denote by \(|X|\) or by \(#X\) the cardinal of a finite set \( X \).

For any algebraic group \( H \) defined over \( \mathbb{Q} \), we set \( H^\infty = H(\mathbb{R}) \) and \( H^+ = H^\infty \) containing the identity. Whenever we put the superscript + to a given group, it will mean that we consider the subgroup of the elements whose infinity part belongs to the connected component of this infinity part.

1.1.2. Locally symmetric spaces and reductive groups. We fix \( G \) a connected reductive group over \( \mathbb{Q} \). We denote by \( Z = Z_G \) the center of \( G \). We fix \( P_0 \) a minimal parabolic subgroup defined over \( \mathbb{Q} \) and a Levi decomposition \( P_0 = M_0.N_0 \) and we denote by \( \mathcal{P}_G \) the set of standard parabolic subgroup \( P \) of \( G \) defined over \( \mathbb{Q} \) (i.e. those containing \( P_0 \)). We denote also \( \mathcal{L}_G \) the set of standard Levi subgroup (i.e. containing \( M_0 \)). For any Levi subgroup \( M \), we will denote by \( \mathcal{W}_M^0 \) its (rational) Weyl group i.e. \( \mathcal{W}_M^0 := N_M(M_0)/M_0 \) (Here \( N_M(M_0) \) denotes the normalizator of \( M_0 \) in \( M \)).

We fix \( K_\infty \) a maximal compact subgroup of \( G_\infty := G(\mathbb{R}) \) and put \( C_\infty^G = K_\infty.Z_\infty \). We denote by \( G_\infty^+ \) the identity component of \( G_\infty \). We also write \( G_\infty^1 \subset G_\infty^+ \) for the kernel of the map from \( G_\infty \) onto the connected component of the \( \mathbb{R} \)-split part of the co-center \( G_\infty/G_\infty^{der} \) of \( G_\infty \).

We fix \( K_{max} \subset G(\mathbb{A}_f) \) a maximal compact subgroup and \( dg \) a Haar measure of \( G_f \) such that
\[
\int_{K_{max}} dg = 1
\]
If \( K \subset G_f \) is a measurable set we write
\[
\text{Meas}(K) = \text{Meas}(K, dg) := \int_K dg.
\]

For any open compact subgroup \( K \subset G_f \), we consider the locally symmetric space
\[
S_G(K) := G(\mathbb{Q})\backslash G(\mathbb{A})/K.C_\infty^G
\]
Let $H = G^+ / C^G \cap G^+_\infty$. In all this paper, we assume that the strong approximation theorem applies to $G^{der}$. In particular, for any open compact subgroup $K \subset G_f$, we have a finite decomposition

$$G(\mathbb{A}) = \bigsqcup_i G(\mathbb{Q}) \times G^+(\mathbb{Q}) \times g_i.K$$

For any $x \in G(\mathbb{A}_f)$ and any open subgroup $K \subset G(\mathbb{A}_f)$, we set $\Gamma(x, K)$ the image of $xKx^{-1} \cap G(\mathbb{Q})^+$ in $G^{ad}(\mathbb{Q}) = G(\mathbb{Q})/Z_G(\mathbb{Q})$. Then we have

$$S_G(K) \cong \bigsqcup_i \Gamma \backslash H_G.$$  

with $\Gamma_i := \Gamma(g_i, K)$. We say that $K$ is neat if none of the $\Gamma_i := \Gamma(g_i, K)$ contains finite order elements. In that case, $S_G(K)$ is a smooth real analytic variety and for each connected component the morphism from its universal covering to itself is étale.

1.2. **Local systems and cohomology.** We will be interested in the cohomology of local systems on $S_G(K)$. They are defined by representations of the fundamental group of each connected component. We recall below different equivalent constructions of these.

1.2.1. **First definition.** If $M$ is a $\mathbb{Q}$-vector space equipped with an action of $G(\mathbb{Q})$, we set $\tilde{M}$ the local system defined as the sheaf of locally constant sections of the cover

$$\tilde{M} := G(\mathbb{Q}) \backslash (G(\mathbb{A}) \times M)/K.C_{\infty} \rightarrow G(\mathbb{Q}) \backslash G(\mathbb{A})/K.C_{\infty} = S_G(K).$$

with left action of $G(\mathbb{Q})$ and right action of $K.C_{\infty}$ defined by the formula

$$\gamma.(g, m).k := (\gamma g k, \gamma . m)$$

for any $\gamma \in G(\mathbb{Q})$, $g \in G(\mathbb{A})$, $k \in K.C_{\infty}$ and $m \in M$.

Let $Z_K := Z_G(\mathbb{Q}) \cap K$. Then a necessary condition for $\tilde{M}$ to be non trivial is that

$$Z_K \text{ acts trivially on } M$$

When this condition is satisfied, the subgroups $\Gamma(x, K)$ act on $M$. Then for each irreducible component $\Gamma \backslash \mathcal{H}$, the local system is defined by:

$$\tilde{M}_i := \Gamma \backslash (\mathcal{H}_G \times M) \rightarrow \Gamma \backslash \mathcal{H}_G$$

and the isomorphism $\tilde{M} \cong \amalg_i \tilde{M}_i$ is induced by the maps $(\gamma.g_i.g_{\infty}.k,m) \mapsto (g_{\infty}, \gamma^{-1}.m)$.
1.2.2. Second definition. If $M$ is a group which is left $K$-module, we can define also the local system

$$\tilde{M}_K := G(\mathbb{Q}) \backslash G(\mathbb{A}) \times M) / K.C_{\infty} \rightarrow G(\mathbb{Q}) \backslash G(\mathbb{A}) / K.C_{\infty} = S_G(K).$$

with left action of $G(\mathbb{Q})$ and right action of $K.C_{\infty}$ given by the formula

$$\gamma.[g,m].k := [\gamma g k^{-1}.m]$$

When the action of $K$ or $G(\mathbb{Q})$ on $M$ in the definitions (1.2.1) and (1.2.2) above extends in a compatible way to an action of $G(\mathbb{A})$, then the two defined local systems $\tilde{M}$ and $\tilde{M}_K$ coincide by the isomorphism $(g,m) \mapsto [(g,g^{-1}.m)]$. Again the sheaf $\tilde{M}$ is non trivial only if the condition (2) is satisfied.

1.2.3. Let $v$ be a place of $\mathbb{Q}$ such that the action of $K$ factorizes through the projection $K \twoheadrightarrow K_v$ with $K_v$ the image of $K$ into $G(\mathbb{Q}_v)$. Assume that the image of $g_i$ in $G(\mathbb{Q}_v)$ be trivial, then we can now describe the local system $\tilde{M}$ on each irreducible component by:

$$\tilde{M}_i := \tilde{M}|_{\Gamma_i \backslash \mathcal{H}_G} = \Gamma_i \backslash (\mathcal{H}_G \times M) \rightarrow \Gamma_i \backslash \mathcal{H}_G$$

with $\gamma.[z,m] = [\gamma z, \gamma m]$ for all $z \in \mathcal{H}_G$ and $\gamma \in \Gamma_i$, the map from the $\tilde{M}$ onto $\sqcup_i \tilde{M}_i$ being given by $[\gamma.g_i.g_{\infty}.k,m] \mapsto [\gamma.g_{\infty}.k,m]$.

1.2.4. Cohomology. We will respectively write $H^\bullet(S_G(K), \mathcal{F})$ and $H^\bullet_c(S_G(K), \mathcal{F})$ for the cohomology and cohomology with compact support of a local system $\mathcal{F}$ on $S_G(K)$. We also denote by $H^\bullet_c(S_G(K), \mathcal{F})$ the image of the canonical map from $H^\bullet_c(S_G(K), \mathcal{F})$ into $H^\bullet_c(S_G(K), \mathcal{F})$. When $\mathcal{F} = \tilde{M}$, we will sometimes drop the symbol “from the notations; so we write $H^\bullet(S_G(K), M)$. When $\tilde{M}$ is defined by an action of $G(\mathbb{Q})$, we also write $H^\bullet_c(S_G, M)$ for the projective limit of the $H^\bullet_c(S_G(K), M)$ over all the open compact subgroups $K \subset G(\mathbb{A}_f)$.

We recall also that the decomposition into connected components induces a canonical isomorphism

$$H^\bullet(S_G(K), M) = \bigoplus_i H^\bullet(\Gamma_i \backslash \mathcal{H}_G, \tilde{M}_i) \cong \bigoplus_i H^\bullet(\Gamma_i, M).$$

1.2.5. Hecke operators. We now briefly recall some equivalent definitions of the action of the Hecke operators on the cohomology.

Assume $x \in G(\mathbb{A}_f)$, then the right translation by $x$ defines an isomorphism $R_x : S_G(K) \rightarrow S_G(x^{-1}Kx)$ and we expect that it induces a map

$$H^\bullet(S_G(x^{-1}Kx), M) \rightarrow H^\bullet_c(S_G, M).$$

This is so indeed if $\tilde{M}$ is defined by a representation of $G(\mathbb{Q})$ (i.e. like in definition (1.2.1)). In that case, the definition above induces a left action of $G(\mathbb{A}_f)$ on $H^\bullet_c(S_G, M)$ such that there is a canonical isomorphism

$$H^\bullet_c(S_G, M)^K \cong H^\bullet_c(S_G(K), M).$$
where the left hand side of the above equation denotes the $K$-invariant of $H^\bullet(S_G, M)$. If $M$ is a $\mathbb{Q}$-vector space, we can therefore define an action of the Hecke algebra $C^\infty_c(G(\mathbb{A}_f), \mathbb{Q})$ on $H^\bullet(S_G, M)$ from our choice of an Haar measure on $G(\mathbb{A}_f)$.

In the case $M$ is not a representation of $G(\mathbb{Q})$ but is a left $K$-module, we need to make some additional assumptions on $M$. Assume that we have $\Delta_f \subset G_f$ a semi-group containing $K$ and acting on $M$ on the left. Then for any $x \in \Delta_f$, the map $m \mapsto x.m$ induces canonically a map $R^x \tilde{M}_{x^{-1}K} \rightarrow \tilde{M}_K$. We therefore have a map in cohomology

$$H^\bullet(S_G(x^{-1}Kx), M) \rightarrow H^\bullet(S_G(K), M)$$

In each case, this enables us to define a left action of the double cosets $KxK$. Moreover these actions coincide when the definitions (1.2.1) and (1.2.2) do. We can also compare this action with the definition (1.2.3). We write $g_i = \gamma_{x,i}g_jh_{x,i}$ with $h \in K$. To the double class $\Gamma_i \gamma_{x,i}^{-1}\Gamma_j$, we can associate the map $H^\bullet(\Gamma_i \backslash \mathcal{H}_G, M) \rightarrow H^\bullet(\Gamma_j \backslash \mathcal{H}_G, M)$. In view of the isomorphism (3), the action of the double coset $KxK$ can equivalently be seen as

$$[KxK] = \oplus_i [\Gamma_i \gamma_{x,i}^{-1}\Gamma_j].$$

1.3. Cohomology and automorphic forms. In this section, we review some of the important known results relating cohomology of arithmetic groups and automorphic forms. The study of this relationship has been originally undertaken by A. Borel and N. Wallach [BW00] and developed by many authors including G. Harder, J. Schwermer, J.-S. Li and the theory has culminated with the results of J. Franke [Fr98] who proved Borel’s conjecture.

1.3.1. Algebraic representations of $G$. We recall here the definition and construction of some irreducible and algebraic representations of $G$. Let $F \subset \mathbb{Q}$ be the smallest splitting field for $G$. We fix a Borel pair $(B_{/F}, T_{/F})$ contained in the pair $(P_{0/F}, M_{0/F}$ and for all field $L$ containing $F$, we denote respectively by $N_{/L}$, $B^\vee_{/L}$ and $N^\vee_{/L}$ the unipotent radical of $B_{/L}$, the Borel subgroup opposite to $B_{/L}$ and the unipotent radical of $B^\vee_{/L}$. For any algebraic dominant weight $\lambda$ of $G_{/L}$ with respect to the Borel pair $(B_{/L}, T_{/L})$, we denote by $\mathbb{V}_\lambda(L)$ the irreducible algebraic representation over $L$ of $G_{/L}$ of highest weight $\lambda$ defined as the set of algebraic functions $G_{/L} \rightarrow \mathbb{A}_L^1$ such that

$$f(n^-tg) = \lambda(t)f(g)$$

for all $n^- \in N^-(L)$, $t \in T(L)$ and $g \in G(L)$. When $G$ is clear from the context, we usually drop it from the notation and write $\mathbb{V}_\lambda(L)$. 

We are interested in the cohomology of $\mathcal{V}_\lambda(\mathbb{C})$ because it can be interpreted in terms of automorphic forms. We will recall below the main results about this fact.

1.3.2. $(\mathfrak{g}, K_\infty)$-cohomology. Let $\mathfrak{g} := \text{Lie}_\mathbb{R}(G^1_\infty)$ and $\mathfrak{k} := \text{Lie}_\mathbb{R}(K_\infty)$. For any $(\mathfrak{g}, K_\infty)$-module $H$, one denotes its $(\mathfrak{g}, K_\infty)$-cohomology by $H^*(\mathfrak{g}, K_\infty; H)$. The reader can consult [BW00] for the definitions and basic properties of this notion. Let $\omega_\lambda$ the character of $Z_\infty$ acting on $\mathcal{V}_\lambda(\mathbb{C})$. We denote by $C^\infty(G(\mathbb{Q}) \backslash G(\mathbb{A})/K, \omega_\lambda)$ the space of $C^\infty$-functions on $G(\mathbb{Q}) \backslash G(\mathbb{A})/K$ which transform by $\omega_\lambda$ under the action of $Z_\infty$. This is a $(\mathfrak{g}, K_\infty)$-module. By noticing that the tangent space at the origin of $S_G(K)$ is canonically isomorphic to $\mathfrak{g}/\mathfrak{k}$ and that multiplication by $g \in G(\mathbb{A})$ gives an isomorphism between the tangent space at the origin and the one at the class of $g$, it is not difficult and classical to obtain an isomorphism:

\[
H^*(\mathfrak{g}, K_\infty; C^\infty(G(\mathbb{Q}) \backslash G(\mathbb{A})/K, \omega_\lambda)) \cong H^*_{dR}(S_G(K), \mathcal{V}_\lambda(\mathbb{C}))
\]

1.3.3. Cuspidal and $L^2$-Cohomology. Let $L^2(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda)$ the space of square integrable functions on $G(\mathbb{Q}) \backslash G(\mathbb{A})$ which tranform by $\omega_\lambda$ under the action of $Z_\infty$. There is a natural action of $G(\mathbb{A})$ on these spaces. Moreover we have a decomposition

\[
L^2(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda) = L^2_\text{cont}(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda) \oplus L^2_\text{cusp}(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda)
\]

where $L^2_\text{cont}$ and $L^2_\text{d}$ denote respectively the continuous and discrete spectrum of $L^2$ for the action of $G(\mathbb{A})$. We also denote by $L^2_\text{cusp}(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda)$ the subspace of automorphic functions $\phi \in L^2(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda)$ satisfying:

\[
\int_{N_P(\mathbb{A})/N_P(\mathbb{Q})} f(ng)dn = 0
\]

for the unipotent radical $N_P$ of any $\mathbb{Q}$-rational parabolic subgroup $P$ of $G$. We have $L^2_\text{cusp} \subset L^2_\text{d}$. Notice also that there is a spectral decomposition:

\[
L^2_\text{d}(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda) = \bigoplus_{\pi} V_{r_{\pi}}(\pi)
\]

where $(\pi, V_\pi)$ runs in a set of irreducible representation with central character at infinity $\omega_\lambda$. Similarly we have:

\[
L^2_\text{cusp}(G(\mathbb{Q}) \backslash G(\mathbb{A}), \omega_\lambda) = \bigoplus_{\pi} V_{r_{\pi}}^{\text{cusp}}(\pi)
\]

where now the representation $\pi$ are irreducible and cuspidal. In the above decomposition $m(\pi)$ and $m_{\text{cusp}}(\pi)$ are non negative integer denoting respectively the multiplicities of $\pi$ in $L^2_\text{d}$ and $L^2_\text{cusp}$.

For an irreducible representation $\pi$ as above, let $V^{\text{fin}}_{\pi}$ be the subspace of vectors that generate a finite dimension vector space under the action of $K_\infty$. It can be shown that under the decomposition above $V^{\text{fin}}_{\pi}$ is contained in
$C^\infty(G(\mathbb{Q})/G(\mathbb{A}), \omega_{\lambda})$-functions (in fact more generally if $\pi_\infty$ is an admissible representation of $G_\infty$, $\pi_\infty^{\text{fin}}$ is a $(\mathfrak{g}, K_\infty)$-module). One defines the cuspidal cohomology as

$$H^\bullet_{\text{cusp}}(S_G(K), \mathcal{V}_{\lambda}(\mathbb{C})) := \bigoplus_{\pi \subset L^2_{\text{cusp}}} H^\bullet(\mathfrak{g}, K_\infty; (\mathcal{V}_\pi^{\text{fin}})^K \otimes \mathcal{V}_{\lambda}(\mathbb{C}))$$

and the square integrable cohomology as

$$H^\bullet_2(S_G(K), \mathcal{V}_{\lambda}(\mathbb{C})) := \bigoplus_{\pi \subset L^2_2} H^\bullet(\mathfrak{g}, K_\infty; (\mathcal{V}_\pi^{\text{fin}})^K \otimes \mathcal{V}_{\lambda}(\mathbb{C}))$$

This is a theorem of A. Borel that both inject via $\delta$ in the cohomology of $S_G(K)$. Then we have the following inclusions:

$$H^\bullet_{\text{cusp}}(S_G(K), \mathcal{V}_{\lambda}(\mathbb{C})) \subset H^\bullet!(S_G(K), \mathcal{V}_{\lambda}(\mathbb{C})) \subset H^\bullet_2(S_G(K), \mathcal{V}_{\lambda}(\mathbb{C}))$$

For $? = \emptyset, !, \text{cusp}$ or 2, we put:

$$H^\bullet?(\tilde{S}_G, \mathcal{V}_{\lambda}(\mathbb{C})) := \lim_{K \subset G_f} H^\bullet!(S_G(K), \mathcal{V}_{\lambda}(\mathbb{C}))$$

It has a natural action of $G_f$. Any irreducible representation $\pi$ has a decomposition $\pi = \pi_f \otimes \pi_\infty$ where $\pi_f$ and $\pi_\infty$ are respectively representations of $G_f$ and $G_\infty$. We now recall which $\pi_\infty$ intervene in the cohomology.

1.3.4. $L$-packet at infinity: For each dominant weight $\lambda$, one defines the "cohomological" packet $\Pi_\lambda$ as the set of essentially unitary representation $\pi_\infty$ of $G(\mathbb{R})$ of central character $\omega_{\lambda}$ and such that

$$H^\bullet(\mathfrak{g}, K_\infty; \pi_\infty^{\text{fin}} \otimes \mathcal{V}_{\lambda}(\mathbb{C})) \neq 0.$$ A cuspidal representation $\pi$ is said cohomological if its archimedean component $\pi_\infty$ belongs to $\Pi_\lambda$ for some weight $\lambda$ (that we call its cohomological weight).

1.3.5. The Harish-Chandra condition. We say that $G_\infty$ satisfies the Harish-Chandra condition if the compact rank of $G_\infty^{\text{der}}$ equals its semi-simple rank. In other words, $G_\infty^{\text{der}}$ contains a compact Cartan subgroup. In that case, it is known by the foundational work of Harish-Chandra that $G_\infty$ has discrete series representations (i.e. with square integrable matrix coefficients). In that case, the dimension of $S_G(K)$ is even and we write $d_G$ for half its real dimension.

Assume $G_\infty$ satisfies the Harish-Chandra condition. Then, if $\lambda$ is dominant and regular, it is known that

**(VZ):** The representations in $\Pi_\lambda$ are in the discrete series (i.e. can be realized in $L^2(G_\infty, \omega_{\lambda})$). Moreover $\pi_\infty \in \Pi_\lambda$ has cohomology only in degree $d_G$. Moreover it has dimension 1.

**(HC):** The set $\Pi_\lambda$ is in bijection with $\{ w.(\lambda + \rho) - \rho ; w \in \mathcal{W}_G/\mathcal{W}_K \}$. 

(VZ) is due to Vogan and Zuckerman and (HC) is due to Harish-Chandra. Even if \( G_\infty \) does not satisfy the Harish-Chandra condition, the representations in \( \Pi_\lambda \) are known to be tempered\(^9\) when \( \lambda \) is regular. By a theorem of N. Wallach, it is known that if \( \pi \) is such that \( \pi_\infty \) is tempered then the respective multiplicities \( m_{\text{cusp}}(\pi) \) and \( m(\pi) \) of \( \pi \) in \( L^2_{\text{cusp}} \) and in \( L^2_\Delta \) are equal. An immediate consequence of these facts is the following (well-known) proposition.

**Proposition 1.3.6.** Assume \( G_\infty \) satisfies the Harish-Chandra condition and that \( \lambda \) is regular, then

(i) We have

\[
H^q_{\text{cusp}}(\tilde{S}_G, \mathcal{V}_\lambda^\vee(\mathbb{C})) = H^q_{(2)}(\tilde{S}_G, \mathcal{V}_\lambda^\vee(\mathbb{C}))
\]

and these groups vanish except for \( q = d_G \).

(ii) For \( q = d_G \), we have an isomorphism of \( G_f \)

\[
H^d_G(\tilde{S}_G, W^\vee(\mathbb{C})) \cong \bigoplus_\pi H^d_G(\mathfrak{g}, K_\infty; \pi_\infty \otimes \mathcal{V}_\lambda) \otimes \pi_f^{m(\pi)} \cong \bigoplus_\pi \pi_f^{m(\pi)}
\]

Here \( \pi = \pi_f \otimes \pi_\infty \) runs in the set of cuspidal representation such that \( \pi_\infty \in \Pi_\lambda \).

1.4. **Franke’s trace formula.** When the group \( G \) is not anisotropic, the cohomology of \( S_G(K) \) is not reduced to its cuspidal or square integral part. In the case of \( GL(2) \), G. Harder has proved it can be decomposed into its cuspidal part and Eisenstein part [H87]. This result has been generalized by him [H93] and J. Schwermer [Sch] in many other cases including the rank one case and when \( \lambda \) is regular. The question has been settled in fairly good generality thanks to the work of J. Franke [Fr98] and works built on it. See for example, the results of J-S Li and J. Schwermer [LS04]. It also results of the works of J. Franke, that there is a trace formula for the cohomology \( H^\bullet(\tilde{S}_G, \mathcal{V}_\lambda^\vee(\mathbb{C})) \) in terms of trace of the square integral cohomology of the Levi subgroup of \( G \). This formula becomes quite simple when the weight \( \lambda \) is regular.

1.4.1. **Eisenstein classes.** Recall that \( \mathcal{P}_G \) and \( \mathcal{L}_G \) denotes respectively the set of standard parabolic subgroup of \( G \) and standard Levi subgroup of \( G \). We also write \( \mathcal{L}_G^c \) for the subset of \( \mathcal{L}_G \) of Levi satisfying the Harish-Chandra condition. For \( P \in \mathcal{P}_G \) with Levi decomposition \( P = MN \), we denote by \( \rho_P(m) := \det(m; n)^{1/2} \) with \( n := \text{Lie } N \). Let

\[
\mathcal{W}_M := \{ w \in \mathcal{W}_G \mid w^{-1}(\alpha) \in R^+, \forall \alpha \in R^+ \cap R_M \}
\]

This is the set of representatives of the cosets \( \mathcal{W}_G/\mathcal{W}_M \) of minimal length. Here \( R^+ \) is the set of positive root with respect to \( (B_L, T_L) \) and \( R_M \) is

\(^9\)This means that the matrix coefficients of this representations belong to \( L^{2+\epsilon}(G_\infty/Z_\infty) \) for all \( \epsilon > 0 \)
the set of root for the pair \((M_{/L}, T_{/L})\). Then we have the so-called Kostant decomposition
\[
H^q(n, \mathbb{V}_\lambda(\mathbb{C})) := \bigoplus_{w \in \mathbb{W}_M} \mathbb{V}_w^{\mathbb{M}_{w(\lambda + \rho_P) - \rho_P}}(\mathbb{C})
\]
where \(\mathbb{V}_w^{\mathbb{M}}\) denotes the irreducible algebraic representation of \(M\) of highest weight \(\mu\). From the definition of \(\mathbb{W}_M\), \(w(\lambda + \rho_P) - \rho_P\) is a dominant weight with respect to the pair \((B_{/L} \cap M_{/L}, T_{/L})\). For further use, let us remind the reader that we have the relation:
\[
w \ast \lambda := w(\lambda + \rho_B) - \rho_B = w(\lambda + \rho_P) - \rho_P
\]
for all \(w \in \mathbb{W}_M\). Since \(H^\text{dim}n(n, \mathbb{C}) = \mathbb{C}(-2\rho_P)\), by Poincaré duality the Kostant decomposition gives:
\[
H^q(n, \mathbb{V}_\lambda(\mathbb{C})) := \bigoplus_{w \in \mathbb{W}_M} \mathbb{V}_w^{\mathbb{M}_{w(\lambda + \rho_P) + \rho_P}}(\mathbb{C})^\vee
\]

Let \(R_P \subset X^*(Z_M)\) be the set of roots for the pair \((Z_M, n)\) and denote by \(R_P^\vee \subset X^*(Z_M)\) the corresponding set of coroots. Then we put
\[
\mathbb{W}^M_{\text{Eis}} := \{ w \in \mathbb{W}_M, w^{-1}(\beta^\vee) \in R^+, \forall \beta \in R_P \}
\]

From the definition, we see that if \(\lambda\) is regular, \(w(\ast \lambda)|_{Z_M \cap G^{\text{der}}} \) is \(R_P\)-dominant if and only if \(w \in \mathbb{W}^M_{\text{Eis}}\). From results of Harder, Schwermer-Li and Franke, it is known that for \(w \in \mathbb{W}^M_{\text{Eis}}\) and for regular \(\lambda\) the Eisenstein series associated to a cohomology class in \(H^\bullet(S_M(K_M), \mathbb{V}^{\mathbb{M}_{w(\lambda)}(\mathbb{C})})\) is in the domain of convergence and therefore defines an Eisenstein class in \(H^\bullet(S_G(K), \mathbb{V}_\lambda^\vee(\mathbb{C}))\). When the weight \(\lambda\) is regular, these authors have furthermore proved that the cohomology can be expressed in terms of cuspial and Eisenstein classes. One formulation of this fact is stated in the next theorem.

For any function \(f \in C^\infty_c(G(\mathbb{A}_f))\) and any \(M \in \mathcal{L}_G\), we denote its constant term \(f_M \in C^\infty_c(M(\mathbb{A}_f))\). Recall that it is defined for any \(m \in M(\mathbb{A}_f)\) by
\[
f_M(m) := \int_{K_m \times N(\mathbb{A}_f)} f(k^{-1}mnk)dn dk
\]
where \(P = MN\) is the Levi decomposition of the unique standard parabolic subgroup of \(G\) of Levi subgroup \(M\). This definition is relevant in view of the following (standard) formula:
\[
\text{tr}(f : \text{Ind}_{P(\mathbb{A}_f)}^G(\mathbb{A}_f)) = \text{tr}(f_M : \sigma)
\]

The induced representation\(^{10}\) here is the set of smooth function on \(G(\mathbb{A}_f)\) such that \(\phi(pg) = \sigma(p) \cdot \phi(g)\) for all \(p \in P(\mathbb{A}_f)\) and \(g \in G(\mathbb{A}_f)\).

\(^{10}\)Notice here that we do not consider the unitary induction. The main reason is that the non-unitary induction preserves rationality and integrality of the Hecke eigenvalues.
Theorem 1.4.2 (Franke). Assume $\lambda$ is regular and $f \in C_c^\infty(G(\mathbb{A}_f))$, then we have:

$$tr(f : H^\bullet(\bar{S}_G, \mathcal{V}_\lambda'(\mathbb{C}))) = \sum_{M \in \mathcal{L}_G} (-1)^{\dim M} \sum_{w \in W_Eis} (-1)^{l(w)} tr(f_M : H^\bullet_{cusp}(\bar{S}_M, \mathcal{V}_w^{LM}(\lambda + \rho_P + \rho_P(\mathbb{C}))^\vee))$$

*Proof.* This follows from formula (2) page 266 of the paper of Franke [Fr98].

2. Spectral theory on $p$-adic Banach spaces

The aim of this section is to set up some basic facts about the spectral theory for the derived category of Banach modules over a Banach algebra. We define the what we call the finite slope cohomology attached to complexes of $p$-adic Banach spaces equipped with completely continuous (or compact) operators. Then we extend it to $p$-adic Frechet spaces. We do not pretend any originality in this section but it gives a convenient frame for the theory developed in the fourth section.

2.1. Perfect complexes of Banach spaces. We introduce the notion of perfect complexes of Banach spaces that will be suitable to our spectral theory. It arises naturally as the theory of perfect complexes in the Grothendieck theory of Lefschetz trace formula in étale cohomology.

2.1.1. In this section, $A$ will be a topologically finitely generated Banach $\mathbb{Q}_p$-algebra. Recall that it is a $\mathbb{Q}_p$ algebra equipped with an ultrametric norm $|.|_A$ satisfying

$$|ab|_A \leq |a|_A \cdot |b|_A \text{ for all } a, b \in A$$

and that we can normalize such that $|x|_A = |x|_p$ for all $x \in \mathbb{Q}_p$. We will assume $(A, |.|)$ satisfies the Hypothesis $M$ of [Co97, A1]. We write $A^0 := \{a \in A \mid |a| \leq 1\}$ and $m := \{a \in A \mid |a| < 1\} \subset A^0$. Then we furthermore assume that $A$ is semi-simple in the sense of [Co97, A1], which means $A^0/m$ is a field and that the norm on it induced by that of $A$ is multiplicative. We again refer to the reference [Co97] for the notions and the basic properties of Banach $A$-modules. We call a Frechet $A$-module a topological $\mathbb{Q}_p$-vectors space $V$ equipped with a continuous $A$-module structure and which is topologically isomorphic to the projective limit of Banach $A$-modules. A Frechet $A$-module will be said compact if the transition maps of the projective limit are completely continuous.
2.1.2. **The categories** $\text{Ban}_A$ **and** $\text{Fre}_A$. For any $\mathbb{Q}_p$-Banach algebra $A$, we consider the category $\text{Ban}_A$ (respectively $\text{Fre}_A$) whose objects are the Banach (respectively Frechet) $A$-modules and the homomorphisms are the continuous $A$-linear maps. These categories are obviously additive but not abelian. However, they are exact in the sense of Quillen, the short exact sequences being those exact in the category of $A$-modules. Moreover $\text{Ban}_A$ satisfies\footnote{The category $\text{Ban}_A$ is quasi-abelian in the sense of [S99]. This means that the pullback (resp. push-forward) of any strict epimorphism (resp. any strict monomorphism) is still a strict epimorphism (resp. strict monomorphism). This fact can be easily verified as in [S99, Prop. 3.2.4].} the axiom 1.3.0 of [La83]. Every morphism $f \in \text{Hom}(E,F)$ has a kernel and a cokernel (and therefore an image and a cokernel). One can check easily that \[ \text{Ker } f = f^{-1}(0), \text{Im } f = \overline{f(E)}, \text{Coker } f = F/\overline{f(E)} \text{ and } \text{Coi } m f = E/f^{-1}(0) \]

Recall that a morphism $f$ is said strict if and only if it induces an isomorphism from $\text{Coi } m f$ onto $\text{Im } f$. This means here that $f(E)$ is closed in $F$. Equivalently, an epimorphism is strict if it is surjective as a morphism of $A$-module and a monomorphism is strict if its image is closed.

2.1.3. Let $\mathcal{C}(\text{Ban}_A)$ the category of complexes of Banach $A$-modules with homomorphisms the maps of degree $0$ between complexes. We denote by $\mathcal{K}(\text{Ban}_A)$ the triangulated category of complexes of objects of $\text{Ban}_A$ “modulo homotopy”. We say that a complex is acyclic if it is exact at every degree and denote by $\mathcal{K}(\text{Ban}_A)\mathcal{K}(\text{Ban}_A)$ the full subcategory of acyclic complexes. This category is “épaisse” and following Deligne, it is therefore possible to consider the derived category $D(\text{Ban}_A)$ as the quotient category $\mathcal{K}(\text{Ban}_A)/\mathcal{K}(\text{Ban}_A)$. The objects of $D(\text{Ban}_A)$ are the same as those of $\mathcal{K}(\text{Ban}_A)$. Recall that if $M^\bullet, N^\bullet \in \text{Ob}(D(\text{Ban}_A))$, a homomorphism from $M^\bullet$ to $N^\bullet$ is a triple $(P^\bullet, s, f)$ where $s \in \text{Hom}_{\mathcal{K}(\text{Ban}_A)}(P^\bullet, N^\bullet)$ and $f \in \text{Hom}_{\mathcal{K}(\text{Ban}_A)}(P^\bullet, M^\bullet)$ such that $s$ is a quasi-isomorphism. The latter means that the cone of $s$ is acyclic.

2.1.4. **Projective Banach $A$-modules.** Recall the following definition.

**Definition 2.1.5.** Let $A$ be a Banach $p$-adic algebra over a $p$-adic field $L$ and $M$ a Banach $A$-module. One says that $M$ is an orthonormalizable $A$-module or is orthonormalizable over $A$ if there exists a family $B = \{m_i; i \in I\}$ of elements of norm $\leq 1$ and such that for any $m \in M$ there is a unique family $(a_i)_{i \in I} \in A^I$ such that $\lim_{i} a_i = 0$ and $m = \sum_{i \in I} a_i.m_i$. We call $B$ an orthonormal basis of $M$.

For any Banach space over $L$, we denote $N^0$ the lattice of elements of norm $\leq 1$. We recall the following lemma.

**Lemma 2.1.6.** Let $M$ be a Banach $A$-module and $a \in A$ such that $|a| < 1$. Then if there exists a subset $B \subset M$ such that the image of $B$ in $M^0/a.M^0$
is a basis of this module over $A^\circ/a.A^\circ$. Then $B$ is an orthonormal basis of $N$. Especially any Banach space over $L$ is orthonormalizable on $L$.

An object $P$ of $\mathcal{B}an_A$ is said projective if for any strict epimorphism $f : N \to M$ and any map $g : P \to M$ there exists a map $h$ from $P$ to $N$ so that the following diagram is commutative.

\[
\begin{array}{ccc}
P & \xrightarrow{h} & N \\
\downarrow{g} & & \downarrow{f} \\
M & \to & M
\end{array}
\]

A complex $M^\bullet$ is called perfect if it is bounded and if $M^q$ is projective for all $q$. We denote $\mathcal{K}_{pf}(\mathcal{B}an_A)$ the full subcategory of $\mathcal{K}(\mathcal{B}an_A)$ of perfect complexes.

**Lemma 2.1.7.** A Banach $A$-module is projective (in the category $\mathcal{B}an_A$) if and only it is a direct factor of an orthonormalizable $A$-module.

**Proof.** Let us prove that an orthonormalizable $P$ is projective. Let $N, M, f$ and $g$ be as above. Since $f$ strict, it induces an isomorphism of $\mathbb{Q}_p$-Banach spaces $N/Ker f$ onto $M$. Then we choose a $\mathbb{Q}_p$-direct factor $M'$ of $Ker f$ inside $N$ so that $f$ induces an isomorphism of $\mathbb{Q}_p$-Banach spaces from $M'$ onto $M$. If $(e_i)_i$ is an $A$-basis of $P$, let $h_i \in M'$ for each $i$ be such that $f(h_i) = g(e_i)$ for all $i$. Since $g$ is continuous and $f|_{M'}$ is an isomorphism of $\mathbb{Q}_p$-Banach spaces, we know that the family $(h_i)_i$ is bounded. Therefore there exists a continuous $A$-linear map from $P$ to $N$ such that $h(e_i) = h_i$ for all $i$ and thus such that $f \circ h = g$. What remains to be proved is formal and left to the reader.

**Lemma 2.1.8.** Let $M^\bullet$ and $N^\bullet$ be two complexes of Banach $A$-modules. Assume that $M^\bullet$ is perfect, then the canonical following morphism is an isomorphism:

\[
\text{Hom}_{\mathcal{K}(\mathcal{B}an_A)}(M^\bullet, N^\bullet) \to \text{Hom}_{\mathcal{D}(\mathcal{B}an_A)}(M^\bullet, N^\bullet)
\]

**Proof.** This is a special case of [La83, Cor. 2.2.3] in which the space $X$ is reduced to one point and the fibred category $C$ over $X$ is $\mathcal{B}an_A$ and $C_0$ is the full subcategory whose objects are the projective objects of $\mathcal{B}an_A$.

2.1.9. **Category of perfect complexes.** We denote $D_{pf}(\mathcal{B}an_A)$ the image of $\mathcal{K}_{pf}(\mathcal{B}an_A)$ in $\mathcal{D}(\mathcal{B}an_A)$. It follows from the lemma above that $D_{pf}(\mathcal{B}an_A)$ is a full subcategory of $\mathcal{D}(\mathcal{B}an_A)$. If $A = L$ is a finite extension of $\mathbb{Q}_p$, every Banach space over $L$ is orthonormalizable. Therefore, $D_{pf}(\mathcal{B}an_L) = \mathcal{D}(\mathcal{B}an_L)$.

2.2. **Compact operators.**
2.2.1. Fredholm determinant. Let $M$ be an orthonormalizable Banach $A$-module and $u$ be a compact (or completely continuous) operator acting on $M$. By definition, recall that this means there exists a sequence of projective and finitely generated Banach $A$-modules $(M_i)$ such that $u|_{M_i}$ converges to $u$ when $i \to \infty$. One can define its Fredholm determinant by:

$$P_M(u,X) = \det(1 - X.u|_M) := \lim_{i \to \infty} \det(1 - X.u_i|M_i)$$

where for all $i$, we have written $u_i$ for the composite of $u|_{M_i}$ with the projection onto $M_i$. This definition is independent of the choice of the sequence $(M_i)$, cf. [Co97]. It extends easily to projective Banach modules.

2.2.2. Trace versus determinant. The first coefficient of the series $\det(1 - X.u|_M)$ is the opposite of the trace $tr(u;M)$. On the other hand, one can recover the Fredholm series from the trace map. There exists a universal sequence of polynomials $12 Q_n(X_1,\ldots,X_n) \in \mathbb{Q}[X_1,\ldots,X_n]$ for $n \geq 1$ such that we have

$$P_M(u,X) = \det(1 - X.u|_M) = \sum_{n=1}^{\infty} tr(Q_n(u,u^2,\ldots,u^n);M)X^n$$

These polynomials are well known, for instance, $Q_1(X_1) = -X_1$, $Q_2(X_1,X_2) = \frac{1}{2}(X_1^2 - X_2)$, etc...

From this, one can see that many properties of the Fredholm determinant follow from the corresponding properties of the trace map. In particular, if we have an $A$-valued linear map $t$ from an ideal of a sub-algebra of $\text{End}_A(M)$, one can define the associated formal series for any element $u$ of this ideal by

$$P_t(u,X) := \sum_{n=1}^{\infty} t(Q_n(u,u^2,\ldots,u^n))X^n$$

2.2.3. We consider the category $\text{Ban}_A^*$ whose objects are pairs $(M,u_M)$ with $M \in \text{Ob}(\text{Ban}_A)$ and $u_M$ be an $A$-linear compact operator on $M$. A morphism $(M,u_M) \to (N,u_N)$ is given by a morphism $M \xrightarrow{f} N$ in $\text{Ban}_A$ such that $f \circ u_M = u_N \circ f$. This category is also exact and has kernel and cokernel. A sequence is exact if its image by the forgetful functor $\text{Ban}_A \to \text{Ban}_A^*$ is an exact sequence in $\text{Ban}_A$. We can define similarly the categories $C(\text{Ban}_A^*)$, $K(\text{Ban}_A^*)$, $K_{pf}(\text{Ban}_A^*)$ and $D(\text{Ban}_A^*)$, $D_{pf}(\text{Ban}_A^*)$.

Lemma 2.2.4. Let $M$, $N$ and $P$ be three projective Banach $A$-modules fitting in an exact sequence in the category $\text{Ban}_A^*$:

$$0 \to (N,u_N) \xrightarrow{f} (M,u_M) \xrightarrow{g} (P,u_P) \to 0$$

Then we have

$$\det(1 - X.u_M|M) = \det(1 - X.u_N|N) \cdot \det(1 - X.u_P|P).$$

---

12 The $Q_n$'s are sometimes called Newton polynomials.
Proof. This follows easily from [Co97, Lemma A.2.4].

2.2.5. Definition. Let \((M^\bullet, u^\bullet)\) \(\in\) \(\text{Ob}(\mathcal{C}(\text{Ban}^*_A))\) such that \(M^\bullet\) is a perfect complex. Then we put

\[
\det(1 - X.u^\bullet|M^\bullet) := \prod_q \det(1 - X.u^q|M^q)^{(-1)^q}.
\]

It follows from Lemma 2.2.4, that \(\det(1 - X.u^\bullet|M^\bullet) = 1\) if \(M^\bullet\) is acyclic.

2.2.6. Let \(M^\bullet \in \text{Ob}(D_{pl}(\text{Ban}_A))\). A homomorphism \(\text{Hom}_{D(\text{Ban}_A)}(M^\bullet, M^\bullet)\) is said to be compact (or completely continuous) if it has a representative \(u^\bullet \in \text{Hom}_{K(\text{Ban}_A)}(M^\bullet, M^\bullet)\) (i.e. in its homotopy class) such that \((M^\bullet, u^\bullet) \in \text{Ob}(\mathcal{C}(\text{Ban}^*_A))\).

Lemma 2.2.7. The operator \(u^\bullet\) is compact if and only if there exists a sequence of operators of finite rank \((u^\bullet_n)\) in \(\text{Hom}_{D(\text{Ban}_A)}(M^\bullet, M^\bullet)\) such that \(\lim_{n \to \infty} u^\bullet_n = u^\bullet\) for all \(q\). Equivalently, there are finite rank projection operators \(e^\bullet_n \in \text{Hom}_{D(\text{Ban}_A)}(M^\bullet, M^\bullet)\) such that \(\lim_{n \to \infty} e^\bullet_n \circ u^q = u^q\) for all \(q\).

Proof. This follows easily from [Co97, A.1.6].

Lemma 2.2.8. Let \(u^\bullet\) and \(v^\bullet\) be two \(A\)-linear compact operators on a perfect complex \(M^\bullet\). If \(u^\bullet\) and \(v^\bullet\) are homotopically equivalent, then \(\det(1 - X.u^\bullet|M^\bullet) = \det(1 - X.v^\bullet|M^\bullet)\).

Proof. From the remark made in \(\S 2.2.2\), it suffices to show that if \(u^\bullet\) and \(v^\bullet\) are homotopically equivalent then they have the same trace. For this, it is sufficient to treat the case where \(v^\bullet = 0\). Then, there are operators \(k^q : M^q \to M^{q-1}\) such that \(u^q = d^q - 1\circ k^q + k^{q+1}\circ d^q\) for all \(q\) with \(d^q\) denoting the differential of the complex \(M^\bullet\) in degree \(q\). Let \((e^\bullet_n)\) be as in the previous lemma such that \(\lim_{n \to \infty} e^\bullet_n \circ u^q = u^q\) for all \(q\). Let us put \(k^q_n := e^\bullet_{n-1} \circ k^q \circ e^\bullet_n\). Since \(e^\bullet_{n+1} \circ d^q = d^q \circ e^\bullet_n\), we have \(\text{tr}(e^\bullet_n \circ u^q) = \text{tr}(e^\bullet_n \circ u^q \circ e^\bullet_n) = \text{tr}(d^q \circ k^q \circ d^q \circ e^\bullet_n) = \text{tr}(d^q \circ k^q \circ d^q \circ e^\bullet_n) = \text{tr}(d^q \circ k^q \circ d^q \circ e^\bullet_n)\). This implies that \(\text{tr}(e^\bullet_n \circ u^q) := \sum_{q} (-1)^q \text{tr}(e^\bullet_n \circ u^q) = 0\) and therefore passing to the limit we have \(\text{tr}(u^\bullet) = 0\).

2.2.9. For any \(M^\bullet \in \text{Ob}(D_{pl}(\text{Ban}_A))\) and any compact \(A\)-linear operator \(u^\bullet\) of \(M^\bullet\), it follows from the previous lemma that the Fredholm determinant \(\det(1 - X.u^\bullet|M^\bullet)\) does not depend of the homotopy class of \(u^\bullet\). For any compact homomorphism \(u \in \text{Hom}_{D_{pl}(\text{Ban}_A)}(M^\bullet, M^\bullet)\), the Fredholm determinant of \(u\) is therefore (well-)defined as the Fredholm determinant of any of its representatives in its homotopy class.
Corollary 2.2.10. Let \((u_N^*, u_M^*, u_P^*)\) be the morphism of a distinguished triangle of \(D_{pf}(\text{Ban}_A)\)

\[
\begin{array}{c}
N^* \longrightarrow M^* \longrightarrow P^* \longrightarrow N^*[1] \\
\downarrow u_N^* \downarrow u_M^* \downarrow u_P^* \downarrow u_N^*[1]
\end{array}
\]

such that \(u_N^*, u_M^*\) and \(u_P^*\) are compact. Then we have

\[
\det(1 - X.u_M^*|M^*) = \det(1 - X.u_N^*|N^*) \cdot \det(1 - X.u_P^*|P^*)
\]

Proof. Since this triangle is distinguished, \((P^*, u_P^*)\) is homotopic to the cone of \((N^*, u_N^*) \rightarrow (M^*, u_M^*)\). The corollary follows from this observation and the previous lemma.

2.3. Spectral decompositions.

2.3.1. Slope decompositions. We recall here a notion\(^{13}\) introduced by Ash-Stevens \([AS00]\) in their work on \(GL_n\). Let \(L/\mathbb{Q}_p\) be a finite extension. A polynomial \(Q(X) \in L[X]\) of degree \(d \in \mathbb{Z}_{\geq 0}\) is said of slope \(\leq h\) if \(Q(0) \in O_L^X\) and if the roots of \(Q^*(X) := X^dQ(1/X)\) in \(\overline{\mathbb{Q}}_p\) have their slope (i.e \(p\)-adic valuation) less or equal to \(h\).

Let \(M\) be a vector space over \(L\) and let \(u\) be a (continuous) linear endomorphism of the vector space \(M\). We do not require \(M\) to be equipped with a \(p\)-adic topology. A \(\leq h\)-slope decomposition of \(M\) with respect to \(u\) is a direct sum decompostion \(M := M_1 \oplus M_2\) such that:

1. \(M_1\) and \(M_2\) are stable under the action of \(u\).
2. \(M_1\) is finitely dimensional over \(L\).
3. The polynom \(\det(1 - X.u|M_1)\) is of slope \(\leq h\).
4. For any polynomial \(Q\) of slope \(\leq h\), the restriction of \(Q^*(u)\) to \(M_2\) is an invertible endomorphism of \(M_2\).

Lemma 2.3.2. Let \(M\) and \(M'\) be two \(L\)-vector spaces. Let \(u\) and \(u'\) be two endomorphisms of \(M\) and \(M'\) respectively. Let \(M = M_1 \oplus M_2\) and \(M' = M'_1 \oplus M'_2\) be \(\leq h\)-slope decomposition of \(M\) and \(M'\) with respect to \(u\) and \(u'\) respectively. Let \(f\) be a (continuous) \(L\)-linear map from \(M\) to \(M'\) satisfying \(f \circ u = u' \circ f\). Then \(f\) maps respectively \(M_1\) and \(M_2\) into \(M'_1\) and \(M'_2\) (i.e. \(f(M_i) \subset M'_i\) for \(i = 1, 2\)).

Proof. Let \(Q(X) := \det(1 - X.u|M_1)\) and \(Q'(X) := \det(1 - X.u'|M'_1)\). Let \(z \in M_1\) and write \(f(z) = x + y\) with \(x \in M'_1\) and \(y \in M'_2\). Since \(Q^*(u).z = 0\), we must have \(Q^*(u').x = -Q^*(u').y = 0\). By hypothesis, \(Q^*(u')\) is invertible.

\(^{13}\)Our definition is actually stronger than theirs since they don’t require that \(M_1\) has a stable direct factor.
Corollary 2.3.3. Let $M$, $u$ and $h$ as in 2.3.1. Then, we have uniqueness of the $\leq h$-slope decomposition of $M$. We will write $M_{\leq h}$ for $M_1$ and $M_{>h}$ for $M_2$.

Proof. Apply the previous lemma for $M = M'$ and $f = id_M$. ■

Corollary 2.3.4. Let $M, M', u, u'$ and $f$ as in the previous lemma and suppose there is a map $\phi : M' \to M$ such that we have a commutative diagram:

\[
\begin{array}{ccc}
M & \xrightarrow{f} & M' \\
\downarrow{\phi} & & \downarrow{u'} \\
M & \xrightarrow{f} & M'
\end{array}
\]

Assume that $M$ and $M'$ have $\leq h$-slope decompositions with respect to $u$ and $u'$. Then $f$ induces an isomorphism between $M_{\leq h}$ and $M'_{\leq h}$.

Proof. By Lemma 2.3.2, $f$ induces a map $M_{\leq h} \to M'_{\leq h}$. We want to show it is an isomorphism. From the definition of the $\leq h$-slope decomposition, the restrictions of $u$ and $u'$ to respectively $M_{\leq h}$ and $M'_{\leq h}$ are invertible. Since we have $\phi \circ f = u$ and $f \circ \phi = u'$, this implies easily that $f$ induces an isomorphism from $M_{\leq h}$ onto $M'_{\leq h}$. ■

Corollary 2.3.5. Let $M$, $u$ and $h$ as in 2.3.1 and $N \subset M$ a subspace stable under the action by $u$. Assume that $M$ has a $\leq h$-slope decomposition. Then $N$ has $\leq h$-slope decomposition if and only if $M/N$ does. When this is the case, we have

- $(M/N)_{\leq h} = M_{\leq h}/N_{\leq h}$ and $N_{\leq h} = N \cap M_{\leq h}$.
- $(M/N)_{>h} = M_{>h}/N_{>h}$ and $N_{>h} = N \cap M_{>h}$.

Proof. Assume $N$ has a slope decomposition (The other case is left to the reader). From the lemma 2.3.2, we have $N_{\leq h} \subset M_{\leq h}$ and $N_{>h} \subset M_{>h}$. Hence $N_{\leq h} = N \cap M_{\leq h}$ and $N_{>h} = N \cap M_{>h}$ therefore $\bar{M} = M/N = \bar{M}_1 \oplus \bar{M}_2$ with $\bar{M}_1 := M_{\leq h}/N_{\leq h}$ and $\bar{M}_2 := M_{>h}/N_{>h}$. The first three conditions of 2.3.1 are obviously satisfied. If $Q$ is a polynomial of slope $\leq h$, $Q^*(u)$ induces an isomorphism of $M_{>h}$ and of $N_{>h}$. It therefore induces an isomorphism on the quotient $\bar{M}_2$ which proves the fourth condition. ■
2.3.6. Finite slope part of $M$ for an operator $u$. Let $M$ and $u$ be as in the section 2.3.1. Let $h' \in \mathbb{Q}$ with $h' \geq h$. Then if $M$ has a $\leq h'$-slope decomposition wrt. $u$, it has a $\leq h$-slope decomposition and we have a $u$-stable decomposition $M^{\leq h'} = M^{\leq h} \oplus M^{>h, \leq h'}$ such that $M^{>h} = M^{>h, \leq h'} \oplus M^{>h'}$. We will say that $M$ has a slope decomposition with respect to $u$ if for an increasing sequence $h_n$ of rationals going to infinity (and therefore for all such sequences) $M$ has a $\leq h_n$-slope decomposition for all $h_n$. Then we put

$$\det(1 - X.u) := \lim_{n \to \infty} \det(1 - X.u|M^{\leq h_n})$$

for $(h_n)_n$ any sequence of rationals going to infinity. It is straightforward to check that this sequence is convergent in $L[[X]]$ and that the limit does not depend of the sequence $(h_n)$. If $M$ has a slope decomposition with respect to $u$, we write sometimes $M_{\text{fs}}$ to denote the inductive limit over $n$ of the $M^{\leq h_n}$'s. We call it the finite slope part of $M$. The space $M_{\text{fs}}$ has obviously a slope decomposition and $M^{\leq h}_{\text{fs}} = M^{\leq h}$ for all $h$.

2.3.7. Let now $N \subset M$ be a $u$-stable subspace of $M$. Assume that $N$ has a slope decomposition. Then by Corollary 2.3.5, so does $M/N$ and we have:

$$\det(1 - X.u|M) = \det(1 - X.u|N). \det(1 - X.u|(M/N))$$

**Theorem 2.3.8.** Let $A$ be a Banach $\mathbb{Q}_p$-algebra, $M$ be a projective Banach $A$-module and $u$ be a compact $A$-linear operator of $M$. Then $P(X,u) := \det(1 - X.u|M)$ is an entire power series with coefficient in $A$ (i.e. $\in A\{\{T\}\}$).

If we have a prime decomposition $P(X,u) = Q(X)S(X)$ in $A\{\{X\}\}$ with $Q$ a polynomial such that $Q(0) = 1$ and $Q^*(0)$ is invertible in $A$, then there exist an entire power series $R_Q(T) \in TA\{\{T\}\}$ whose coefficients are polynomials in the coefficients of $Q$ and $S$ and we have a decomposition of $M$

$$M = N_u(Q) \oplus F_u(Q)$$

of closed sub $A$-modules such that

1. The projector on $N_u(Q)$ is given by $R_Q(u)$,
2. $Q^*(u)$ annihilates $N_u(Q)$,
3. $Q^*(u)$ is invertible on $F_u(Q)$.

If moreover $A$ is noetherian then $N_u(Q)$ is projective of rank $r$ and

$$\det(1 - X.u|N_u(Q)) = Q(X).$$

**Proof.** This follows directly from results of Serre’s and Coleman’s works and their proofs and some generalizations by Buzzard. See [Co97, Se62, Bu04].
If $A = L =$ is a finite extension of $\mathbb{Q}_p$, an immediate consequence of the previous result is that $M$ has a $\leq h$-slope decomposition for any $h \in \mathbb{Q}$. Moreover the definitions of $\det(1 - X.u|M)$ of §2.3.6 and §2.2 coincide. The following proposition is not really needed but it shows that taking the Hausdorff quotient does not harm when considering finite slope part for a given operator.

**Proposition 2.3.9.** Let $N \xrightarrow{j} M$ a continuous injection of $L$-Banach spaces (we don’t assume the image is closed). Let $u_N$ and $u_M$ be respectively compact endomorphisms of $N$ and $M$ such that $j \circ u_N = u_M \circ j$. Then $M/j(N)$ have slope decompositions with respect to $u_{M/N} = u_M$ (mod $j(N)$) and

$$\det(1 - X.u_M) = \det(1 - X.u_N). \det(1 - X.u_{M/N})$$

Let $\overline{j(N)}$ the closure of the $j(N)$ inside $M$. Then $u$ induces a compact operator $\tilde{u}_{M/N}$ on the Hausdorff quotient $M/N = M/\overline{j(N)}$ of $M/N$ and we have:

$$\det(1 - X.u_{M/N}) = \det(1 - X.\tilde{u}_{M/N}).$$

**Proof.** By Serre’s theorem (Theorem 2.3.8 with $A = L$), $N$ has a slope decomposition with respect to $u_N$ and therefore so $j(N)$ does with respect to $u_M$ since $j$ is injective and $j \circ u_N = u_M \circ j$. The first formula follows from 2.3.7. We now prove the second part of the corollary. Notice first that

$$j(N) = j(N)^{\leq h} \oplus j(N)^{> h}. \tag{9}$$

Indeed let $z_n = x_n + y_n$ be a sequence of $N$ with $x_n \in N^{\leq h}$ and $y_n \in N^{>h}$ such that $j(z_n)$ is converging in $M$. To prove our claim, it suffices to show for example that $j(y_n)$ converges in $M^{>h}$. Let $Q = \det(1 - X.u|M^{\leq h})$. Then the sequence $Q^*(u).j(z_n) = Q^*(u).j(y_n)$ must converge. Since $Q^*(u)$ is a continuous isomorphism of the Banach subspace $M^{>h}$ it is bi-continuous by the open mapping theorem. Therefore $y_n$ converges to $y$ and we have proved (9). We deduce easily from the fact that $M^{\leq h}$ and $M^{>h}$ are closed and the inclusion $j(N)^{\leq h} \subset M^{\leq h}$ and $j(N)^{>h} \subset M^{>h}$ that (9) is the $\leq h$-slope decomposition of $\overline{j(N)}$. Since $N^{\leq h}$ is finite dimensional, we have $j(N^{\leq h}) = \overline{j(N)^{\leq h}}$ and from the decomposition (9), this is equal to the $\leq h$-slope part of $\overline{j(N)}$. Therefore $\det(1 - X.u_N|N^{\leq h}) = \det(1 - X.u_M|\overline{j(N)}^{\leq h})$. This equality for all $h$ implies that $\det(1 - X.\overline{j(N)}) = \det(1 - X.u_M|\overline{j(N)})$ and the last claim follows from the first equality for the lemma applied to $j(N) \subset M$ and $\overline{j(N)} \subset M$. \[Q.E.D.\]

2.3.10. **Fredholm determinant for complexes revisited.** We assume that $M^\bullet$ is a perfect complex of Banach vector spaces over $L$ a finite extension of $\mathbb{Q}_p$. Let $u^\bullet : M^\bullet \rightarrow M^\bullet$ a continuous endomorphism of $M^\bullet$ such that for all $q$, the operator $u^q \in \text{End}_L(M^q)$ is a compact operator.
Let us denote by \( d^q \) the differential homomorphism of the resolution from \( M^q \) to \( M^{q+1} \). By definition, this homomorphism is continuous and therefore \( \text{Ker} \ d^q \) is a Banach subspace of \( M^q \). However \( \text{Im} \ d^{q-1} \subset \text{Ker} \ d^q \) is not necessarily closed and therefore \( \tilde{H}^q(M^\bullet) = \text{Ker} \ d^q/\text{Im} \ d^{q-1}(M^{q-1}) \) might not be Hausdorff. We denote by \( \tilde{H}^q(M^\bullet) \) its maximal Hausdorff quotient. We have \( \text{Ker} \ d^q/\text{Im} \ d^{q-1}(M^{q-1}) = \tilde{H}^q(M^\bullet) \).

On the other hand, since \( d^q \) is continuous and commutes with \( u^q \), \( \text{Ker} \ (d^q) \) is a Banach space with action of \( u^q \). It therefore has a slope decomposition and this implies that \( M^q/\text{Ker} \ (d^q) \cong \text{Im} \ (d^q) \) has a slope decomposition. This is true for all \( q \)'s therefore \( \tilde{H}^q(M^\bullet) = \text{Ker} \ (d^q)/\text{Im} \ (d^{q-1}) \) has a slope decomposition. Let us write \( \tilde{H}_f^q(M^\bullet) \) its finite slope part. By the proposition above and its proof we can therefore deduce that

\[
\tilde{H}_f^q(M^\bullet) = \tilde{H}^q(M^\bullet)_{fs}
\]

**Corollary 2.3.11.** With the notations as above, we have

\[
\det(1 - X.u^q|M^\bullet) = \prod_q \det(1 - X.u^q|\tilde{H}^q(M^\bullet))^{(-1)^q}.
\]

**Proof.** We put \( M = \text{Ker} \ d^q, N = M^{q-1}/\text{Ker} \ d^{q-1} \) with its structure of quotient Banach space and let \( j \) the continuous injective homomorphism from \( N \) into \( M \) induced by \( d^q \) so that \( j(N) = \text{Im} \ d^{q-1} \). By the previous proposition, we have

\[
det(1 - X.u^q|\tilde{H}^q(M^\bullet)) = \det(1 - X.u^q|\tilde{H}^q(M^\bullet)) = \frac{\det(1 - X.u^q|\text{Ker} \ d^q)}{\det(1 - X.u^q|\text{Im} \ (d^{q-1}))}
\]

On the other hand, from the exact sequence \( 0 \rightarrow \text{Ker} \ d^q \rightarrow M^q \rightarrow \text{Im} \ d^q \rightarrow 0 \) by the previous proposition we have:

\[
det(1 - X.u^q|M^q) = \det(1 - X.u^q|\text{Ker} \ d^q). \det(1 - X.u^q|\text{Im} \ d^q)
\]

Making now the alternate product over \( q \) and combining the above two equalities provide the desired result.

**2.3.12. Generalization to compact \( p \)-adic Frechet spaces or \( p \)-adic nuclear spaces.** Recall that a \( p \)-adic topological vector space \( V \) is called a compact \( p \)-adic Frechet space if it is the projective limite of \( p \)-adic Banach spaces \( V_n \) such that the transition maps \( V_n \rightarrow V_m \) for \( n > m \) are completely continuous. An endomorphism \( u \) of \( V \) will be said compact if it is continuous and if for each \( n \) we have a commutative diagram of continuous maps:

\[
\begin{array}{ccc}
V & \longrightarrow & V_{n-1} \\
\downarrow u & & \downarrow u' \\
V & \longrightarrow & V_n
\end{array}
\]
where the horizontal arrows are the canonical projection maps coming from the projective limit. By composing \( u'_n \) with the transition map \( V_n \rightarrow V_{n-1} \) we get an endomorphism \( u_n \) of the Banach space \( V_n \) which is completely continuous. It is easy to check that \( u_n \) is uniquely determined by \( u \) and that we have the following commutative diagram for any \( n \):

\[
\begin{array}{ccc}
V & \xrightarrow{u} & V_n \\
\downarrow u_n & & \downarrow u_{n-1} \\
V & \xrightarrow{u'_n} & V_{n-1}
\end{array}
\]

If the \( V_n \) are projective Banach space on some Banach algebra \( A \), then we put

\[
tr(u; V) := tr(u_n; V_n)
\]

and it is clear from the above diagram that this definition is independent of \( n \). Similarly we can write slope decomposition for \( V \) as we did for \( p \)-adic Banach spaces. More generally, it is easy to see that all the previous discussion on compact operators on complexes of \( p \)-adic Banach spaces extends \textit{mutatis mutandis} to the case of compact operators on complexes of compact Frechet spaces. We will take this fact for granted in the following sections and apply the results explicitly stated for Banach spaces to the case of compact \( p \)-adic Frechet spaces without further notice. We need to state the following lemma.

**Lemma 2.3.13.** Let \( u \) be a compact operator on a compact Frechet space \( V \) over a finite extension of \( \mathbb{Q}_p \). For any \( h \geq 0 \), there is a \( \leq h \)-slope decomposition of \( V \) with respect to \( u \). Moreover, we have:

\[
V^{\leq h} \cong V_n^{\leq h}
\]

for all \( n \) where for each \( n \), \( V_n = V_n^{\leq h} \oplus V_n^{> h} \) is the slope decomposition of \( V_n \) with respect to \( u_n \). This fact holds as well for compact maps between complexes of compact Frechet spaces and the induced slope decomposition on their cohomology.

**Proof.** By Lemma 2.3.2, the projection \( V_m \rightarrow V_n \) for \( n > m \) induces projections on the \( \leq h \)-slope decompositions of \( V_m \) and \( V_n \) with respect to \( u_m \) and \( u_n \). This implies that \( V^{\leq h} = \lim_{\leftarrow n} V_n^{\leq h} \) and \( V^{> h} = \lim_{\leftarrow n} V_n^{> h} \) are well defined and provide a \( \leq h \)-slope decomposition for \( V \). We are left now to prove that the projections \( V_n^{\leq h} \rightarrow V_m^{\leq h} \) are actually isomorphisms. By an induction argument, it is sufficient to prove this for any \( m > n \). But for \( m = n' \) as in the diagram above, this follows from Corollary 2.3.4. The result holds clearly when one replaces \( V \) by a complex of compact Frechet spaces and this implies the result for the cohomology by the arguments used in this section. \( \blacksquare \)
3. *p*-adic Overconvergent coefficients

Let $L$ be a finite extension of $\mathbb{Q}_p$. The goal of this section is to define the system of overconvergent$^{14}$ coefficients that will be used to interpolate the cohomology of the local systems $V_{\lambda}(L)$. As in the original $GL(2)$-situation carried over by H. Hida in the ordinary case and by G. Stevens in general, the idea to do this is to replace $V_{\lambda}(L)$ by a system of coefficients which doesn’t depend on the weight but endowed with an action$^{15}$ of $G$ which does depend on the weight. When $G = GL(n)$, one recovers the construction due to A. Ash and G. Stevens in [AS00] which they recently generalized in [AS06].

3.1. Basic Notations and Definitions.

3.1.1. Algebraic data. In this section, $G$ is a connected reductive group over $\mathbb{Q}_p$ that we suppose quasi-split$^{16}$ and splitting over a finite unramified extension of $\mathbb{Q}_p$. We fix $T$ a maximal torus of $G$ and $B$ a Borel subgroup containing $T$. By our assumptions, we can (and do) choose $F/\mathbb{Q}_p$ a finite Galois and unramified extension of $\mathbb{Q}_p$ over which $G$ is split. Then $(B_{/F}, T_{/F})$ defines a Borel pair of $G_{/F}$. We denote by $N$ the unipotent radical of $B$ and $B^-$ (resp. $N^-$) the opposite Borel subgroup (resp. opposite unipotent radical).

We set the lattice of algebraic weights $X^*(T) := \text{Hom}_{gp}(T_{/F}, \mathbb{G}_{m/F}) \hookrightarrow \text{Hom}_{F}(t_{/F}, F)$ and algebraic co-weights $X^*_s(T) := \text{Hom}(\mathbb{G}_{m/F}, T_{/F})$ and we denote by $(.,.)$ the canonical pairing on $X^*_s(T) \otimes X^*(T)$. We let $R^+ \subset X^*(T)$ be the set of positive roots with respect to $(B, T)_{/F}$. For each root $\alpha \in R$, we denote $H_\alpha$ (resp. $\alpha^\vee$) the corresponding coroot in $t_{/F}$ (resp. in $X^*_s(T)$; recall that $(\alpha, \alpha^\vee) = \alpha(H_\alpha) = 2$. For each root $\alpha$, we also choose a basis $X_\alpha$ of $g_\alpha = \{ X \in g_{/F} | \text{ad}(t).X = \alpha(t)X \ \forall t \in T \}$ such that $[X_\alpha, X_{-\alpha}] = H_\alpha$. A weight $\lambda \in X^*(T)$ is called dominant with respect to $B$ if $\lambda(H_\alpha) \geq 0$ for all positive root $\alpha$ and we write $X^*(T)^+$ for the cone of dominant weights.

We denote by $W$ the Weyl group of the pair $(G_{/F}, T_{/F})$ acting on $T_{/F}$ and therefore on the lattices $X^*(T)$ and $X^*_s(T)$. It is generated by elements of order two called simple reflexions $s_\alpha$ for $\alpha$ running among the simple roots of $R$. The action on the weights is given by the well-known formula $s_\alpha(\lambda) = \lambda - \lambda(H_\alpha)\alpha$ for any $\alpha \in R$. We will also need the notion of length of an element of $W$. It can be defined as the smallest integer $l$ such that there

---

$^{14}$This terminology is non standard. It is used as a reminiscence of the notion of overconvergent modular forms.

$^{15}$Not an action of $G$ in fact but of some sub semi-group of it containing an Iwahori subgroup.

$^{16}$These assumptions are certainly unnecessary if one wants to use the language of Bruhat-Tits’ buildings.
is a decomposition $w = s_{\alpha_1} \cdots s_{\alpha_l}$ where the $\alpha_i$'s are simple roots. Such a decomposition is called a reduced decomposition.

3.1.2. Iwahori subgroups and semi-groups. We fix $I \subset G(\mathbb{Q}_p)$ an Iwahori subgroup in good position with respect to $B$. By this, we mean that we have fixed compatible integral models for $G, B, T, N, N^-$ over $\mathbb{Z}_p$ such that $I = I_1$ where we have put for every integer $m \geq 1$:

$I_m := \{g \in G(\mathbb{Z}_p) | g \mod p^m \in B(\mathbb{Z}/p^m\mathbb{Z})\}$
$I'_m := \{g \in G(\mathbb{Z}_p) | g \mod p^m \in N(\mathbb{Z}/p^m\mathbb{Z})\}$

We have $I_m/I'_m \cong T(\mathbb{Z}/p^m\mathbb{Z})$. Recall that we have the Iwahori decomposition:

$I_m = I_m^- T(\mathbb{Z}_p).N(\mathbb{Z}_p)$

with $I_m^- := I_m \cap N^-(\mathbb{Q}_p)$. We consider $T^+$ the set of elements $t \in T(\mathbb{Q}_p)$ such that

$t^{-1}.N(\mathbb{Z}_p).t \subset N(\mathbb{Z}_p)$

and $T^{++} \subset T^+$ the set of elements $t$ such that

$\bigcap_{i \geq 1} t^{-i}.N(\mathbb{Z}_p).t^i = \{1\}$

and we put $\Delta_m^+ = I_m T^+ I_m$ and $\Delta_m^{++} = I_m T^{++} I_m$. We will drop the index $m$ from the notation, when it is equal to 1. Using the Iwahori decomposition, it is straightforward to see that any element $g \in \Delta_m^+$ has a unique decomposition:

(10) $g = n_g^- t_g n_g^+ \quad \text{with} \quad n_g^- \in I_m^-, \ t_g \in T^+ \text{ and } n_g^+ \in N(\mathbb{Z}_p)$

The set $T^+$ and $T^{++}$ are sub semi-groups of $T(\mathbb{Q}_p)$ and we clearly have $T(\mathbb{Z}_p) \subset T^+$. Since $T(\mathbb{Q}_p)/T(\mathbb{Z}_p)$ is isomorphic to a sum of copies of $\mathbb{Z}$, we may choose a splitting\footnote{This choice is similar to the choice of uniformizing elements in the definition of Hecke operators at places dividing $p$ in [Hi88].} $\xi$ of the canonical projection $T(\mathbb{Q}_p) \to T(\mathbb{Q}_p)/T(\mathbb{Z}_p)$ which induces an isomorphism of groups:

$T(\mathbb{Q}_p) \cong T(\mathbb{Z}_p) \times T(\mathbb{Q}_p)/T(\mathbb{Z}_p)$

We will also write $\xi$ for the composite $T(\mathbb{Q}_p) \to T(\mathbb{Q}_p)/T(\mathbb{Z}_p) \to T(\mathbb{Q}_p)$. Notice that $\xi(T^+) \subset T^+$ since $\xi(t)t^{-1} \in T(\mathbb{Z}_p)$ for all $t \in T(\mathbb{Q}_p)$. If $T$ is split over an unramified extension of $\mathbb{Z}_p$, we can (and do) choose $\xi$ so that for any algebraic character $\lambda^{alg} \in X^*(T)$, we have

(11) $\lambda^{alg}(\xi(t)) = |\lambda^{alg}(t)|^{-1}$

for all $t \in T(\mathbb{Q}_p)$.\footnote{This choice is similar to the choice of uniformizing elements in the definition of Hecke operators at places dividing $p$ in [Hi88].}
3.1.3. The left $\ast$-action of $I$ and $\Delta^+$ on some $p$-adic spaces. We consider the following $p$-adic cells:

\[ \Omega_0 := I_1 T(\mathbb{Z}_p) \backslash I \subset B^{-}(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p) \]
\[ \Omega_1 := I_1^{-} \backslash I \subset N^{-}(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p) \]

By the Iwahori decomposition, we have $\Omega_0 \cong N(\mathbb{Z}_p)$ and $\Omega_1 \cong B(\mathbb{Z}_p)$. For any element $x \in G(\mathbb{Q}_p)$, let us denote by $[x]$ its class in $B^{-}(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p)$. Then the right translation by $I$ defines an action on $\Omega_0$ by $[x] \ast g = [xg]$. We can extend this action into an action of $\Delta^+$. For this it is convenient to introduce the $p$-adic spaces:

\[ \Omega_0^+ := I_1 T(\mathbb{Z}_p) \backslash \Delta^+ \subset B^{-}(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p) \]
\[ \Omega_1^+ := I_1 \backslash \Delta^+ \subset N^{-}(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p) \]

We have a retraction $s : \Omega_0^+ \to \Omega_0$ for the natural inclusion $\Omega_0 \subset \Omega_0^+$ defined by $[g] \mapsto s([g]) := [\xi(t_g^{-1})g]$ where the element $t_g$ is defined via the decomposition (10) and $\xi$ is the section defined in the previous paragraph. Since $\xi(t_g) = 1$ when $g \in I$, this is a well-defined retraction of the inclusion $\Omega_0 \subset \Omega_0^+$. Then the action\(^{18}\) of $g \in \Delta^+$ on $\Omega_0$ is defined by:

\[ [x] \ast g := s([xg]) = [\xi(t_g)^{-1}xg] \]

We define the action of $I$ and $\Delta^+$ on $\Omega_1$ using the same retraction of $\Omega_1 \subset \Omega_1^+$.

**Lemma 3.1.4.** The above formula gives a well defined left action of the semi-group $\Delta^+$ on $\Omega_1$ that extends the natural action of $I$.

**Proof.** On needs to show that $[x] \ast gg' = ([x] \ast g) \ast g'$ for any $g, g' \in \Delta^+$. This follows from the fact that $t_{gg'} = t_g t_{g'}$ which is easily checked using the Iwahori decomposition. Indeed we have: $[x] \ast gg' = [\xi(t_{g'}^{-1})xg] = [\xi(t_g t_{g'})]g' = ([x] \ast g) \ast g'$. Moreover, if $g \in I$, $\xi(t_g) = 1$. Therefore the action of $\Delta^+$ restricted to $I$ is the same as the right translation by $I$. ■

3.2. Local analytic induction.

3.2.1. Analytic functions. We now recall some definitions and some fact on locally analytic functions. We will call $p$-adic space any topological space $X$ which is isomorphic\(^{19}\) to an open subset of $\mathbb{Q}_p^r$ for some $r$. We will always identify such a space with an open subset of $\mathbb{Q}_p^r$ and the definitions below will not depend of this identification. In the examples we will consider later $X$ will be either a compact open subset of $G(\mathbb{Q}_p)$ or $\Omega_0$ that we will identify with $N(\mathbb{Z}_p)(\subset G(\mathbb{Q}_p))$ via the Iwahori decomposition.

\(^{18}\)The reader should keep in mind now and in all this paper that the $\ast$-action depends of the splitting character $\xi$.

\(^{19}\)defined up to a (locally) $\mathbb{Q}_p$-algebraic isomorphism
Let $L$ be a finite extension of $\mathbb{Q}_p$. A continuous function on such a space, $f : X \to L$, is said $L$-analytic if it can be expressed as a converging power series:

$$f(x_1, \ldots, x_r) = \sum_{n_1, \ldots, n_r} \alpha_{n_1, \ldots, n_r} (x_1 - a_1)^{n_1} \cdots (x_r - a_r)^{n_r}$$

for all $(x_1, \ldots, x_r) \in X$ where $\alpha_{n_1, \ldots, n_r} \in L$ for some $\alpha = (a_1, \ldots, a_r) \in X$. Of course, it is algebraic if almost all the $\alpha_{n_1, \ldots, n_r}$'s are zero. Basic examples of analytic functions are given by the logarithm or exponential functions respectively defined on $p$-adic Lie groups and Lie algebras.

For any integer $n \in \mathbb{Z}$, we will say that $f : X \to L$ is $n$-locally $L$-analytic if $X$ can be covered by disks of radius $p^{-n}$ over which $f$ is $L$-analytic. It is said locally $L$ analytic if it is $n$-locally $L$-analytic for some $n$. We usually denote by $A(X, L)$ the space of locally $L$-analytic functions on $X$ and by $A_n(X, L) \subset A(X, L)$ those that are $n$-locally analytic. Of course, we have:

$$A(X, L) = \bigcup_{n \geq 0} A_n(X, L)$$

If $X$ is compact, each $A_n(X, L)$ is a $p$-adic Banach space equipped with sup norm:

$$\|f\|_n := \text{Sup}_a |\alpha_{n_1, \ldots, n_r}(a)|_p p^{-n} \sum_{i=1}^r n_i$$

where the $a = (a_1, \ldots, a_r)$'s run into the set of centers of disks of radius $p^{-n}$ inside $X$ and where the $\alpha_{n_1, \ldots, n_r}(a)$'s are the coefficients of the Taylor expansion at the point $a$ described as in the expression (12). The $L$-vector space $A(X, L)$ is then naturally equipped with the inductive limit topology of the $A_n(X, L)$’s. We have the well-known elementary lemma.

**Lemma 3.2.2.** Assume $X$ is compact, then the inclusions $A_n(X, L) \subset A_{n+1}(X, L)$ are completely continuous.

**Proof.** Since $X$ is compact, it easy to reduce this statement to the compactness of the restriction map: $A_n(p^n \mathbb{Z}_p^r) \to A_{n+1}(p^{n+1} \mathbb{Z}_p^r)$. This fact is an elementary exercise left to the reader.

Let $\mathcal{D}(X, L)$ (resp. $\mathcal{D}_n(X, L)$) be the continuous $L$-dual of $A(X, L)$ (resp. $A_n(X, L)$). The space $\mathcal{D}(X, L)$ is called the space of $L$-valued distribution on $X$. Then $\mathcal{D}(X, L)$ is the projective limit over $n$ of the $\mathcal{D}_n(X, L)$. An immediate corollary of the previous lemma is:

**Corollary 3.2.3.** If $X$ is compact, $\mathcal{D}(X, L)$ is a compact Frechet space.

3.2.4. **Weights.** A $p$-adic weight is a continuous (for the $p$-adic topology) group homomorphism

$$\lambda : T(\mathbb{Z}_p) \to \mathbb{Q}_p^\times.$$  

A weight is called algebraic if it can be obtained as the composite

$$T(\mathbb{Z}_p) \hookrightarrow T(\mathbb{F}) \xrightarrow{\lambda_{\mathbb{F}}} \mathbb{F}^\times \subset \mathbb{Q}_p^\times.$$
for some $\lambda^{alg} \in X^*(T)$. In fact, we can see that any weight is locally analytic:

**Lemma 3.2.5.** Let $L \subset \overline{\mathbb{Q}}_p$ be a finite extension of $F$. Any continuous $p$-adic character $\lambda \in \text{Hom}_{cont}(T(\mathbb{Z}_p), L^\times)$ is $n$-locally $L$-analytic for some $n \geq 0$. We sometimes denote by $n_\lambda$ the smallest $n$ for which this is the case.

**Proof.** This is a special case of Lemma 3.4.6. Let $t := \text{Lie } T_{/\mathbb{Z}_p}$. Then $H \mapsto \log(\lambda(exp(H)))$ is well defined if $H$ is sufficiently closed to 0 in $t$. It is $\mathbb{Z}_p$-linear and so defines an element $\lambda^{an} \in \text{Hom}(t, L) = X^*(T) \otimes L$. Then we have $\lambda(t) = \exp(\lambda^{an}(\log(t)))$ if $t$ is sufficiently closed to 1 in $T(\mathbb{Z}_p)$. In particular, $\lambda$ is analytic on a neighborhood of 1 and it is therefore locally analytic.\]

Notice that $\lambda$ is $n$-locally algebraic for some $n$ if and only if $\lambda^{an} \in X^*(T)$. In that case, we write $\lambda^{alg}$ for the corresponding algebraic character and we have a decomposition

$$\lambda = \lambda^{alg} \cdot \epsilon$$

with $\epsilon$ a finite order character factorizing through $T(\mathbb{Z}_p/p^n \mathbb{Z})$. We will say in that case that $\epsilon$ of $\lambda$ is of level $p^n$. We will say that $\lambda$ is arithmetic if it is locally algebraic and if $\lambda^{alg}$ is dominant (i.e. $\lambda^{alg} \in X^*(T)^\times$).

**3.2.6. Locally analytic induction spaces.** Let $L \subset \overline{\mathbb{Q}}_p$ be a finite extension of $\mathbb{Q}_p$ and $\lambda$ be an $L$-valued weight (i.e. $\lambda \in \text{Hom}_{cont}(T(\mathbb{Z}_p), L^\times)$). Then we denote $A_\lambda(L) \subset A(I, L)$ the space of locally $L$-analytic function on $I$ such that:

$$f(n^-tg) = \lambda(t)f(g)$$

for all $n^- \in I^-_L$, $t \in T(\mathbb{Z}_p)$ and $g \in I$. This space is a closed subspace of the topological space $A_\lambda(I, L)$ and is therefore a compact inductive limit of $L$-Banach spaces. By the Iwahori decomposition, we see that we have a canonical linear homeomorphism $\psi_\lambda : A_\lambda(L) \cong A(\Omega_0, L)$ via the map $f \mapsto \psi_\lambda(f)$ where $\psi_\lambda(f)$ is defined by

$$\psi_\lambda(f)([g]) := f(n_g), \quad \forall g \in I.$$

Therefore, we see that $A_\lambda(L)$ satisfies the topological properties of $A(\Omega_0, L)$. In particular, its $L$-dual, that we denote $D_\lambda(L)$ is a compact Frechet space. Our space $A_\lambda(L)$ is equipped with a continuous left action of $I$ defined by $(g,f)(h) := f(hg)$ for all $g, h \in I$. It is easy to check that this action is continuous. We therefore inherit a (dual) continuous right action of $I$ on $D_\lambda(L)$.

Since elements of $f$ are left invariant by $I^-$, we have also a natural inclusion $A_\lambda(L) \subset A(\Omega_1, L)$. If $f \in A_\lambda(L)$, let us write $\hat{f}$ the corresponding element in $A(\Omega_1, L)$. Then we have $\hat{f}([g]) := f(g)$. We have a natural action of $T(\mathbb{Z}_p)$ on $A(\Omega_1, L)$. If $\phi \in A(\Omega_1, L)$ and $t \in T(\mathbb{Z}_p)$, we set

$$(t, \phi)([g]) := \phi([tg])$$
It is easy to check that it is well defined and that \( \phi = \hat{f} \) for some \( f \in \mathcal{A}_\lambda(L) \) if and only if \( t.\phi = \lambda(t)\phi \). In other words we have an identification
\[
\mathcal{A}_\lambda(L) = \mathcal{A}(\Omega_1, L)[\lambda] := \{ \phi \in \mathcal{A}(\Omega_1, L) \mid t.\phi = \lambda(t)\phi \}
\]
We now consider the \( * \)-action of \( \Delta^+ \) on these spaces. For any \( g \in \Delta^+ \) and \( \phi \in \mathcal{A}(\Omega_1, L) \), we defined \( g*\phi \) by:
\[
(g*\phi)([x]) := \phi([x]*g)
\]
for all \([x] \in \Omega_1\).

Lemma 3.2.7. The \( * \)-action of \( \Delta^+ \) commutes with the natural action of \( T(Z_p) \) on \( \mathcal{A}(\Omega_1, L) \). In particular, \( \mathcal{A}_\lambda(L) \) is stable by the \( * \)-action of \( \Delta^+ \). Moreover, for any \( g \in I \), the \( * \)-action of \( I \) on \( \mathcal{A}_\lambda(L) \) coincides with the natural left action:
\[
(g*f)([h]) = f(hg)
\]
for all \( g, h \in I \).

Proof. Let \( x \in I \), \( t \in T(Z_p) \) and \( g \in \Delta^+ \), then we have \( (t.(g*\phi))([x]) = (g*\phi)([tx]) = \phi([\xi(tg)^{-1}txg]) = \phi([t\xi(tg)^{-1}]xg) = (t.\phi)([tg^{-1}xg]) = (g*(tg^{-1}x))([x]) \). This obviously implies that \( \mathcal{A}_\lambda(L) \) is stable by the \( * \)-action. Let us check the last point now. Indeed we have \([h]*g = [hg] \) if \( g \in I \), therefore \( (g*f)([h]) = f([h]*g) = f([hg]) \).

We consider the dual right action of \( \Delta^+ \) on \( \mathcal{D}_\lambda(L) \). This \( * \)-action is a very important ingredient of the theory developed in this paper. In particular, the following lemma (although easy) is crucial\(^{20}\).

Lemma 3.2.8. If \( \delta \in \Delta^{++} \), then the right \( * \)-action of \( \delta \) defines a compact operator of the compact Frechet space \( \mathcal{D}_\lambda(L) \).

Proof. We may suppose that \( \delta \in T^{++} \) since the action of \( I \) is continuous. Let us put \( \mathcal{A}_{m,\lambda}(L) := \psi^{-1}_\lambda(\mathcal{A}_m(\Omega_0, L)) \). To prove the lemma, we check that the \( * \)-action of \( \delta \) on \( \mathcal{A}_{m,\lambda}(L) \) factorizes through the natural inclusion \( \mathcal{A}_{m-1,\lambda}(L) \subset \mathcal{A}_{m,\lambda}(L) \). Since this one is completely continuous by Lemma 3.2.2, this will prove our claim. If \( f \in \mathcal{A}_{m,\lambda}(L) \), then
\[
(13) \quad \psi_\lambda(\delta*f)([n]) = \psi_\lambda(f)([\xi(\bar{\delta})^{-1}n\delta]) = \lambda(\xi(\bar{\delta})^{-1}\delta)\psi_\lambda(f)([\delta^{-1}n\delta])
\]
for all \( n \in N(Z_p) \). We make a choice of a basis of \( \mathfrak{n} \) which gives a system of coordinates of \( N(Z_p) \) that we denote by \( x_1(n), \ldots, x_r(n) \in Z_p \) for all \( n \in N(Z_p) \). Let \( T_\delta \) be the matrix of the action of \( Ad(\delta^{-1}) \) on \( N(Z_p) \). Since \( \delta \in T^{++} \), the \( p \)-adic limit of \( (T_\delta)^k \) is 0 when \( k \to \infty \). Therefore the entries of the matrix \( T_\delta \) are divisible by \( p \). Now if \( f(x_1, \ldots, x_r) \) is an analytic function of radius of convergence \( p^{-m} \) this implies that \( f((x_1, \ldots, x_r)^T T_\delta) \) has a radius of convergence at least \( p^{-m+1} \). In view of the identity (13) above, this implies that our claim follows.\(^{20}\)

\(^{20}\)In other words, this lemma is saying that the action of \( \delta \) improves the local analyticity.
3.2.9. Locally algebraic induction. Let $\lambda$ be an arithmetic weight with the decomposition $\lambda = \lambda^{alg}\cdot \epsilon$ with $\epsilon$ a finite order character of $T(\mathbb{Z}_p)$ of conductor $p^m$ and $\lambda^{alg} \in X^*(T)^+$. We then denote by $V_{\lambda}(L)$ the subset of functions $f \in A_\lambda(L)$ which are locally $L$-algebraic.

Let us assume that $L$ contains $F$. Recall that $B^-_L$ is the Borel subgroup opposite to $B^-_L$. Then we write $(\text{Ind}_{B^-_L}G/L)^{alg}$ for the set of $L$-algebraic functions $f : G/L :\to \mathbb{A}^1_L$ such that $f(bg) = \lambda^{alg}(b)f(g)$ for all $b \in B^-(L)$ and $g \in G(L)$ and where $\lambda^{alg}$ is seen as a character of $B^-(L)/L$ via the canonical projection $B^-(L)/L :\to T(L)/L$.

We have the following proposition.
Proposition 3.2.11. Let $\lambda$ be a weight and $\alpha$ be a simple root. Assume that $\lambda^{an}(H_\alpha) = N \in \mathbb{Z}_{\geq -1}$. Then there exists an intertwining (for the $*$-action of $I$) map $\Theta_\alpha$

$$A_\lambda(L) \to A_{s_\alpha \ast \lambda}(L)$$

defined by

$$\Theta_\alpha(f) = l(X_\alpha)^{N+1}f$$

Moreover we have

$$\Theta_\alpha(g \ast f) = \xi(t_g)^{s_\alpha \ast \lambda - \lambda}t \ast \Theta_\alpha(f)$$

for all $g \in \Delta^+$. 

Proof. The fact that $\Theta_\alpha$ commutes with the action of $I$ is clear from its definition. We will need to prove that it lands in $A_{\lambda_{\alpha-N-1}}(L)$. Let $f \in A_\lambda(L)$. First notice that

$$l(H_\alpha).f = -\lambda^{an}(H_\alpha)f$$

since $l(t).f = \lambda(t)^{-1}f$ for any $t \in T(\mathbb{Z}_p)$. Now put $f_1 := \Theta_\alpha(f) = l(X_\alpha)^{N+1}f$. One first sees that $f_1(n^-g) = f_1(g)$ for any $n^- \in I^-$ and any $g \in I$. In order to prove this claim, we first check that $l(X_{-\beta}).f_1 = 0$ for any simple root $\beta$. If $\beta \neq -\alpha$, this is due to the fact that in this case we have $[X_{-\beta}, X_\alpha] = 0$. If $\beta = -\alpha$, we use the relation in the enveloping algebra of $g$:

$$[X_{-\alpha}, X_{\alpha}^{i+1}] = -(i+1)X_{\alpha}^{i}(H_\alpha + i)$$

valid for any integer $i \geq 0$. Now $l(X_{-\alpha}).f = 0$ since $f(n^-g) = f(g)$ for any $n^- \in I^-$. Therefore

$$l(X_{-\alpha}).f_1 = l(X_{-\alpha}X_{\alpha}^{N+1}).f = l([X_{-\alpha}, X_{\alpha}^{N+1}]).f$$

Therefore $l(X_{-\alpha}).f_1 = 0$ by the relation above for $i = N = \lambda^{an}(H_\alpha)$ and the relation (16). This implies that $l(X).f_1 = 0$ for all $X \in \text{Lie}(N_{/L}^\alpha)$ since the $X_{-\alpha}$’s generate Lie $(N_{/L}^\alpha)$ as a Lie algebra. This easily implies that $f_1(n^-g) = f_1(g)$ for all $n^- \in I^-$ and $g \in I$ (for instance one can use the log and exponential map). Now, for any $t \in T(\mathbb{Z}_p)$, we have

$$l(t,X_{\alpha}^{N+1}).f = \alpha(t)^{N+1}l(X_{\alpha}^{N+1}.t).f = \alpha^{N+1}(t)\lambda^{-1}(t)l(X_{\alpha}^{N+1}).f$$

Therefore $l(t).f_1 = \lambda^{-1}\alpha^{N+1}(t)f_1$ and $f_1 \in A_{\lambda_{\alpha-N-1}}(L)$. We conclude by noticing that $s_\alpha \ast \lambda = \lambda \alpha^{-N-1}$. 

We have the following proposition:

Proposition 3.2.12. Let $\lambda$ be a locally algebraic dominant weight. Then we have a canonical isomorphism:

$$V_\lambda(L) \cong A_\lambda(L) \cap \bigcap_{\alpha \in \Phi} \text{Ker}(\Theta_\alpha)$$

where $\Phi$ stands for the set of simple roots for the Borel pair $(B_{/F}, T_{/F})$.  

Proof. We give an elementary proof here. Notice that this proposition is a refinement\(^{21}\) of the exactness in degree 1 of the locally analytic BGG complex (see next paragraph).

We first prove \( V_{\lambda}(L) \subset \bigcap_{\alpha \in \Phi} \text{Ker} (\Theta_\alpha) \). Let \( f \in V_{\lambda}(L) \). We may assume without loss of generality that \( f \) is actually algebraic. Then, for each simple root \( \alpha \), \( \Theta_\alpha(f) \) belongs to the algebraic induction from \( B^- \) to \( G \) of the algebraic character \( s_\alpha^* \lambda \). Therefore \( \Theta_\alpha(f) = 0 \) since the weight \( s_\alpha(\lambda^{alg} + \rho) - \rho \) is no longer dominant. So the first inclusion is proved.

We now prove the opposite inclusion. Take \( f \in \bigcap_{\alpha \in \Phi} \text{Ker} (\Theta_\alpha) \). Since \( f \) is locally \( L \)-analytic, the restriction of \( f \) to a neighborhood \( U \) of the identity is an analytic function which is invariant by left translation by elements in \( U \cap N^{-}(F) \). Now since \( f \in \text{Ker}(\Theta_\alpha) \), for all \( g \in U \), the function \( n \mapsto f(n g) \) is a locally polynomial function on \( N_\alpha \) for \( N_\alpha \) the image by the exponential map (which is an algebraic map on \( n \)) of a neighborhood of 0 in \( F.X_\alpha \subset n/F \). Now since the \( N_\alpha \)'s for \( \alpha \in \Phi \) generate a neighborhood of the identity in \( N(F) \), the restriction of \( f \) to this neighborhood will be algebraic. Because \( \lambda \) is locally algebraic by assumption, we deduce that \( f \) is algebraic on a neighborhood of the identity in \( B(F) \). This implies that \( f \) is locally algebraic as claimed since \( N^{-}.B \) is Zariski dense in \( G \).

3.2.13. Integral structure. Recall that \( O_L \) is the ring of integers of \( L \). We put \( A(I, O_L) \subset A(I, L) \) the \( O_L \)-submodule of functions \( f \) taking values in \( O_L \). For any weight \( \lambda \in X(O_L) \), we consider the topological \( O_L \)-module \( A_\lambda(O_L) := A_\lambda(L) \cap A(I, O_L) \) and its \( O_L \)-dual \( D_\lambda(O_L) \). If \( \lambda \) is arithmetic, we can also define \( V_\lambda(O_L) := V_\lambda(L) \cap A(I, O_L) \). From the definition of the \(*\)-action, it is clear that these \( O_L \)-submodules are stable under the action of \( \Delta^\pm \). With regard to the formula (15), this gives an important information about the \( p \)-divisibility of the usual left action. The \(*\)-action can then be viewed as the optimal normalization of the usual left action on \( V_{\lambda^{alg}}(L) \) that preserves the integrality.

3.3. The locally analytic BGG-resolution. The fact that there should be a locally analytic version of the BGG-resolution is an outcome of a conversation with M. Harris.

3.3.1. Let \( L \) be a finite extension of \( F \) and let \( \lambda \) be an \( L \)-valued arithmetic weight. The purpose of this paragraph is to define a bounded complex of Frechet spaces \( C^*_\lambda(L) \) in terms of the spaces of distributions we have defined previously which gives a resolution of \( V^\vee_\lambda(L) := \text{Hom}_{cont}(\nabla_\lambda(L), L) \). Such a resolution is nowadays well-known as the Berstein-Gelfand-Gelfand complex when one replaces respectively distributions by Verma modules and \( V^\vee_\lambda(L) \)

\(^{21}\)Since it gives a precise form of the differential maps in degree 1 of the BGG complex that could be explicitly described as it was done in [BGG].
by $\mathcal{V}^\lambda_L(L)$. We just have to adapt the usual theory to the locally $L$-analytic context.

3.3.2. Let $X$ be a $p$-adic space as in the section 3.2.1. We have defined the space $\mathcal{A}(X, L)$ of locally $L$-analytic functions on $X$. More generally, we denote by $\mathcal{A}^i(X, L)$ the space of locally $L$-analytic differential $i$-forms on $X$. Then, $\mathcal{A}^0(X, L) = \mathcal{A}(X, L)$. We also denote by $LC(X, L)$ the space of locally constant $L$-valued functions on $X$. We have exterior differential maps $d_i$ from $\mathcal{A}^i(X, L)$ to $\mathcal{A}^{i+1}(X, L)$. Clearly, $LC(X, L)$ is the kernel of $d_0$. More generally, it is easy to check that we have a locally $L$-analytic version of the Poincaré lemma:

**Lemma 3.3.3.** Let $d$ be the dimension of $X$. Then the following sequence is exact:

$$0 \rightarrow LC(X, L) \rightarrow \mathcal{A}(X, L) \xrightarrow{d_0} \mathcal{A}^1(X, L) \xrightarrow{d_1} \mathcal{A}^2(X, L) \xrightarrow{d_2} \cdots \rightarrow \mathcal{A}^d(X, L) \rightarrow 0$$

**Proof.** The corresponding Poincaré lemma for sheaf of locally analytic differential forms can be proved in the same way as in the classical case of real analytic differential forms. The local analyticity condition is important here since integration may decrease the radius of convergence (on closed disks) of $p$-adic power series. The exact sequence now follows from the Poincaré lemma since a $p$-adic space is completely discontinuous. The details are left to the reader and can probably be found in the literature.

3.3.4. We will apply this lemma when $X = \Omega_0 = B^-(\mathbb{Z}_p) \cap I/I$. In that case, we have a natural action of $I$ on $\mathcal{A}^i(\Omega_0, L)$. If $\omega \in \mathcal{A}^i(\Omega_0, L)$, $g \in I$ and $X_1, \ldots, X_i$ belongs to the tangent space of $\Omega_0$ at $x \in \Omega_0$, then:

$$(g.\omega)(x)(X_1, \ldots, X_i) := \omega(x \ast g)(X_1 \ast g, \ldots, X_i \ast g)$$

where $X \mapsto X \ast x$ is the map between the tangent spaces $T_{\Omega_0,x}$ and $T_{\Omega_0,x \ast g}$ of $\Omega_0$ at respectively $x$ and $x \ast g$ induced by the map $x \mapsto x \ast g$. It is then straightforward to check that the differential maps $d^i$ are equivariant for the action of $I$.

3.3.5. **Analytic induction of $B^-$-representations.** For any finite dimensional analytic $L$-representation $V$ of $B^-(\mathbb{Z}_p) \cap I$, we denote by $\mathcal{A}(V)$ the space of locally analytic functions $f$ from $I$ to $V$ such that $f(b^- g) = b^-.f(g)$ for any $g \in B^-(\mathbb{Z}_p) \cap I$. Let $\mathfrak{g}$ and $\mathfrak{b}^-$ be the $F$-Lie algebras of $G$ and $B^-$ respectively. They are respectively equipped with the adjoint action of $G(F)$ and $B^-(F)$. We can therefore consider $\mathfrak{g}/\mathfrak{b}^-$ as a representation of $B^-(\mathbb{Z}_p) \cap I$. This action is $F$-algebraic.
Lemma 3.3.6. For any integer $i$ between 0 and $d$, we have a canonical $I$-equivariant isomorphism

$$\mathcal{A}^i(\Omega_0, L) \cong \mathcal{A}((\mathfrak{g}/\mathfrak{b}^-)^* \otimes_F L)$$

where $*$ stands for $F$-dual.

Proof. Let $\omega \in \mathcal{A}^i(\Omega_0, L)$. We consider the function $f_\omega$ on $I$ taking values in $\wedge^i(\mathfrak{g}/\mathfrak{b}^-)^* \otimes_F L$ defined by:

$$f_\omega(g)(X_1 \wedge \cdots \wedge X_i) = \omega([g])(X_1 \ast g, \ldots, X_i \ast g)$$

where we have identified $T_{\Omega_0,[id]}$ with $\mathfrak{g}/\mathfrak{b}^-$. It is now easy to check that the map $\omega \mapsto f_\omega$ is $I$-equivariant and that it defines an isomorphism.

3.3.7. For simplicity, we now assume $\lambda$ is an algebraic dominant weight. Let $\mathcal{A}_\lambda^i := \mathcal{A}^i(\Omega_0, F) \otimes_F \mathbb{V}_\lambda(L)$. Tensoring the exact sequence of lemma 3.3.3 for $X = \Omega_0$ by $\mathcal{V}_\lambda(L)$ gives the $I$-equivariant exact sequence:

$$0 \to \mathcal{V}_{\lambda \circ \iota}(L) \to \mathcal{A}_\lambda^0 \xrightarrow{d_0} \mathcal{A}_\lambda^1 \xrightarrow{d_1} \mathcal{A}_\lambda^2 \xrightarrow{d_2} \cdots \to \mathcal{A}_\lambda^i \to 0$$

On the other hand, we have the $I$-equivariant isomorphism

$$\mathcal{A}_\lambda^i = \mathcal{A}^i(\Omega_0, L) \otimes_F \mathcal{V}_\lambda(L) \cong \mathcal{A}((\wedge^i(\mathfrak{g}/\mathfrak{b}^-)^*) \otimes \mathcal{V}_\lambda(L))$$

Now, we remark that as an algebraic representation of $B^-$, we have a stable filtration of $(\mathfrak{g}/\mathfrak{b}^-)^* \otimes_F \mathcal{V}_\lambda(L)$:

$$0 = F_0 \subset F_1 \subset F_2 \subset \cdots \subset F_r = (\mathfrak{g}/\mathfrak{b}^-)^* \otimes_F \mathcal{V}_\lambda(L)$$

such that for all $j \geq 1$, $F_j/F_{j-1}$ is one dimensional over $L$ with action of $B^-$ given by some algebraic character $\xi_j$. We denote by $S_i(\lambda)$ the set of these characters. By the isomorphism (18), the above filtration induces a stable filtration on $\mathcal{A}_\lambda^i$ with graded pieces isomorphic to $\mathcal{A}_{\xi_j}(L)$ for $\xi_j \in S_i(\lambda)$.

3.3.8. Infinitesimal characters. Recall that $t := \text{Lie } T$. Harish-Chandra has defined a homomorphism $\vartheta$ from $Z(\mathfrak{g})$, the center of the universal algebra of $\mathfrak{g}$, into $U(t)$, the universal algebra of $t$. Recall that the natural action of the Weyl group $W_G$ on $t$ induces an automorphism of $U(t)$. Then, the Harish-Chandra homomorphism $\vartheta$ induces an isomorphism

$$Z(\mathfrak{g}) \cong U(t)^{W_G}$$

For a given algebraic character $\xi$ of $T$, let $d\xi$ be the corresponding character of $U(t)$. We set $\chi_\xi := \vartheta \circ d\xi$. For any irreducible algebraic representation $W$ of $U(\mathfrak{g})$, the induced action of $Z(\mathfrak{g})$ on $W$ is given by a character $\chi_W$, called the infinitesimal character of $W$. For any representation space $W$ of $U(\mathfrak{g})$ and any character $\chi$ of $Z(\mathfrak{g})$, we denote by $W_\chi$, the $\chi$-generalized eigenspace of $W$. Similarly, if now $W$ is a locally analytic representation of $I$, differentiation yields an action of $U(\mathfrak{g})$ on $W$. It can be easily seen that
$W_\chi$ is stable under the $I$-action and that the functor $W \mapsto W_\chi$ is exact. It is well known that we have $\chi_{V_\lambda} = \chi_\lambda$. Similarly, one can remark that for any character $\lambda \in X^*(T)$, the infinitesimal character of $A_\lambda(L)$ is given by $\chi_\lambda$.

3.3.9. Construction of the locally analytic BGG resolution. Let us write for short $A_{i,\chi_\lambda}^i := (A_{i})_{\chi_\lambda}$. By applying the exact functor $W \mapsto W_\chi$ to the exact sequence (17), we have the exact sequence:

$$0 \to V_\lambda(L) \to A_{0,\chi_\lambda}^0 \overset{d_0}{\to} A_{1,\chi_\lambda}^1 \overset{d_1}{\to} A_{2,\chi_\lambda}^2 \overset{d_2}{\to} \cdots \to A_{d,\chi_\lambda}^d \to 0$$

(19)

Now we recall the following well-known fact, for example see [BGG]. Let $\xi \in X^*(T)$. Then $\xi \in S_i^\lambda(L)$ with $\chi_\xi = \chi_\lambda$ if and only if there exist $w \in W$ of length $i$ such that $\xi = w \cdot \lambda$. Moreover this character appears with multiplicity one. Using the filtration of $A_{i}^i$ and the fact recalled above, we deduce that we have a filtration of $I$-modules on $A_{i,\chi_\lambda}^i$ such that the corresponding graded object is isomorphic to

$$\left(A_{i,\chi_\lambda}^i\right)^{gr} \cong \bigoplus_{w | l(w) = i} A_{w \cdot \lambda}(L)$$

(20)

Now, we remark that since $g$ is reductive, we have an isomorphism of $g$-modules $A_{i,\chi_\lambda}^i \cong \left(A_{i}^i\right)^{gr}$. Since these space are locally analytic representation, this isomorphism is left equivariant for the action of a neighborhood of the identity in $I$. Since such a subgroup is finite index in $I$ and that $L$ is characteristic zero, this isomorphism holds as an isomorphism of $I$-modules.

We write $C_{i}^i(L)$ for the continuous $L$-dual of $A_{i,\chi_\lambda}^i$. Then we have proved the following theorem:

**Theorem 3.3.10.** Let $\lambda$ be an arithmetic weight of level $p^m$. There exists a long exact sequence of right $I_m$-modules:

$$\cdots \to C_{i+1}^i(L) \overset{d_i}{\to} C_{i}^i(L) \to \cdots \to C_{0}^i(L) \to V_{\chi}^\vee(L) \to 0$$

where for each $q$ we have:

$$C_{i}^i(L) = \bigoplus_{w \in W_G, l(w) = i} D_{w \cdot \lambda}(L)$$

(21)

**Proof.** For algebraic dominant weight, this follows from dualizing the exact sequence (19) and the isomorphisms (20). In the general case, it suffices to remark that for any locally algebraic weight $\mu = \mu^{alg}$, $f \mapsto f_\mu$ where $f_\mu$ is defined as in formula (14) induces an isomorphism between $A_{\mu^{alg}}(L)$ and $A_{\mu}(L)$ and between $W_{\mu^{alg}}(L)$ and $W_{\mu}(L)$ when $\mu^{alg}$ is dominant. \[\blacksquare\]
3.3.11. Remark. It could be proved that the maps $d_q$ are defined as follows. Let $i \geq 1$ and $w \in W_G$ of length $i$. Let $\alpha$ be a simple root. Assume that $l(s_\alpha w) = i + 1$. Then $w^{-1}(\alpha) > 0$ and therefore $w(\lambda^{alg})(H_\alpha) = \lambda^{alg}(H_{w^{-1}(\alpha)}) \geq 0$ since $\lambda^{alg}$ is dominant. We deduce

$$w \ast \lambda^{alg}(H_\alpha) = w(\lambda^{alg})(H_\alpha) + (w(\rho) - \rho)(H_\alpha) \geq -1$$

and we therefore have a map $\Theta_\alpha : \mathcal{A}_{w^\alpha}(L) \to \mathcal{A}_{s_\alpha w^\alpha}(L)$ defined by the Proposition 3.2.11. Summing over the simple roots $\alpha$ satisfying $l(s_\alpha w) = i + 1$ and then over the $w$ of length $i$, we get after dualizing the map

$$d_i : C^{i+1}_\lambda(L) \to C^i_\lambda(L).$$

The proof of this description of these differential maps is left to the reader since it is not going to be used anywhere in this paper although it would imply the following proposition for which we have a shorter and more conceptual proof. Let us introduce some notations first. For each $q$, we have a decomposition $d_q = \sum_{w,w'} d_{w,w'}$ where $d_{w,w'}$ is the map from $\mathcal{D}_{w^\alpha}(L)$ to $\mathcal{D}_{w^\alpha}(L)$ induced by $d_q$ with $l(w) = q + 1$ and $l(w') = q$.

**Proposition 3.3.12.** Let $w, w' \in W_G$ such that $l(w) = l(w') + 1$, then we have

$$d_{w,w'}(v \ast t) = (\xi(t)w'^{\lambda^{alg}} - w^{\lambda^{alg}})d_{w,w'}(v) \ast t$$

for each $t \in T^+$ and $v \in \mathcal{D}_{w^\alpha}(L)$

**Proof.** For any arithmetic weight $\lambda$, let us denote by $\mathcal{D}_\lambda^G(L)$ the continuous dual of the locally analytic induction $\mathcal{A}_\lambda^G(L)$ := $(\text{ind}_{B^-(\mathbb{Q}_p)} B^+(\mathbb{Q}_p) \mathcal{L}(\lambda))^{an}$ defined as the space of locally analytic $L$-valued function of $G(\mathbb{Q}_p)$ such that

$$f(n^-t g) = \lambda(t)f(g) \quad \forall g \in G(\mathbb{Q}_p), t \in T(\mathbb{Q}_p), n^- \in N^-(\mathbb{Q}_p).$$

Here we have extended $\lambda = \lambda^{alg} \epsilon$ to a character of $T(\mathbb{Q}_p)$ by putting:

$$\lambda(t) := \lambda^{alg}(t)\epsilon(t)(t)^{-1} \quad \forall t \in T(\mathbb{Q}_p)$$

Rewriting the construction of the locally analytic BGG complex with $B^-(\mathbb{Q}_p) \backslash G(\mathbb{Q}_p)$ in place of $B^-(\mathbb{Z}_p) \cap I \backslash I$ provides a resolution of $V_\lambda(L)^\vee$ as a $G(\mathbb{Q}_p)$-representation in which we replace the $\mathcal{D}_{w^\alpha}(L)$’s by the $\mathcal{D}_{w^\alpha}(L)$’s. The maps of the complex are then $G(\mathbb{Q}_p)$-equivariant for the action induced by the usual right translation in the argument of the locally analytic functions in $\mathcal{A}_{w^\alpha}(L)$. Now the restriction maps $\mathcal{A}_{w^\alpha}(L) \to \mathcal{A}_{w^\alpha}(L)$ induce a $\Delta^+$-equivariant (for the $\ast$-action) inclusion of complexes:

$$C^{G, \omega}_\lambda(L) = \bigoplus_{w \in W_G, l_G(w) = q} \mathcal{D}_{w^\alpha}(L) \hookrightarrow C^q_\lambda(L) = \bigoplus_{w \in W_G, l_G(w) = q} \mathcal{D}_{w^\alpha}(L)$$

compatible with the $G(\mathbb{Q}_p)$-equivariant maps $d_{w,w'}$. Since we have the following relation between the $\ast$-action and the usual right translation action
on $A_{w,\lambda}^G(L)$

$$t \ast f = \xi(t)^{-w \lambda} t \cdot f \quad \forall t \in T^+ \text{ and } \forall f \in A_{w,\lambda}^G(L)$$

we deduce that we have the relation of the proposition from the fact that the maps $d_{w,w'}$ are $G(\mathbb{Q}_p)$-equivariant for the usual right translation action.

3.4. **Analytic variation and weight spaces.** We explain in this section how the spaces $A_{\lambda}(L)$ can be interpolated when $\lambda$ varies in the space of continuous $\mathbb{Q}_p \times \mathbb{Z}$-valued characters of $T(\mathbb{Z}_p)$. We first recall the rigid analytic structure of this space.

3.4.1. **Open and closed disks.** Let $a \in \mathbb{Q}_p$ and $r$ a rational power of $p$. We denote by $B_{a,r}^\circ$ (resp. $B_{a,r}$) the open unit disk (resp. the closed unit disk) of $\mathbb{Q}_p$ of center $a$ and radius $r$. These spaces are rigid analytic spaces defined over $\mathbb{Q}_p$ in the sense of Tate. These closed disks are in fact affinoid domains: The ring of analytic function on $B_{a,r}^\circ$ is given by the Tate algebra:

$$\mathcal{O}(B_{a,r}^\circ) := \left\{ \sum_{n=0}^{\infty} a_n (z - a)^n \mid \lim_{n \to \infty} |a_n|r^n = 0 \right\}.$$ 

The rigid analytic structure of $B_{a,r}^\circ$ is obtained by taking the following admissible covering of it by closed disks

$$B_{a,r} = \bigcup_{r_n < r} B_{a,r_n}$$

where $r_n$ is any sequence of rational powers of $p$ converging to $r$.

3.4.2. **Weight spaces.** For any finitely generated $\mathbb{Z}_p$-module $S$, we can give a rigid analytic structure to $\text{Hom}_{cont}(S, \mathbb{Q}_p^\times)$. For any algebraic extension $L$ of $\mathbb{Q}_p$, let us write $\mathfrak{X}_S(L) := \text{Hom}_{cont}(S, L^\times)$. We write $S_{\text{tor}}$ for the torsion part of $S$ and we fix a decomposition $S \cong S_{\text{tor}} \times S_{\text{free}}$ with $S_{\text{free}}$ a free $\mathbb{Z}_p$-submodule of $S$. Let $r$ the rank of $S_{\text{free}}$ over $\mathbb{Z}_p$. The choice of a $\mathbb{Z}_p$-basis of $S_{\text{free}}$ gives therefore an isomorphism

$$(22) \quad \mathfrak{X}_S(\mathbb{Q}_p) \cong S_{\text{tor}}^* \times (B_{1,1}(\mathbb{Q}_p)^0)^r$$

with $S_{\text{tor}} := \text{Hom}_{gp}(S_{\text{tor}}, \mathbb{Q}_p)$. We will fix such a basis once and for all. Let $K$ be a finite extension of $\mathbb{Q}_p$ containing the values of all the characters in $S_{\text{tor}}$. Then for any finite extension $L$ of $K$, we have $\mathfrak{X}_S(L) = S_{\text{tor}}^* \times (B_{1,1}(L)^0)^r$. This gives $\mathfrak{X}_S(\mathbb{Q}_p)$ a rigid analytic structure over $\mathbb{Q}_p$. Moreover $\mathfrak{X}_S$ is isomorphic over $K$ to a disjoint union of finitely many open unit disks of dimension $r$.

3.4.3. **Remark.** Notice that if $S'$ is a $\mathbb{Z}_p$-submodule of $S$, then $\mathfrak{X}_{S'/S'}$ can be identified to the Zariski closure of the characters of $\mathfrak{X}_S(\mathbb{Q}_p)$ which are trivial on $S'$. This observation will be useful in the next section.
3.4.4. **Rigid analytic neighborhoods of $S$.** Let $x_1, \ldots, x_r$ be the system of coordinates of $S_{free}$ attached to the chosen basis giving the identification (22). For each integer $n$, consider the affinoid

$$S_n^{rig} := S_{tor} \times \bigcup_{(a_1, \ldots, a_r)} B_{a_1, p^{-n}} \times \cdots \times B_{a_r, p^{-n}}$$

where $(a_1, \ldots, a_r)$ runs in a set of representatives of $(\mathbb{Z}/p^n\mathbb{Z})^r$. By the system of coordinates $x_1, \ldots, x_r$, we can embed $S$ into $S_n^{rig}(\overline{Q}_p)$ via the identification $S = S_n^{rig}(\mathbb{Q}_p)$ for all non negative integer $n$. So $S_n$ can be seen as a rigid analytic neighborhood of $S$ and the ring of rigid analytic functions on $S_n$ is isomorphic to the set of $n$-locally analytic functions on $S$. In other words, for any finite extension $L$ of $\mathbb{Q}_p$ we have

$$A_n(S, L) = \mathcal{O}(S_n^{rig}/L)$$

The construction above can be made for any $p$-adic space $X$ in the sense of our definition of §3.2.1. We have considered here the compact case in which our rigid analytic neighborhoods are actually affinoid neighborhoods.

3.4.5. Let $\mathfrak{U} \subset \mathfrak{X}_S$ be a rigid analytic subspace. For any $s \in S$, we denote $\langle s \rangle_{\mathfrak{U}}$ the function on $\mathfrak{U}(\overline{Q}_p)$ defined by $\langle s \rangle_{\mathfrak{U}}(\lambda) = \lambda(s)$ for any $\lambda \in \mathfrak{U}(\overline{Q}_p) \subset \text{Hom}_{cont}(S, \overline{Q}_p^\times)$. Then $\langle s \rangle_{\mathfrak{U}}$ is an analytic function on $S$ and the map $s \mapsto \langle s \rangle_{\mathfrak{U}}$ defines continuous injective homomorphism from $S$ into $\mathcal{O}(\mathfrak{U})^\times$.

The following lemma is the essential ingredient for the construction of analytic families of locally analytic induction spaces.

**Lemma 3.4.6.** For any affinoid subdomain $\mathfrak{U} \subset \mathfrak{X}_S$ defined over $L$, there exists a smallest integer $n(\mathfrak{U})$, such that any element $\lambda \in \mathfrak{U}(\mathbb{Q}_p)$ defined over a finite extension $L/\mathbb{Q}_p$ is $n(\mathfrak{U})$-locally $L$-analytic. Moreover the map $(\lambda, s) \mapsto \lambda(s)$ induces a rigid analytic map $\mathfrak{U} \times S_{n(\mathfrak{U})} \rightarrow B_{1,1}$ defined over $L$.

**Proof.** Since it is possible to cover $\mathfrak{U}$ with a finite number of closed disks, we may assume that $\mathfrak{U}$ is a closed disk. So let $\mathfrak{U} = B_{\lambda_0, R}$ for some $R < 1$. We can even assume $\lambda_0$ is the trivial character. Let $u_1, \ldots, u_d$ be a $\mathbb{Z}_p$-basis of $S_{free}$ defining the identification (22) and for any $\lambda \in \mathfrak{X}_S(\overline{Q}_p)$. Let us put $\lambda_i = \lambda(u_i)$. Then we have $\lambda \in \mathfrak{U}(\overline{Q}_p)$ if and only if $|\lambda_i - 1| \leq R < 1$. Now fix some integer $n = n_R$ depending only on $R$ such that $|\lambda_i^{p^n} - 1| \leq p^{-1}$ for all $i = 1, \ldots, r$. Now if $s \in p^nS_{free}$, we have $\lambda(s) = \prod_i \lambda_i^{s_i} = \prod_i (\lambda_i^{p^n})^{s_i/p^n}$ where the $s_i$'s belong to $p^n\mathbb{Z}_p$ and are the coordinates of $s$ with respect to the chosen basis $(u_1, \ldots, u_d)$. Therefore for all $s \in p^nS_{free}$ and $\lambda \in \mathfrak{U}(\overline{Q}_p)$, we have:

$$\lambda(s) = \prod_i \left( \sum_{n_i=1}^{\infty} \left( \frac{s_i/p^n}{n_i} \right) (\lambda_i^{p^n} - 1)^{n_i} \right)$$
where we have denoted \( y \mapsto \binom{y}{n} \) for the well-known function on \( \mathbb{Z}_p \) defined by
\[
y(y - 1)(y - 2) \cdots (y - n + 1) \quad \forall y \in \mathbb{Z}_p
\]
The series (24) is convergent for \((s_1, \ldots, s_r) \times (\lambda_1, \ldots, \lambda_r) \in B_{0, p^{-n}} \times B_{1, R}\) by our choice of \( n \) and thanks to the well-known lemma 3.4.7 below. The claims of our lemma follow from this observation.

**Lemma 3.4.7.** The series \((1 + z)^s = \sum_n \binom{s}{n} z^n\) converges for \( z, s \in \mathbb{C}_p \) such that \( |z| \leq p^{-1} \) and \( |s|_p \leq 1 \).

**Proof.** This follows from an elementary evaluation of the \( p \)-adic valuation of the binomial coefficients and this is well known.

3.4.8. **Analytic families of analytic inductions.** We will consider now the case \( S = T(\mathbb{Z}_p) \) and denote by \( \mathcal{X}_T \) the corresponding weight space.

Let \( \mathcal{U} \subset \mathcal{X}_T \) be an affinoid subdomain defined over a finite extension \( L/\mathbb{Q}_p \) and choose an integer \( n \geq 0 \). We define \( \mathcal{A}_{\mathcal{U}, n} \) as the set of rigid analytic functions \( f \) on \( \mathcal{U} \times (\Omega_1)_n^{rig}/L \) such that
\[
f(\lambda, [tn]) = \lambda(t)f(\lambda, [n])
\]
for all \( \lambda \in \mathcal{U}(\mathbb{Q}_p), t \in T(\mathbb{Z}_p)_n^{rig}(\mathbb{Q}_p), n \in N(\mathbb{Z}_p)_n^{rig}(\mathbb{Q}_p) \). This space might be trivial. However we have the following lemma.

**Lemma 3.4.9.** Let \( \mathcal{U} \subset \mathcal{X}_T \) be an affinoid subdomain and \( n \) an integer such that \( n \geq n(\mathcal{U}) \). Then we have a canonical bicontinuous isomorphism:
\[
\mathcal{A}_{\mathcal{U}, n} \cong \mathcal{O}(\mathcal{U}) \hat{\otimes}_L \mathcal{A}_n(N(\mathbb{Z}_p), L).
\]

In particular \( \mathcal{A}_{\mathcal{U}, n} \) is a non trivial \( \mathcal{O}(\mathcal{U}) \)-orthonormalizable Banach space.

**Proof.** The inclusion \( \mathcal{U} \times N(\mathbb{Z}_p)_n^{rig} \hookrightarrow \mathcal{U} \times (\Omega_1)_n^{rig} \), induces a continuous map
\[
\mathcal{A}_{\mathcal{U}, n} \to \mathcal{O}(\mathcal{U} \times N(\mathbb{Z}_p)_n^{rig}) \cong \mathcal{O}(\mathcal{U}) \hat{\otimes}_K \mathcal{A}_n(N(\mathbb{Z}_p), K)
\]
By the relation (25), it is straightforward to see that this map is injective. To prove the surjectivity, it suffices to show that any pure tensor \( \phi \otimes f \) is in the image. So consider the function
\[
\psi(\lambda, [tn]) := \phi(\lambda) \lambda(t)f(n)
\]
defined for any \( (\lambda, t, n) \in (\mathcal{U} \times T(\mathbb{Z}_p)_n^{rig} \times N(\mathbb{Z}_p)_n^{rig})(\mathbb{Q}_p) \). By our assumption \( n \geq n(\mathcal{U}) \) and Lemma 3.4.6, this function is clearly rigid analytic and its image by the restriction map (26) is \( \phi \otimes f \). Therefore (26) is an isomorphism and since it is a surjective continuous between Banach spaces its inverse is also continuous by the open mapping theorem. This proves our claim.
Corollary 3.4.10. For any \( n \geq n(\frak{U}) \), the inclusion map \( \frak{A}_{\frak{U},n} \subset \frak{A}_{\frak{U},n+1} \) is completely continuous.

Proof. These inclusion maps are induced by the inclusions
\[
\frak{A}_n(N(\mathbb{Z}_p), K) \subset \frak{A}_{n+1}(N(\mathbb{Z}_p), K)
\]
which are completely continuous, thus our claim.

We put now
\[
\frak{A}_{\frak{U}} := \bigcup_{n \geq n(\frak{U})} \frak{A}_{\frak{U},n}
\]
and define the continuous \( \mathcal{O}(\frak{U}) \)-duals
\[
\frak{D}_{\frak{U}} := \text{Hom}_{\mathcal{O}(\frak{U})}(\frak{A}_{\frak{U}}, \mathcal{O}(\frak{U})) \quad \text{and} \quad \frak{D}_{\frak{U}} := \text{Hom}_{\mathcal{O}(\frak{U})}(\frak{A}_{\frak{U}}, \mathcal{O}(\frak{U})).
\]
It follows from the previous lemma and corollary that \( \frak{D}_{\frak{U}} \) is an orthonormalizable \( \mathcal{O}(\frak{U}) \)-module and that \( \frak{D}_{\frak{U}} \) is a \( \mathcal{O}(\frak{U}) \)-projective compact Frechet space.

3.4.11. \( * \)-Action of \( \Delta^+ \). We can define the \( * \)-action on the spaces \( \frak{A}_{\frak{U},n} \) as in the case \( \frak{U} \) is reduced to a singleton. For this, we remark that the right \( * \)-action of \( \Delta^+ \) on \( \Omega_1 \) being algebraic extends into an action of \( \Delta^+ \) on \( (\Omega_1)_n^{\text{rig}} \) for all \( n \geq 0 \). Similarly we remark also that the left action of \( \mathcal{T}(\mathbb{Z}_p) \) on \( \Omega_1 \) defined in §3.2.6 can be extended into a left action of \( \mathcal{T}(\mathbb{Z}_p)_{n}^{\text{rig}} \) on \( (\Omega_1)_n^{\text{rig}} \).

If \( t \in \mathcal{T}(\mathbb{Z}_p)_{n}^{\text{rig}} \) and \( f \in \mathcal{O}((\Omega_1)_n^{\text{rig}}) \), we write \( t.f \) for the action of \( f \) obtained by left translation on the argument of \( f \). Now as in §3.2.6, we have the identification:
\[
\frak{A}_{\frak{U},n} \cong \{ f \in \mathcal{O}((\Omega_1)_n^{\text{rig}}) \otimes \mathcal{O}(\frak{U}) \mid t.f \otimes 1 = f \otimes (t)_\frak{U} \forall t \in \mathcal{T}(\mathbb{Z}_p)_{n}^{\text{rig}} \}
\]
Since the \( * \)-action of \( \Delta^+ \) commutes with the left action of \( \mathcal{T}(\mathbb{Z}_p)_{n}^{\text{rig}} \), it follows that we have a left action of \( \Delta^+ \) on \( \frak{A}_{\frak{U},n} \). We deduce that we have a left action of \( \Delta^+ \) on \( \frak{A}_{\frak{U}} \) and a right action on \( \frak{D}_{\frak{U}} \).

3.4.12. Remark. Notice that if we consider \( \langle \cdot \rangle_\frak{U} \) the \( \mathcal{O}(\frak{U}) \)-valued character of \( \mathcal{T}(\mathbb{Z}_p) \) given by \( t \mapsto \langle t \rangle_\frak{U} \) where \( \langle t \rangle_\frak{U} \in \mathcal{O}(\frak{U})^\times \) is the analytic function on \( \frak{U} \) defined by \( \lambda \mapsto \lambda(t) \) then \( \frak{A}_{\frak{U},n} \) can therefore be seen as the \( n \)-locally \( \mathcal{O}(\frak{U}) \)-analytic induction of \( \langle \cdot \rangle_\frak{U} \). When \( \frak{U} \) is reduced to a single point \( \frak{U} = \{ \lambda \} \), we recover the definition of \( \frak{A}_{\lambda,n}(L) \) for a \( n \)-locally analytic character \( \lambda \in \mathcal{X}(L) \). In particular, we have the following lemma.

Lemma 3.4.13. Let \( L \) be a finite extension of \( K \) and \( \lambda \in \frak{U}(L) \), then we have the canonical isomorphisms of \( \Delta^+ \)-modules
\[
\frak{A}_{\frak{U}} \otimes_\lambda L \cong \frak{A}_\lambda(L) \quad \text{and} \quad \frak{D}_{\frak{U}} \otimes_\lambda L \cong \frak{D}_\lambda(L)
\]

Proof. This follows from the definitions and Lemma 3.4.9.
We also have the very important lemma:

**Lemma 3.4.14.** If \( \delta \in \Delta^{++} \), then the \( \ast \)-action of \( \delta \) defines a compact operator of the \( \mathcal{O}(\mathfrak{U}) \)-projective compact Frechet space \( \mathcal{D}_U \).

**Proof.** Assume \( K \) is the field of definition of \( \mathfrak{U} \). By Lemma 3.4.9, we have the bi-continuous isomorphism

\[
\mathcal{D}_U \cong \mathcal{O}(\mathfrak{U}) \widehat{\otimes}_K \mathcal{D}(N(\mathbb{Z}_p), K)
\]

From this remark, it is easy to see that the proof of our claim follows exactly the same lines as the proof of Lemma 3.2.8. The details are left to the reader. \( \blacksquare \)

## 4. Overconvergent Finite Slope Cohomology

In this section, \( G/\mathbb{Q} \) is a reductive group as in the first section. We fix a prime \( p \) and we assume that \( G/\mathbb{Q}_p \) is quasi-split as in the previous section.

### 4.1. Hecke algebras and finite slope representations.

In this subsection, we define the notion of finite slope representation for the group \( G \). We start by defining some Hecke algebras.

#### 4.1.1. The Hida-Hecke algebra.

We will use freely the notations of section 3. For all positive integer \( m \), let \( \Delta_m^- := (\Delta_m^+)^{-1} \) and \( \Delta_m^- := (\Delta_m^{++})^{-1} \). As usual we will drop \( m \) from the notation when it is equal to 1. We define similarly \( T^- \) and \( T^{--} \). The spaces of distributions \( \mathcal{D}_\lambda(L) \) and their quotient \( \mathcal{V}^{\text{alg}}_\lambda(L) \) we have defined in section 3 are equipped with the right \( \ast \)-action of \( \Delta^+ \). We will consider them now as left \( \Delta^- \)-modules since we have made the choice to consider the adelic action on the left to define Hecke operators.

Let \( m \) be a positive integer and let \( C_c^\infty(\Delta_m^-/I_m, \mathbb{Z}_p) \) be the subspace of \( \mathbb{Z}_p \)-valued locally constant functions with compact support in \( \Delta_m^- \) which are bi-invariant by \( I_m \). This is an algebra for the convolution product defined with the Haar measure on \( G(\mathbb{Q}_p) \) such that \( I_m \) is of measure 1. For \( t \in T^- \), we write \( u_t = u_{t,m} = I_m t I_m \in C_c^\infty(\Delta_m^-/I_m, \mathbb{Z}_p) \) for the characteristic function of the double class \( I_m t I_m \subset \Delta_m^- \). Then it is well known and it can be easily checked that

\[
u_t u_{t'} = u_{tt'}
\]

for any \( t, t' \in T^- \). Therefore, the map \( t \mapsto u_t \) defines an algebra homomorphism \( \mathbb{Z}_p[T^-/T(\mathbb{Z}_p)] \rightarrow C_c^\infty(\Delta_m^-/I_m, \mathbb{Z}_p) \). Then we put \( \mathcal{U}_p = \mathcal{U}_p(G) := \mathbb{Z}_p[T^-/T(\mathbb{Z}_p)] \) and we will identify its elements as \( \mathbb{Z}_p \)-valued functions with compact support on \( \Delta_m^- \) which are bi-invariant by \( I_m \) for \( m \) chosen according to the space on which we will let \( \mathcal{U}_p \) act.
4.1.2. **Slope of a character of** $T^-$ **or of** $\mathcal{U}_p$. The notion of slope we introduce here is equivalent to a notion introduced by Emerton in [Em06]. Recall that

$$X^*(T/F) := \text{Hom}_{\text{alg}}(T/F, \mathbb{G}_m/F)$$

and

$$X_*(T/F) := \text{Hom}_{\text{alg}}(\mathbb{G}_m/F, T)$$

where $F$ is the smallest Galois extension of $\mathbb{Q}_p$ that splits $G$. Since $T$ is defined over $\mathbb{Q}_p$, we have an action of the Galois group $\text{Gal}(F/\mathbb{Q}_p)$ on $X^*(T/F)$ and $X_*(T/F)$. Recall also that we have a Galois equivariant duality pairing

$$(-, -) : X^*(T/F) \otimes X_*(T/F) \rightarrow \mathbb{Z}$$

such that $\mu \circ \mu^\vee(t) = t^{(\mu, \mu^\vee)}$ for any $\mu \in X^*(T/F), \mu^\vee \in X_*(T/F)$ and $t \in \mathbb{G}_m$. Let $X_*(T/F)^+$ be the dual cone of the cone generated by the positive roots of $X^*(T)$. Then by definition, for any $\mu^\vee \in (X_*(T/F)^+)^{\text{Gal}(F/\mathbb{Q}_p)}$, we have $\mu^\vee(p) \in T^{--}$.

Let $\theta$ be now a $\overline{\mathbb{Q}}_p$-valued character of $\mathcal{U}_p$. If $\theta(u_t) = 0$ for some $t \in T^-$ we say that the slope of $\theta$ is infinite and we write $\mu_\theta = \infty$. Otherwise $\theta$ induces a homomorphism of monoids from $T^-/T(\mathbb{Z}_p)$ into $\overline{\mathbb{Q}}_p^\times$ and can be easily extended to $T(\mathbb{Q}_p)/T(\mathbb{Z}_p)$. Such a character is said of finite slope. Equivalently $\theta$ is finite slope if $\theta(u_t) \neq 0$ for at least one $t \in T^-$. This can be checked easily since for any $t' \in T^{--}$, there exists a positive integer $N$ such that $t^N = t't''$ with $t'' \in T^{--}$.

When $\theta$ is of finite slope, the slope of $\theta$ is the element $\mu_\theta$ of

$$X^*(T/F)^{\text{Gal}(F/\mathbb{Q}_p)} \subset X^*(T/F)^{\text{Gal}(F/\mathbb{Q}_p)} \otimes \mathbb{Q}$$

defined by

$$(\mu_\theta, \mu^\vee) = v_p(\theta(u_{\mu^\vee(p)}))$$

for all $\mu^\vee \in (X_*(T/F)^+)^{\text{Gal}(F/\mathbb{Q}_p)}$ and where $v_p$ denotes the $p$-adic valuation of $\overline{\mathbb{Q}}_p$ normalized by $v_p(p) = 1$. In particular, we have

$$|(a, \mu_\theta)(t)|_p = |\theta(u_t^a)|_p$$

for any integer $a$ such that $a, \mu_\theta \in X^*(T/F)$ and $t \in T^-$. Notice that if $\theta$ is integrally valued, $\mu_\theta$ belongs to the obtuse positive cone $X^*(T)_{+, \mathbb{Q}}$ generated over $\mathbb{Q}_+$ by the simple roots relative to the pair $(B, T)$. Of course $X^*(T)_{+, \mathbb{Q}} \supset X^*(T)_{+, \mathbb{Q}}^+$ and the inclusion is strict in general. If $\mu, \mu' \in X^*(T)_{+, \mathbb{Q}}$, we write $\mu \geq \mu'$ if and only if $\mu - \mu' \in X^*(T)_{+, \mathbb{Q}}$

**Definition 4.1.3.** Let $\lambda_{\text{alg}}$ be an algebraic character of $T/F$ and $\mu = \mu_\theta$. This slope will be said non critical with respect to $\lambda_{\text{alg}}$ if $\mu_\theta - \lambda_{\text{alg}} + w\star \lambda_{\text{alg}} \notin X^*(T)_{+, \mathbb{Q}}$ for each $w \neq \text{id}$. When $\lambda_{\text{alg}}$ is implicit in the context we will just say that $\theta$ or $\mu_\theta$ is non critical.
4.1.4. Finite slope part of a $U_p$-module. Let $L \subset \overline{\mathbb{Q}}_p$ be a finite extension of $\mathbb{Q}_p$ and let $V$ be a (possibly non Hausdorff) quotient of Banach (or compact Frechet) as in chapter 2 $L$-vector topological spaces equipped with an action of $U_p$ such that the action of $u_t$ is completely continuous for any $t \in T^{-\infty}$.

For any character $\theta$ of $T^{-}$ in $\overline{\mathbb{Q}}_p^\times$, we denote by $V_{\overline{\mathbb{Q}}_p}[\theta]$ the subspace of $V \otimes_L \overline{\mathbb{Q}}_p$ of vectors $v$ such that for all $t \in T^{-}$, $(u_t - \theta(u_t))^q.v = 0$ for some integer $q$. Since the operators $u_t$ commute and their action is completely continuous on $V$, the $V_{\overline{\mathbb{Q}}_p}[\theta]$’s are finite dimensional if $\theta$ is of finite slope.

Let $\mu \in X^*(T)_{\mathbb{Q}}^{\text{Gal}(F/\mathbb{Q}_p)}$ and $V$ as above. We put

$$V_{\overline{\mathbb{Q}}_p}^{\leq \mu} := \bigoplus_{\mu \leq \mu} V_{\overline{\mathbb{Q}}_p}[\theta] \subset V_{\overline{\mathbb{Q}}_p},$$

then this space is finite dimensional over $\overline{\mathbb{Q}}_p$. We have $V_{\overline{\mathbb{Q}}_p}^{\leq \mu} = V_{\overline{\mathbb{Q}}_p}^{\leq \mu} \otimes_L \overline{\mathbb{Q}}_p$ for $V_{\overline{\mathbb{Q}}_p}^{\leq \mu} := V_{\overline{\mathbb{Q}}_p}^{\leq \mu} \cap V$. For any $t \in T^{-\infty}$ and $h \in \mathbb{Q}$, we can define as in chapter 2, $V_{\overline{\mathbb{Q}}_p}^{\leq h}$ and set $V_{f_{1}}$ the inductive limit over $h$ of the $V_{\overline{\mathbb{Q}}_p}^{\leq h}$ when $h \to \infty$. Since $U_p$ is commutative, this space is clearly stable by the action of $U_p$ and we have

$$V_{\overline{\mathbb{Q}}_p}^{\leq h} = \bigoplus_{v_{\mu}(\theta(u_t)) \leq h} V_{\overline{\mathbb{Q}}_p}[\theta].$$

It implies that the inductive limit of the $V_{\overline{\mathbb{Q}}_p}^{\leq \mu}$ for $\mu \in X^*(T)_{\mathbb{Q}}^{+}$ is equal to $V_{f_{1}}$.

4.1.5. Global Hecke algebras. We define the Hecke algebra $\mathcal{H}_p$ by

$$\mathcal{H}_p = \mathcal{H}_p(G) := C_c^\infty(G(\mathbb{A}_f), \mathbb{Q}_p) \otimes U_p \subset C_c^\infty(G(\mathbb{A}_f), \mathbb{Q}_p).$$

To define the algebra structure on $\mathcal{H}_p$, we choose that the product is given by the convolution product for the Haar measure $dg$ on $G(\mathbb{A}_f)$ such that $\text{Meas}(K_{\text{max}}^p, I, dg) = 1$ with $K_{\text{max}}^p$ be the prime to $p$ part of $K_{\text{max}}$ which we defined in 1.1.1.

We denote by $\mathcal{H}_p^I$ the ideal of $\mathcal{H}_p$ generated by $f = f^p \otimes u_t$ with $f^p \in C_c^\infty(G(\mathbb{A}_f), \mathbb{Q}_p)$ and $t \in T^{-\infty}$. For any open compact subgroup $K^p \subset G(\mathbb{A}_f)$, we write

$$\mathcal{H}_p(K^p) := C_c^\infty(K^p \backslash G(\mathbb{A}_f)/K^p, \mathbb{Q}_p) \otimes U_p$$

for the subalgebra of $\mathcal{H}_p$ of functions which are bi-invariant by $K^p$.

If $S$ is a finite set of primes not containing $p$, we also consider the Hecke algebra $R_{S,p}$ defined by

$$R_{S,p} := C_c^\infty(K_{S\cup\{p\}}^\infty \backslash G(\mathbb{A}_f^{S\cup\{p\}}, \mathbb{Z}_p)/K_{S\cup\{p\}}^\infty, \mathbb{Q}_p) \otimes U_p$$

where $K_{m}^{S\cup\{p\}}$ stands for a maximal compact of $G(\mathbb{A}_f^{S\cup\{p\}})$ which is hyperspecial at every prime $\ell \notin S \cup \{p\}$. It is well known that this algebra is
commutative. Moreover, if $K^p \subset K_m$ is hyperspecial away from $S$, $R_{S,p}$ can be seen as a subalgebra of the center of $\mathcal{H}_p(K^p)$ via the map $f \mapsto 1_{K_S} \otimes f$ where $K_S$ stands for the open compact subgroup of $\prod_{i \in S} G(\mathbb{Q}_i)$ such that $K^p = K_S.K_m^{S,p}$. Here we have denoted $1_{K_S}$ the characteristic function of $K_S$.

**Definition 4.1.6.** A $\mathbb{Q}_p$-valued character $\theta$ of $R_{S,p}$ will be said of finite slope if its restriction to $\mathcal{U}_p$ is (i.e. $\theta(u_t) \neq 0$ for all $t \in T^-$).

We further generalize the above definition to admissible representations of $\mathcal{H}_p$.

**4.1.7. Finite slope admissible representations of $\mathcal{H}_p$.** Let $(\sigma,V)$ be an admissible representation of $\mathcal{H}_p$ defined over a $p$-adic field $E$. Recall that this means that for any open compact subgroup $K^p \subset G(\mathbb{A}_f)$, the action of an element of $\mathcal{H}_p(K^p)$ on $V$ defines an endomorphism of finite rank. Since $\mathcal{H}_p$ is the inductive limit of the $\mathcal{H}_p(K^p)$'s, the character map $f \mapsto tr(\sigma(f))$ is well defined and will be denoted by $J_\sigma$. It is a classical fact that $J_\sigma$ determines $\sigma$ up to semi-simplification. Assume now that $\sigma$ is absolutely irreducible. Since $\mathcal{U}_p$ is included in the center of $\mathcal{H}_p$, the action of $\mathcal{U}_p$ on $V$ is then given by a character of degree one. We then say that $\sigma$ is of finite slope if this character is and if $\sigma^{K^p}$ contains an $O_E$-lattice stable by the action of $\mathbb{Z}_p$-valued Hecke operators in $\mathcal{H}_p(K^p)$.

We will say that this representation is of level $K^p$ if the action of $\mathcal{H}_p(K^p)$ is non trivial. In that case, we write $V^{K^p}$ or $\sigma^{K^p}$ for the image of $\sigma(1_{K^p})$ and we have an action of $\mathcal{H}_p(K^p)$ on this subspace. It is well-known that this representation determines $\sigma$ entirely. Let $S$ be a finite set of primes such that $K^p$ is maximal hyperspecial away from $S$. Since $R_{S,p}$ is included in that center of $\mathcal{H}_p(K^p)$, $R_{S,p}$ acts on $\sigma^{K^p}$ by a character we denote $\theta_\sigma$. Then we say that $\sigma$ is of finite slope if and only $\theta_\sigma$ is. A general admissible representation of $\mathcal{H}_p$ will be said of finite slope if all its absolutely irreducible sub-quotients are.

**4.1.8. $p$-regularized constant terms and parabolic induction.** Let $P \subset G$ be a standard parabolic subgroup (i.e. $P$ contains the fixed minimal parabolic subgroup $P_0$). In particular $P_{/\mathbb{Q}_p}$ contains the Borel subgroup $B$. We fix a Levi decomposition $P = MN$ such that $M_{/\mathbb{Q}_p}$ contains $T$. Such an $M$ will be called a standard Levi subgroup of $G$. Then we can consider the Hecke algebras $\mathcal{H}_p(M)$ and $\mathcal{U}_p(M)$ and admissible finite slope representations or characters of them.

For any standard Levi subgroup $M \in \mathcal{L}_G$ recall that $\mathcal{W}^M$ are the elements $w$ of the Weyl group of $G$ such that $w^{-1}(\alpha) > 0$ for all positive root $\alpha$ for the pair $(B \cap M, T)$. Let $w \in \mathcal{W}^M$, we are going to define a linear map from $\mathcal{H}_p(G)$ into $\mathcal{H}_p(M)$ $f \mapsto f^M_{reg}$. To do so, we first define the image of an element $f \in \mathcal{H}_p'$ of the form $f = f^p \otimes u_t$. Notice first that for $w \in \mathcal{W}^M$
and \( t \in T^- \), then \( wt^{-1} w \) belongs to \( T^- \) where \( T^- \) is defined as the set of \( t \in T(F_p) \) such that \( tN(Z_p) \cap M(Z_p) t^{-1} \subset N(Z_p) \). This follows from the very definition of \( W^M \) which tells us that \( B \cap M = wBw^{-1} \cap M \) for all \( w \in W^M \).

For any \( t \in T(F_p) \) and \( w \in W^M \), we also write
\[
\epsilon_{\xi, w}(t) := \xi(t)^{w(\rho) + \rho} | t^{w(\rho) + \rho} |_p
\]
It is easily checked that \( \epsilon_{\xi, w} \) induces a character of \( T(F_p) / T(Z_p) \) taking values in \( O_F^* \). If \( \xi \) satisfies the condition (11), then this character is trivial since \( w^{-1}(\rho p) + \rho p = \sum_{\alpha \in R_p \cap w^{-1}(R_p)} \alpha \). The reason of introducing this normalization factor will become clear in the proof of Proposition 4.6.3.

We then define \( f_{M,w}^{reg} \) by
\[
f_{M,w}^{reg} := \epsilon_{\xi, w}(t) f_M^p \otimes u_{wt^{-1},M}
\]
where \( f_M^p \) stands for the (non unitary) constant term defined as in section 1.4.1. By the remark above, \( u_{wt^{-1},M} \) is a well-defined element of \( U_p(M) \). For general \( f \), we extend the definition by linearity. Now if \( \sigma_f^p \) is an irreducible admissible representation of \( M(A_f^p) \) and if \( I_M^G(\sigma_f^p) \) is the (non unitary) parabolic induction then we have recalled in section 1.4.1 that
\[
tr(f^p; I_M^G(\sigma_f^p)) = tr(f_M^{reg}; \sigma_f^p)
\]
If \( \sigma \) is an irreducible finite slope representation of \( H_p(G) \) then we denote by \( I_{M,w}^G(\sigma) \) the admissible finite slope representation defined by:
\[
I_{M,w}^G(\sigma) = I_M^G(\sigma_f^p) \otimes \theta_{\sigma, M,w}
\]
where \( \theta_{\sigma, M,w} \) is the character of \( U_p(G) \) defined by
\[
\theta_{\sigma, M,w} \mapsto \theta_{\sigma}(u_{wt^{-1},M})
\]
Then it follows from the definitions and what we have recalled that we have the character identity:
\[
J_{I_{M,w}^G(\sigma)}(f) = J_{\sigma}(f_{M,w}^{reg})
\]

### 4.1.9. \( p \)-stabilization of automorphic representations.

The main examples of finite slope representations are obtained as follows. Let \( \pi = \pi_f \otimes \pi_{\infty} \) be an irreducible cohomological automorphic representation of \( G(A) \) of weight \( \lambda_{alg} \). It is defined over a number field and we can therefore extends the scalar to a \( p \)-adic number field \( L \). Then \( H_p \) has a non trivial action on \( I_m^\pi \) for some integer \( m \) sufficiently large and there exists some character \( \epsilon \) of \( I_m / I_m' \) such that \( \pi_f^m \otimes L(\epsilon^{-1}) \) contains a non trivial subspace invariant by \( I_m \) and over which we therefore have an action of \( H_p \). An irreducible constituent of this space for the action of \( H_p \) is called a \( p \)-stabilization of \( \pi \). It is a standard fact that can be checked using the theory of Jacquet modules that a given representation \( \pi \) has only finitely many \( p \)-stabilizations. Notice also that
this notion is purely local at \( p \). If such a \( p \)-stabilization is of finite slope, it will be called a finite slope automorphic representation of \( G \) of weight \( \lambda = \lambda^{\text{alg}} \epsilon \). It is then straightforward to see that it will also appear in the cohomology of \( V_{\lambda^{\text{alg}}}(L) \) with \( \lambda = \epsilon \lambda^{\text{alg}} \).

4.1.10. Finite slope character distributions. Let \( L \) be a finite extension of \( \mathbb{Q}_p \). We call an \( L \)-valued virtual finite slope character distribution \( J \) a \( \mathbb{Q}_p \)-linear map \( J : \mathcal{H}_p' \rightarrow L \) such that there exists a collection of finite slope (absolutely) irreducible representations \( \{ \sigma_i; i \in \mathbb{Z}_{>0} \} \) and integers \( m_i \in \mathbb{Z} \) such that

(i) For all \( t \in T^{--}, h \in \mathbb{Q} \) and \( K^p \), there are finitely many indexes \( i \) such that \( m_i \neq 0 \) and \( v_p(\theta_{\sigma_i}(u_t)) \leq h \) and \( \sigma_i^{K^p} \neq 0 \).

(ii) For all \( f \in \mathcal{H}_p' \), we have

\[
J(f) = \sum_{i=1}^{\infty} m_i J_{\sigma_i}(f)
\]

Notice that the sum in (ii) is convergent thanks to the condition (i). If the \( m_i \) are non negative, \( J \) is called a finite slope character distribution. We also say that \( J \) is an effective finite slope character distribution. In that case, for each open compact \( K^p \), we can consider the space \( V_J(K^p) \) as the completion of \( \oplus_i (V_{\sigma_i}^{K^p})^{\leq m_i} \) for the norm defined by \( \| \sum_i v_i \| = \text{sup}_i \| v_i \| . \) This defines a \( p \)-adic Banach space over \( \mathbb{C}_p \) over which \( \mathcal{H}_p(K^p) \) acts continuously and such that the action of the elements of \( \mathcal{H}_p' \) is completely continuous. Moreover, for each \( f \in \mathcal{H}_p'(K^p) \), we have

\[
\text{tr}(f; V_J(K^p)) = J(f).
\]

If \( J \) is a virtual finite slope character distribution, for a given irreducible finite slope representation \( \sigma \), we write \( m_{J\sigma}(\sigma) \) the integer such that

\[
J(f) = \sum_{\sigma} m_{J\sigma}(\sigma) J_\sigma(f)
\]

If \( t \in T^{--}, h \in \mathbb{Q} \) and an open compact subgroup \( K^p \subset G(K^p) \), we denote by \( \Sigma_J(K^p, t, h) \) the (finite) set of classes of irreducible \( \sigma \) such that \( m_{J\sigma}(\sigma) \neq 0 \), \( v_p(\theta_{\sigma}(u_t)) \leq h \) and \( \sigma^{K^p} \neq 0 \).

4.1.11. Fredholm determinants attached to a virtual finite slope character distribution. Let \( J \) be a virtual finite slope character distribution and \( f \in \mathcal{H}_p(K^p) \) of the form \( f = f^p \otimes u_t \) with \( t \in T^{--} \). Then we put

\[
P_{J,f}(T) := \prod_{i=1}^{\infty} \det(1 - T \sigma_i(f))^{m_i}
\]

This is clearly a ratio of Fredholm series.
If \( \alpha \in \overline{\mathbb{Q}}_p^\times \) and \( \sigma \) is an irreducible finite slope representation, we denote by \( m_\sigma(f, \alpha) \) the multiplicity of the eigenvalue \( \alpha \) for the Hecke operator \( f \). Then

\[
m_f(f, \alpha) := \sum_\sigma m_\sigma(\sigma).m_\sigma(f, \alpha)
\]

is a well defined finite sum by the condition (i) and \( m_f(f, \alpha) \) is the order of the zero \( T = \alpha^{-1} \) for the meromorphic function \( P_f(f, T) \) on \( \Lambda_1^\rig \). This integer is called the multiplicity of the eigenvalue \( \alpha \) in \( J \) for the operator \( f \).

**Lemma 4.1.12.** If for all \( f \in \mathcal{H}_p^\rig \), \( P_f(f, T) \) is an entire power series then \( J \) is an effective finite slope character distribution.

**Proof.** Let \( \sigma_0 \) such that \( m_f(\sigma_0) \neq 0 \). We want to prove that \( m_f(\sigma_0) > 0 \). Let \( K_p \) such that \( \sigma_0^{K_p} \neq 0 \). Fix \( t \in T^{--} \) and let \( h = v_p(\theta_{\sigma_0}(u_t)) \). Put also

\[
h' := \text{Min}\{v_p(\theta_\sigma(u_t)), \forall \sigma \in \Sigma_f(K_p, t, h) \text{ such that } m_f(\sigma) \neq 0 \text{ and } \sigma^{K_p} \neq 0\}
\]

From the condition (i), it is easy to see that \( h' > h \). Since \( \Sigma_f(K_p, t, h) \) is finite, we know by Jacobson’s lemma that there exists \( f_1 \in \mathcal{H}_p(K_p) \) such that for all \( \sigma \in \Sigma_f(K_p, t, h) \), we have \( \sigma(f_1) = id_{\sigma^{K_p}} \) if \( \sigma \cong \sigma_0 \) and \( \sigma(f_1) = 0 \) otherwise. Now consider \( f = (1_{K_p} \otimes u_{tN})f_1 \) with \( N > v_1/(h' - h) \) with \( v_1 \) the valuation of the denominator of \( f_1 \). Then we have:

\[
P_f(f, T) = \det(1 - T.\sigma_0(1_{K_p} \otimes u_{tN}))^{m_f(\sigma_0)}S(T)
\]

where \( S(T) = \prod_{|v_p(\theta_\sigma(u_t))| > h} \det(1 - T\sigma((1_{K_p} \otimes u_{tN}).f_1))^{m_f(\sigma)} \) is a meromorphic function with the set of zeroes and poles of \( p \)-adic norm greater or equal to \( p^{h'N - v_1} \). Since by assumption \( P_f(f, T) \) is an entire function of \( T \) and the set of zeroes of \( \det(1 - T.\sigma_0(1_{K_p} \otimes u_{tN})) \) are of \( p \)-adic norm smaller or equal to \( p^{hN} \), this implies that \( m_f(\sigma_0) > 0 \). \( \blacksquare \)

4.1.13. Assume now that \( J \) is effective, we have \( P_{J, f}(T) = \det(1 - T. f; V_J(K_p)) \). Let \( t \in T^{--} \) and suppose that we have a factorization \( P_{J, u_t}(T) = Q(T)S(T) \) with \( Q \) a polynomial such that \( Q(0) = 1 \) and \( Q \) and \( S \) relatively prime. Then we know that by Theorem 2.3.8, that we have a decomposition stable by \( u_t \)

\[
V_J(K_p) = N_J(Q) \oplus F_J(Q)
\]

such that \( Q^*(u_t) \) acts trivially on \( N_J(Q) \) and is invertible on \( F_J(Q) \). Moreover there is a power series \( R_{Q, S} \) such that \( R_{Q, S}(u_t) \) is the projector of \( V_J(K_p) \) onto \( N_J(Q) \).

Since \( u_t \) is in the center of \( \mathcal{H}_p(K_p) \), this decomposition is stable by the action of \( \mathcal{H}_p(K_p) \) and we have for all \( f \in \mathcal{H}_p(K_p) \)

\[
(27) \quad J_{Q, t}(f) := J(f \circ R_{Q, S}(u_t)) = tr(f \circ R_{Q, S}(u_t); V_J(K_p)) = tr(f; N_J(Q))
\]

therefore \( J_{Q, t} \) is a character of \( \mathcal{H}_p(K_p) \) of degree \( \text{deg } Q \).
4.2. Automorphic finite slope representations. We would like now to define the cohomology of arithmetic subgroup with coefficient in the $p$-adic topological $\Delta^-$-modules we have defined in chapter 3 and study the action of $\mathcal{H}_p$ on them. Because the standard resolution of group cohomology by inhomogeneous cochains is not of finite type, it is however not suitable for topological properties. We will therefore use projective resolution of finite type that exist thanks to the work of Borel-Serre. Ideally, we would like the cohomology of $D_U$ to be projective over $O(U)$. In general, this is not quite true because of the possible presence of torsion in the cohomology and also because the cohomology might not be Hausdorff. To bypass these difficulties, we will work in the derived category of perfect complexes in the sense of the chapter 2. We will also construct finite slope character distributions for each $p$-adic weight and show these are analytic functions of the weight. We will use some of the notations and definitions of the section 1.1.2.

4.2.1. Resolution for arithmetic subgroups. Let $\Gamma \subset G(\mathbb{Q})/Z_G(\mathbb{Q}) \subset G^{\text{ad}}(\mathbb{Q})$ be a subgroup containing no non trivial elements of finite order. Therefore it acts freely and continuously from the left on the symmetric space $\mathcal{H}_G := G_\infty/Z_\infty K_\infty$ so that $\Gamma \backslash \mathcal{H}_G$ is a $C^\infty$ manifold. Let $d$ be its dimension. Unless $G$ is anisotropic this quotient is not compact and by the work of Borel-Serre, there exists a canonical compactification $\Gamma \backslash \overline{\mathcal{H}}_G$ where $\overline{\mathcal{H}}_G$ is a contractile real manifold with corners [BS73]. This fact will be useful to prove the following lemma.

**Lemma 4.2.2.** Let $\Gamma$ as above, then there exist length $d$ finite free resolutions of the trivial $\Gamma$-module $\mathbb{Z}$. In other words, there exist exact sequences of $\Gamma$-modules of the form:

$$0 \to C_d(\Gamma) \to \cdots \to C_1(\Gamma) \to C_0(\Gamma) \to \mathbb{Z} \to 0$$

where the $C_i(\Gamma)$'s are free $\mathbb{Z}[\Gamma]$-modules of finite rank.

**Proof.** Since $\Gamma \backslash \overline{\mathcal{H}}_G$ is compact, we may choose a finite triangulation of $\Gamma \backslash \mathcal{H}_G$. We pull it back to $\mathcal{H}_G$ by the canonical projection $\mathcal{H}_G \to \Gamma \backslash \mathcal{H}_G$ and denote by $C_q(\Gamma)$ the free $\mathbb{Z}$-module over the set of $q$-dimensional simplexes of the triangulation obtained by pull-back of $\mathcal{H}_G$. This is the module of $q$-chains obtained form this triangulation. Since the action of $\Gamma$ on $\mathcal{H}_G$ is free, the $C_q(\Gamma)$ are free $\mathbb{Z}[\Gamma]$-module and they are of finite type since the chosen triangulation of $\Gamma \backslash \mathcal{H}_G$ is finite. We therefore obtain a complex of free $\mathbb{Z}[\Gamma]$-modules of finite rank:

$$0 \to C_d(\Gamma) \xrightarrow{\partial_{d-1}} \cdots \xrightarrow{\partial_1} C_1(\Gamma) \xrightarrow{\partial_0} C_0(\Gamma) \to 0$$

computing the homology of $\mathcal{H}_G$. Since $\mathcal{H}_G$ is contractile, this complex is exact except in degree zero. In degree zero, we have

$$C_0(\Gamma)/\partial_0(C_1(\Gamma)) = H_0(\mathcal{H}_G, \mathbb{Z}) = \mathbb{Z}$$

which implies our claim.■
4.2.3. These resolutions are obviously not unique but two such resolutions are \( \mathbb{Z}[\Gamma] \)-homotopy equivalent. This is a standard fact true for any projective resolutions in abelian categories. We will use this fact in the following situation. Consider \( \Gamma' \subset \Gamma \) a finite index subgroup, then the restriction to \( \Gamma' \) of any such resolution \( C_\bullet(\Gamma) \) for \( \Gamma \) is \( \mathbb{Z}[\Gamma'] \)-homotopy equivalent to any resolution \( C_\bullet(\Gamma') \) for \( \Gamma' \). We will use these resolutions to study the cohomology of these arithmetic groups. If \( M \) is a \( \Gamma \)-module, then we can compute \( H^i(\Gamma, M) = \text{Ext}^i_\Gamma(\mathbb{Z}, M) \) by taking the cohomology of \( C^\bullet(\Gamma, M) := \text{Hom}_\Gamma(C_\bullet(\Gamma), M) \). This complex is particularly nice because of the following corollary.

**Corollary 4.2.4.** For any \( \Gamma \) and \( M \) as above, each term of the complex \( C^\bullet(\Gamma, M) \) is isomorphic to finitely many copies of \( M \).

**Proof.** This follows from the fact that the \( C_q(\Gamma) \)'s are free of finite rank over \( \mathbb{Z}[\Gamma] \).

It is well known that we can define an action of Hecke operators on \( H^\bullet(\Gamma, M) \). We will be explaining how we can directly define an action of them on \( C^\bullet(\Gamma, M) \).

4.2.5. **Fonctoriality.** We first consider a somehow general situation. Assume that we have two groups \( \Gamma \) and \( \Delta \) together with a group homomorphism \( \phi : \Gamma \rightarrow \Delta \). Assume also that we have a right \( \Gamma \)-module \( N \) and a right \( \Delta \)-module \( M \) with a map of abelian groups \( f : M \rightarrow N \), such that \( f(m.\phi(\gamma)) = f(m).\gamma \) for all \( m \in M \) and \( \gamma \in \Gamma \). If we consider \( M \) as a \( \Gamma \)-module via \( \phi \), saying that \( f \) is compatible is equivalent to saying it is \( \Gamma \)-equivariant. A pair \( (\phi, f) \) like this is called compatible. It is trivial that \( f \) induces a map from \( M^\Delta \) into \( N^\Gamma \).

Let \( C_\bullet(\Gamma) \) and \( C_\bullet(\Delta) \) be respectively two finite free resolutions of \( \mathbb{Z} \) by \( \mathbb{Z}[\Gamma] \) and \( \mathbb{Z}[\Delta] \)-modules of finite rank. By considering \( C_\bullet(\Delta) \) as a \( \Gamma \)-module by \( \phi \), it is a \( \Gamma \)-resolution of \( \mathbb{Z} \). Since \( C_\bullet(\Gamma) \) is a \( \Gamma \)-projective resolution of \( \mathbb{Z} \), it follows from the universal property of projective modules that we have a map, unique up to homotopy, \( C_\bullet(\Gamma) \rightarrow C_\bullet(\Delta) \) and compatible with \( \phi \).

We deduce we have a map compatible with \( \phi \):

\[
\text{Hom}_\mathbb{Z}(C_\bullet(\Delta), M) \xrightarrow{(\phi^\bullet)^* \otimes f} \text{Hom}_\mathbb{Z}(C_\bullet(\Gamma), N)
\]

By taking respectively \( \Gamma \) and \( \Delta \) invariants, it induces a map \( C^\bullet(\Delta, M) \xrightarrow{f^\bullet} C^\bullet(\Gamma, N) \). Again this is uniquely defined up to homotopy.

If \( \Gamma \subset \Delta \), \( M = N \) and \( \phi \) is the identity map, we obtain the restriction map

\[
\text{Res}^\Delta_{\Gamma} : C^\bullet(\Gamma, M) \rightarrow C^\bullet(\Gamma', M)
\]

that induces the usual restriction map on the cohomology.

Assume now \( \Gamma' \subset \Gamma \) of finite index. Let us fix a system of representatives \( \{\gamma_i\}_i \) of \( \Gamma' \backslash \Gamma \) (i.e. \( \Gamma = \sqcup \Gamma' \gamma_i \)). The corestriction map is obtained as follows.
Again we choose free and finitely generated resolutions $C_\bullet(\Gamma')$ and $C_\bullet(\Gamma)$. Then $C_\bullet(\Gamma)$ is also a free and finitely generated resolution of the trivial $\mathbb{Z}[\Gamma']$-module $\mathbb{Z}$ since $\mathbb{Z}[\Gamma]$ is free of finite rank over $\mathbb{Z}[\Gamma']$. Therefore we have a $\Gamma'$-equivariant homotopy $\tau_{\Gamma,\Gamma'} : C_\bullet(\Gamma) \to C_\bullet(\Gamma')$. So we have maps

$$\text{Hom}_{\Gamma'}(C_\bullet(\Gamma), M) \xrightarrow{\text{Hom}(\tau_{\Gamma,\Gamma'}, \text{id}_M)} \text{Hom}_{\Gamma'}(C_\bullet(\Gamma), M) \xrightarrow{\sum_i \gamma_i} \text{Hom}_\Gamma(C_\bullet(\Gamma), M)$$

where the second map is the usual average sum $m \mapsto \sum_i m.\gamma_i$ that sends $\Gamma'$-invariant to $\Gamma$-invariants. We call this composite the corestriction map

$$\text{Cor}\Gamma' : C^\bullet(\Gamma', M) \to C^\bullet(\Gamma, M).$$

It induces the usual corestriction map in cohomology. Again, this is uniquely defined up to homotopy.

4.2.6. Hecke operators. We refer to [Sh71] for the abstract definition and properties of Hecke operators. Let $\Delta$ be a semi-group containing $\Gamma$ and $\Gamma'$ and such that $\delta \Gamma \delta^{-1} \cap \Gamma'$ is of finite index in $\Gamma'$ for all $\delta \in \Delta$. Then we can consider the abstract Hecke operators $\Gamma' \delta \Gamma \in \mathbb{Z}[\Gamma' \setminus \Delta/\Gamma]$. We say that $\Gamma$ and $\Gamma'$ are commensurable. Assume $M$ is a right $\Delta$-module, then we can define the map $[\Gamma' \delta \Gamma] : C^\bullet(\Gamma', M) \to C^\bullet(\Gamma, M)$ as the composition:

$$[\Gamma' \delta \Gamma] = \text{Cor}\Gamma' \circ [\delta] \circ \text{Rest}\Gamma'$$

and where $[\delta]$ is defined by the pair of compatible maps $(x \mapsto \delta x \delta^{-1}, m \mapsto m.\delta)$ respectively from $\Gamma \cap \delta^{-1} \Gamma' \cap \delta$ onto $\delta \Gamma \delta^{-1} \cap \Gamma'$ and from $M$ into $M$. Again the action of $\Gamma' \delta \Gamma$ is well defined up to homotopy.

Consider now a third subgroup $\Gamma'' \subset \Delta$ which is commensurable with $\Gamma'$ and $\Gamma$. Then we can compose the double classes $\Gamma' \delta \Gamma$ and $\Gamma'' \delta \Gamma'$ and get an element $\Gamma'' \delta \Gamma' \circ \Gamma' \delta \Gamma \in \mathbb{Z}[\Gamma'' \setminus \Delta/\Gamma]$ (see the chapter 3 of [Sh71] for example). Then we have

**Lemma 4.2.7.** The maps $[\Gamma'' \delta \Gamma'] \circ [\Gamma' \delta \Gamma]$ and $[\Gamma'' \delta \Gamma' \circ \Gamma' \delta \Gamma]$ are equivalent up to homotopy.

**Proof.** This follows easily from the definitions and the fact that this is true when we define the maps on the level of the $\Phi$-invariants for $\Phi = \Gamma, \Gamma', \Gamma''$. We leave the details to the reader.

4.2.8. The adelic point of view. Let $K$ be a neat open compact subgroup of $G(\mathbb{A}_f)$ and let $M$ be a left $K$-module acting through its projection on $K_p$ the image of $K$ in $G(\mathbb{Q}_p)$. We fix a decomposition as (1) so that the $p$-part of each $g_i$ is trivial. Recall that $\Gamma(g_i, K)$ is defined as the image of $g_i K g_i^{-1} \cap G(\mathbb{Q})^+$ in $G(\mathbb{Q})/Z_G(\mathbb{Q})$. We put

$$R \Gamma^\bullet(K, M) := \bigoplus_i C^\bullet(\Gamma(g_i, K), M)$$

We can make another description. Consider the space $\overline{S}_G := G(\mathbb{Q}) \setminus G(\mathbb{A}_f) \times \overline{\mathcal{H}}_G$. Then $\overline{S}_G(K) = \overline{S}_G/K$ is the Borel-Serre compactification of $S_G(K)$. Let $\pi_K$ be the canonical projection $\overline{S}_G \to \overline{S}_G(K)$. Then choose a finite
triangulation of $\mathcal{S}_G(K)$ and its pullback by $\pi_K$. Let us denote $C^q(K)$ the corresponding chain complex. It is equipped with a right action of $K$. It is an easy exercise to check that if we consider the decomposition of $\mathcal{S}_G(K)$ in connected components determined by the $g_i$’s and the triangulation on each connected component $\mathcal{F}_G/\Gamma(g_i, K)$ associated to the chain complex $C^\bullet(\Gamma(g_i, K))$ (in the proof of Lemma 4.2.2), then we have the isomorphism

$$R\Gamma^\bullet(K, M) \cong \text{Hom}_K(C^q(K), M)$$

where the right action of $K$ on $M$ is given as usual by $m.k := k^{-1}.m$. In particular, this implies that if we had chosen another system of representatives $g'_i$, we would have obtained another complex homotopical to the first one. Therefore it defines an object in the homotopy category of abelian groups whose cohomology computes the cohomology of the local system $\tilde{M}$ on $S_G(K)$.

Moreover, the map $M \mapsto R\Gamma^\bullet(K, M)$ is functorial with respect to left $K$-module and there is an isomorphism:

$$H^\bullet(R\Gamma^\bullet(K, M)) \cong H^\bullet(S_G(K), M)$$

Suppose more generally that we have a pair $(\phi, f)$ where $\phi : K' \to K$ is a continuous and open group homomorphism and $f : M \to M'$ is a map of abelian groups where $M$ (resp. $M'$) is equipped with a left $K$-action (resp. with a left $K'$-action) such that $f(\phi(k').m) = k'.f(m)$ for all $k' \in K$ and $m \in M$. Using the description $R\Gamma^\bullet = \text{Hom}_K(C^\bullet(K), M)$ and the arguments of §4.2.5, we can define a map

$$R\Gamma^\bullet(K, M) \xrightarrow{(\phi^* \cdot f)} R\Gamma^\bullet(K', M')$$

uniquely defined up to homotopy.

We now make a description using the decomposition in connected components associated to the $g_i$’s and $g'_i$’s respectively for $K$ and $K'$. For simplicity, we assume that $\phi$ extends to a map from $G(\mathbb{A})$ to itself since it will be the case for all the examples that will be considered. For each $i$, let $j_i$ such that $\phi(g'_i) = \gamma_i g_{j_i} k_i \in G(\mathbb{Q})g_{j_i} K$. We can define maps $\phi_i : \Gamma(g'_i, K') \to \Gamma(g_{j_i}, K)$ and $f_i$ by:

$$\phi_i(x) := \gamma_i^{-1}\phi(x)\gamma_i \quad f_i(m) := f(\gamma_i m)$$

Since the $p$-component of $g_{j_i}$ is trivial, the $p$-component of $\gamma_i$ belongs to the $p$-component of $K$ and therefore $\gamma_i$ acts on $M$ which justifies the definition of $f_i$. It is easy to check that the pairs $(\phi_i, f_i)$ satisfy the assumption of §4.2.5. We therefore have a map from $C^\bullet(\Gamma(g_{j_i}, K), M) \to C^\bullet(\Gamma(g'_i, K'), M')$. Summing up over the $i$’s, we get the map

$$R\Gamma^\bullet(K, M) \xrightarrow{(\phi^* \cdot f)} R\Gamma^\bullet(K', M')$$

which is defined up to a homotopy.
4.2.9. Completely continuous action. It is useful and important for our application to notice that if $f$ satisfies certain properties then so does the map $(\phi^*, f)$ between the complexes. For example if $M$ and $M'$ are Banach spaces or compact Frechet spaces equipped with continuous actions of $K$ and $K'$ and if $f$ is completely continuous, then so is the map induced by $(\phi^*, f)$ at the level of the complexes. This follows from the very definition of our map, the fact that composition between continuous and compact maps is compact and that each term of the complex $R^\Gamma(K', M')$ is isomorphic to a finite number of copies of $M'$.

4.2.10. Special cases. Of course, if $f$ is the identity map and $K'$ is an open subgroup of $K$ we get the restriction map that we denote by $\text{Res}_{K}^{K'}$.

An other special case arises also if $\Delta_f \subset G(A_f)$ is a semi-group acting such that there is a left action of $\Delta_f$ on $M$ via the projection of $\Delta_f$ into $G(Q_p)$. For any $x \in \Delta_f$, we consider $\phi = \text{Int}^{-1}x : K' = xKx^{-1} \rightarrow K$ given by $\text{Int}^{-1}x(k) = x^{-1}kx$ and the map $M \rightarrow M$ given by $m \mapsto x.m$. We therefore get a map:

$$R^\Gamma(K, M) \xrightarrow{R^\Gamma(K, x)} R^\Gamma(xKx^{-1}, M)$$

which depends only of the coset $x.K$ modulo homotopy.

Consider now two open subgroups $K', K''$ of $\Delta_f$ and $x \in \Delta_f$. Then we have the decompositions:

$$K'xK = \bigcup_j x_j K \quad \text{and} \quad K' = \bigcup_j k_j (K' \cap xKx^{-1})$$

with $x_j = k_j x$ for $j$ running in a finite set of indexes. Notice that $x_j K x_j^{-1} = xKx^{-1}$ is independent of $j$. Therefore it makes sense to define the action of the double coset $K'xK$ from $R^\Gamma(K, M)$ into $R^\Gamma(K', M)$ by

$$[K'xK] := \sum_j R^\Gamma(K, x_j) = \sum_j R^\Gamma(K' \cap xKx^{-1}, k_j) \circ \text{Res}_{K'' \cap xKx^{-1}}^{K' \cap xKx^{-1}} \circ R^\Gamma(x, K)$$

Again this action is defined up to homotopy and depends (up to homotopy) uniquely of the coset decomposition of $K'xK$ above. One can see also it is homotopic to

$$\sum_j R^\Gamma(K' \cap xKx^{-1}, k_j) \circ R^\Gamma(x, x^{-1}K'x \cap K) \circ \text{Res}^{K}_{x^{-1}K'x \cap K}.$$  

When $K' \supset K$ and $x = 1$, we recover the corestriction map.

We now compare this action with the one defined by arithmetic subgroups. For this purpose, it is convenient to make $M$ a right $\Delta_f^{-1}$-module by the action $m.\delta^{-1} := \delta.m$ for all $\delta \in \Delta_f$ and $m \in M$. For each $i$, we write $g_i x = \gamma_{x,i} g_j h g_{\infty}$ with $h \in K$ as in \S 1.2.5. Then $\gamma_{x,i} \in \Delta_f \cap G(Q)$. Then we have the equality in the homotopy category:

$$[KxK] = \oplus_i [\Gamma_i \gamma_{x,i}^{-1} \Gamma_j].$$
where $[\Gamma_i\gamma^{-1}_{\mathbb{Z}_p}\Gamma_j]$ is the map from $C^\bullet(\Gamma_i, M)$ into $C^\bullet(\Gamma_j, M)$ defined previously. Of course, this equality is up to homotopy. The reader should compare with the relation (6) which was seen at the level of cohomology.

4.2.11. Action of an automorphism on the resolutions. We fix $\iota$ an automorphism of $G$ such that $K^\iota = K$ and an automorphism $\iota_M$ of $M$ such that:

$$g.\iota_M(m) = \alpha_M(g'.m)$$

for all $g \in K$ and $m \in M$. Therefore $(\iota, \iota_M)$ induces an automorphism of $R\Gamma^\bullet(K, M)$ in the homotopy category. We can also describe this map using the decomposition in connected components. For any arithmetic subgroup $\Gamma$, we have a canonical isomorphism from $\text{Hom}_\Gamma(C^\bullet(\Gamma), M)$ onto $\text{Hom}_{\Gamma_\mathbb{Q}}(C^\bullet(\Gamma^\mathbb{Q}), M)$ induced by $\phi \mapsto \phi^\iota$ for all $\phi \in \text{Hom}_\Gamma(C^\bullet(\Gamma), M)$ with $\phi^\iota(n) := \iota_M(\phi(n))$. Now note that since $K^\iota = K$, we should have $\Gamma(x, K)^\iota = \Gamma(x^\iota, K)$. Since for any representative systems $\{g_i\}, \{g'_i\}$ is another system of representatives, we can see that the map induced by $(\iota, \iota_M)$ is obtained from the maps above for $\Gamma = \Gamma(g_i, K)$ for each $i$ up to homotopy.

4.3. Finite slope cohomology.

4.3.1. We will use freely the notations and assumptions of Chapter 2. Let $A$ be a $\mathbb{Q}_p$-Banach algebra. Let $K^p$ be a neat open compact subgroup of $G(k^p_f)$. For such $K^p$, we choose representatives $g_i$ for the cosets $G(\mathbb{Q}) \backslash G(k_f) \times \mathcal{H}_G)/K^p.I$ that are trivial at $p$. Then, it follows from the previous discussion that the map $M \mapsto R\Gamma^\bullet(K^p, I_m, M)$ defines a functor from the category of left $A[\Delta^\mathbb{Z}_p/I_p]$-Frechet modules in the homotopy category of $\mathcal{F}re(A)$. We let the algebra $U_k$ act on the cohomology of $S_G(K^p, I_m)$ with coefficients $\mathbb{M}$ or on a complex $R\Gamma(K^p, I_m, M)$ through the projection on $C^\infty_c(\Delta^\mathbb{Z}_p/I_m, \mathbb{Z}_p)$ and the canonical action of the latter on the cohomology or the complex. Moreover, $R\Gamma^\bullet(K^p, I_m, M)$ is equipped with an action of the Hecke operators $\mathcal{H}_p(K^p)$ that defines an algebra homomorphism

$$\mathcal{H}_p(K^p) \rightarrow \text{End}_{D^\mathbb{Z}_p(\mathcal{F}re(A))}(R\Gamma^\bullet(K^p, I_m, M)).$$

4.3.2. Weight space revisited. Let $Z(K^p) := Z_G(\mathbb{Q}) \cap K^p.I$. Then the natural map of $Z(K^p)$ inside $\Gamma(g_i, K^p.I)$ is trivial for each $i$. Therefore $D_\lambda$ and $V_\lambda(L)$ are $\Gamma(g_i, K^p.I)$-modules only if $\lambda$ is trivial on $Z(K^p)$. This is the condition (2). We set $\mathfrak{X} = \mathfrak{X}_{K^p} \subset \mathfrak{X}_T$ to be the Zariski closure of the weights $\lambda$ which are trivial on $Z(K^p)$ for sufficiently small $K^p$. Let $Z_p(K^p)$ be the $p$-adic closure of $Z(K^p)$ inside $T(\mathbb{Z}_p)$. Then we have

$$\mathfrak{X}_{K^p}(L) := \text{Hom}_{\text{cont}}(T(\mathbb{Z}_p)/Z_p(K^p), L)$$

for any finite extension $L$ of $\mathbb{Q}_p$. Moreover $\mathfrak{X}_{K^p}$ is of dimension $rk_{\mathbb{Z}_p}T(\mathbb{Z}_p) - rk_{\mathbb{Z}_p}Z_p(K^p)$. Notice that if $G$ is $\mathbb{Q}$-split or semi-simple $Z_p(K^p)$ is trivial since $K^p$ is neat by assumption. Otherwise, its rank depends on the rank of some global units together with some Leopold defect. For instance, if
Proof. Let $G = GSp(2n, F)$ for a totally real field $F$ then $\mathcal{X}_G$ is of dimension $(n+1)[F : Q] - ([F : Q] - 1 - \delta_{F,p}) = n[F : Q] + 1 + \delta_{F,p}$ where $\delta_{F,p}$ designs the defect of the Leopoldt conjecture for $(F,p)$.

If $S$ is a finite set of prime and $K^p$ is maximal hyperspecial away from $S$, then $Z_p(K^p)$ does not depend of $K^p$ if it is sufficiently small. In general, when $K^p$ decreases $\mathcal{X}_{K^p}$ can get more connected components. However its dimension will stay the same.

4.3.3. Finite slope cohomology. Let $M$ be any left $L[\Delta^-/\mathbb{Z}_p(K^p)]$-module. We assume that $M$ is a $L$-Banach or a compact $L$-Frechet for which the elements in $\Delta^-$ act completely continuously. Let $t \in T^-$. We equip the complex $R\Gamma^*(K^pI_m, M)$ with an action of the Hecke operators $u_t$ (defined up to homotopy). By the definition of this action and the assumption on $M$, this operator is completely continuous on this complex and the latter has finite slope decomposition with respect to $u_t$. By the results of Chapter 2, this induces a slope decomposition for its cohomology. We then write $H^q_t(S_G(K^pI_m), M) \subset H^q(S_G(K^pI_m), M)$ for the finite slope part of its cohomology. Since for any $t,t' \in T^-$ there exits an $N$ such that $t^N = t't''$ for $t'' \in T^-$ and $u_t$ commutes with $u_{t'}$, it is easy to see that the finite slope part does not depend of the choice of $t$. We also put

$$H^q_t(\mathcal{S}_G, M) := \lim_{\kappa \rightarrow p} H^q_t(S_G(K^p, I), M)$$

The spaces $M$ that we will mainly consider are $\mathcal{D}_\lambda(L)$ and $\mathcal{V}_\lambda^\vee(L)$ for $\lambda \in \mathcal{X}_{K^p}(L)$.

4.3.4. Finite slope $p$-adic automorphic representations. Let $\lambda \in \mathcal{X}_{K^p}(\overline{\mathbb{Q}}_p)$. An irreducible finite slope representation $\sigma$ of $\mathcal{H}_p$ will be called $p$-adic automorphic of weight $\lambda$ if it appears as a subquotient of the representation of $\mathcal{H}_p$ on $H^q_t(S_G, \mathcal{D}_\lambda(L))$ for some integer $q$ and some $p$-adic field $L$. It will be further called $(M,w)$-ordinary Eisenstein if there exist $M \in \mathcal{L}_G$, $w \in \nu^M$ and a finite slope $p$-adic automorphic character $\sigma_M$ of $M$ of weight $\lambda$ such that $J_\sigma$ is a direct factor of the character $f \mapsto J_f(J_{M,w}^{eq})$ for all $f \in \mathcal{H}_p$ and $J_f$ the character of an automorphic finite slope representation for $M$. Moreover $M$ is supposed to be minimal for this property.

Proposition 4.3.5. Let $\lambda \in \mathcal{X}_{K^p}(L)$. For any irreducible finite slope representation $\sigma$ of $G$, there is an integer $m^q(\sigma, \lambda) \in \mathbb{Z}$ such that for all $f \in \mathcal{H}_p$, we have

$$\text{tr}(f; H^q_t(S_G, \mathcal{D}_\lambda(L))) = \sum_{\sigma} m^q(\sigma, \lambda) J_\sigma(f)$$

In particular, $\sigma$ is automorphic of weight $\lambda$ if $m^q(\sigma, \lambda) \neq 0$ for some $q$.

Proof. Let $t \in T^-$ and any $h \in \mathbb{Q}$. Then the $h$-slope part for $u_t$ of $H^q_t(S_G, \mathcal{D}_\lambda(L))$ is $H^q_t(S_G, \mathcal{D}_\lambda(L))^{\leq h} := \lim_{\kappa \rightarrow p} H^q_t(S_G(K^p, I), \mathcal{D}_\lambda(L))^{\leq h}$. It is
equipped with an action of \( \mathcal{H}_p \) since \( u_t \) is in the center of \( \mathcal{H}_p \) and this representation of \( \mathcal{H}_p \) is clearly admissible. Therefore we have a decomposition

\[
tr(f; H^q_{\ell \mathbb{s}}(\tilde{S}_G, D_\lambda(L))^{\leq h}) = \sum_{\sigma \in \mathcal{V}_p(\sigma_1)} m^q(\sigma, \lambda) J_{\sigma}(f)
\]

for all \( f \in \mathcal{H}_p \). The proposition then follows easily by considering this equality with \( f \in \mathcal{H}_p' \) and letting \( h \) go to infinity.

One defines the overconvergent Euler-Poincaré multiplicity by

\[
m^\dagger_G(\sigma, \lambda) := \sum q (-1)^q m^q(\sigma, \lambda)
\]

In the sequel of this section, we want to relate the action of the Hecke operators on the finite slope cohomology of \( D_\lambda(L) \) to the one of \( V_\lambda(L) \). We start by the following important lemma which goes back to Hida.

**Lemma 4.3.6.** Let \( M \) be a left \( \Delta^-/\mathbb{Z}_p \)-module. Let \( t \in T^{--} \) and \( m \) a positive integer. Then the following commutative diagram is commutative in the homotopy category of complexes of abelian groups.

\[
\begin{array}{c}
R\Gamma(K^p.I_m, M) \xrightarrow{u^m_t} R\Gamma(K^p.I_m, M) \\
\uparrow [I_{m+1}.t.I_m] \quad \uparrow \\
R\Gamma(K^p.I_{m+1}, M) \xrightarrow{u^{m+1}_t} R\Gamma(K^p.I_{m+1}, M)
\end{array}
\]

In particular, if \( M \) is a Frechet \( L[\Delta^-/\mathbb{Z}_p(K^p)]\)-vector space over which the elements of \( \Delta^{--} \) act completely continuously, the restriction map induces an isomorphism on the finite slope parts:

\[
H^\bullet_{\ell \mathbb{s}}(S_G(K^p I), M) \xrightarrow{\sim} H^\bullet_{\ell \mathbb{s}}(S_G(K^p I_m), M).
\]

**Proof.** The first part is a consequence of the definition of the action of double cosets and of the fact that the decomposition in right coset of the double cosets \( I_m t I_m \) and \( I_{m+1} t I_m \) are the same. This last fact follows from \( I_{m+1} \cap t^{-1} I_m t = I_m \cap t^{-1} I_m t \) for \( t \in T^{--} \). To prove the second part of our lemma, we apply Lemma 2.3.4 to the following commutative diagram that follows from the first part of our lemma.

\[
\begin{array}{c}
H^\bullet(K^p.I_m, M) \xrightarrow{u^m_t} H^\bullet(K^p.I_m, M) \\
\uparrow [I_{m+1}.t.I_m] \quad \uparrow \\
H^\bullet(K^p.I_{m+1}, M) \xrightarrow{u^{m+1}_t} H^\bullet(K^p.I_{m+1}, M)
\end{array}
\]
4.3.7. Let $\lambda$ be an algebraic dominant character of $T$. The next lemma shows that the finite slope part of the cohomology of $\mathbb{V}_\lambda^\vee(L)$ can be replaced by finite slope part of the cohomology of $V^\vee(\lambda, L)$.

**Lemma 4.3.8.** Let $\lambda = \lambda^{alg} \epsilon$ be an arithmetic weight of conductor $p^{\lambda}$.
Then for any $m \geq n_\lambda$, we have

$$H^\bullet_{fs}(SG(Kp.I), V^\vee(\lambda, L)) \cong H^\bullet_{fs}(SG(Kp.I_m), V^\vee_{\lambda^s}(\epsilon, L))$$

**Proof.** Let $V_{\lambda,n}(L)$ be the subspace of locally algebraic functions on $I$ which are $n$-locally analytic on $I'_{n_\lambda}$.
Then $V_\lambda(L) = \lim_{\rightarrow} V_{\lambda,n}(L)$. By Lemma 2.3.13, the canonical map

$$\tilde{H}^\bullet(SG(Kp.I_m), V^\vee_{\lambda^s}(\epsilon, L)) \rightarrow H^\bullet(SG(Kp.I_m), V^\vee_{\lambda^s}(L))$$

induces an isomorphism on the finite slope part. The previous Proposition applied to the $M = V^\vee_{\lambda^s}(L)$ together with the case $n = 0$ of the isomorphism above imply our claim since $V_\lambda(\epsilon, L) = V_{\lambda,0}(L)$.

**Definition 4.3.9.** For any $t \in T^-$ and any $\lambda \in X^+(T)$, we put

$$N(\lambda, t) := \inf_{w \neq id} |t^{w*\lambda - \lambda}|_p.$$ 

We are now ready to compare the cohomology of $D_\lambda(L)$ and of $\mathbb{V}_{\lambda^{alg}}(\epsilon, L)$.

**Proposition 4.3.10.** Let $\lambda = \lambda^{alg} \epsilon \in X(L)$ be an arithmetic weight of conductor $p^{\lambda}$ and $\mu$ be a non critical slope with respect to $\lambda^{alg}$. Then for any positive integer $m \geq n_\lambda$, we have the canonical isomorphisms:

$$H^\bullet(SG(Kp.I), D_\lambda(L))_{\leq \mu} \cong H^\bullet(SG(Kp.I_m), \mathbb{V}_\lambda^\vee(\epsilon, L))_{\leq \mu}.$$ 

Similarly, for any rational $h < v_p(N(\lambda, t))$ and any Hecke operator $f = f^p \otimes u_t$ with $t \in T^-$, we have:

$$H^\bullet(SG(Kp.I), D_\lambda(L))_{\leq h} \cong H^\bullet(SG(Kp.I_m), \mathbb{V}_{\lambda^{alg}}^\vee(\epsilon, L))_{\leq h}$$

for the $\leq h$-slope decomposition with respect to the action of $f$.

**Proof.** We just prove the first part. The second part can be proved similarly. By the previous lemmas, it suffices to show that

$$H^\bullet(SG(Kp.I), D_\lambda(L))_{\leq \mu} \cong H^\bullet(SG(Kp.I), \mathbb{V}_\lambda^\vee(\epsilon, L))_{\leq \mu}$$

For any simple root $\alpha$, recall that we have defined in Proposition 3.2.11 a homomorphism of left $I$-module

$$\Theta_\alpha : A_\lambda(L) \rightarrow A_{s_\alpha*\lambda}(L)$$
Let us write $\Theta^*_\alpha$ for the dual homomorphism. Then by Proposition 3.2.12, we have a canonical exact sequence:

$$\bigoplus_{\alpha \in \Delta} D_{s_{\alpha^*\lambda}}(L) \to D_{\lambda}(L) \to V_{\lambda}^\vee(L) \to 0$$

Let us fix an ordering $\alpha_1, \ldots, \alpha_r$ of the simple roots in $\Delta$ and for each integer $i$ between 1 and $r$, $\Theta^*_i = \Theta^*_{\alpha_1} + \cdots + \Theta^*_{\alpha_i}$. For $i = 0$, we define $\Theta^*_0 = 0$. Then $\text{Coker} \Theta^*_0 = D_\lambda(L)$. $\text{Coker} \Theta^*_r \cong V_{\lambda}^\vee(L)$ and for each integer $i \in \{1, \ldots, r\}$, we have an exact sequence:

$$0 \to Q_i \to \text{Coker} \Theta^*_i \to \text{Coker} \Theta^*_{i-1} \to 0$$

where $Q_i$ is the exact quotient of $D_{s_{\alpha^*\lambda}}(L)$ making the short sequence exact.

This induces the long exact sequence

$$H^q(S_G(K^p,I), Q_i)_{\leq \mu - (\lambda^\text{alg}(H_{\alpha_i}) + 1)\alpha_i} \to H^q(S_G(K^p,I), \text{Coker} \Theta^*_i)_{\leq \mu} \to H^q(S_G(K^p,I), Q_i)_{\leq \mu - (\lambda^\text{alg}(H_{\alpha_i}) + 1)\alpha_i}$$

There is a shift in the slope truncation because the operator $\Theta^*_\alpha$ is not exactly equivariant for the action of $U_\theta$. In fact, we have the following formula for any eigenvector $v$ in $H^\bullet(S_G(K^p.I_m), Q_i)[\theta]$

$$u_\lambda(\Theta^*_\alpha(v)) = \alpha(t)^{\lambda^\text{alg}(H_{\alpha_i}) + 1}\Theta^*_\alpha(u_\lambda.v) = \theta(t)\alpha_i(t)^{\lambda^\text{alg}(H_{\alpha_i}) + 1}\Theta^*_\alpha(v)$$

which implies our claim since the character of $\Theta^*_\alpha(v)$ is therefore of slope $\mu_\theta - (\lambda^\text{alg}(H_{\alpha_i}) + 1)\alpha_i$.

Now since $Q_i$ contains a stable $O_L$-lattice under the left action of $\Delta^-$, the slope of any character occurring in $H^\bullet(S_G(K^p,I), Q_i)$ must belong to $X^*(T)_{Q_i^+}$. Since $\mu$ is not critical with respect to $\lambda$, $\mu_\theta - (\lambda^\text{alg}(H_{\alpha_i}) + 1)\alpha_i \notin X^*(T)_{Q_i^+}$ which implies $H^\bullet(S_G(K^p,I), Q_i)_{\leq \mu - (\lambda^\text{alg}(H_{\alpha_i}) + 1)\alpha_i} = 0$. Therefore $H^q(K^p.I, \text{Coker} \Theta^*_{i-1})_{\leq \mu}$ is independent of $i$. This fact for $i = r$ and $i = 0$ means that

$$H^\bullet(S_G(K^p,I), D_\lambda(L))_{\leq \mu} \cong H^\bullet(S_G(K^p,I), V_{\lambda}^\vee(L))_{\leq \mu}.$$

4.3.11. More multiplicities. Let $\theta$ be a finite slope $L$-valued character of the Hecke algebra $R_{S,p}$. For any $\lambda \in X(L)$ and any $K^p$ which is maximal outside $S$, let us consider

$$m^\dagger(\theta, \lambda, K^p) := \sum_q (-1)^q \dim_L H^q(S_G(K^p,I), D_\lambda(L))[\theta]$$

We also define when $\lambda$ is arithmetic:

$$m^\text{cl}(\theta, \lambda, K^p) := \sum_q (-1)^q \dim_L H^q(S_G(K^p,I), V_{\lambda}^\vee(L))[\theta]$$

An immediate consequence of the previous proposition is the following classicity result on multiplicities:
Corollary 4.3.12. Let λ be an arithmetic weight. Then for any θ such that
μ_θ is non critical with respect to λ^{alg}, we have

\[ m^{cl}(\theta, \lambda, K^p) = m^\dagger(\theta, \lambda, K^p) \]

4.4. A spectral sequence. Fix λ an arithmetic weight of level p^m. We can refine the classicity result explained above by using the BGG complex. For this purpose, we consider the following double complex

\[ C^j_\lambda := R\Gamma^j(K^pI_m, C^j_\lambda(L)) = \bigoplus_{w|t(w)=j} R\Gamma^j(K^pI_m, D_{w^*\lambda}(L)) \]

Since the BGG complex is exact except in degree 0 where its cohomology is isomorphic to \( V^\vee_\lambda(L) \), the spectral sequence that one obtains by taking cohomology with respect to j first degenerates and converges to \( H_{fs}^i(S_G(K^pI_m), V^\vee_{\lambda^{alg}}(\epsilon, L)) \).

On the other hand, the spectral sequence obtained by taking cohomology with respect to i first has an \( E^{i,j}_1 \) term given by \( \bigoplus_{w|t(w)=j} H_{fs}^i(S_G(K^pI_m), D_{w^*\lambda}(L)) \). Then Proposition 4.3.10 is a corollary of the following theorem.

**Theorem 4.4.1.** Let \( \lambda = \lambda^{alg}\epsilon \) be an arithmetic weight of level p^m and a slope \( \mu \in X^*(T)_{\mathbb{Q}} \). Then we have the following spectral sequence:

\[ \bigoplus_{w|t(w)=j} H_{fs}^i(K^pI_m, D_{w^*\lambda}(L)) \leq \mu + w^*\lambda - \lambda \Rightarrow H_{fs}^{i+j}(S_G(K^pI_m), V^\vee_{\lambda^{alg}}(\epsilon, L)) \leq \mu. \]

**Proof.** This follows from the fact that the two spectral sequences attached to the double complex \( C^{i,j}_\lambda \) converge to the same limit. The slope truncation follows from the fact due to Proposition 3.3.12 that the differential map \( E^{i,j}_1 \to E^{i,j+1}_1 \) is equivariant with respect to the action of \( U_p \) if one renormalizes the *-action of \( u_t \) on \( H_{fs}^i(K^pI_m, D_{w^*\lambda}(L)) \) by multiplying by the factor \( \xi(t)^{w^*\lambda^{alg}} \).

4.5. The p-adic automorphic character distributions. In the beginning of this chapter, we have defined finite slope p-adic character distributions as certain p-adic linear functionals on \( \mathcal{H}^\prime_p \). In this section, we define the finite slope p-adic (virtual) character distributions of the p-adic automorphic spectrum that we will decompose as alternating sums of cuspidal and Eisenstein parts.

4.5.1. Definition of \( I^\dagger_G \) and \( I^\dagger_G \). Let \( L \) be a finite extension of \( \mathbb{Q}_p \) and fix \( \lambda \in X(L) \). For \( f \in \mathcal{H}^\prime_p \) we put

\[ I^\dagger_G(f, \lambda) := tr(f; H_{fs}^\bullet(S_G, D_{\lambda}(L))) \]
If \( f \in \mathcal{H}_p'(K^p) \), we easily see that
\[
I_G^\dagger(f, \lambda) = \text{Meas}(K^p, dg) \times tr(f; H^*_\acute{\alpha}(S_G(K^p.I), \mathcal{D}_\lambda(L)))
\]
\[
= \text{Meas}(K^p, dg) \times tr(f; R\mathcal{T}^\bullet(K^p.I, \mathcal{D}_\lambda(L)))
\]
This second equality comes from Corollary 2.3.11. If \( \lambda \in \mathcal{X}(L) \) is algebraic dominant, one also defines \( I^c_G(f, \lambda) \) by:
\[
I^c_G(f, \lambda) := tr^*(f; H^*(\tilde{S}_G, \mathcal{V}^\vee_{\lambda, alg}(L))
\]
where the superscript “ \(*\)” is here to remind the reader that \( \mathcal{V}^\vee_{\lambda, alg}(L) \) is considered as a left \( \Delta^- \)-module for the \( * \)-action. If \( f = f^p \otimes u_t \) with \( t \in T^- \), it follows from the comments of §1.2.5, the relation (15) and Lemma 4.3.8 that we have the following formula:
\[
(29) \quad I^c_G(f, \lambda) = \xi(t)^\lambda \cdot tr^*(f; H^*(\tilde{S}_G, \mathcal{V}^\vee_{\lambda}(\mathbb{C}))
\]
where the superscript “ \( *t \)” means that we have considered the standard action of the Hecke operators on \( H^*(\tilde{S}_G, \mathcal{V}^\vee_{\lambda}(\mathbb{C})) \) as defined in §1.2.5.

**Lemma 4.5.2.** Let \( \lambda \) be an algebraic dominant weight and let \( f = f^p \otimes u_t \in \mathcal{H}_p'(K^p) \). Then the following congruence holds.
\[
I^\dagger_G(f, \lambda) \equiv I^c_G(f, \lambda) \mod N(\lambda, t) \text{Meas}(K^p, dg)
\]
with \( N(\lambda, t) \) the power of \( p \) defined in definition 4.3.9.

**Proof.** Let \( K^p \) such that \( f^p \) is bi-\( K^p \)-invariant. Let \( h \) the largest slope (strictly) less than \( v_p(N(\lambda, t)) \) and ocuring in the cohomology of \( \mathcal{D}_\lambda(L) \) or \( \mathcal{V}_\lambda(L) \). Then one has
\[
tr(f; H^*_\acute{\alpha}(S_G(K^p.I), \mathcal{D}_\lambda(L))) \leq h \equiv I^\dagger_G(f, \lambda) \mod N(\lambda, t) \text{Meas}(K^p, dg)
\]
\[
tr(f; H^*(S_G(K^p.I_m), V^\vee_{\lambda}(L))) \leq h \equiv I^c_G(f, \lambda) \mod N(\lambda, t) \text{Meas}(K^p, dg)
\]
By Proposition 4.3.10, the left hand-side of both congruences are equal and the lemma is proved.

4.5.3. **Twist with respect to a pair \((w, \lambda)\).** For any pair \((w, \lambda)\) with \( w \in W \) and \( \lambda \) a locally algebraic weight, one defines a \( \mathbb{Q}_p \)-linear automorphism of the Hecke algebra \( \mathcal{H}_p \)
\[
f \mapsto f^{w, \lambda}
\]
defined by:
\[
f^{w, \lambda} := \xi(t)^{w\lambda_{\text{alg}} - \lambda_{\text{alg}}} f^p \otimes u_t
\]
if \( f = f^p \otimes u_t \) with \( t \in T^- \) and \( f^p \in C_c^\infty(G(\mathbb{A}_f^p), \mathbb{Q}_p) \) and extended to \( \mathcal{H}_p \) by linearity. For any character \( \theta \) of \( R_{S,p} \), we then consider the twisted character \( \theta^{w, \lambda} \) defined by:
\[
\theta^{w, \lambda}(f) := \theta(f^{w, \lambda})
\]
for all \( f \in R_{S,p} \). Similarly, for any irreducible finite slope representation \( \sigma \), we denote by \( \sigma^{w,\lambda} \) the twisted finite slope representation defined by
\[
\sigma^{w,\lambda}(f) := \sigma(f^{w,\lambda}).
\]
It is straightforward to verify that we have
\[
\mu_{\theta^w,\lambda} = \mu_{\theta} + \lambda^{alg} - w^* \lambda^{alg}
\]
In particular, when \( \mu_{\theta} \) is not critical with respect to \( \lambda^{alg} \), \( \mu_{\theta^w,\lambda} / \in X^*(T)_{Q,+} \)
and therefore \( m^\dagger(\theta^{w,\lambda} w, \lambda, K^p) = 0 \) as long as \( w \neq id \) since the cohomology as an integral structure (if the multiplicity is not zero, that means \( \theta^{w,\lambda} \)
must be integrally valued and its slope must belong to \( X^*(T)_{Q,+} \)). In view of Corollary 4.5.5 below, this gives another proof of Corollary 4.3.12.

**Theorem 4.5.4.** Let \( f \in H'_p \), then for any locally algebraic character \( \lambda \), we have
\[
I_{cl}^G(f, \lambda) = \sum_{w} (-1)^l(w) I_{cl}^G(f^{w,\lambda}, w^* \lambda)
\]

**Proof.** One applies the finite slope spectral sequence of Theorem 4.4.1. One needs again to pay attention to the fact that the action on the BGG resolution is the standard action (i.e. the action of \( t \) on \( D_{w^*\lambda}(L) \) is the \( * \)-action multiplied by \( \xi(t)^{w\lambda^{alg}} \)), it is why the twists of the Hecke operators appear here since the distribution \( I_{cl}^G \) is the trace with respect to the \( * \)-action. The details are left to the reader.

Recall that for any irreducible finite slope representation \( \sigma \), we have defined in (28) the Euler-Poincaré multiplicity \( m_{\dagger}^G(\sigma, \lambda) \). It satisfies
\[
I_{cl}^G(f, \lambda) = \sum_{\sigma} m_{\dagger}^G(\sigma, \lambda) J_{\sigma}(f)
\]
where the sum runs over (absolutely) irreducible finite slope representations. If moreover \( \lambda \) is locally algebraic, we can also define \( m^{cl}(\sigma, \lambda) \) in a similar way by replacing \( I_{cl}^G(f, \lambda) \) by \( I_{cl}^G(f, \lambda) \). Then we have the following straightforward corollary.

**Corollary 4.5.5.** Let \( \lambda \) be an arithmetic weight. Then for any finite slope irreducible representation \( \sigma \), we have
\[
m_{cl}^{G}(\sigma, \lambda) = \sum_{w \in W} (-1)^l(w) m_{\dagger}^G(\sigma^{w,\lambda}, w^* \lambda)
\]
There is a similar formula for the multiplicities \( m^\dagger(\theta, \lambda, K^p) \) and \( m^{cl}(\theta, \lambda, K^p) \).
4.6.1. Definitions of $I_{G,M,w}^\dagger$ and $I_{G,0}^\dagger$. For any standard Levi $M \in \mathcal{L}_G$ and $w \in W^M$, recall that we have defined linear maps from $\mathcal{H}_p(M)$ into $\mathcal{H}_p(G)$ defined by $f \mapsto f^\text{reg}_{M,w}$ to relate the character of the parabolic induction of an admissible finite slope to the character of the representation which is induced. We define character distributions $I_{G,0}^\dagger$ and $I_{G,M,w}^\dagger$ for any $M \in \mathcal{L}_G$ and $w \in W^M$, by induction on the $rk(G)$. If $rk(G) = 0$, we put:

$$I_{G,0}^\dagger(f,\lambda) = I_G^\dagger(f,\lambda)$$

Assume now that $rk(G) = r$ and that these distribution are defined for groups of rank less than $r$. Then, for any proper Levi $M \in \mathcal{L}_G$ and $f = f^p \otimes u$, we put

$$I_{G,M,w}^\dagger(f,\lambda) := I_{M,0}^\dagger(f^\text{reg}_{M,w}, w \ast \lambda + 2\rho_P)$$

where $2\rho_P$ stands for the sum of positive roots of the unipotent radical of the standard parabolic subgroup of Levi $M$ and

$$I_{G,M}^\dagger(f,\lambda) := \sum_{w \in W^M} (-1)^{l(w) + \dim n_M} I_{G,M,w}^\dagger(f,\lambda)$$

where $n_M$ stands for the Lie algebra of the standard parabolic of Levi $M$. We define:

$$I_{G,0}^\dagger(f,\lambda) := I_G^\dagger(f,\lambda) - \sum_{M \in \mathcal{L}_G, M \neq G} I_{G,M}^\dagger(f,\lambda)$$

Let $\lambda = \lambda_{alg} \epsilon$ be an arithmetic weight of level $p^m$. In view of the formula (29), we define for $f \in \mathcal{H}_p(K^p)$:

$$I_{G,0}^\dagger(f,\lambda) := M_{\text{eas}}(K^p).\xi(t)^{\lambda}.tr^{st}(f; H^\text{cusp}_{alg}(S_G(K^p, I_m), V^{\lambda}_{\epsilon}(C)))$$

Lemma 4.6.2. For any $f = f^p \otimes u \in \mathcal{H}_p$ and regular arithmetic weight $\lambda$, we have:

$$I_{G,0}^\dagger(f,\lambda) = \sum_{M \in \mathcal{L}_G} \sum_{w_0 \in W^M} \sum_{w \in W^M} (-1)^{l(w) + \dim n_M} \xi(t)^{\lambda - w^{-1}w_0 \ast \lambda}.I_{M,0}^\dagger(f^\text{reg}_{M,w}, w_0 \ast \lambda + 2\rho_{PM})$$

Proof. This is a consequence of the trace formula of Franke and a standard computation that we explain now. In order to have lighter notations, we write the proof only when $\lambda$ is algebraic (i.e. $\epsilon = 1$) and $f = 1_{K^p} \otimes u_t$ since the proof is strictly the same in the general case. We first fix a standard parabolic $P$ of Levi subgroup $M$. For any algebraic dominant character $\mu$, let us write $\sigma_\mu := H^\text{cusp}_{alg}(S_M, V^{\mu}_{\epsilon}(C))^K$ viewed as a representation of $M(\mathbb{Q}_p)$. Let $P$ be the standard parabolic subgroup with Levi $M$ and let $N$ be its unipotent radical. Then by the relation (8), we have

$$tr^{st}(f_M, \sigma_\mu) = tr^{st}(u_t : Ind_{P(\mathbb{Q}_p)}^G(\sigma_\mu)),$$
Here again, the subscript “st” stands as usual for “standard action” and
the parabolic induction is the smooth non-unitary parabolic induction. If
\( \phi \in (\text{Ind}_{P(\mathbb{Q}_p)}^{G(\mathbb{Q}_p)})^I \sigma_\mu \) and \( w \in \mathcal{W}^M \) then \( \phi(w) \) is invariant by \( wIw^{-1} \cap M(\mathbb{Q}_p) = I \cap M(\mathbb{Q}_p) = I_M \) since \( w \in \mathcal{W}^M \). Therefore from the decomposition
\[
G(\mathbb{Q}_p) = \bigsqcup_{w \in \mathcal{W}^M} P(\mathbb{Q}_p)wI
\]
we see that the map \( \phi \mapsto (\phi(w))_{w \in \mathcal{W}^M} \) defines an isomorphism:
\[
\left( \text{Ind}_{P(\mathbb{Q}_p)}^{G(\mathbb{Q}_p)} \right)^I \cong (\mathcal{W}^M)^{\mathcal{W}^M}
\]
Then a classical computation gives:
\[
\text{tr}^{st}(u_I : (\text{Ind}_{P(\mathbb{Q}_p)}^{G(\mathbb{Q}_p)})^I \sigma_\mu) = \sum_{w \in \mathcal{W}^M} \left[ N_w(\mathbb{Z}_p) : tN_w(\mathbb{Z}_p)t^{-1}, \text{tr}^{st}(I_Mwtw^{-1}I_M : \sigma_\mu^I) \right] = \sum_{w \in \mathcal{W}^M} \frac{[N_w(\mathbb{Z}_p) : tN_w(\mathbb{Z}_p)t^{-1}]}{\text{Meas}(K^p)} \xi(t)^{-w^{-1}pI_M^\dagger} \rho(1_{K^p} \otimes u_{wtw^{-1},M,\mu})
\]
Here we have considered \( I_Mwtw^{-1}I_M \) as the element \( u_{wtw^{-1},M} \in U_p(M) \)
thanks to the remarks of §4.1.8 and \( N_w := N \cap w^{-1}NW \). Notice that
\[
[N_w(\mathbb{Z}_p) : tN_w(\mathbb{Z}_p)t^{-1}] = \prod_{\alpha \in RP \cap w^{-1}(RP)} |\alpha(t)|_p^{-1} = |t^{w^{-1}(w_0(\lambda + \rho_P) + \rho_P}) + \rho_R|_p^{-1}
\]
If \( \mu = w_0 * \lambda + 2\rho_P = w_0(\lambda + \rho_P) + \rho_P \) for some \( w_0 \in \mathcal{W}^M_{Eis} \), we therefore have
\[
\xi(t)^\lambda [N_w(\mathbb{Z}_p) : tN_w(\mathbb{Z}_p)t^{-1}] \xi(t)^{-\mu} = \xi(t)^{\lambda - w^{-1}(w_0(\lambda + \rho_P) + \rho_P)} |t^{w^{-1}(\rho_P) + \rho_P}|_p^{-1} = \xi(t)^{\lambda - w^{-1}(w_0(\lambda + \rho_P) + \rho_P) + w^{-1}(\rho_P) + \rho_P} \epsilon_{\xi,w}(t) = \xi(t)^{\lambda - w^{-1}w_0*\lambda} \epsilon_{\xi,w}(t)
\]
Recall also that we have
\[
\epsilon_{\xi,w}(t)^{-1}(1_{K^n})_M \otimes u_{wtw^{-1},M} = \text{Meas}(K^p)^{-1} f_{M,w}^{\text{reg}}
\]
Combining all the previous identity, we get:
\[
(31) \quad \xi(t)^\lambda : \text{tr}^{st}(f_M, H_{cusp}^*(\hat{S}_G, \mathbb{V}^M_{w_0*\lambda + 2\rho_P}(\mathbb{C}))^\vee) = \sum_{w \in \mathcal{W}^M} \xi(t)^{\lambda - w^{-1}w_0*\lambda} I_M^\dagger \rho(1_{K^n} \otimes u_0 * \lambda + 2\rho_P)
\]
Recall that by Theorem 1.4.2 due to J. Franke, since \( \lambda \) is regular, we have:
\[
\text{tr}^{st}(f : H^*(\hat{S}_G, \mathbb{V}^\vee_{w_0}(\mathbb{C}))) = \sum_{M \in L_G} \sum_{w_0 \in \mathcal{W}^M_{Eis}} (-1)^{l(w_0) + \dim_M} \text{tr}^{st}(f_M : H_{cusp}^*(\hat{S}_M, \mathbb{V}^M_{w_0*\lambda + 2\rho_P}))
\]
therefore after multiplying by $\xi(t)^\lambda$ we get:

$$I_{cl}^\dagger G(f,\lambda) = \sum_{M \in \mathcal{L}_G} \sum_{w_0 \in \mathcal{W}_{Eis}^M} (-1)^{l(w_0) + \dim M} \xi(t)^\lambda \text{tr}^st(f_M : H^\bullet_{\text{cusp}}(S_{\tilde{M}}, \mathbb{V}_{w_0 + \lambda + 2\rho_P M}))$$

The statement we have claimed now results from the combination of this formula and (31).

**Corollary 4.6.3.** Let $f = f^p \otimes u_t \in \mathcal{H}_p(K^p)$ be $\mathbb{Z}_p$-valued and let $\lambda$ be a regular arithmetic weight. Then we have the congruence

$$I_{G,0}^\dagger(f,\lambda) \equiv I_{G,0}^\dagger(f,\lambda) \pmod{\text{Meas}(K^p, dg).N(\lambda, t)}$$

**Proof.** Notice first that since $f = f^p \otimes u_t \in \mathcal{H}_p(K^p)$ is $\mathbb{Z}_p$-valued, the images of $f$ by all the character distributions we have defined are $\text{Meas}(K^p) \mathbb{Z}_p$-valued. We prove this proposition by induction on the rank of $G$. The case of rank 0 follows from the previous paragraph (see Lemma 4.5.2). We now assume the proposition is satisfied for all proper Levi subgroups $M$ of $L_G$. If $w_0 \neq w$, then $N(\lambda, t)$ divides $\xi(t)^{\lambda - w^{-1} w_0 + \lambda}$ therefore it follows from the previous lemma that we have the following congruence modulo $\text{Meas}(K^p) N(\lambda, t)$:

$$I_{G,0}^\dagger(f,\lambda) \equiv \sum_{w_0 \in \mathcal{W}_{Eis}^M} (-1)^{l(w_0) + \dim M} I_{M,0}^\dagger(f^\text{reg}_{M, w_0}, w + \lambda + 2\rho_P M)$$

By Lemma 4.5.2, we also have

$$I_{G}^\dagger(f,\lambda) \equiv I_{G,0}^\dagger(f,\lambda) \pmod{\text{Meas}(K^p, dg).N(\lambda, t)}$$

We can now conclude using the induction hypotheses and the definition of $I_{G,0}^\dagger$.

4.6.4. For any $\lambda \in \mathcal{X}(\mathbb{Q}_p)$, By Proposition 4.3.5, we have

$$I_{G}^\dagger(f,\lambda) = \sum_\sigma m^\dagger(\sigma,\lambda) J_\sigma(f)$$

with $m^\dagger(\sigma,\lambda) = \sum g(-1)^g m^g(\sigma,\lambda) \in \mathbb{Z}$ and where the set of $\sigma$ of bounded slope and such that $m^\dagger(\sigma,\lambda) \neq 0$ is finite. By induction on the rank of $G$, we see easily that $I_{G,0}^\dagger(f,\lambda)$ and $I_{G,M,w}^\dagger(f,\lambda)$ are finite slope character distributions and we have spectral decompositions:

$$I_{G,0}^\dagger(f,\lambda) = \sum_\sigma m_0^\dagger(\sigma,\lambda) J_\sigma(f)$$

and

$$I_{G,M,w}^\dagger(f,\lambda) = \sum_\sigma m_{G,M,w}^\dagger(\sigma,\lambda) J_\sigma(f)$$
where $m_{G,M,w}^\dagger$ and $m_{G,0}^\dagger(\sigma, \lambda) \in \mathbb{Z}$ denote the corresponding multiplicities. If $\lambda$ is a dominant algebraic weight, we denote also $m_{G,0}^{cl}(\sigma, \lambda)$ the multiplicity of $\sigma$ with respect to the finite slope character distributions $f \mapsto I_{G,0}^\dagger(f, \lambda)$.

**Corollary 4.6.5.** Let $\lambda$ be a regular arithmetic weight. If $\sigma$ is not critical with respect to $\lambda^{alg}$, then we have:

$$m_{G,0}^{cl}(\sigma, \lambda) = m_{G,0}^\dagger(\sigma, \lambda)$$

**Proof.** This is an easy consequence of Corollary 4.6.3 using an appropriate $t \in T^{-\infty}$. The details are left to the reader.

**Definition 4.6.6.** Let $(\lambda_n)_n$ be a sequence of algebraic dominant weight in $X(\mathbb{Q}_p)$ such that $(\lambda_n)_n$ is converging $p$-adically to a weight $\lambda$ in $X(\mathbb{Q}_p)$. We say that this sequence is highly regular if for all positive simple root $\alpha$, we have

$$\lim_{n \to \infty} \lambda_n(H_\alpha) = +\infty$$

This notion is used in the following situation. If $t \in T^{-\infty}$, then

$$\lim_{n \to \infty} N(\lambda_n, t) = 0$$

where the limit is understood for the $p$-adic topology.

**Corollary 4.6.8.** Let $(\lambda_n)_n$ be a highly regular sequence of dominant weight converging $p$-adically to a weight $\lambda \in X(L)$. Then for any Hecke operator $f = f^p \otimes u_t \in \mathcal{H}_p'$, we have

$$\lim_{n \to \infty} I_{G,?}^{cl}(f, \lambda_n) = I_{G,?}^{\dagger}(f, \lambda)$$

for $? = \emptyset, 0$.

**Proof.** This is a direct consequence of the congruences of Lemma 4.5.2 and Corollary 4.6.3.

4.7. Automorphic Fredholm Series.

4.7.1. Definition. We consider automorphic Fredholm series only when $G(\mathbb{R})$ has discrete series. Under this hypothesis, $d_G$ stands for half the dimension of the corresponding locally symmetric space. For any $f \in \mathcal{H}_p'$ and $\lambda \in X(\overline{\mathbb{Q}}_p)$ and $? = \emptyset, 0$, let us denote $P_{G,?}^\dagger(f, \lambda, X)$ the Fredholm power series associated to the finite slope character distribution:

$$h \mapsto (-1)^{d_G} Meas(K^p)^{-1} I_{G,?}^{\dagger}(h, \lambda)$$

for $K^p$ the maximal open compact subgroup of $G(K^p_f)$ such that $f$ is $K^p$ bi-invariant. If moreover $\lambda$ is an arithmetic weight, we set:

$$P_{G,?}^{cl}(f, \lambda, X) := \det(1 - X.f; H^\bullet(S_G(K^p, I), \mathcal{V}^{\lambda^{alg}}_\lambda(L)))^{-1/d_G}$$
Lemma 4.7.2. Assume \( \lambda \) is a regular arithmetic weight. Then, the power series
\[
P_{G,0}^{\mu \cdot \ell}(f, \lambda, X) := \frac{P_{G,0}^1(f, \lambda, X)}{P_{G,0}^\text{cl}(f, \lambda, X)}
\]
is a meromorphic function of \( X \) on \( \mathbb{C}_p \) (i.e. the ratio of two Fredholm series in \( X \)) with coefficients in \( O_L \) and its set of zeroes and poles lies in
\[
\{ x \in \mathbb{C}_p^\times, s.t. \ |x|_p \geq N(\lambda, t) \}
\]

Proof. This follows from the definition of the Freedholm power series and Corollary 4.6.5.

Let \( \Lambda_X := \mathbb{Z}_p[[T(\mathbb{Z}_p)/\mathbb{Z}_p]] \subset \mathcal{O}(\mathfrak{X}) \) and \( \Lambda_{X, \mathbb{Q}_p} = \Lambda_X \otimes \mathbb{Q}_p \). We have the following theorem.

Theorem 4.7.3. Let \( f \in \mathcal{H}_p^0(K^p) \) and \( \mathfrak{X} = \mathfrak{X}_{K^p} \) then the following properties hold.

(i) The functions of \( \lambda \) defined by \( I_G^\dagger(f, \lambda) \), \( I_{G,M,w}^\dagger(f, \lambda) \) and \( I_{G,0}^\dagger(f, \lambda) \) belongs to \( \Lambda_{X, \mathbb{Q}_p} \). In particular, they are analytic on \( \mathfrak{X} \).

(ii) If \( G_\infty \) has no discrete series, then \( I_{G,0}^\dagger(f, \lambda) \equiv 0 \).

(ii)’ If \( M_\infty \) has no discrete series or if \( \dim(\mathfrak{X}_{K^p \cap M}) < \dim(\mathfrak{X}_{K^p}) \) then \( I_{G,M,w}^\dagger(f, \lambda) \equiv 0 \).

(iii) Assume \( f = f^p \otimes u_t \) with \( t \in T^{--} \), then we have \( P_{G,0}^1(f, \lambda, X) \in \Lambda_{\mathfrak{X}} \{\{X\}\} \). In other words, it defines an analytic function on \( \mathfrak{X} \times \mathbb{A}_{\rig}^{\dagger} \).

Proof. Again from the definitions, it suffices to prove (i) for \( I_G^\dagger(f, \lambda) \) since the other cases will follow from an induction argument on the rank of \( G \).

Let \( \mathfrak{U} \subset \mathfrak{X} \) be a an open affinoid subdomain and let \( n \geq n_\mathfrak{U} \). Then we have
\[
R\Gamma^\text{\cdot}(K^p, I, \mathcal{D}_{\mathfrak{U}, n}) \otimes_{\lambda} L \cong R\Gamma^\text{\cdot}(K^p, I, \mathcal{D}_{\mathfrak{U}, n}(L))
\]
for any \( \lambda \in \mathfrak{U}(L) \). Therefore \( F_\mathfrak{U} := \text{Meas}(K^p) \text{tr}(f, R\Gamma^\text{\cdot}(K^p, I, \mathcal{D}_{\mathfrak{U}, n})) \) is function inside \( \mathcal{O}(\mathfrak{U}) \) satisfying \( F_\mathfrak{U}(\lambda) = I_G^\dagger(f, \lambda) \) for any \( \lambda \in \mathfrak{U}(\mathbb{C}_p^\times) \). Let \( \mathcal{O}^0(\mathfrak{U}) \) the ring of analytic functions on \( \mathfrak{U} \) which are bounded by 1. If \( f \) is \( \mathcal{O}^\text{\cdot}(K^p)^{-1} \mathbb{Z}_p \)-valued, \( F_\mathfrak{U} \in \mathcal{O}^0(\mathfrak{U}) \) since \( f \) preserves the \( \mathcal{O}^0(\mathfrak{U}) \)-lattice \( R\Gamma^\text{\cdot}(K^p, I, (\mathcal{D}_{\mathfrak{U}, n})^0) \). Here \( (\mathcal{D}_{\mathfrak{U}, n})^0 \) is the \( \mathcal{O}^0(\mathfrak{U}) \)-dual of the lattice of functions \( f \) of \( \mathcal{A}_{\mathfrak{U}, n} \) bounded by 1 on \( \mathfrak{U} \times I \). Since this can be done for any such \( \mathfrak{U} \subset \mathfrak{X} \), we deduce that \( I_G^\dagger(f, \lambda) \in \lim_{\mathfrak{U}} \mathcal{O}^0(\mathfrak{U}) = \Lambda_{\mathfrak{X}} \). Therefore (i) follows.

For the proof of (ii), we see from the point (i) that it suffices to prove the vanishing for algebraic dominant weight since those are Zariski dense in \( \mathfrak{X} \). Let \( \lambda \) be such a weight and let \( (\lambda_n)_n \) be a highly regular sequence converging...
Fredholm series $F$ and basic properties of the hypersurface $Z$ the projection of $\pi_1 Z$ and $D$ and $p$.

Since $\lambda \neq 0$, one can conclude since this is an analytic function of $\lambda$ from the assertion (ii) for the group $M$. The second assertion follows from the fact that for any algebraic dominant $\lambda \in \mathfrak{x}_K$ such that $w \ast \lambda + 2\rho_p$ is non trivial on $Z_M(\mathbb{Q}) \cap K^p$. We have

$$I_{M,0}^1(f_{M,w}, w \ast \lambda + 2\rho_p) \equiv 0 \pmod{\text{Meas}(K^p)\mathcal{N}_M(wt^{-1}, w \ast \lambda + 2\rho_p)}.$$ 

Since those $\lambda$’s are Zariski dense by our hypothesis on the dimensions of the weight spaces for $G$ and $M$, this implies using a highly regular sequence that $I_{M,0}^1(f_{M,w}, w \ast \lambda + 2\rho_p) = 0$. Using again the Zariski density of those $\lambda$’s, one can conclude since this is an analytic function of $\lambda$ by (i).

We now prove the point (iii) for which we may assume that $G_\infty$ has discrete series by the point (ii). Let $\mathfrak{U} \subset \mathfrak{x}$ as above in the proof of (i). We may and furthermore assume that it contains algebraic weights. This implies that algebraic weights are dense in $\mathfrak{U}$. We will also assume $\mathcal{O}(\mathfrak{U})$ is factorial which is the case for instance if $\mathfrak{U}$ is a closed disc. Since $\mathfrak{x}$ can be covered by a union of such discs, we may assume that. We need to prove that $P_{G,0}^1(f, \lambda, X) \in \mathcal{O}^0(\mathfrak{U})\{\{X\}\}$. From the construction and the description above in the proof of (i), this series is the ratio of two series in $\mathcal{O}^0(\mathfrak{U})\{\{X\}\}$. Since $\mathcal{O}(\mathfrak{U})$ is factorial, by Theorem 1.3.11 of [CM], we have a prime factorization of $P_{G,0}^1(f, \lambda, X)$ as:

$$P_{G,0}^1(f, \lambda, X) = \prod_{i \in I} P_i^{m_i}(X)$$ 

with $m_i \in \mathbb{Z}_{\geq 0}$ and $\{P_i(X)\}_{i}$ a set of distinct prime Fredholm series in $\mathcal{O}^0(\mathfrak{U})\{\{X\}\}$. We can therefore write $P_{G,0}^1(f, \lambda, X) = \frac{N(\lambda, X)}{D(\lambda, X)}$ with $N(\lambda, X)$ and $D(\lambda, X)$ relatively prime Fredholm series.

Before continuing the proof, we refer the reader to §5.1.4 for the definition and basic properties of the hypersurface $Z(F) \subset \mathfrak{U} \times \mathbb{A}^1_{\text{rig}}$ defined for any Fredholm series $F(\lambda, X) \in \mathcal{O}(\mathfrak{U})\{\{X\}\}$.

Assume now that $D(\lambda, X) \neq 1$. Since $(N, D) = 1$, $Y := Z(D) - Z(D) \cap Z(N)$ is a non empty open rigid subvariety of the hypersurface $Z(D)$. Since the projection of $\pi : Z(D) \to \mathfrak{U}$ is flat, for any affinoid subdomain $\mathfrak{W} \subset Y$, $\pi(\mathfrak{W})$ is an open affinoid subdomain of $\mathfrak{U}$ and it therefore contains a Zariski dense set of algebraic weights.

Let us fix such a $\mathfrak{W}$ and let $w = (\lambda, x) \in \mathfrak{W}(\overline{\mathbb{Q}}_p)$ such that $\lambda \in \mathfrak{U}(\mathbb{Q}_p)$ is an algebraic character. Since $x \neq 0$, we can easily choose an element $w' = (\lambda', x')$, $p$-adically close to $w$ inside $\mathfrak{W}(\overline{\mathbb{Q}}_p)$ so that $\lambda'$ is regular dominant and $|x'|_p < N(\lambda', t)$. Since $(\lambda', x')$ is a pole of $P_{G,0}^1(f, \lambda, X)$, it therefore follows
from Lemma 4.7.2, that \( x' \) is a pole of the rational fraction \( P_{G,0}^{d}(f, \lambda', X) \). But since \( \lambda' \) is regular dominant,

\[
P_{G,0}^{d}(f, \lambda', X) = \text{det}(1 - X.f|H_{1}^{d}(G)(S_{G}(K^{p}, I, \mathcal{V}_{\lambda_{\alpha}}(L)))
\]

and is therefore a polynomial and has no pole. This contradiction implies \( D(\lambda, X) = 1 \) and therefore \( P_{G,0}^{d}(f, \lambda, X) \in \mathcal{O}^{0}(\{X\}) \) as claimed.

**Corollary 4.7.4.** For any finite slope representation \( \sigma, w \in W_{Eis}^{M} \) and \( \lambda \in \mathcal{X}(\overline{\mathbb{Q}}_{p}) \), we have

\[
(-1)^{d_{M}} m_{G,M,w}^{\dagger}(\sigma, \lambda) \geq 0
\]

and \( m_{G,M,w}^{\dagger}(\sigma, \lambda) \) is always 0 unless \( M \in \mathcal{L}_{G}^{c} \). In particular, for each \( \lambda \in \mathcal{X}(\overline{\mathbb{Q}}_{p}) \), the map \( f \mapsto (-1)^{d_{M}} I_{G,M,w}^{\dagger}(f, \lambda) \) is an effective finite slope character distribution.

**Proof.** Since \( I_{G,M,w}^{\dagger}(f, \lambda) = I_{M,0}^{\dagger}(f_{\text{reg}}^{M,w}) \), it is sufficient to prove the result for \( G = M \). This is a consequence of Lemma 4.1.12 together with the parts (iii) and (ii) of Theorem 4.7.3.

4.7.5. A twisted version. Let \( \iota \) be a finite order automorphism of \( G \) preserving the pair \((B_{F}, T_{F})\) for \( F \) the finite extension of \( \mathbb{Q}_{p} \) that splits \( G \) and the center of \( G \). Especially it preserves the Iwahori subgroups \( I_{m} \) and the subgroup \( T(Z_{p}) \). It therefore acts on \( \mathfrak{X} \) by \( \lambda(t) := \lambda(t^{\iota}) \) and this action preserve the cone of dominant weights. We denote by \( \mathfrak{X}^{\iota} \subset \mathfrak{X} \) the subvariety of weights \( \lambda \) fixed by \( \iota \). Since \( \iota \) preserves \( I \), it acts on \( f \in \mathcal{A}(I, L) \) by \((\iota.f)(g) := f(g^{\iota}) \). Moreover if \( \lambda \in \mathfrak{X}^{\iota}(L) \), this action leaves \( \mathcal{A}_{\lambda} \) stable. The Frechet spaces \( \mathcal{D}_{\lambda} \) inherits an action of \( \iota \) compatible with the action of \( \iota \) on the groups \( I \) in the sense of \S 4.2.11. For any \( f \in \mathcal{H}_{p}^{\iota} \), we can therefore study the traces of \( \iota \times f \) (a notation for \( \iota \) composed with \( f \)) on the Frechet spaces or Frechet complexes we have defined. Especially, we can define the distributions \( I_{G}^{\iota}(\iota \times f, \lambda) \), \( I_{G,0}^{\iota}(\iota \times f, \lambda) \) and of \( I_{G,M}^{\iota}(\iota \times f, \lambda) \) as well as a twisted multiplicity \( m^{\iota}(\sigma \times \iota, \lambda) \) with \( * = \dagger \) or \( \cap \). We can also define the corresponding power series \( P_{G}^{\iota}(\iota \times f, \lambda, X) \), \( P_{G,0}^{\iota}(\iota \times f, \lambda, X) \) and of \( P_{G,M}^{\iota}(\iota \times f, \lambda, X) \). The following definition will be relevant in the Theorem below which is the twisted version of Theorem 4.7.3.

**Definition 4.7.6.** We say that \( \iota \) is of Cartan type if there exists \( g_{\infty} \in G_{\infty} \) such that Int\((g_{\infty}) \circ \iota \) is a Cartan involution of \( G_{\infty} \). For instance, if \( G_{\infty} \) has discrete series, one can show that \( \iota = \text{id} \) is of Cartan type.

Let \( \Lambda_{\mathfrak{X}} := \mathbb{Z}_{p}[[T^{\iota}/Z_{p}]] \subset \mathcal{O}(\mathfrak{X}^{\iota}) \) and \( \Lambda_{\mathfrak{X}, \mathbb{Q}_{p}} = \Lambda_{\mathfrak{X}} \otimes \mathbb{Q}_{p} \). In the twisted situation, a variant of Theorem 4.7.3 is the following.

**Theorem 4.7.7.** For any \( f \in \mathcal{H}_{p}^{\iota} \), the following properties hold.

(i) The functions of \( \lambda \) defined by \( I_{G}^{\iota}(\iota \times f, \lambda) \), \( I_{G,M}^{\iota}(\iota \times f, \lambda) \) and \( I_{G,0}^{\iota}(\iota \times f, \lambda) \) belongs to \( \Lambda_{\mathfrak{X}, \mathbb{Q}_{p}} \). In particular, they are analytic on \( \mathfrak{X}^{\iota} \).
(ii) If $\iota$ is not of Cartan type, then $I^\dagger_{G,0}(t \times f, \lambda) = 0$ for all $\lambda \in X^i(\underline{Q}_p)$.

(iii) Assume $f = f^p \otimes u_t$ with $t \in T^{--}$, then we have $P^\dagger_{G,0}(t \times f, \lambda, X) \in \Lambda_X \{\{X\}\}$. Especially, it defines an analytic function on $X^i \times \mathbb{A}_{\mathrm{rig}}^1$.

**Proof.** It is similar to the proof of Theorem 4.7.3. A detailed construction and proof will appear in Zhengyu Xiang’s thesis. In particular, he needs to write the decomposition of the twisted finite slope character distribution attached to rational parabolic subgroups which are stable by the involution $\iota$. It can be done exactly in the same way. On has to replace the trace formula of Franke by the associated twisted trace formula which can be in turn obtained from Franke’s spectral sequence expressing the cohomology of $V^\vee_{\iota}(\mathbb{C})$ as a limit of the spectral sequence constructed out of the cuspidal cohomology of the standard Levi subgroups when $\lambda$ is regular. ■

4.7.8. The next two sections will be devoted to some applications of the important analyticity property of the distributions $I^\dagger_{G,?}(f, \lambda)$ we have defined in the previous paragraphs. The first application is the construction of Eigenvarieties à la Coleman-Mazur. The second is the proof of a formula for these distribution in geometric terms à la Arthur-Selberg.

5. CONSTRUCTION OF EIGENVARIETIES

5.1. Spectral Varieties.

5.1.1. Analytic families of finite slope character distributions. Let $\mathfrak{X}$ be a rigid analytic space defined over an extension of $\mathbb{Q}_p$. A $\mathbb{Q}_p$-linear map

$$ J = J_X : \mathcal{H}^p \rightarrow \Lambda_X \mathbb{Q}_p \subset \mathcal{O}(\mathfrak{X}) $$

is called a $\mathfrak{X}$-family of character distribution if for all $\lambda \in X(\underline{Q}_p)$, the composite $J_\lambda$ of this map with the evaluation map at $\lambda$ is an effective finite slope character distribution. For any irreducible finite slope representation $\sigma$, we write $m_J(\sigma, \lambda) \in \mathbb{Z}_{\geq 0}$ for the multiplicity of $J_\sigma$ in $J_\lambda$. Let $K^p$ be an open compact subgroup of $G(\mathbb{A}_f^p)$, the goal of this section is to attach to the pair $(J_X, K^p)$ an Eigenvariety over $\mathfrak{X}$ parametrizing the spherical Hecke eigensystems of the irreducible finite slope representations $\sigma$ for which $m_J(\sigma, \lambda) > 0$ and $\sigma^{K^p} \neq 0$. We will then apply our construction to the analytic families of finite slope distributions we have studied in the previous chapter. Let $S$ be the smallest finite set of primes such that $K^p$ is hyperspecial away from $S$. In our main application, $\mathfrak{X}$ will be the weight space $X_{K^p}$ (which is actually only depending upon $S$) introduced in the previous chapter and $J$ will be $I^\dagger_{G,0}$. One can also construct Eisenstein components attached to the distributions $I^\dagger_{G,M,w}$’s.
5.1.2. **Remark.** Before starting up the task that we propose to perform in this chapter, we would like to mention that our construction extends a construction of K. Buzzard in [Bu07] who did such a construction with the weaker hypothesis that for each affinoid \( \mathcal{U} \subset \mathfrak{X} \), there is a \( \mathfrak{U} \)-family of orthonormalizable \( \mathcal{O}(\mathfrak{U}) \)-Banach spaces equipped with an action of the Hecke algebra and such that certain Hecke operators at \( p \) are completely continuous on them.

5.1.3. Let \( f \in \mathcal{H}'_p \). Then for each \( \lambda \in \mathfrak{X}(\overline{\mathbb{Q}}_p) \), let us write \( P_J(f, \lambda, X) \) the Fredholm power series (in \( X \)) attached to \( f \) and \( J_\lambda \). Then we can write \( P_J(f, \lambda, X) = 1 - J_\lambda(f)X + \ldots \). Thus we see that the first term of the \( X \)-expansion for \( P_J(f, \lambda, X) \) is an analytic function of \( \lambda \). A similar statement is also true for all the coefficients of \( P_J(f, \lambda, X) \) since the coefficient of \( X^n \) can be expressed as a homogenous polynomial of degree \( n \) in \( J_\lambda(f), J_\lambda(f^2), \ldots, J_\lambda(f^n) \). Therefore there exists \( P_J(f, X) \in \Lambda_{x, \overline{\mathbb{Q}}_p} \{ \{ T \} \} \) such that \( P_J(f, X)(\lambda) = P_J(f, \lambda, X) \) for all \( \lambda \in \mathfrak{X}(\overline{\mathbb{Q}}_p) \).

5.1.4. **Fredholm hypersurfaces.** We recall some of the definitions due to Coleman and Mazur of Fredholm hypersurfaces. We refer the reader to [CM] and [Bu07] for the notions and properties recalled here. One says that an element \( P \in \mathcal{A}_\mathfrak{M} \{ \{ X \} \} \) is a Fredholm series if \( P(0) = 1 \). For such a \( P \), we denote by \( Z(P) \) the rigid subvariety of \( \mathfrak{X} \times \mathbb{A}^{1\text{rig}} \) cut out by \( P \). It is called a Fredholm hypersurface and its projection onto \( \mathfrak{X} \) is flat. \( Z(P)(\overline{\mathbb{Q}}_p) \) is equipped with the natural topology such that the inclusion \( Z(P)(\overline{\mathbb{Q}}_p) \subset \overline{\mathbb{Q}}_p \times \mathfrak{X}(\overline{\mathbb{Q}}_p) \) is continuous. An admissible affinoid subdomain of \( Z(P) \) can be obtained as follows. Let \( \mathfrak{U} \subset \mathfrak{X} \) be an affinoid subdomain and assume we have a factorization \( P|_\mathfrak{U} = Q \cdot R \) with \( Q, R \in \mathcal{O}(\mathfrak{U}) \{ \{ X \} \} \) with \( Q \) a polynomial of degree \( d \) relatively prime to \( R \) such that \( Q(0) = 1 \). Then \( \mathcal{M}_{Q, \mathfrak{U}} := \text{Sp}(\mathcal{O}(\mathfrak{U})[X]/(X^dQ(X^{-1}))(\overline{\mathbb{Q}}_p)) \) imbeds naturally in \( Z(P)(\overline{\mathbb{Q}}_p) \) where for any Tate algebra \( A \), we denote by \( \text{Sp}(A) \) the corresponding rigid affinoid variety as in [BGR]. Moreover \( \mathcal{M}_{Q, \mathfrak{U}} \) is open if and only if \( \mathfrak{U} \) is. Any such subset will be called admissible. It is not difficult to check that it defines a Grothendieck topology on the ring space \( Z(P) \) by taking finite covering by admissible open subsets. This gives \( Z(P) \) the structure of a rigid analytic variety. Of course, this ringed space is not necessarily reduced. Its reduction \( Z(P)_{\text{red}} \) is a union of irreducible components that are themselves of the form \( Z(P) \) for irreducible Fredholm series \( P \).

5.1.5. **Spectral varieties attached to \( J \).** For any \( f = f^p \otimes u_t \in \mathcal{H}'_p(K^p) \) with \( t \in T^{--} \), we denote by \( \mathfrak{J}_J(f) := Z(P_J(f)) \subset \mathfrak{X} \times \mathbb{A}^{1\text{rig}} \) the Fredholm hypersurface cut out by the Fredholm series \( P_J(f, \lambda, X) \).

**Proposition 5.1.6.** Let \( x = (\lambda_x, \alpha_x) \in \mathfrak{X}(\overline{\mathbb{Q}}_p) \times \overline{\mathbb{Q}}_p^X \). Then \( x \in \mathfrak{J}_J(f)(\overline{\mathbb{Q}}_p) \) if and only if \( \alpha_x^{-1} \) appears as an eigenvalue of \( V_{J_{\lambda_x}}(K^p) \) with a non trivial multiplicity.
5.2. First Construction of the Eigenvarieties.

5.2.1. We fix $K^p \subset G(A_f^p)$. Let $S$ be the smallest finite set of primes away from which $K^p$ is hypersepcial. Let $\bar{R}_{S,p}$ be the $p$-adic completion of $R_{S,p}[u_t^{-1}, t \in T^-]$. For any subfield $L \subset \overline{Q}_p$, we define

$$\mathfrak{A}_{S,p}(L) = \text{Hom}_{ct,alg}(\bar{R}_{S,p}, L).$$

By construction, the characters of $R_{S,p}$ contained in $\mathfrak{A}_{S,p}(L)$ are those of finite slope. The canonical $p$-adic topology of $\mathfrak{A}_{S,p}(L)$ is the topology induced by the metric $|\theta - \theta'| = \text{Sup}_{f \in R_{S,p}} |\theta(f) - \theta'(f)|_p$. In particular, for all $f \in \bar{R}_{S,p}$, the map from $\mathfrak{A}_{S,p}(L)$ into $L$ defined by $\theta \mapsto \theta(f)$ is continuous. We consider $\mathfrak{Y} = \mathfrak{Y}_{S,p} := \mathfrak{X} \times \mathfrak{A}_{S,p}$. A point $y$ of $\mathfrak{Y}(\overline{Q}_p)$ is a pair $(\lambda_y, \theta_y)$ where $\lambda_y$ is a weight and $\theta_y$ is a homomorphism $R_{S,p} \to \overline{Q}_p$ of finite slope.

5.2.2. Construction of $\mathfrak{E}_{K^p,J}$. Let $\hat{R}_S$ be the $p$-adic completion of the $\mathbb{Z}_p$-valued smooth function on $G(A_f^{SU(p)})$ which are bi-invariant by $K_m^{SU(p)}$. A Hecke operator $f \in \mathcal{H}_p^\prime$ will be said $K^p$-admissible if it is of the form $f = 1_{K_x} \otimes f' \otimes u_t$ with $f' \in \hat{R}_S$ and $t \in T^{--}$. For any such $f$, one define a map of ringed spaces $R_f$ from $\mathfrak{Y}_{S,p}$ into $\mathfrak{X} \times \mathbb{A}^{1}_{\text{rig}}$ by $y = (\lambda_y, \theta_y) \mapsto (\lambda_y, \theta_y(f)(-1))$ on the set of $L$-points and on the ring of functions $R_f^\ast : \mathcal{O}(\mathfrak{X})\{(X)\} \to \mathcal{O}(\mathfrak{X})\otimes \hat{R}_{S,p}$ defined by

$$\sum_{n=0}^{\infty} a_n \cdot X^n \mapsto \sum_{n=0}^{\infty} a_n \cdot (f)^{-n}$$

We define $\mathfrak{E}_{K^p,J}$ as the following infinite fiber product over $\mathfrak{Y}_{S,p}$:

$$\mathfrak{E}_{K^p,J} := \prod_f R_f^{-1}(\mathfrak{Y}_J(f))$$

where the fiber product is indexed on the set of $K^p$-admissible Hecke operators $f$. For each admissible $f$, we will denote by $r_f$ the restriction of $R_f$ to the Eigenvariety.

From the definition, $\mathfrak{E}_{K^p,J}$ is clearly a ringed space whose underlying topological space is the set of $\overline{Q}_p$-points $\mathfrak{E}_{K^p,J}(\overline{Q}_p)$ with the topology induced by the canonical $p$-adic topology of $\mathfrak{A}_{S,p} \times \mathfrak{X}(\overline{Q}_p)$. Of course, we have:

$$\mathfrak{E}_{K^p,J}(\overline{Q}_p) = \bigcap_f R_f^{-1}(\mathfrak{Y}_J(f)(\overline{Q}_p))$$

By definition of the canonical topology of $\mathfrak{A}_{S,p}(\overline{Q}_p)$, the maps $r_f$ are therefore continuous. We also need to define a $G$-topology of $\mathfrak{E}_{K^p,J}$. We say that an open subset of $\mathfrak{E}_{K^p,J}$ is an admissible open subset if it is union or intersections of open subset of the form $(r_{f_1} \times \cdots \times r_{f_r})^{-1}(\mathfrak{M})$ where $f_1, \ldots, f_r$ are
$K^p$-admissible operators and $\mathfrak{M}$ is an open admissible affinoid subdomain (for the strong G-topology) of $\mathfrak{Z}_J(f_1) \times \cdots \times \mathfrak{Z}_J(f_r)$. Similarly, we defined the admissible coverings as the inverse images by the projection $r_f$’s of the admissible coverings of the corresponding spectral varieties. Naturally $\mathfrak{E}_{K^p,J}$ is also a ringed space for its G-topology. Notice also that by construction, for any $K^p$-admissible $f$, we have a map of ringed spaces $r_f : \mathfrak{E}_{K^p,J} \to \mathfrak{Z}_J(f)$ fitting in a canonical diagram:

$$
\begin{array}{ccc}
\mathfrak{E}_{K^p,J} & \xrightarrow{r_f} & \mathfrak{Z}_J(f) \\
\downarrow w & & \\
\mathfrak{X} & \xrightarrow{\mathfrak{Z}_G,J(f)} & \\
\end{array}
$$

In the next subsections, we will prove the desired expected properties of the Eigenvarieties we have defined from those of the spectral varieties. We first give a description of the points of the Eigenvariety $\mathfrak{E}_{K^p,J}$. Let us denote by $m_J(\lambda, \theta, K^p)$ the multiplicity of $\theta$ in $V_{J_\lambda}(K^p)$. Then we have the following

**Proposition 5.2.3.** Let $K^p$ be an open compact subgroup of $G(h^p_f)$ and let $y = (\lambda_y, \theta_y) \in (X \times \mathfrak{M}_{S,p})(\overline{\mathbb{Q}}_p)$. Then $m_J(\lambda_y, \theta_y, K^p) > 0$ if and only if $y \in \mathfrak{E}_{K^p,J}(\overline{\mathbb{Q}}_p)$. Moreover if $y = (\lambda_y, \theta_y) \in \mathfrak{E}_{K^p,J}(\overline{\mathbb{Q}}_p)$, then there exists a $K^p$-admissible $f$ such that

$$
r_f^{-1}(r_f(y)) = \{y\}.
$$

**Proof.** The argument of this lemma is essentially due to Coleman and Mazur. For any $f \in \mathcal{H}'_p(K^p)$ and $\beta \in \overline{\mathbb{Q}}_p$, let us denote by $m_J(\lambda_y, f, \beta, K^p)$ the multiplicity of the eigenvalue $\beta$ for $f$ acting on $V_{J_\lambda}(K^p)$. Then we have

$$
m_J(\lambda_y, f, \theta_y(f), K^p) = \sum_{\theta(f) = \theta_y(f)} m_J(\lambda_y, \theta, K^p)
$$

Assume now that $m_J(\lambda_y, \theta_y, K^p) > 0$. Then for any $K^p$-admissible $f$, we deduce from the formula above that $m_J(\lambda_y, f, \theta_y(f), K^p) > 0$ and therefore

$$
r_f(y) = (\lambda_y, \theta_y(f)^{-1}) \in \mathfrak{Z}_J(f)(\overline{\mathbb{Q}}_p) \text{ by Proposition 5.1.6. Since this is true for all } K^p\text{-admissible } f, \text{ we deduce that } y \in \mathfrak{E}_{K^p,J}(\overline{\mathbb{Q}}_p).
$$

Let now $L$ be the finite extension of $\mathbb{Q}_p$ such that $y \in \mathfrak{E}_{K^p,J}(L)$. Let $t \in T^-$ and $h = v_p(\theta_y(u_t))$. Let us consider the action of $R_{S,p}$ on the $L$-Banach space $V_{J_\lambda}(K^p)$ and let $V := V_{J_\lambda}(K^p)^{\leq h}$ its $\leq h$-slope part of $V_{J_\lambda}(K^p)$ for the action of the operator $1_{K^p} \otimes u_t$. Let $A$ be the image of $R_{S,p}$ inside $\text{End}_L(V)$ and consider $f_1, f_2, \ldots, f_r$ be a subset of $R_{S,p}$ whose images in $A$ form a system of generators of $A$ over $L$. Let $R \in \mathbb{Z}_p$ of positive $p$-adic valuation such that two distinct eigenvalues $\alpha$ and $\alpha'$ of the operators $1_{K^p} \otimes u_t, f_1, \ldots, f_r$ acting on $V$ must satisfy $v_p(\alpha - \alpha') < v_p(R)$. Then we consider the operators $h_1, \ldots, h_r$ defined by $h_1 = f_1$ and the induction formula $h_{i+1} = f_{i+1} \cdot (1 + R.h_i)$ and we take $f = (1_{K^p} \otimes u_t)(1 + R.h_q)$. Let now
\( \theta \) be a character of \( R_{S,p} \) occurring in the representation \( V_{\lambda_y}(K^p) \) and such that \( \theta(f) = \theta_g(f) \). In particular, this implies that \( v_p(\theta(u_t)) = v_p(\theta_y(u_t)) \) and therefore \( \theta \) occurs in \( V \). Moreover this implies that \( v_p(\theta(u_t) - \theta_y(u_t)) \geq v_p(R) \) and therefore \( \theta(u_t) = \theta_y(u_t) \) by our assumption on \( R \). We deduce that \( \theta(h_q) = \theta_y(h_q) \). Repeating the previous argument we deduce that \( \theta(f_q) = \theta_y(f_q) \) and then by a descending induction that \( \theta(f_i) = \theta_y(f_i) \) for \( i = q, q - 1, \ldots, 1 \) and therefore \( \theta = \theta_y \) since \( \theta \) and \( \theta_y \) agree on a system of generators of the Hecke algebra acting on \( V \).

For this \( f \), we therefore have \( m_J(\lambda_y, f, \theta_y(f), K^p) = m_J(\lambda_y, \theta_y, K^p) \) and since \( r_f(y) \in \mathcal{F}_J(f) (\overline{\mathbb{Q}_p}) \) this implies that \( m_J(\lambda_y, \theta_y, K^p) > 0 \) by Proposition 5.1.6 and we have \( r_f^{-1}(r_f(y)) \cap \mathcal{E}_{K^p,J}(\overline{\mathbb{Q}_p}) = \{ y \} \).

### 5.3. Second Construction

We now give a construction of a rigid analytic variety whose set of points is in bijection with \( \mathcal{E}_{J,K^p}(\overline{\mathbb{Q}_p}) \). We first construct the local pieces and we show how we can glue them together to construct a rigid analytic space over \( \mathfrak{X} \).

#### 5.3.1. Construction of local pieces

We fix \( t \in T^- \) and write \( f_0 \) for the \( K^p \)-admissible Hecke operator \( f_0 := 1_{K^p} \otimes u_t \). Let \( \mathfrak{U} \subset \mathfrak{X} \) be an affinoid subset of \( \mathfrak{X} \) and let \( \mathfrak{M}_{Q,\mathfrak{U}} \) be the admissible affinoid subset of \( \mathfrak{M}_J(f_0) \) over \( \mathfrak{U} \) attached to an admissible factorization \( P_J(f, X)|_{\mathfrak{U}} = Q(X)S(X) \in \mathcal{O}(\mathfrak{U})\{\{X\}\} \). For any \( \lambda \in \mathfrak{U}(\overline{\mathbb{Q}_p}) \), let us write \( Q_\lambda(X) \) for the evaluation of \( Q(X) \) at \( \lambda \). Then recall that there is a unique \( \mathcal{H}_p(K^p) \)-stable decomposition (see §4.1.13)

\[
V_{J_\lambda}(K^p) = N_{J_\lambda}(Q_\lambda) \oplus F_{J_\lambda}(Q_\lambda)
\]

such that \( N_{J_\lambda}(Q_\lambda) \) is finite dimensional of dimension \( \text{deg}(\mathfrak{V}) \), \( Q_\lambda(X) \) is the characteristic polynomial of \( f \) acting on \( N_{J_\lambda}(Q_\lambda) \) and \( Q_\lambda(f) \) is invertible on \( F_{J_\lambda}(Q_\lambda) \). Let \( R_{Q,S}(X) \in \mathcal{O}(\mathfrak{U})\{\{X\}\} \) be the entire power series attached to \( Q \) and \( S \) by Theorem 2.3.8. Then for any \( \lambda \in \mathfrak{U}(\overline{\mathbb{Q}_p}) \), \( R_{Q,S}(f_0)(\lambda) \) acts on \( V_{J_\lambda}(K^p) \) as the projector on \( N_{J_\lambda}(Q_\lambda) \) with respect to the above decomposition. In particular, for any \( f \in \mathcal{H}_p(K^p) \) the trace \( J_{Q,S}(f) \) of \( f \) acting on \( N_{J_\lambda}(Q) \) is equal to \( J(f,R_Q(f_0)(\lambda)) \) (see §4.1.13). This implies that the map \( T_{Q,\mathfrak{U}} : f \mapsto J(f,R_Q(f_0)) \in \mathfrak{U} \) is a pseudo-representation of \( \mathcal{H}_p(K^p) \) of dimension \( \text{deg}(\mathfrak{V}) \) (see for instance [Ta91] for the definitions and basic properties of pseudo-representations). Then we put \( R_{\mathfrak{U}} := R_{S,R} \otimes \mathcal{O}(\mathfrak{U}) \) and \( h_{J,Q,\mathfrak{U}} := R_{\mathfrak{U}}/Ker(T_{Q,\mathfrak{U}}) \cap R_{\mathfrak{U}} \) with

\[
\text{Ker}(T_{Q,\mathfrak{U}}) := \{ f \in \mathcal{H}_p(K^p) \otimes \mathcal{O}(\mathfrak{U}) | T_{Q,\mathfrak{U}}(ff') = 0, \forall f' \in \mathcal{H}_p(K^p) \}
\]

By the basic properties of pseudo-representations, we see that \( h_{J,Q,\mathfrak{U}} \) is a finite algebra over \( \mathcal{O}(\mathfrak{U}) \) and is therefore an affinoid algebra. Let us assume that \( \mathfrak{U} \) is reduced. By the theory of pseudo-representations, a theorem of Taylor [Ta91] implies that \( h_{J,Q,\mathfrak{U}} \) is the image of \( R_{\mathfrak{U}} \) by a semi-simple representation \( \rho_{J,Q,\mathfrak{U}} \) of \( \mathcal{H}_p(K^p) \) of dimension \( \text{deg}(\mathfrak{V}) \) defined over a finite extension of the total ring of fractions of \( \mathcal{O}(\mathfrak{U}) \). Moreover for all
Moreover the map \( R \) is reduced to a point \( \mathfrak{U} = \{ \lambda \} \), then the kernel of the canonical surjective map 

\[
Y_{J,Q,\mathfrak{U}} := Sp(h_{J,Q,\mathfrak{U}})
\]

for the corresponding affinoid variety. There is a canonical map \( Y_{J,Q,\mathfrak{U}} \rightarrow \mathfrak{U} \) which fits in a canonical diagram

\[
\begin{array}{ccc}
Y_{J,Q,\mathfrak{U}} & \subset & \mathfrak{U}_{S,p} = \mathfrak{X} \times \mathfrak{R}_{S,p} \\
\downarrow & & \downarrow \\
\mathfrak{U} & \subset & \mathfrak{X}
\end{array}
\]

Moreover the map \( R_{f_0} \) induces a canonical surjective map

\[
r_{f_0} : Y_{J,Q,\mathfrak{U}} \rightarrow W_{Q,\mathfrak{U}} \subset \mathfrak{Z}_f(f_0)
\]

above \( \mathfrak{U} \) which is finite since both the source and the target are finite over \( \mathfrak{U} \).

In this construction, \( \mathfrak{U} \) is not necessarily supposed to be open. In the particular case \( \mathfrak{U} \) is reduced to a point \( \mathfrak{U} = \{ \lambda \} \), then \( Y_{J,Q,\{\lambda\}} = Sp(h_{J,Q,\{\lambda\}}) \) and this is the set of finite slope characters \( \theta \) of \( R_{S,p} \) such that \( Q_\lambda(\theta(u_\mathfrak{U})^{-1}) = 0 \) and \( m_{J,\mathfrak{U}}(\lambda, \theta, K^p) > 0 \). Moreover \( h_{J,Q,\{\lambda\}} \) is the unique quotient of \( R_{S,p} \) having these characters.

**Lemma 5.3.2.** Let \( \mathfrak{U}' \subset \mathfrak{U} \) be an affinoid subdomain (not necessarily open) then the kernel of the canonical surjective map \( h_{J,Q,\mathfrak{U}} \otimes_{\mathcal{O}(\mathfrak{U})} \mathcal{O}(\mathfrak{U}') \rightarrow h_{J,Q,\mathfrak{U}'} \) is contained in the nilradical of \( h_{J,Q,\mathfrak{U}} \otimes_{\mathcal{O}(\mathfrak{U})} \mathcal{O}(\mathfrak{U}') \). In particular,

\[
Y_{J,Q,\mathfrak{U}}(\mathfrak{T}_p) = r_{f_0}^{-1}(W_{Q,\mathfrak{U}}(\mathfrak{T}_p)) = \{ (\lambda, \theta) \in (\mathfrak{E}_{J,K^p} \times \mathfrak{X}(\mathfrak{U})) | Q_\lambda(\theta(f_0)^{-1}) = 0 \}
\]

**Proof.** We may clearly assume that \( \mathfrak{U} \) is reduced as this case will imply trivially the general case. Let \( f \) be in the kernel of this map. Then the coefficients of the characteristic polynomial \( Ch_{J,Q,\mathfrak{U}}(f, X) \) must belong to the kernel of \( \mathfrak{b} := ker(\mathcal{O}(\mathfrak{U}) \rightarrow \mathcal{O}(\mathfrak{U}')) \). By Cayley-Hamilton’s theorem \( Ch_{J,Q,\mathfrak{U}}(f, \rho_{J,Q,\mathfrak{U}}(f)) = 0 \) and therefore \( f^{deg(Q)} \) can be expressed as a polynomial in \( f \) with coefficients in \( \mathfrak{b} \). This implies that \( f \) is nilpotent in \( h_{J,Q,\mathfrak{U}} \otimes_{\mathcal{O}(\mathfrak{U})} \mathcal{O}(\mathfrak{U})/\mathfrak{b} = h_{J,Q,\mathfrak{U}} \otimes_{\mathcal{O}(\mathfrak{U})} \mathcal{O}(\mathfrak{U}') \) which proves the first part of the proposition. The second part follows from the case \( \mathfrak{U}' = \{ \lambda \} \) for any \( \lambda \in \mathfrak{U}(\mathfrak{T}_p) \) and the description of \( Y_{J,Q,\{\lambda\}} \) which was done before.

5.3.3. **Gluing of the local pieces.** We need to show that the pieces \( Y_{J,Q,\mathfrak{U}} \)'s glue together when the \( W_{Q,\mathfrak{U}} \) do in the spectral variety \( \mathfrak{Z}_f(f_0) \).

**Lemma 5.3.4.** Let \( \mathfrak{U}' \subset \mathfrak{U} \) be an inclusion of open affinoid subdomains of \( \mathfrak{X} \) then the canonical surjective map \( h_{J,Q,\mathfrak{U}} \otimes_{\mathcal{O}(\mathfrak{U})} \mathcal{O}(\mathfrak{U}') \rightarrow h_{J,Q,\mathfrak{U}'} \) is an isomorphism.

**Proof.** Since \( \mathfrak{U}' \subset \mathfrak{U} \) is an inclusion of open affinoid subdomains of \( \mathfrak{X} \), the map \( \mathcal{O}(\mathfrak{U}) \rightarrow \mathcal{O}(\mathfrak{U}') \) is flat. Let \( R_{\mathfrak{U}} := R_{S,p} \otimes \mathcal{O}(\mathfrak{U}) \), then \( h_{J,Q,\mathfrak{U}} = R_{\mathfrak{U}} / ker(T_{Q,\mathfrak{U}}) \).
Proof. Since \( (E) \) rigid analytic variety \( 9.3.2/1 \) and \( 9.3.3/1 \) of [BGR] that the \( Y \) done by other authors (for example see section 5 of [Bu07]) from Propositions 5.3.6. From the previous proposition and lemma, we can deduce as it was Assume that we have a factorization \( Q = Q'Q'' \) with \( (Q', Q'') = 1 \) in \( \mathcal{O}(\mathfrak{U})[X] \). Then the canonical inclusion map \( \mathfrak{W}_{Q', \mathfrak{U}} \hookrightarrow \mathfrak{W}_{Q, \mathfrak{U}} \) induces the following canonical isomorphism \( Y_{J, Q', \mathfrak{U}} \cong Y_{J, Q, \mathfrak{U}} \times \mathfrak{W}_{Q, \mathfrak{U}} \mathfrak{W}_{Q', \mathfrak{U}} \longrightarrow Y_{J, Q, \mathfrak{U}} \) \( \mathfrak{W}_{Q', \mathfrak{U}} \longrightarrow \mathfrak{W}_{Q, \mathfrak{U}} \)

\[
\begin{align*}
Y_{J, Q', \mathfrak{U}} & \cong Y_{J, Q, \mathfrak{U}} \times \mathfrak{W}_{Q, \mathfrak{U}} \\
& \longrightarrow Y_{J, Q, \mathfrak{U}} \\
\mathfrak{W}_{Q', \mathfrak{U}} & \longrightarrow \mathfrak{W}_{Q, \mathfrak{U}}
\end{align*}
\]

Proof. Since \( (Q', Q'') = 1 \), we have \( N_{J, \lambda}(Q) = N_{J, \lambda}(Q') \oplus N_{J, \lambda}(Q'') \) for all \( \lambda \in \mathfrak{U}(\overline{k}_p) \). Moreover if we write \( 1 = Q'(X)R'(X) + Q''(X)R''(X) \) in \( \mathcal{O}(\mathfrak{U})[X] \), the evaluation at \( \lambda \) of \( \epsilon_0' := Q''(f_0)R''(f_0) \) (resp. \( \epsilon_0'' := Q'(f_0)R'(f_0) \)) acting on \( N_{J, \lambda}(Q) \) is the projector onto \( N_{J, \lambda}(Q') \) (resp. onto \( N_{J, \lambda}(Q'') \)). We deduce that

\[
(33) \quad \ker(T_{Q, \mathfrak{U}}) = \ker(T_{Q', \mathfrak{U}}) \cap \ker(T_{Q'', \mathfrak{U}})
\]

Indeed notice first that the splitting above shows that \( T_{Q, \mathfrak{U}} = T_{Q', \mathfrak{U}} + T_{Q'', \mathfrak{U}} \) and therefore the intersection is included inside the left hand side of the equality (33). Now if \( g \in \ker(T_{Q, \mathfrak{U}}) \), then \( T_{Q', \mathfrak{U}}(gf) = T_{Q, \mathfrak{U}}(gf\epsilon_0') = 0 \) for all \( f \in \mathcal{O}_\mathfrak{U} \) which implies that \( \ker(T_{Q, \mathfrak{U}}) \subset \ker(T_{Q', \mathfrak{U}}) \). Similarly \( \ker(T_{Q, \mathfrak{U}}) \subset \ker(T_{Q'', \mathfrak{U}}) \) which finishes the proof of (33). On the other hand, \( \mathcal{O}_\mathfrak{U} = \ker(T_{Q', \mathfrak{U}}) + \ker(T_{Q'', \mathfrak{U}}) \) since any \( f \in \mathcal{O}_\mathfrak{U} \) can be written as \( f\epsilon_0'' + f\epsilon_0' \). By the chinese remainder theorem, this implies we have a canonical isomorphism:

\[
h_{J, Q, \mathfrak{U}} \cong h_{J, Q', \mathfrak{U}} \times h_{J, Q'', \mathfrak{U}}
\]

compatible with the canonical maps from \( R_{S, p} \) in the algebras \( h_{J, Q, \mathfrak{U}} \), \( h_{J, Q', \mathfrak{U}} \) and \( h_{J, Q'', \mathfrak{U}} \) respectively. This implies easily the claim of the proposition. ■

5.3.6. From the previous proposition and lemma, we can deduce as it was done by other authors (for example see section 5 of [Bu07]) from Propositions 9.3.2/1 and 9.3.3/1 of [BGR] that the \( Y_{J, Q, \mathfrak{U}} \) glue together into a reduced rigid analytic variety \( \mathfrak{C}_{J, K'} \) with a finite map \( r_{f_0} \) over \( \mathfrak{Z}_J(f_0) \) such that for each pair \( (Q, \mathfrak{U}) \), we have

\[
\mathfrak{C}_{J, K'} \times \mathfrak{Z}_J(f_0) \mathfrak{W}_{Q, \mathfrak{U}} = Y_{J, Q, \mathfrak{U}}
\]
The cocycle conditions defining the descent data are satisfied since they are satisfied for the spectral variety $Z_f(f_0)$. Moreover by Lemma 5.3.2, $E_{J,K^p}(\mathcal{O}_p) = E_{J,K^p}(\mathcal{O}_p)$. This implies that $E_{J,K^p}$ is a rigid analytic space whose corresponding reduced closed subspace is $E_{J,K^p}$. We will therefore denote the later by $E_{J,K^p}^\text{red}$. We may summarize our results by the following theorem:

**Theorem 5.3.7.** Let $J$ and $K^p$ as before. Then $E_{J,K^p} \subset \mathcal{Y}_{S,p}$ is a rigid analytic equidimensional space over $\mathbb{Q}_p$ satisfying the following properties.

(i) For any $y = (\lambda_y, \theta_y) \in \mathcal{Y}_{S,p}(\mathcal{O}_p)$, then $y \in E_{J,K^p}(\mathcal{O}_p)$ if and only if $m_J(\lambda, \theta, K^p) > 0$.

(ii) For any $K^p$-admissible Hecke operator $f$, the projection map

$$r_f : E_{J,K^p} \rightarrow Z_f(f)$$

is a finite surjective morphism.

(iii) $E_{J,K^p}$ is equi-dimensional of dimension $\dim X$.

**Proof.** The point (i) is Proposition 5.2.3. The point (iii) follows from the fact that $E_{J,K^p}$ is a rigid analytic space over $\mathbb{Q}_p$ and the fact that $h_{J,Q,\mathcal{U}}$ is a finite torsion free $O(\mathcal{U})$-algebra. We are left with the point (ii). The surjectivity follows from the fact that for any $K^p$-admissible $f$, we have

$$m_J(\lambda_y, f, \theta_y(f), K^p) = \sum_0^{\theta(f) = \theta_y(f)} m_J(\lambda_y, \theta, K^p)$$

and the characterization of the points of $E_{J,K^p}$ and $Z_f(f)$ given by Propositions 5.1.6 and 5.2.3. Now let $(Q, \mathcal{U})$ as before and let $Q_J^*(X) := Ch_{J,Q,\mathcal{U}}(f, X)$. Then the map $r_J^*$ is induced by the $O(\mathcal{U})$-algebra homomorphism

$$O(\mathcal{U})[X]/(Q_J^*(X)) \rightarrow h_{J,Q,\mathcal{U}}$$

induced by $X \mapsto f$. Since $h_{J,Q,\mathcal{U}}$ is finite over $O(\mathcal{U})$ and the image of $Y_{J,Q,\mathcal{U}}$ by $r_f$ is clearly $Sp(O(\mathcal{U})[X]/(Q_J^*(X)))$, we deduce that $r_f$ is finite on $E_{J,K^p}^\text{red}$. Since it factorizes through $E_{J,K^p}$, it is also finite on the latter. This finishes the proof of our theorem.

**Corollary 5.3.8.** Every irreducible component of $E_{J,K^p}$ projects surjectively onto a Zariski dense subset of $X$.

**Proof.** Let $Y$ be an irreducible component of $E_{J,K^p}$ and let $y \in Y(\mathcal{O}_p)$ lying on only one irreducible component of $E_{K^p}$. By Proposition 5.2.3, we can choose a $K^p$-admissible $f$ such that $r_f^{-1}(r_f(y))$ is reduced to $\{y\}$. Let $Y$ be an irreducible component of $Z_J(f)$ containing $r_f(y)$. Because $r_f$ is finite and surjective, there is one irreducible component $Y'$ of $r_f^{-1}(Y)$ such that $r_f(Y') = Y$. In particular, $Y'(\mathcal{O}_p) \cap r_f^{-1}(r_f(y)) \neq \emptyset$ and therefore
5.3.9. Families of irreducible finite slope representations of $\mathcal{H}_p(K^p)$. An irreducible component of $\mathcal{E}_{K^p, J}$ can be seen as a family of finite slope characters of $R_{S,p}$. We now want to generalize this to representations of $\mathcal{H}_p(K^p)$ having positive multiplicity with respect to $J$. We have the following proposition.

**Proposition 5.3.10.** Let $\lambda_0 \in \mathcal{X}(\overline{\mathcal{O}}_p)$ and $\sigma_0$ be an irreducible finite slope representation such that $m_J(\lambda_0, \sigma_0) > 0$. Let $y_0 = (\lambda_0, \theta_{\sigma_0})$ be the corresponding point of the Eigenvariety $\mathcal{E}_{J,K^p}$. Then there exist

(i) a finite flat covering $\mathcal{V}$ over an affinoid open subdomain $\mathcal{W}$ of $\mathcal{E}_{J,K^p}$ containing $y_0$ which is finite and generically flat over its projection $\mathcal{U} \subset \mathcal{X}$ in to weight space.

(ii) a point $x_0 \in \mathcal{V}(\overline{\mathcal{O}}_p)$ above $y_0$.

(iii) For all $x \in \mathcal{W}(\overline{\mathcal{O}}_p)$, a (non empty) finite set $\Pi_x$ of irreducible finite slope representations $\sigma$ of $\mathcal{H}_p(K^p)$ such that $\theta_\sigma = \theta_x$ is the character of $R_{S,p}$ attached to the projection of $x$ into $\mathcal{W}(\overline{\mathcal{O}}_p) \subset \mathcal{E}_{J,K^p}(\overline{\mathcal{O}}_p)$.

(iv) a non trivial linear map $I_{\mathcal{W}} : \mathcal{H}_p(K^p) \rightarrow \mathcal{O}(\mathcal{W})$

such that if for any $x \in \mathcal{W}(\overline{\mathcal{O}}_p)$, we write $I_x$ for the composite of $I_{\mathcal{W}}$ with the evaluation map at $x$ from $\mathcal{O}(\mathcal{W})$ into $\overline{\mathcal{O}}_p$ and $\lambda_x$ for the image of $x$ in $\mathcal{X}(\overline{\mathcal{O}}_p)$ then

(a) For all $x \in \mathcal{W}(\overline{\mathcal{O}}_p)$, $I_x = \sum_{\sigma \in \Pi_x} m_x(\sigma)J_\sigma$ with $m_x(\sigma) > 0$ only if $m_J(\lambda_x, \sigma) > 0$,

(b) There exists a Zariski dense subset $\mathcal{W}(\overline{\mathcal{O}}_p)^{\text{generic}} \subset \mathcal{W}(\overline{\mathcal{O}}_p)$ such that $\Pi_x$ is a singleton $\{\sigma_x\}$ and $m_x(\sigma) = m_J(\lambda_x, \sigma_x)$ is constant for all $x \in \mathcal{W}(\overline{\mathcal{O}}_p)^{\text{generic}}$.

(c) $\sigma_0 \in \Pi_x$.

(d) Let $\theta_{\mathcal{W}}$ be the canonical character of $R_{S,p}$ corresponding to $\mathcal{W}$, then $I_{\mathcal{W}}(ff') = \theta_{\mathcal{W}}(f)I_{\mathcal{W}}(f')$ for all $f \in R_{S,p}$ and $f' \in \mathcal{H}_p(K^p)$.

**Proof.** Let $y_0 = (\lambda_0, \theta_0)$ with $\theta_0 = \theta_{\sigma_0}$. Then $y_0 \in \mathcal{E}_{J,K^p}(\overline{\mathcal{O}}_p)$. Let $\mathcal{W}$ be an affinoid neighborhood of $y_0$ inside $\mathcal{E}_{J,K^p}^{ad}$. We may assume that $Y = Y_{J,Q,\mathcal{U}}$ for some admissible pair $(Q, \mathcal{U})$ with $\mathcal{U}$ an open affinoid neighborhood of $\lambda_0$ inside $\mathcal{X}$. Then we consider the character $T_{J,Q,\mathcal{U}}$ representation $\rho_{J,Q,\mathcal{U}}$. Because the image of $\mathcal{H}_p(K^p) \otimes \mathcal{O}(\mathcal{U})$ by $\rho_{J,Q,\mathcal{U}}$ is finite over $\mathcal{O}(\mathcal{U})$, after extending the scalar to a finite extension of $\mathcal{O}(Y)$ or which is the same after taking a finite cover $Y'$ of $Y$, it decomposes as a sum of isotypical components $T_{J,Q,\mathcal{U}} = T_1 + \cdots + T_m$ where the $T_i$'s are characters of isotypical representations of $\mathcal{H}_p(K^p)$ defined on the fraction ring of $\mathcal{O}(Y')$. Since there
are isotypical, the action of $R_{S,p}$ on the semi-simple representation of each $T_i$ is given by characters taking values in the ring of analytic functions of some irreducible components of $Y$. Moreover there exists a point $x_0$ of $Y'(\mathbb{Q}_p)$ above $y_0 = (\lambda_0, \theta_0) \in Y(\mathbb{Q}_p)$ such that the specialization of $T_{J,Q,U}$ at $x_0$ contains $J_{\sigma_0}$ as a summand. A fortiori it exists $i_0$ such that the specialization at $x_0$ at $T_{i_0}$ contains $J_{\sigma_0}$ as a summand. Let $\mathfrak{Y}$ be the irreducible component of $Y'$ containing $x_0$ such that the character $T_{i_0}$ is defined over the fraction field of $O(V)$ and let $\mathfrak{W}$ be the image of $\mathfrak{Y}$ via the finite projection $Y' \to Y$. Let us call $I_{\mathfrak{Y}}$ the composite of $T_{i_0}$ with the projection $O(Y') \to O(\mathfrak{Y})$. Then we must have $I_{\mathfrak{Y}}(ff') = \theta_\mathfrak{W}(f)I_{\mathfrak{Y}}(f')$. From the definitions and construction, it is clear that (a), (c) and (d) are satisfied. The point (c) is a direct consequence of the following easy fact: If a character $I_{\mathfrak{Y}}$ from an algebra $A$ into an affinoid algebra $O(V)$ is generically irreducible, then the set of $y \in V(\mathbb{Q}_p)$ such that the specialization at $y$ of $I_{\mathfrak{Y}}$ is reducible is a proper closed affinoid subspace of $V$.

5.4. Application to finite slope automorphic character distributions. We can apply the formal result of the previous section to the families of finite slope character distributions we have constructed in the previous chapter. Let $L_{G}^c \subset \mathcal{L}_G$ be the subset of standard Levi subgroups of $G$ having discrete series. For each $J = (-1)^{d_M}J^1_{G,M,w}$ when $M \in L_{G}^c$ and $w \in \mathcal{W}_{Eis}^M$, we obtain an Eigenvariety $\mathfrak{E}_{Kp,M,w}$. If $G(\mathbb{R})$ has discrete series, we denote $\mathfrak{E}_{Kp,0}$ the previous Eigenvariety when $M = G$. We also write
\[
\mathfrak{E}_{Kp} := \bigcup_{M \in L_{G}^c} \bigcup_{w \in \mathcal{W}_{Eis}^M} \mathfrak{E}_{Kp,M,w},
\]
\[
\mathfrak{E}_{Kp,M} := \bigcup_{w \in \mathcal{W}_{Eis}^M} \mathfrak{E}_{Kp,M,w} \quad \mathfrak{E}_{Kp,Eis} := \bigcup_{M \in L_{G}^c} \mathfrak{E}_{Kp,M}.
\]
From the previous section and the construction and properties of the automorphic $p$-adic finite slope distributions of the previous chapter, these Eigenvarieties are equidimensional. It is also useful to notice the following proposition:

**Proposition 5.4.1.** Let $M, M' \in L_{G}^c$ with $M \neq M'$, then the intersection of the subvarieties $\mathfrak{E}_{Kp,M}$ and $\mathfrak{E}_{Kp,M'}$ is of dimension smaller than the dimension of $X_{Kp}$.

**Proof.** By an easy reduction step, we can reduce to the case $M' = G$ and $M$ any proper Levi of $G$ in $L_{G}^c$. Assume the statement of this proposition is wrong. That means that we have an irreducible component in the intersection of dimension $dim \mathfrak{X}$. By the corollary above, we can find a non critical point $y$ such that $\lambda_y$ is very regular point (as regular as we want in fact) in this intersection. It would be classical and associated to cuspidal representation and an Eisenstein series at the same time. This cuspidal representation
would be CAP in the sense of Piatetski-Shapiro. By a result of M. Harris [Ha84], this is not possible if $\lambda_y$ is chosen sufficiently regular.

5.4.2. Non critical and classical points. A point $y = (\lambda_y, \theta_y) \in \mathcal{E}_{K^p}(\overline{\mathbb{Q}}_p)$ is called classical if $\lambda_y$ is arithmetic and if $\theta_y$ is attached to an automorphic classical finite slope representation of weight $\lambda_y^{\text{alg}}$. A point $y = (\lambda_y, \theta_y)$ is said non critical if $\lambda_y$ is an arithmetic weight and if $\theta_y$ is non critical with respect to $\lambda_y^{\text{alg}}$. Finally $y$ is said regular if $\lambda_y$ is arithmetic regular. By the discussion of the previous chapter (in particular Corollary 4.6.5), we know that any non critical regular point of the Eigenvariety is classical. In particular, these points in any open affinoid subdomain of the Eigenvariety are Zariski dense.

5.4.3. Families of finite slope automorphic representations. Let $\pi$ be an automorphic representation of $G(\mathbb{A})$ occurring in the cohomology with the system of coefficient $W_{\lambda}^\vee(\mathbb{C})$. It is defined over a $\mathbb{Q}_p$ after we have fixed embeddings of $\mathbb{Q}$ in $\mathbb{C}$ and $\mathbb{Q}_p$. We assume that $\pi_{f}^{m,K^p}$ is non zero for some $m > 0$ and some open compact subgroup $K^p$. We further fix a $\mathbb{Q}_p$-valued finite order character $\epsilon$ of $T(\mathbb{Z}/p^m\mathbb{Z})$ and $\theta_0$ a finite slope character of $R_{S,p}$ occurring in $\pi_{f}^{m,K^p} \otimes \overline{\mathbb{Q}}_p(\epsilon^{-1})$. This determine what we have called a $p$-stabilization of $\pi$ and we suppose that it is of finite slope. Let $\sigma_0$ be the irreducible constituent of the restriction of $\pi_{f}^{m,K^p} \otimes \overline{\mathbb{Q}}_p(\epsilon^{-1})$ to $\mathcal{H}_p(K^p)$ such that $J_{\sigma_0}(fg) = \theta_0(f)J_{\sigma_0}(g)$ for any $f \in R_{S,p}$ and any $g \in \mathcal{H}_p(K^p)$. Then $\sigma_0$ is a finite slope automorphic representation. Then the following theorem is perhaps the most striking result of this paper. Since non critical points are Zariski dense in any open affinoid subdomain of $\mathcal{E}_{K^p}$ so are classical points.

**Theorem 5.4.4.** Assume that $m_{0}^{\dagger}(\sigma_0, \lambda_0) \neq 0$. Then, there exists

1. an affinoid open neighborhood $\mathcal{U} \subset \mathcal{X}$ of $\lambda_0$,
2. a finite cover $\mathcal{V}$ of $\mathcal{U}$ with structural morphism $w$,
3. a homomorphism $\theta_{\mathcal{V}} : R_{S,p} \rightarrow \mathcal{O}(\mathcal{V})$,
4. a character distribution $I_{\mathcal{V}} : \mathcal{H}_p(K^p) \rightarrow \mathcal{O}(\mathcal{V})$,
5. a point $y_0 \in \mathcal{V}(\overline{\mathbb{Q}}_p)$ above $\lambda_0$,
6. A Zariski dense subset $\Sigma \subset \mathcal{V}(\overline{\mathbb{Q}}_p)$ such that $\lambda_y = w(y)$ is an arithmetic weight $\forall y \in \Sigma$,
7. For each $y \in \Sigma$, a finite set $\Pi_{y}$ of irreducible finite slope cohomological cuspidal representations of weight $\lambda_y = w(y)$.

satisfying the following:

(i) The specialization of $\theta_{\mathcal{V}}$ at $y_0$ is equal to $\theta_0$,
(ii) The character distribution $I_{\sigma_0}$ is an irreducible component of the specialization $I_{y_0}$ of $I_{\mathcal{V}}$ at $y_0$. 
(iii) For any \( y \in \Sigma \), the specialization \( \theta_y \) of \( \theta \) at \( y \) is a character occurring in the representation of \( R_{S,p} \) in \( \pi^{K_p} \) for all \( \pi \in \Pi_y \).

(iv) For each \( y \in \Sigma \) the specialization \( I_y \) of \( I \) at \( y \) satisfies:
\[
I_y(f) = \sum_{\sigma \in \Pi_y} m^{cl}(\sigma, \lambda_y) \text{tr}(\pi_y(f))
\]
where \( m^{cl}(\sigma, \lambda_y) \) is the Euler-Poincaré characteristic of \( \sigma \) defined as:
\[
m^{cl}(\sigma, \lambda_y) := \sum (-1)^i \text{dim}_{C} \text{Hom}_{\mathcal{H}_p}(\sigma, \lim_{K_p} H^i(S_G(K_p, I_m), \mathcal{V}^{\vee}_{\lambda_y^{alg}}(\epsilon_y, C)))
\]
with \( \lambda_y = \lambda_{alg}^{y} \epsilon_y \).

Moreover \( \Pi_y \) contains only one representation for \( y \) in a Zariski dense subset of \( \Sigma \).

Proof. We just apply Proposition 5.3.10 to \( J = (-1)^{dc} I_{G,0}^{\dagger} \). Then we consider \( \Sigma \) as the subset of points \( y = (\lambda, \theta) \) of \( \mathcal{U}(\overline{\mathbb{Q}}_p) \) such that \( \lambda \) is arithmetic regular and \( \theta \) is of non critical slope with respect to \( \lambda \). This set is easily seen to be Zariski dense in \( \mathcal{U}(\overline{\mathbb{Q}}_p) \) since the projection of \( \mathcal{U} \) onto \( \mathcal{X} \) contains the arithmetic point \( \lambda_0 \). Moreover these points are classical and correspond to cuspidal representations by Corollary 4.6.5. More precisely for \( y \in \Sigma \), and \( \sigma \in \Pi_y \), we have \( m_{G,0}^{\dagger}(\sigma, \lambda_y) = m^{cl}(\sigma, \lambda_y) \). This conclude the proof of this Theorem.■

5.5. Examples.

5.5.1. About the hypothesis. We explain now that the hypothesis of the previous theorem are satisfied for a very large class of automorphic representations. We assume \( G(\mathbb{R}) \) has discrete series. For \( \pi_f \) an irreducible representation of \( G_f \) and \( \lambda \) a dominant algebraic weight, let us define the Euler-Poincaré multiplicity of \( \pi_f \) with respect to \( \lambda \) by:
\[
m_{EP}(\pi_f, \lambda) = \sum_i (-1)^i \text{dim}_{C} \text{Hom}_{G_f}(\pi_f, H^i(\tilde{S}_G, \mathcal{V}^{\vee}_{\lambda}(C)))
\]
when the weight is regular let us also define
\[
m(\pi_f, \lambda) := (-1)^{dc} \sum_{\pi_{\infty} \in \Pi_{\lambda}} m(\pi_f \otimes \pi_{\infty})
\]
By the results recalled in the first chapter, we then have
\[
m(\pi_f, \lambda) = m_{EP}(\pi_f, \lambda)
\]
If \( \sigma \) is a \( p \)-stabilization of \( \pi_f \), we therefore have
\[
m^{cl}(\sigma, \lambda) = m(\pi_f, \lambda) \times \text{dim} \text{Hom}_{\mathcal{H}_p}(\sigma, (\pi_f|_{\mathcal{H}_p})^{ss})
\]
where \( (\pi_f|_{\mathcal{H}_p})^{ss} \) stands for the semi-simplification of the restriction of \( \pi_f \) to \( \mathcal{H}_p \). So if this \( p \)-stabilization is non critical with respect to \( \lambda \) then \( m^{\dagger}(\sigma, \lambda) \) is
non zero if and only if $m(\pi_f, \lambda) \neq 0$ which is the case for example when $\pi_f$ is attached to a cuspidal representation of weight $\lambda$. This applies in particular for all cuspidal forms of regular weight for symplectic or unitary groups over totally real fields. In those cases, the previous theorem applies and there exist families passing through $\sigma$.

However if $m(\pi_f, \lambda) \neq 0$ but $\sigma$ is critical, it is not clear in general that $m^1(\sigma, \lambda) \neq 0$. In what follows, we look at some examples of this situation.

5.5.2. An example in the $GL(2)$-case. Let $G = GL(2)_{/\mathbb{Q}}$. Assume $\pi_f = \text{triv}$ is the trivial one dimensional representation and $\lambda_0 = 1$ is the trivial weight. There is only one $p$-stabilization $\sigma$ since $\pi_f$ is one dimensional and this is the trivial representation itself. The $U_p$ operator attached to the double class of $\text{diag}(1, p^{-1})$ has eigenvalue $p$ and the eigenvalue of $T_\ell$ for $\ell \neq p$ is $1 + \ell$. It is easy to check that $\pi_f$ shows up only in degree 0 since the Eisenstein series $E_2$ is not holomorphic. Therefore in that case $m^{cl}(\sigma, \lambda) = 1$. However $m^1_0(\sigma, \lambda)$ must vanish since otherwise one would have a $p$-adic family of slope 1 passing through the $p$-adic form $E_2(q) - E_2(p)q$ and we know that this is impossible by a theorem of Coleman-Gouvea-Jochnowitz (see also [SU02]). We could in fact show that $m^1_{E_{\text{fil}}}(\sigma, \lambda) = 0$ in that case using the multiplicity formula of Corollary 4.5.5. Notice that $m^1_{E_{\text{fil}}}(\sigma, \lambda) = 0$ since $\sigma$ is not ordinary.

5.5.3. An example in the $GSp(4)$-case. In this example, we will use the standard notations without defining all of them in detail. In particular, we refer the reader to [TU99] or [SU06a] for the definitions on the group $G = GSp(4)$ and its corresponding automorphic forms. Let $(B, T)$ be the Borel pair with $T$ the diagonal torus and $B$ the Borel subgroup stabilizing the standard flag of the symplectic space attached to $G$. Let $s_1$ and $s_2$ the symmetries of $X^*(T)$ attached respectively to the small and long simple roots attached to the pair $(B, T)$. An algebraic weight $\lambda$ is a triple $(a, b; c)$ with $a, b, c \in \mathbb{Z}$ and $a + b \equiv c \pmod{2}$ it maps $T$ to the multiplicative group by the rule $\text{diag}(t_1, t_2, t_1^{-1} \nu, t_2^{-1} \nu) \mapsto t_1^{a-1} t_2^{c-2} \nu^{(c-a-b)/2}$. A weight is dominant if $a \geq b \geq 0$. The simple short and long roots are respectively $(1, -1; 0)$ and $(0, 2; 0)$ and the corresponding simple reflexion $s_1$ and $s_2$ act on $X^*(T)$ by $s_1(a, b; c) = (b, a; c)$ and $s_2(a, b; c) = (a, -b; c)$. Since $\rho = (2, 1; 0)$, we have $s_1 \ast (a, b; c) = (b - 1, a + 1; c)$ and $s_2 \ast (a, b; c) = (a, -b - 2; c)$.

We denote respectively by $M_S \cong GL_2 \times \mathbb{G}_m$ and $M_K \cong GL_2 \times \mathbb{G}_m$ the standard Levi of the Siegel and Klingen parabolic subgroup of $G$. The corresponding isomorphisms are given in the Siegel case by

$$(g, \nu) \mapsto \text{diag}(g, t^{-1} g^{-1} \nu)$$
and in the Klingen case by

\[
\begin{pmatrix}
  a & b \\
  c & d
\end{pmatrix}, x \mapsto \begin{pmatrix}
  x & 0 & 0 & 0 \\
  0 & a & 0 & 0 \\
  0 & 0 & (ad - bc)x^{-1} & b \\
  0 & c & 0 & d
\end{pmatrix}
\]

One can easily check that \(W_{Eis}^{MS} = \{id, s_2\}\) and \(W_{Eis}^{MK} = \{id, s_1\}\).

Let \(\pi\) be a unitary cuspidal representation of \(PGL(2) / \mathbb{Q}\) whose corresponding classical Hecke newform \(f\) is of weight \(2k - 2\) with \(k\) an integer greater than \(2\). We make the following assumption:

\[L(f, k - 1) = L(\pi, 1/2) = 0\]

Under this hypothesis, there exists a unique cuspidal non-tempered representation \(SK(\pi)\) on \(GSp(4) / \mathbb{Q}\) such that its degree 4 \(L\)-function is given by

\[L(SK(\pi), s) = L(\pi, s)\zeta(s - 1/2)\zeta(s + 1/2)\]

and such that each local component of \(SK(\pi)\) at a finite place is the non tempered Langlands quotient of the unitary parabolic induction from the Siegel parabolic \(Ind_{GM}^{GS}(\pi_f \otimes \| \cdot \|^{1/2} \times \| \cdot \|^{-1/2})\), \(\text{i.e. \(\pi_f \otimes \| \cdot \|^{1/2} \times \| \cdot \|^{-1/2}\)}\) with notations of Sally-Tadić [ST]).

The corresponding \(p\)-adic Galois representation is up to twist given by

\[\rho_{SK(\pi)} = \rho_f \oplus \mathbb{Q}_p(1-k) \oplus \mathbb{Q}_p(2-k)\]

where we have denoted by \(\rho_f\) the \(p\)-adic Galois representation attached to \(f\) having determinant the cyclotomic character to the \((3 - 2k)\)-th power. This automorphic representation is called a Saito-Kurokawa lifting of \(f\). When \(k > 2\), \(SK(\pi) \otimes |\nu|^{3-k}\) is cohomological of weight \(\lambda_k = (k - 3, k - 3; 2k - 6)\). Here we have denote by \(|\nu|\) the adelic norm of the multiplier of \(G\).

Let \(\epsilon = \epsilon(\pi, 1/2) = \pm 1\). This sign determines the nature of the archimedean component of \(SK(\pi)\). When \(\epsilon = 1\) then \(SK(\pi)_\infty\) and its dual are non tempered and cohomological in degree 2 and 4. Therefore \(SK(\pi)_f\) shows up in the cuspidal cohomology in degree 2 and 4 with multiplicity one. If \(\epsilon = -1\) then \(SK(\pi)_\infty\) and its conjugate are the holomorphic and antiholomorphic discrete series. Therefore \(SK(\pi_f)\) appears in the cuspidal cohomology of degree 3 with multiplicity two. As remarked by Harder, in both cases there are also Eisenstein classes attached to \(SK(\pi_f)\) providing a multiplicity one subspace in the Eisenstein cohomology in degree 2 and 3 isomorphic to \(SK(\pi_f)\). All together, we deduce that \(m_{EP}(SK(\pi)_f) = -2\) if \(\epsilon = -1\) and \(m_{EP}(SK(\pi)_f) = 2\) if \(\epsilon = +1\). In other words \(m_{EP}(SK(\pi)_f) = 2\epsilon(\pi, 1/2)\).

For an account of these facts recalled here and their credits the reader can consult [H93, Sc03, SU06a, Wa1, Wa2].

Let us assume that \(\pi\) is unramified at \(p\) and that we can fix a root \(\alpha\) of the Hecke polynomial of \(f\) at \(p\) such that \(0 < v = v_p(\alpha) < k - 2\) (the case \(v = 0\) can be done but it requires a bit more work and the corresponding result is
Therefore the eigenvalues are therefore respectively eigenvalue of $U$ explained that there exists a $p$-stabilization $\sigma_\alpha$ of $SK(\pi) \otimes |v|^{3-k}$ such that the eigenvalue of $U_{1,p}$ is $\alpha$ and the one of $U_{2,p}$ is $\alpha p^{k-2}$. After renormalization, the eigenvalues are therefore respectively $\alpha$ and $\alpha p$.

This implies that the slope of this $p$-stabilization is given by $\mu_{\sigma_\alpha} = (v + 1, v - 1; 0)$ with $v = v_p(\alpha_p)$. We want to compare $\mu_{\sigma_\alpha}$ to $w * \lambda_k - \lambda_k$ for $w = s_1, s_2$. We have $s_1 * \lambda_k - \lambda_k = (-1, 1; 0)$ and $s_2 * \lambda_k - \lambda_k = (0, -2k + 4; 0)$. Therefore $\mu_{\sigma_\alpha} + s_1 * \lambda_k - \lambda_k = (v, v; 0)$ belongs to the boundary of the obtuse cone and therefore $\mu_\sigma$ is critical. Notice also that $\mu_\sigma + s_2 * \lambda_k - \lambda_k = (1 + v, v - 2k + 3; 0)$ does not belong to the obtuse cone by our assumption on $v$. From these remarks we can deduce that

$$m^{cl}(\sigma_\alpha, \lambda_k) = m^\dagger(\sigma_\alpha, \lambda_k) - m^\dagger(\sigma^{s_1, \lambda_k}_\alpha, s_1 * \lambda_k)$$

We will show the following

**Proposition 5.5.4.** With the above hypothesis and notations, we have:

$$m^\dagger_0(\sigma_\alpha, \lambda_k) = 2(\epsilon(\pi, 1/2) - 1)$$

In particular it is non zero if and only if $\epsilon = -1$.

**Proof.** First we notice that $m^{cl}(\sigma, \lambda_k) = m_{EP}(SK(\pi)_f)$. To show the Proposition, we now need to make use of the formula (34). To relate $m^\dagger(\sigma_\alpha, \lambda_k)$ to $m^\dagger_0(\sigma_\alpha, \lambda_k)$ and also to compute $m^\dagger(\sigma^{s_1, \lambda_k}_\alpha, s_1 * \lambda_k)$, we now have to study the Eisenstein multiplicities.

If $m^\dagger_{G, MK, w}(\sigma_\alpha, \lambda_k) \neq 0$ then there exist $\sigma_w$ for $w = id$ or $s_1$ a finite slope representation of $GL(2)/\mathbb{Q}$ and a Dirichlet character $\chi_w$ such that if $w = id$ then $\sigma_w$ is of weight $(k - 3, 6 - 2k)$ with $\theta_{\sigma_w}(U_p) = \alpha$ and $\chi_w(p) = \theta_{\sigma}(U_{2,p}) = pa$ or if $w = s_1$ then $\sigma_w$ is of weight $(k - 2, 6 - 2k)$ with $\theta_{\sigma_w}(U_p) = ap$ and $\chi_{\text{id}}(p) = \theta_{\sigma_w}(p, \text{id}) = \theta_{\sigma}(U_{2,p}) = pa$. Since we know that $\alpha$ is a Weil number of weight $2k - 3$, we see that these situations cannot occur. Therefore $m^\dagger_{G, MK, id}(\sigma_\alpha, \lambda_k) = m^\dagger_{G, MK, s_1}(\sigma_\alpha, \lambda_k) = 0$. Similarly, we could show that $m^\dagger_{G, MK, w}(\sigma^{s_1, \lambda_k}_\alpha, s_1 * \lambda_k) = 0$ for $w \in \{id, s_1\}$. We also have the same vanishing results if we replace $MK$ by $T$ by similar but simpler arguments. We therefore deduce that

$$m^\dagger(\sigma_\alpha, \lambda_k) = m^\dagger_0(\sigma_\alpha, \lambda_k) - m^\dagger_{G, MS, id}(\sigma_\alpha, \lambda_k) + m^\dagger_{G, MS, s_2}(\sigma_\alpha, s_2 * \lambda_k)$$

If $m^\dagger_{G, MS, id}(\sigma_\alpha, \lambda_k) \neq 0$, we have $\alpha = \theta_{\sigma_\alpha}(U_{1,p}) = \chi(p)$ for some Dirichlet character $\chi$. This is impossible since $\alpha$ is a Weil number of weight $2k - 3$. If $m^\dagger_{G, MS, s_2}(\sigma_\alpha, \lambda_k) \neq 0$, there exists a finite slope (cuspidal) representation $\sigma_2$ of $GL(2)$ of weight $2k - 2$ and Dirichlet characters $\chi_2$ and $\chi'_2$ such that
\[ \alpha = \theta_{\sigma_\alpha}(U_{1,p}) = \theta_{\sigma_\beta}(U_p)\chi_2(p) \] and \( p\cdot\alpha = \theta_{\sigma_\alpha}(U_{2,p}) = \theta_{\sigma_2}(U_p)\chi_2'(p) \). This is impossible, we therefore have

\[ m^\dagger(\sigma_\alpha, \lambda_k) = m^\dagger_0(\sigma_\alpha, \lambda_k). \]

We now need to compute and \( m^\dagger(\sigma_\alpha, \lambda_k) \) for \( w = \{ id, s_2 \} \). Write \( \sigma'_\alpha = \sigma^s_{\alpha_1} \lambda_k \) and \( \lambda'_k = s_1 \cdot \lambda_k = (k - 4, k - 2; 6 - 2k) \). We have \( \theta_{\sigma'_\alpha}(U_{1,p}) = \alpha \) and \( \theta_{\sigma'_\alpha}(U_{2,p}) = p^{-1}\theta_{\sigma_\alpha}(U_{2,p}) = \alpha \). If \( m^\dagger_{G,M_5, id}(\sigma^s_{\alpha_1} \lambda_k, s_1 \cdot \lambda_k) \neq 0 \) then \( \alpha = \theta_{\sigma'_\alpha}(U_{1,p}) = \chi(p) \) for some Dirichlet character \( \chi \) which is again impossible since \( \alpha \) is a Weil number. Now from the formula defining the distribution \( I_{G,M_5,s_2} \) we see that \( m^\dagger_{G,M_5,s_2}(\sigma^s_{\alpha_1} \lambda_k, s_1 \cdot \lambda_k) = m^\dagger_{GL(2), 0}(\pi_\alpha, (0; 2k - 4)) = -2 \) where \( \pi \) is the \( p \)-stabilization of \( \pi \) such that \( \theta_{\pi_\alpha}(U_p) = \alpha \). Therefore we deduce that

\[ m^\dagger(\sigma'_\alpha, \lambda'_k) = m^\dagger_0(\sigma'_\alpha, \lambda'_k) - 2 \]

Combining all the previous considerations, we therefore get:

\[ m^\dagger_0(\sigma_\alpha, \lambda_k) = 2\epsilon - 2 + m^\dagger_0(\sigma'_\alpha, \lambda'_k) \]

Since \( m^\dagger_0(\sigma'_\alpha, \lambda'_k) \leq 0 \), this in particular implies that \( m^\dagger_0(\sigma_\alpha, \lambda_k) < 0 \) if \( \epsilon = -1 \). In fact, one can show that \( m^\dagger_0(\sigma'_\alpha, \lambda'_k) = 0 \) otherwise one would get a 3-dimensional family of generically big Galois representations specializing to \( \rho_{SK}(\pi) \) and that would have a stable line by inertia and corresponding to the line \( \mathbb{Q}_p(2 - k) \) when specialized at the point corresponding to \( \rho_{SK}(\pi) \).

Then by arguments similar to those of [SU06a, SU06b], one would get infinitely many elements in the Selmer groups corresponding to the Galois representations \( \mathbb{Q}_p(-1) \) or \( \rho_f(k - 2) \). But the former can’t exist by Class Field Theory and the latter is known to be impossible by a theorem of Kato [K]. This finishes the proof of our proposition. It shows that, the use of non-tempered cuspidal representation does not lead to results like the one of [SU06a] when the sign of the functional equation is +1. This is why it is better to use Eisenstein series as it is explained in [SU06b]. This result also implies that the main theorem of [SU06a] is also true in the non ordinary case. We leave the verification of details of this fact to the conscientious reader. 

5.6. The twisted Eigenvarieties for \( GL_n \). In this section, we assume (for simplicity)\(^{22}\) that \( G = GL_{n/F} \) over a totally real number field or a CM fields \( F \). We denote by \( F^+ \) its maximal totally real subfield and by \( c \) the complex conjugation automorphism of \( F \).

Let \( T \) and \( B \) be respectively the diagonal torus of \( G \) and the group of upper triangular matrices in \( G \). Let \( J \) be the anti-diagonal matrix defined by

\[ J = (\delta_{i,n-j})_{1 \leq i,j \leq n} \]

\(^{22}\)One could extend this to a more general situation.
We consider the involution $\iota$ defined by $\iota(g) = g' := J^t g^{-1} J^{-1}$ if $F$ is totally real and by $\iota(g) = g' := J^t g^{-c} J^{-1}$ if $F$ is CM. This is clearly an involution of Cartan type.

It is easy to check that $T$ and $B$ are stable under the action of $\iota$. A weight $\lambda \in \mathcal{X}'(\overline{\mathbb{Q}}_p)$ is such that

$$\lambda(\text{diag}(t_1, \ldots, t_n)) = \chi_1(t_1) \ldots \chi_n(t_n)$$

with $\chi_j = \chi_{n-j}$ if $F$ is totally real and $\chi_j = \chi_{n-j}^c$ if $F$ is CM and where the $\chi_i$'s are characters of $(O_F \otimes \mathbb{Z}_p)$. So $\dim \mathcal{X}' = ([n/2] - 1).[F^+: \mathbb{Q}] + 1 + \delta_{F^+,p}$. This is the subvariety of essentially self-dual weights.

For any $f \in C_v^*(G(\mathbb{A}_f), \mathbb{Q}_p)$, we set $f^\iota$ defined by:

$$f^\iota(g) := f(g^\iota)$$

and for any character $\theta$ of $R_{S,p}$ we denote by $\theta^\iota$ the character defined by

$$\theta^\iota(f) = \theta(f^\iota).$$

Then it is possible to construct rigid analytic spaces $\mathcal{E}_{K^p,0}^\iota$ by applying the construction we have made in the beginning of this section for the finite slope character distributions $I_{GL_n,0}^\dagger(f \times \iota, f, \lambda)$ and we have the following theorem.

**Theorem 5.6.1.** Let $K^p$ be an open compact subgroup of $GL_n(\mathbb{A}_f \otimes F)$. The ringed spaces $\mathcal{E}_{K^p,0}^\iota$ are rigid analytic varieties and the following properties hold.

(i) For any $y = (\lambda_y, \theta_y) \in \mathcal{E}_{K^p}^\iota(\overline{\mathbb{Q}}_p)$, then $\theta_y = \theta_y^\iota$ and $\lambda_y = \lambda_y^\iota$. In particular $\mathcal{E}_{K^p}^\iota$ sits over $\mathcal{X}^\iota$.

(ii) Let $y = (\lambda_y, \theta_y) \in (\mathcal{X} \times \mathcal{Y}_{S}^+) \otimes_{\overline{\mathbb{Q}}_p}$. Then $y \in \mathcal{E}_{K^p,0}^\iota(\overline{\mathbb{Q}}_p)$ if and only if $m^\iota(\lambda, \theta \times \iota, K^p) \neq 0$.

(iii) For any $K^p$-admissible Hecke operator $f$, the projection map $\mathcal{E}_{K^p,0}^\iota(\overline{\mathbb{Q}}_p) \rightarrow \mathcal{Y}_G(f)$ is a finite surjective morphism.

(iv) The restriction of the map $\mathcal{E}_{K^p}^\iota \rightarrow \mathcal{X}^\iota$ to any irreducible component is generically flat. In particular, $\mathcal{E}_{K^p}^\iota$ is equidimensional and have the same dimension as dim $\mathcal{X}^\iota$.

5.7. **Some more Eigenvarieties.** We would like to end this section by discussing some conjectures on $p$-adic families. What we have constructed here is the Zariski closure of all the points $y = (\theta, \lambda)$ for which $m^\iota(\theta, \lambda, K^p)$ does not vanish and we have proved that they form a nice rigid analytic variety $\mathcal{E}_{K^p}$ which is generically flat over weight space $\mathcal{X}$. But what about the other cohomological systems of Hecke eigenvalues for which the Euler-Poincaré multiplicity vanishes? Can we still construct an Eigenvariety containing all the points $(\theta, \lambda)$ such that $H^\star(S_G(K^pI_m), D_\lambda)[\theta] \neq 0$? What is the dimension of the irreducible components passing through such a point when $m^\iota(\theta, \lambda, K^p) = 0$. We would like to give some speculative answers to these questions.
5.7.1. The full Eigenvariety. A point \( y = (\theta, \lambda) \in \mathcal{Y}_{S,p}(\overline{\mathcal{U}}_p) \) is said cohomological of level \( K^p \) if \( H^r(S_G(K^p \mathcal{I}_m), \mathcal{D}_\lambda)[\theta] \neq 0 \).

We want to give a construction of a variety that contains all the cohomological points. This construction is mainly due to Ash-Stevens\(^{23}\) but our construction is a variant. I will only sketch it. We fix \( f = u_t \) with \( t \in T^{--} \).

We consider the action of \( f \) on the Banach spaces \( R\Gamma^q(K^p \mathcal{I}_m, \mathcal{D}_{\mathcal{U}_{t,n}}) \)'s. For each degree \( q \), let \( R^q_{\mathcal{U}}(f, \lambda, X) \in \mathcal{O}(\mathcal{U})\{\{X\}\} \) the Fredholm determinant of \( f \) acting on \( R\Gamma^q(K^p \mathcal{I}_m, \mathcal{D}_{\mathcal{U}_{t,n}}) \) and let \( R_{\mathcal{U}}(f, \lambda, X) := \prod_q R^q_{\mathcal{U}}(\lambda, X) \) (we don’t take alternating product here). Since we can make this construction for any \( \mathcal{U} \), we can easily see that there exists \( R_{\mathcal{U}}(f, \lambda, X) \in \Lambda_X\{\{X\}\} \) that specializes to \( R_{\mathcal{U}}(f, \lambda, X) \) by the canonical map \( \Lambda_X \to \mathcal{O}(\mathcal{U}) \). We then denote \( \mathfrak{Z}(f) \) the spectral variety\(^{24}\) associated to \( R_{\mathcal{U}}(f, \lambda, X) \). We now choose \( \mathfrak{W} \subset \mathfrak{Z}(f) \) an admissible affinoid subdomain of \( \mathfrak{Z}(f) \). We denote by \( \mathfrak{U} \) its image by the projection onto weight space \( X \). Let \( e_{\mathfrak{W}} \) the idempotent attached to \( \mathfrak{W} \) by the associated factorization of the Fredholm series of \( f \). Consider the complex \( e_{\mathfrak{W}}.R\Gamma(K^p \mathcal{I}_m, \mathcal{D}_\mathcal{U}) \). Each term is of finite rank over \( \mathcal{O}(\mathcal{U}) \) and we consider the action of \( R_{S,p} \) on it modulo homotopy. Let \( B_{\mathfrak{W}} \) be the \( \mathcal{O}(\mathcal{U}) \) algebra generated by the image of \( R_{S,p} \) in \( \text{End}_{D^p}(e_{\mathfrak{W}}.R\Gamma(K^p \mathcal{I}_m, \mathcal{D}_\mathcal{U})) \) which is of finite type over \( \mathcal{O}(\mathcal{U}) \). Then put \( \mathfrak{E}(\mathfrak{W}) := \text{Sp}(B_{\mathfrak{W}}) \). It is a finite affinoid domain over \( \mathcal{U} \). We define the Eigenvariety \( \mathfrak{E}_{K^p} \) by gluing the \( \mathfrak{E}(\mathfrak{W}) \). A detail of the gluing of similar pieces has been written up by Zhengyu Xiang [Xii10]

5.7.2. Conjectures. It would not be difficult to check that the Eigenvariety \( \mathfrak{E}_{K^p} \) we have constructed in this paper is the union of the components of \( \mathfrak{E}_{K^p} \) of dimension \( d \). We would like to formulate two conjectures on the dimension of the other components.

**Conjecture 5.7.3.** Let \( x = (\lambda, \theta) \) be a point of the Eigenvariety contained in only one irreducible component \( C \) of \( \mathfrak{E}_{K^p} \). Then the projection of \( C \) onto \( X \) is codimension \( d \) in weight space if and only if there exist two non negative integers \( p, q \) and a positive integer \( m(\theta, \lambda, K^p) \) such that

(a) The \( \theta \)-generalized eigenspace of \( H^r(S_G(K^p \mathcal{I}_m), \mathcal{D}_\lambda(L)) \) is non zero only if \( p \leq r \leq q \) and its dimension is \( m(\theta, \lambda, K^p) \times \left(\frac{q-p}{r-p}\right) \).

(b) \( d = q - p \)

We now give a few examples to support this conjecture.

**Example 1:** \( G = SL(2, F) \) with \( F \) a totally real field of degree \( d \) over \( \mathbb{Q} \).

In that case, weight space is dimension \( d \). Consider \( x = (\theta, k) \) with \( \theta \) the system of Hecke eigenvalue associated to an Eisenstein series of weight \( k \). It

\(^{23}\)They proved basically that the Eigenvariety is locally (for its canonical \( p \)-adic topology) rigid analytic which is actually all we need for the conjectures that we state here.

\(^{24}\)It is not hard to see that \( \mathfrak{Z}(f) \subset \mathfrak{Z}(f) \) but the latter might be much bigger as it depends of the resolution we have chosen unlike \( \mathfrak{Z}(f) \).
is determined by a Hecke character $\psi$ of the idele class group of $F$. If the $p$-stabilization is chosen ordinary, then it is known that there is a $p$-adic family of Eisenstein series of dimension $1 + \delta$ where $\delta$ is the defect of the Leopoldt conjecture for $F$ and $p$. The study of the Eisenstein cohomology, see [H87], shows that the Eisenstein classes occur in degree $q$ only if $d \leq q \leq 2d - 1$ with multiplicity $\binom{d-1}{q-d}$ since the rank of the group of units is $d - 1$. We see that in that case, our conjecture is satisfied if and only if Leopoldt conjecture is true for $(F,p)$.

**Example 2:** $G = D^\times$ with $D$ a quaternion algebra over a number field having exactly one complex place and which is ramified at all the real places. In that situation, the cuspidal cohomology is non trivial only in degree 1 and 2 so in this situation $q = 2$ and $p = 1$ and it is expected by the conjecture that the projection onto weight space of the irreducible components are codimension 1. In fact, in the ordinary case this is a theorem of Hida [Hi94].

**Example 3:** $G = GL(n, \mathbb{Q})$. We write $n = 2m$ or $n = 2m + 1$ according to the parity of $n$. In this situation, the cuspidal cohomology $H^*_{\text{cusp}}(SG(K), V^{\lambda})$ with regular $\lambda$ vanishes except in degree $i$ with $m^2 \leq i \leq m^2 + m - 1$ if $n$ even and $m(m+1) \leq i \leq m(m+1) + m$ if $m$ odd. Notice also that the cohomology vanishes if $\lambda$ is not essentially selfdual (See [Cl90] for these assertions). The prediction of our conjectures then says that the dimension of the Eigenvariety should be $2m - (m - 1) = m + 1$ in the even case and $2m + 1 - m = m + 1$ in the odd case (compare to a conjecture of Hida in [Hi98]). One can remark that $m + 1$ is actually the dimension of the subvariety of essentially self-dual weights denoted $X'$ in the previous section. For $n = 3$, the arguments of Hida in [Hi94] implies that our conjecture is true in the $GL(3)$-case.

The following proposition that has been proved independently by G. Stevens and by the author gives some more evidence for the conjecture above. Its proof will be published in an other paper in which we hope to give more evidences of the Conjecture 5.7.3.

**Proposition 5.7.4.** Let $x = (\lambda, \theta)$ be a point of the Eigenvariety $E_{K^p}$. Assume that $H^r(SG(K^p I_m), D_\lambda(L)) \neq 0$ for exactly $q$ consecutive degrees $r$. Then there is a component of the Eigenvariety containing $x$ of dimension at least $\dim X - d$.

This especially means that our conjecture states the opposite inequalities. It should be therefore seen as a non abelian generalization of Leopoldt conjecture. We end this section by a giving a refined conjecture when there are several irreducible components (of possibly different dimensions).

**Conjecture 5.7.5.** Let $x = (\lambda, \theta)$ be a point of the Eigenvariety $E_{K^p}$ and let $C_1, \ldots, C_s$ the irreducible components containing $x$.

For each $i = 1, \ldots, s$, there exists $p_i, q_i, m_i$ such that:
(a) $\theta$-generalized eigenspace of $H^r(S_G(K^p I_m), D_\lambda(L))$ has rank $\sum_{i=1}^s m_i \times \left( q_i - p_i \right)$.  
(b) The component $C_i$ has dimension $\dim \mathfrak{X} - d_i$ with $d_i = q_i - p_i$.

6. A $p$-adic Trace Formula

6.1. Spectral side of the $p$-adic trace formula. Let $\lambda \in \mathfrak{X}(\mathbb{Q}_p)$. By section §4, we know that we can write the $p$-adic finite slope character distribution $f \mapsto I^1_G(f, \lambda)$ defined over $\mathcal{H}_p'$ as a sum:

\begin{equation}
I^1_G(f, \lambda) = \sum_{\sigma} m^\pm_G(\lambda, \sigma). I_{\sigma}(f)
\end{equation}

where $\sigma$ runs in the set of irreducible finite slope representations of $\mathcal{H}_p$. This sum is infinite but we know it is $p$-adically convergent.

The aim of this section is to apply the $p$-adic analyticity with respect to the weight of the map $\lambda \mapsto I^1_G(f, \lambda)$ to establish a formula for (35) in geometric terms similar to Arthur-Selber type trace formulas. Inspired by Franke’s trace formula for the Lefschetz numbers, we introduce an overconvergent version of it and show that it equals the corresponding $p$-adic automorphic distribution $I^1_G(f, \lambda)$. It is possible to obtain a similar result for the distribution $I^1_{G,0}$ but we have decided to do this in a future paper to keep this article under a reasonable length.

6.2. Franke’s trace formula for Lefschetz numbers. The purpose of this paragraph is to recall Franke’s formula. We start by recalling the main terms involved in it.

6.2.1. Tamagawa numbers. Let $H_{/\mathbb{Q}}$ be a connected reductive group. Assume $H(\mathbb{R})$ contains a compact Cartan subgroup and let $\tilde{H}(\mathbb{R})$ the compact modulo center inner form of $H(\mathbb{R})$. We denote by $A_H$ the maximal split-torus of the center of $H$ and $K_H(\mathbb{R})$ one of its maximal compact subgroup. Let $dh$ be a Haar measure on $H$. Then the Tamagawa number $\chi(H) = \chi(H, dh)$ associated to $H$ is defined by

\[ \chi(H, dh) := (-1)^{d_H} \frac{\text{vol}(H(\mathbb{Q}) \backslash H(\mathbb{A})/A_H(H(\mathbb{R}))^0)}{\text{vol}(H(\mathbb{R})/A_H(H(\mathbb{R}))^0)} \cdot \frac{w_H(\mathbb{R})}{w_{K_H(\mathbb{R})}} \]

where $dh$ denotes an Haar measure on $H(\mathbb{R})$ and where the Haar measures used for $\tilde{H}(\mathbb{R})$ and $H(\mathbb{R})$ correspond by the (inner) isomorphism between $H_{/\mathbb{C}}$ and $\tilde{H}_{/\mathbb{C}}$. The cardinality of the Weyl group of $H(\mathbb{R})$ and $K_H(\mathbb{R})$ are respectively denoted by $w_H(\mathbb{R})$ and $w_{K_H(\mathbb{R})}$. The factor $\frac{w_H(\mathbb{R})}{w_{K_H(\mathbb{R})}}$ is then equal to the number of representations in a discrete series $L$-packet of $H(\mathbb{R})$. 
6.2.2. Semi-simple elements. We write $G(\mathbb{Q})^{ss}$ for the set of semi-simple elements of $G(\mathbb{Q})$. For all $\gamma \in G(\mathbb{Q})^{ss}$, we write $G_\gamma$ for the centralizer of $\gamma$ in $G$, $G_\gamma^0$ for its connected component and we put $i(\gamma) := [G_\gamma : G_\gamma^0]$. To define the integral orbitals intervening in the trace formula, we use the fixed Haar measure on $G$ we have taken at the beginning of this paper. Let $h \in C^\infty_c(G(\mathbb{A}_f), \mathbb{Q})$, then we define the orbital integral:

$$O_\gamma(h, dm_\gamma) := \int_{G(\mathbb{A}_f)/G_\gamma(\mathbb{A}_f)} h(g\gamma g^{-1})d\bar{g}$$

where $d\bar{m}$ is the quotient of the Haar measure $dg$ by the Haar measure $dg_{G_\gamma}$ on $G_\gamma$. If $\gamma \in G(\mathbb{Q})^{ss}$, following Franke, we define $\epsilon(\gamma) \in \{-1, 0, 1\}$ by putting $\epsilon(\gamma) = 0$ if $G_\gamma(\mathbb{R})$ does not contain a Cartan subgroup which is compact modulo $A_{G_\gamma}(\mathbb{R})$. Otherwise we put, $\epsilon(\gamma) = (-1)^{\dim A_{G_\gamma}(\mathbb{R})/A_{G_\gamma}(\mathbb{R})}$.

**Theorem 6.2.3** (Franke). Let $f$ be any Hecke operators and $\lambda$ be an algebraic dominant weight, then we have:

$$\text{tr}(f; H^*(\bar{S}_G, \mathcal{V}_\lambda^\vee(\mathbb{C}))) = (-1)^{d_G} \sum_{\gamma \in G(\mathbb{Q})^{ss}/\sim} \epsilon(\gamma) \frac{\chi(G_\gamma^0, dg_\gamma)}{i(\gamma)}O_\gamma(f, dg_\gamma)tr(\gamma, \mathcal{V}_\lambda^\vee(\mathbb{C}))$$

**Proof.** This is formula (24) of [Fr98] built on the formula of Theorem 1.4.2 and Arthur’s trace formula on $L_2$-Lefschetz numbers.

6.3. A formula for $I^\dagger_G(f, \lambda)$. Before establishing our $p$-adic trace formula, we introduce a certain $p$-adic function on $\Delta$.

**Lemma 6.3.1.** For any $g \in \Delta$ as above, the map $\lambda \mapsto \Phi^\dagger_G(g, \lambda) := \text{tr}(g, \mathcal{D}_\lambda(L))$ is analytic on $\mathcal{X}_T(\mathbb{Q}_p)$.

**Proof.** For any affinoid subdomain $\mathfrak{U} \subset \mathcal{X}_T$ and $\lambda \in \mathfrak{U}(L)$, we have

$$(36) \quad \mathcal{D}_{\mathfrak{U}, n} \otimes L \cong \mathcal{D}_{\lambda, n}(L)$$

for any $n \geq n_\mathfrak{U}$. Now $\mathcal{D}_{\mathfrak{U}, n}$ is $\mathcal{O}(\mathfrak{U})$-orthonormalizable and therefore $\phi_\mathfrak{U} := \text{tr}(\gamma, \mathcal{D}_{\mathfrak{U}, n}) \in \mathcal{O}(\mathfrak{U})$ is analytic on $\mathfrak{U}$ and by (36) satisfies $\phi_\mathfrak{U}(\lambda) = \text{tr}(g; \mathcal{D}_{\lambda, n}) = \Phi^\dagger_G(g, \lambda)$ for all $\lambda \in \mathfrak{U}(\mathbb{Q}_p)$.

The following lemma is analogue to Corollary 4.6.8.

**Lemma 6.3.2.** Let $\lambda$ be an algebraic dominant weight and $(\lambda_n)_n$ be a very regular sequence converging to $\lambda$. Then for any $g \in \Delta$, we have:

$$\lim_{n \to \infty} \lambda_n(\xi(t_g))\text{tr}(g, \mathcal{V}_\lambda^\vee(L)) = \Phi^\dagger_G(g, \lambda)$$
Proof. Let \( g \in \Delta^{-} \). Then it follows from Theorem 3.3.10 and Proposition 3.3.12 that we have the congruence:

\[
tr(g; D_{\lambda}(L)) \equiv \lambda(\xi(t_{g}))tr(g; V_{\lambda}^{\gamma}(L)) = \lambda(\xi(t_{g}))tr(g; V_{\lambda}^{\gamma}(L)) \mod N(\lambda, t_{g})
\]

We deduce now the result from (32) and the analyticity of the map \( \lambda \mapsto \Phi_{G}^{\dagger}(\gamma, \lambda) \).

We are now ready to state and prove a formula for the distribution \( I_{G}^{\dagger} \). It is given by the following theorem. We consider a Haar measure \( \lambda \) such that the \( p \)-component gives the measure 1 to the Iwahori subgroup \( I \). Then we have the following:

**Theorem 6.3.3.** Let \( f = f^{p} \otimes f_{p} \in \mathcal{H}_{p}^{f} \) and \( \lambda \in \mathfrak{X}(\overline{\mathbb{Q}}_{p}) \), then we have:

\[
I_{G}^{\dagger}(f, \lambda) = (-1)^{d_{G}} \sum_{\gamma \in G(\mathbb{Q})^{ss}/\mathbb{Z}} \chi(G_{\gamma}^{0}, dg_{\gamma}) O_{\gamma}(f^{p}, dg_{\gamma}) I_{G,\gamma}^{\dagger}(f, \lambda)
\]

where the sum is taken over the conjugacy classes of \( \mathbb{R} \)-elliptic semi-simple elements of \( G(\mathbb{Q}) \) and with

\[
I_{G,\gamma}^{\dagger}(f, \lambda) = \int_{G(\mathbb{Q}_{p})/G_{\gamma}(\mathbb{Q}_{p})} f_{p}(x\gamma x^{-1}) \Phi_{G}^{\dagger}(x\gamma x^{-1}, \lambda) dx
\]

Proof. It is sufficient to prove the formula for \( f = f^{p} \otimes u_{t} \). It is clear that both right and left hand side of the formula are analytic functions of \( \lambda \). To prove the equality, it is therefore sufficient to prove it for \( \lambda \) algebraic and dominant. For such a \( \lambda \), consider a highly regular sequence \( (\lambda_{n})_{n} \) converging \( p \)-adically to \( \lambda \). We multiply both sides of the trace formula of Theorem 6.2.3 for each \( \lambda_{n} \) by \( \xi(t)^{\lambda_{n}} \) and consider the term corresponding to some semi-simple element \( \gamma \):

\[
\xi(t)^{\lambda_{n}} \frac{\chi(G_{\gamma}^{0}, dg_{\gamma})}{i_{G}(\gamma)} O_{\gamma}(f^{p}, dg_{\gamma}) tr(\gamma, V_{\lambda}^{\gamma}) =
\]

\[
\frac{\chi(G_{\gamma}^{0}, dg_{\gamma})}{i_{G}(\gamma)} \xi(t)^{\lambda_{n}} O_{\gamma}(f^{p}, dg_{\gamma}) \int_{G(\mathbb{Q}_{p})/G_{\gamma}(\mathbb{Q}_{p})} f_{p}(x\gamma x^{-1}) tr(\gamma, V_{\lambda}^{\gamma}(L)) dx =
\]

\[
\frac{\chi(G_{\gamma}^{0}, dg_{\gamma})}{i_{G}(\gamma)} O_{\gamma}(f^{p}, dg_{\gamma}) \int_{G(\mathbb{Q}_{p})/G_{\gamma}(\mathbb{Q}_{p})} f_{p}(x\gamma x^{-1}) \xi(t)^{\lambda_{n}} tr(x^{-1}\gamma x, V_{\lambda}^{\gamma}(L)) dx
\]

Then pass to the limit when \( n \) goes to infinity. Then we get from Lemma 6.3.2:

\[
\frac{\chi(G_{\gamma}^{0}, dg_{\gamma})}{i_{G}(\gamma)} O_{\gamma}(f^{p}, dg_{\gamma}) \int_{G(\mathbb{Q}_{p})/G_{\gamma}(\mathbb{Q}_{p})} f_{p}(x\gamma x^{-1}) \Phi_{G}^{\dagger}(x^{-1}\gamma x, \lambda) dx
\]

Therefore the limit of the right hand side of the trace formula of Franke for \( \lambda_{n} \) multiplied by \( \xi(t)^{\lambda_{n}} \) has limit the right hand side of the formula stated in the theorem. The fact that the limit of the left hand side is \( I_{G}^{\dagger}(f, \lambda) \) was known by Corollary 4.6.8.
