Eisenstein series - take II
higher rank

http://www.math.huji.ac.il/~erezla

June 19, 2006
Let $G$ be a split reductive group over $\mathbb{Q}$. $G(\mathbb{A})^1 = \bigcap_{\chi \in X^*(G)} \ker |\chi|$ where $X^*(G)$ is the lattice of characters of $G$. For example, $G = GL_n$, $G(\mathbb{A})^1 = \{g \in GL_n(\mathbb{A}) : |\det g| = 1\}$. We always have $\text{vol}(G(F)\backslash G(\mathbb{A})^1) < \infty$ and $G(\mathbb{A})^1 \backslash G(\mathbb{A}) \cong \mathbb{R}_{>0}^k$ for some $k$. Given $f$ on $G(F)\backslash G(\mathbb{A})$ and a parabolic $P = MU$ the constant term along $P$ is defined by

$$f_P(g) = \int_{U(F)\backslash U(\mathbb{A})} f(ug) \, du$$

It is a function on $M(F)U(\mathbb{A})\backslash G(\mathbb{A})$. Define

$$L^2_{\text{cusp}}(G(F)\backslash G(\mathbb{A})^1) = \{\varphi \in L^2(G(F)\backslash G(\mathbb{A})^1) : f_P \equiv 0 \text{ for all proper parabolic } P\}$$

**FACT:** $L^2_{\text{cusp}}(G(F)\backslash G(\mathbb{A})^1)$ decomposes discretely. The theory of Eisenstein series reduces, in some sense, the study of $L^2(G(F)\backslash G(\mathbb{A}))$ to the study of $L^2_{\text{cusp}}(M(F)\backslash M(\mathbb{A}))$ for all Levi subgroup $M$ of $G$.

Let $A^0_G = A^0(G(F)\backslash G(\mathbb{A})^1)$ denote the “algebraic” part of $L^2_{\text{cusp}}(G(F)\backslash G(\mathbb{A})^1)$: functions
which span a finite length subrepresentation ($\delta$-finite) and which are $K$-finite. Thus, $\mathcal{A}_G^0 = \bigoplus \pi \mathcal{A}_{G,\pi}^0$, where $\pi$ range over cuspidal representations of $G(\mathbb{A})$.

cuspidal Eisenstein series - maximal parabolic case
Let $P = MU$ maximal parabolic. Also fix a “good” maximal compact $K = \prod_v K_v$ of $G(\mathbb{A})$. Let $T_M$ be the center of $M$ in the derived group of $G$. It is isomorphic to the multiplicative group $\mathbb{G}_m$. Let $A_M$ be $\mathbb{R}_{>0}$ imbedded in $T_M(\mathbb{A})$. Let $\varpi$ be the fundamental weight corresponding to $P$. It can be viewed as a rational multiple of a character of $M$. We get a quasi-character $|\varpi| : M(F) \backslash M(\mathbb{A}) \to \mathbb{R}_{>0}$
For example, if $G = GL_n$, $M = GL_{n_1} \times GL_{n_2}$, $n_1 + n_2 = n$, $K = O(n, \mathbb{R}) \prod_{p<\infty} GL_n(\mathcal{O}_p)$ and
$|\varpi|(g_1, g_2) = \left( \frac{|\det g_1|^{1/n_1}}{|\det g_2|^{1/n_2}} \right)^{1/2}$. 
We denote by $\mathcal{A}^0_P = \mathcal{A}^0(M(F)U(\mathbb{A}) \backslash G(\mathbb{A}))$ the space of functions $\varphi : G(\mathbb{A}) \to \mathbb{C}$ such that $\varphi(amug) = \delta_P(a)^{\frac{1}{2}} \varphi(g)$ for $m \in M(F)$, $u \in U(\mathbb{A})$, $a \in A_M$ and for all $k \in K$ the function $m \mapsto \varphi(mk) \in \mathcal{A}_{cusp}(M)$. We have $\mathcal{A}^0_P = \bigoplus \pi \mathcal{A}^0_{P,\pi}$ (sum over cuspidal $\pi$ of $M$).

We can identify $\mathcal{A}^0_P = \text{Ind}_{P(\mathbb{A})}^{G(\mathbb{A})} \mathcal{A}^0_M$ by

\[
\varphi \mapsto f(g) = \delta_P^{-\frac{1}{2}} \varphi(\cdot g)
\]

\[
f \mapsto \varphi(g) = [f(g)](m)
\]

Set

\[
\varphi_s(g) = |\varpi|^s (m) \varphi(mk)
\]

for $g = umk$, $u \in U(\mathbb{A})$, $m \in M(\mathbb{A})$, $k \in K$ and $s \in \mathbb{C}$. With the action $I(g, s) \varphi = (\varphi_s(\cdot g))_{-s}$ $\mathcal{A}^0_P$ becomes $\text{Ind}_{P(\mathbb{A})}^{G(\mathbb{A})} \mathcal{A}^0_M \otimes |\varpi|^s$. We write $\mathcal{A}^0_P(s)$ the space $\mathcal{A}^0_P(s)$ with the action $I(g, s)$. The isomorphism $\mathcal{A}^0_{M,\pi} \simeq \text{Hom}_{M(\mathbb{A})}(\pi, \mathcal{A}^0_M) \otimes \pi$ gives rise to $\mathcal{A}^0_{P,\pi} \simeq \text{Hom}_{M(\mathbb{A})}(\pi, \mathcal{A}^0_M) \otimes I_P(\pi, s)$. 
Define

\[ E(g, \varphi, s) = \sum_{\gamma \in P(F') \setminus G(F)} \varphi_s(\gamma g) \]

Properties:

- series is absolutely convergent for \( \text{Re}(s) \gg 0 \).

- admits meromorphic continuation to the whole plane and a functional equation.

- only finitely many poles for \( \text{Re}(s) > 0 \), all simple and they lie on the real line. The residues are in \( L^2(G(F) \setminus G(\mathbb{A})^1) \).

- holomorphic for \( \text{Re}(s) = 0 \).

Whenever regular, \( E(\cdot, \varphi, s) \) defines an intertwining map \( \mathcal{A}_P^0(s) \to \mathcal{A}_G \) (automorphic forms on \( G \)).
Let $\bar{P} = M\bar{U}$ be the opposite parabolic. Then $E_{\bar{P}} = M(s)\varphi$ ($\varphi_s$, if $\bar{P}$ is conjugate to $P$) where

$$M(s)\varphi = \int_{\bar{U}(A)} \varphi_s(ug)\, du.$$ 

The latter is an intertwining operator $A^0_P(s) \rightarrow A^0_{\bar{P}}(-s)$. (Note that $\varpi_{\bar{P}} = \varpi_{P}^{-1}$.) $M(s)$ admits similar analytic properties.

The functional equations are

$$E(g, M(s)\varphi, -s) = E(g, \varphi, s)$$
$$M(\bar{P}, -s) \circ M(P, s) = \text{Id}$$

Remarks about proofs:

Key Fact: for $\text{Re}(s) \gg 0$, $E(\cdot, \varphi, s)$ is the unique form satisfying

$$F_P = \varphi_s$$
$$F_{\bar{P}} \text{ has exponent } -s$$
$$F_Q \equiv 0 \text{ for } Q \neq P, \bar{P}$$
One direction is a straightforward computation. The other uses $L^2$-argument.

The Key Fact implies the meromorphic continuation and the functional equation. It also implies that the residues are in $L^2$.

$M(P,s)^* = M(\bar{P}, \bar{s})$, and therefore the functional equation implies that $M(s)$ is unitary for $\text{Re} \ s = 0$, therefore holomorphic.

Maass-Selberg relations: for $s = \sigma + it$

$$\|A^T E(\cdot, \varphi, s)\|_2^2 = \frac{e^{\sigma T}(\varphi, \varphi) - e^{-\sigma T}(M(s)\varphi, M(s)\varphi)}{\sigma} + \frac{\text{Im} e^{i t T}(M(s)\varphi, \varphi)}{t}$$

where

$$(\varphi_1, \varphi_2) = \int_{A_M \text{M}(F)U(\mathbb{A})\backslash G(\mathbb{A})} \varphi_1(g)\varphi_2(g) \ dg$$

Consequences:
$E(\varphi, s)$ is holomorphic whenever $M(s)$ is.
LHS ≥ 0. This implies, that for σ > 0, t ≠ 0 
M(s) has no pole, otherwise \(-e^{-\sigma T}(M(s)\varphi, M(s)\varphi)/\sigma\)
will dominate the RHS. Similarly, for σ = 0 a
pole must be simple for the same reason.

The meromorphic continuation works for smooth
functions (not necessarily \(K\)-finite). However
it does not hold for non-\(\mathfrak{z}\)-finite functions!

Fix a maximal torus \(T_0\) of \(G\) and a Borel sub-
group \(B\) containing \(T_0\). Let \(W = N_G(T_0)/T_0\) be
the Weyl group of \(G\). Suppose that \(\tau_p\) is an un-
ramified representation of \(G(\mathbb{Q}_p)\). Then \(\tau_p\) is a
subquotient of \(\text{Ind}_G^{G(\mathbb{Q}_p)} B(\mathbb{Q}_p) \chi_p\) for some unramified
character \(\chi_p\) of the torus \(T_0(\mathbb{Q}_p)\). The orbit of
\(\chi_p\) under \(W\) is determined by \(\pi_p\). If \(\psi_1, \ldots, \psi_r\)
is a basis for the lattice \(X^*(T_0)\) of rational
characters of \(T_0\), then \(\chi(t_p) = \prod_{j=1}^r |\chi_j(t_p)|^{s_j}\)
for some \(s_j \in \mathbb{C}\) uniquely determined up to
\(2\pi i/\log p\). In a more invariant way, \(\chi_p\) is deter-
mined by an element \(\mu\) in \(a^*_{0, \mathbb{C}} = X^*(T_0) \otimes \mathbb{C}\).
(determined up to $2\pi i a_0/(\log p)$, as well as $W$ action). Now, we can define a complex group $L^G$ with torus $L^T_0$ such that $X^*(L^T_0) = X^*(T_0)$ and the roots of $T_0$ are the co-roots of $L^T_0$. We can identify $L^T_0(\mathbb{C})$ with $X^*(L^T_0) \otimes \mathbb{C}^* = X^*(T_0) \otimes \mathbb{C}^*$. The semi-simple classes of $L(G)$ are identified with $X^*(T_0) \otimes \mathbb{C}^*/W$. Thus, we obtained a conjugacy class $\lambda(\tau_p)$ of $L^G(\mathbb{C})$ by taking the image of $\mu$ under the map $a_0^*,\mathbb{C} \rightarrow X^*(T_0) \otimes \mathbb{C}^*/W$ induced by $z \mapsto p^z$. This is the Frobenius-Hecke parameter of $\tau_p$.

Back to the intertwining operators

On $A^0_{P,\pi} = \text{Hom}(\pi, A^0_{M,\pi}) \otimes I_P(\pi, s)$ $M(s) = \text{Id} \otimes M(\pi, s)$ where $M(\pi, s) : I_P(\pi, s) \rightarrow I_{\bar{P}}(\pi, s)$. If $\pi = \otimes \pi_v$, $M(\pi, s) = \otimes M_v(\pi_v, s)$.

If $\pi_p$ is unramified with parameter $\mu_p \in a^*_{0,\mathbb{C}}$ then on the unramified vector $M(\pi_p, s)$ is given by the scalar

$$\prod_{\alpha} \frac{1 - p^{-\langle \mu_p + s\varpi, \alpha \rangle} - 1}{1 - p^{-\langle \mu_p + s\varpi, \alpha \rangle}}$$
where the product is over all roots $\alpha$ of $T_M$ in $U$. (Gindikin-Karpelevic formula - analogy from the real case)

In $^LG$ there is a corresponding parabolic $^LP$ with Levi $^LM$ and unipotent $^LU$. Decompose the representation Ad of $^LM$ on $^L(U)$ as $\oplus_{j=1}^k r_j$ where $r_j$ corresponds to the roots $\alpha$ of $^LU$ (i.e., the co-roots $\alpha^\vee$ of $U$) for which $(\varpi, \alpha^\vee) = j$ (that is, writing $\alpha^\vee$ as a sum of simple co-roots, the coefficient corresponding to the simple root defining $P$ is $j$). In fact, $r_j$ corresponds to the $j$-th constituent in the lower central series for $^LU$, and $r_j$ is irreducible. The above expression can be written as

$$\prod_{j=1}^k \frac{\det(1 - p^{-j(s+1)}\bar{r}_j(\lambda(\pi_p)))}{\det(1 - p^{-js}\bar{r}_j(\lambda(\pi_p)))}.$$ 

Thus, on $A_{\pi,s}^0 M(s)$ is given roughly as

$$\prod_{j=1}^k \frac{L(js, \pi, \bar{r}_j)}{L(js + 1, \pi, \bar{r}_j)}$$
where for a representation $r : LG \to GL_n(\mathbb{C})$

$$L(s, \pi, r) = \prod_p \det(1 - p^{-s}r(\lambda(\pi_p)))^{-1} \quad \text{Re}(s) \gg 0.$$ 

This implies the meromorphic continuation (strip by strip) of the $L(s, \pi, r_j)$'s.

Langlands insights:

- From the structure of the Gindikin-Karpelevic formula come up with the $L$-group
- General notion of $L$-functions
- Conjecture general analytic properties of $L$-functions
- functoriality conjecture: any $L$-function is an automorphic function of $GL_n$. 
These revolutionary ideas came (in a domino effect) from the computation of the constant term of cuspidal Eisenstein series, carried out by Langlands in the 60’s (Euler products manuscript, Yale University). It is therefore a turning point in the theory of automorphic forms.

Examples: \( G = \text{GL}_n, \ M = \text{GL}_{n_1} \times \text{GL}_{n_2}, \pi = \pi_1 \otimes \pi_2, \pi_i \) a cuspidal representation of \( \text{GL}_{n_i}(\mathbb{A}) \). In this case \( k = 1 \) and \( r_1 : \text{GL}_{n_1}(\mathbb{C}) \times \text{GL}_{n_2}(\mathbb{C}) \rightarrow \text{GL}_{n_1n_2}(\mathbb{C}) \) is the tensor product representation. It gives rise to Rankin-Selberg \( L \)-functions.

\( G = \text{Sp}_{2(n+m)}, \ M = \text{GL}_n \times \text{Sp}_{2m}, \pi = \tau \otimes \sigma, \ L\ M = \text{GL}_n(\mathbb{C}) \times \text{SO}_{2m+1}(\mathbb{C}). \) In this case \( k = 2 \). \( r_1 : L\ M \rightarrow \text{GL}_{n(2m+1)}(\mathbb{C}) \) is the tensor product representation of \( \text{GL}_n(\mathbb{C}) \times \text{GL}_{2m+1}(\mathbb{C}) \) restricted to \( L\ M \) while \( r_2 : L\ M \rightarrow \text{GL}_{(n/2)}(\mathbb{C}) \) is the exterior square representation \( \wedge^2 \) of \( \text{GL}_n(\mathbb{C}). \) (In the case \( m = 0 \) only the latter appears.) Similarly for other classical groups.
Exceptional cases $G = G_2$; one of the maximal parabolic subgroups gives rise to the 4-dimensional symmetric cube representation of $GL_2(\mathbb{C})$.

$G = E_8$, $M = GL_2 \times GL_3 \times GL_5$ (up to isogeny). Here $k = 6$ and

$$ r_1 : GL_2(\mathbb{C}) \times GL_3(\mathbb{C}) \times GL_5(\mathbb{C}) \to GL_{30}(\mathbb{C}) $$

in the (triple) tensor product representation.

$G = E_8$, $M = GL_5 \times GL_4$ (up to isogeny). Here $k = 5$ and $r_1 : GL_5(\mathbb{C}) \times GL_4(\mathbb{C}) \to GL_{40}(\mathbb{C})$ is given by $r_1(g_1, g_2) = \wedge^2(g_1) \otimes g_2$.

$G = E_8$, $M = GL_8$; $k = 3$ and $r_1$ is the exterior cube (56-dimensional) representation of $GL_8(\mathbb{C})$.

$G = E_8$, $M = Spin(14)$; $k = 2$ and $r_1$ is the (64-dimensional) spin representation of $Spin(14)$. 
General case $P = MU$ any parabolic, $T_M$ the center of $M$ in the derived group of $G$ (a torus of dimension $r$ — the co-rank of $M$), $A_M \cong \mathbb{R}^r_{>0}$ the positive real points in $T_M(\mathbb{A})$, $X^*(M)$ - the lattice (of rank $r$) of characters of $M$ trivial on the center of $G$. We form the vector space $a^*_M = X^*(M) \otimes \mathbb{R} = X^*(T_M) \otimes \mathbb{R}$; $a^*_{M,\mathbb{C}} = X^*(M) \otimes \mathbb{C}$. This space gives rise to quasi-character $m \mapsto |m|^\lambda : M(F) \backslash M(\mathbb{A}) \to \mathbb{C}^*$ defined by

$$|m\chi \otimes s| = |\chi(m)|^s = \prod_{p \leq \infty} |\chi(m_p)|_p^s$$

Consider the space

$$\mathcal{A}^2_P = \{ \varphi : M(F)U(\mathbb{A}) \backslash G(\mathbb{A}) \to \mathbb{C} | \delta_P(m)^{-\frac{1}{2}} \varphi(mk) \in \mathcal{A}^2_M \text{ for all } k \in K \}$$

where $\mathcal{A}^2_M$ is the space of $K$-finite functions on $A_M M(F) \backslash M(\mathbb{A})$, which span a finite length representation in $L^2_{disc}(M(F) \backslash M(\mathbb{A}))$. Again $\mathcal{A}^2_P = \text{Ind}^{G(\mathbb{A})}_{P(\mathbb{A})} \mathcal{A}^2_M$ and by twisting

$$\varphi_\lambda(umk) = |m^\lambda| \varphi(mk)$$
we have $A_P^2(\lambda) = \text{Ind}_{P(\mathbb{A})}^{G(\mathbb{A})} A_M^2 \otimes | \cdot \lambda |$ for any $\lambda \in a_{M}^*, \mathbb{C}$. As before, the Eisenstein series are defined by

$$E(g, \varphi, \lambda) = \sum_{\gamma \in P(F) \backslash G(F)} \varphi\lambda(\gamma g)$$

Whenever regular, they define intertwining maps $A_P^2(\lambda) \to A^G$. We also have the intertwining operators

$$M_{P'\mid P}(\lambda) : A_P^2(\lambda) \to A_{P'}^2(\lambda)$$

defined for any $P'$ with Levi $M$ by

$$M_{P'\mid P}(\lambda)\varphi(g) = \int_{(U_P(\mathbb{A}) \cap U_{P'}(\mathbb{A})) \backslash U_{P'}(\mathbb{A})} \varphi\lambda(ug) \, du$$

Properties

- $E(\varphi, \lambda)$ and $M(\lambda)$ converge for $\text{Re}(\langle \lambda, \alpha^\vee \rangle) \gg 0$ for all $\alpha \in \Delta_P$. 
• admit meromorphic continuation to $\mathfrak{a}_{M,\mathbb{C}}^*$ and functional equations

\[ E_{P'}(M_{P'|P}(\lambda)\varphi, \lambda) = E_P(\varphi, \lambda) \]

\[ M_{P''|P'}(\lambda)M_{P'|P}(\lambda) = M_{P''|P}(\lambda) \]

• The singularities lie on hyperplane $\langle \lambda, \alpha^\vee \rangle = c, \alpha \in \Sigma_P$.

• holomorphic for $\text{Re}(\lambda) = 0$. $M_{P'|P}(\lambda)$ is unitary there.

The Eisenstein series are the building blocks for the decomposition of $L^2(G(F)\backslash G(\mathbb{A}))$. This is Langlands’ theory which consists of two parts:

1. $L^2$-decomposition using square-integrable Eisenstein series.
2. constructing the square-integrable automorphic forms as residues of Eisenstein series.

The first part is more "rigid" in a sense, but originally it relied on the second part (which was completed first). In fact, even the analytic properties of square-integrable Eisenstein series were not known before the second part. Nowadays, there is an independent proof of this (due to Bernstein), and in principle the first part can be done independently of the second part. (For the local analogue, the Plancherel formula - cf. Waldspurger, following Harish-Chandra.)

Example:

\[(\theta_f, \varphi)_{\Gamma \backslash \mathcal{H}} = (f, \varphi_U)_{\mathbb{R}_{>0}}\]

Therefore the space spanned by \(\theta_f\) is the orthogonal complement of \(L^2_{cusp}(\Gamma \backslash \mathcal{H})\). Now,

\[(\theta_{f_1}, \theta_{f_2})_{\Gamma \backslash \mathcal{H}} = ((\theta_{f_1})_U, f_2)_{\mathbb{R}_{>0}} = (M f_1, f_2)_{\mathbb{R}_{>0}}\]
where \( Mf(y) = \int_\mathbb{R} f(y/(x^2 + y^2)) \, dx \). We have
\[
\hat{Mf}(s) = \int_{\text{Re } s = s_0 \gg 0} \phi(s) \hat{f}(-s) \, ds
\]
By isometry of Fourier transform
\[
(f_1, f_2) = \int_{\text{Re } s = s_0} \hat{f}_1(s)\overline{\hat{f}_2(-\overline{s})} \, ds
\]
We get
\[
(\theta f_1, \theta f_2) = \int_{\text{Re } s = s_0} \hat{f}_1(s)\overline{\hat{f}_2(-\overline{s})} \, ds +
\int_{\text{Re } s = s_0 \gg 0} \hat{f}_1(s)\phi(s)\overline{\hat{f}_2(\overline{s})} \, ds =
\int_{\text{Re } s = 0} \hat{f}_1(s)\overline{\hat{f}_2(s)} \, ds +
\int_{\text{Re } s = 0} \hat{f}_1(s)\phi(s)\overline{\hat{f}_2(-s)} \, ds + \text{Res}_{s = \frac{1}{2}} \phi(s) \cdot \hat{f}_1(\frac{1}{2})\overline{\hat{f}_2(\frac{1}{2})}
\]
On the other hand,
\[
(\theta f_1, \theta f_2) = \int_{\text{Re } s = s_0 \gg 0} (\hat{f}_1(s)E(\cdot, s), \theta f_2)
\]
which can be written as
\[
(\int_{\text{Re } s = 0} \hat{f}_1(s)E(\cdot, s) \, ds, \int_{\text{Re } s = 0} \hat{f}_2(s)E(\cdot, s) \, ds) +
\]
$\hat{f}_2(s_0)(\int_{\text{Res } s=0} \hat{f}_1(s)E(\cdot, s) \, ds, \text{Res}_{s_0} E) +$

$\int_{\text{Res } s=0} \frac{1}{2} E, \int_{\text{Res } s=0} \hat{f}_2(s)E(\cdot, s) \, ds) +$

$\int_{\text{Res } s=0} \frac{1}{2} \hat{f}_2(s_0)(\text{Res}_{s=1/2} E, \text{Res}_{s=1/2} E)$

Comparing, we get

$$(\text{Res}_{s=1/2} E(\cdot, s), \text{Res}_{s=1/2} E(\cdot, s)) = \text{Res}_{s=1/2} \phi(s),$$

$$(\text{Res}_{s=1/2} E(s) \, ds, \int_{\text{Res } s=0} \hat{f}(s)E(\cdot, s) \, ds) = 0$$

and

$$(\int_{\text{Res } s=0} \hat{f}_1(s)E(\cdot, s) \, ds, \int_{\text{Res } s=0} \hat{f}_2(s)E(\cdot, s) \, ds) =$$

$$\int_{\text{Res } s=0} (\hat{f}_1(s) + \phi(s)\hat{f}_1(-s))(\hat{f}_2(s) + \phi(s)\hat{f}_2(-s))$$

$L^2(G(F)\backslash G(\mathbb{A})) = \bigoplus_{[M]} L^2_{[M]}(G(F)\backslash G(\mathbb{A}))$ where $[M]$ ranges over classes of Levi subgroups up to association.
Let $\mathcal{P}(M)$ be the class of parabolic subgroups with Levi $M$ (up to conjugation). $L^2_{[M]}(G(F)\backslash G(\mathbb{A}))$ is isometric to the space

$$F = (F_P)_{P \in \mathcal{P}(M)} : \text{ia}_M^* \to \bigoplus_{P \in \mathcal{P}(M)} \overline{A}_P^2$$

satisfying $F_{P'}(\lambda) = M_{P'|P}(\lambda)F_P(\lambda)$ for all $P, P' \in \mathcal{P}_M$, $\lambda \in \text{ia}_M^*$ and such that

$$\|F\|^2 = \int_{\text{ia}_M^*} \|F_P(\lambda)\|^2 \, d\lambda < \infty$$

The isometry is given by $F \mapsto \int_{\text{ia}_M^*} E_P(\cdot, F(\lambda), \lambda) \, d\lambda$ (independent of $P \in \mathcal{P}(M)$). In the other direction

$$f \mapsto F_P(\lambda) = \sum_{\{\varphi\}} (f, E_P(\cdot, \varphi, \lambda))$$

where $\varphi$ ranges over an orthonormal basis of $A_P^2$.

Residual spectrum: Given $M$ and a cuspidal representation $\pi$ of $M(\mathbb{A})$. Let $\phi : M(F)U(\mathbb{A})\backslash G(\mathbb{A}) \to \mathbb{C}$ be such that $\delta_P(m)^{-\frac{1}{2}} \phi(mk) \in A_{M,\pi}^0$ but for
which $\phi(amk)$ is compactly supported in $A_M$ for $m \in M(\mathbb{A})^1$. We form

$$\theta_\phi(g) = \sum_{\gamma \in P(F) \setminus G(F)} \phi(\gamma g)$$

It is absolutely convergent and rapidly decreasing. Let

$$\hat{\phi}(\lambda)(\cdot) = \left( \int_{A_M} a^{-\lambda} \delta(a) a^{-\frac{1}{2}} \phi(a \cdot) \, da \right)_{-\lambda} \in A_P^0$$

The functions $\hat{\phi}$ are Paley-Wiener functions on $a_M^*, \mathbb{C}$ with values in a finite-dimensional subspace of $A_P^0$. By Mellin inversion,

$$\theta_\phi(g) = \sum_{\gamma \in P(F') \setminus G(F')} \int_{\text{Re } \lambda = \lambda_0} \hat{\phi}(\lambda)(\gamma g) = \int_{\text{Re } \lambda = \lambda_0} E(\lambda, \hat{\phi}(\lambda), \lambda) \, d\lambda.$$

for $\text{Re } \lambda \gg 0$.

Let $L^2_{(M, \pi)}$ be the space spanned by $\theta_\phi$. We write $(M, \pi) \equiv (M', \pi')$ if $M' = gMg^{-1}$ and $\pi' = \pi^g$ for some $g \in G(F)$. Let $[(M, \pi)]$ denote the class of $(M, \pi)$.
The starting point is:

\[ L^2(G(F) \backslash G(\mathbb{A})) = \bigoplus_{[M,\pi]} L^2_{(M,\pi)}(G(F) \backslash G(\mathbb{A})) \]

**residue operators**: Consider the space of meromorphic functions \( \mathcal{M}(a^*_M,C) \) on \( a^*_M,C \) whose only singularities are along hyperplanes of the form

\[ L_{\alpha,c} = \{ \lambda \in a^*_M,C : \langle \lambda, \alpha^\vee \rangle = c \} \quad \alpha \in \Delta_P, \ c \in \mathbb{C} \]

Let \( V \) be an affine subspace of \( a^*_M,C \) which is given by intersections of hyperplanes \( L_{\alpha,c} \). Let \( V^0 \) denote the vector part of \( V \) which a subspace of \( a^*_M \). A residue operator along \( V \) is a linear map \( \text{Res}_V : \mathcal{M}(a^*_M,C) \to \mathcal{M}(V) \) which is given by a linear combination of the following operators. Given a chain \( V = V_k \subsetneq V_{k-1} \subsetneq \ldots V_0 = a^*_M,C \) with \( V_{i+1} = V_i \cap L_{\alpha_i,c_i} \) and points \( z_i \in V^0_{i-1} \setminus V^0_i, \ i = 1, \ldots, k \) we look at the composition of \( r_i : \mathcal{M}(V_{i-1}) \to \mathcal{M}(V_i) \) where \( r_if(v) = \text{Res}_{s=0} f(v + sz_i) \). Of course \( \text{Res}_V \) depends on some choices.
Simplest case:

$$\text{Res}_V f = \left( \prod_{i=1}^{k} \left( \langle \lambda, \alpha_i^\vee \rangle - c_i \right) f(\lambda) \right)_V$$

for functions such that the right-hand side is holomorphic.

notation: if $V$ is defined over $\mathbb{R}$ (that is $V \cap \mathfrak{a}_M^* \neq 0$) we let $o(V) \in \mathfrak{a}_M^* \cap V$ be the shortest point in $V$ (the “origin” of $V$).

We also speak about equivalences of subspaces $V$ under the Weyl group, and denote an equivalence class by $[V]$.

General statement: For any $(M, \pi)$ there exist a finite collection of singular subspaces $V$ of $\mathfrak{a}_M^* \otimes \mathbb{C}$ and canonical residue operators $\text{Res}_V$ such that $V$ is defined over $\mathbb{R}$ if $V$ is singular;

$$\mathcal{E} = \sum_w \text{res}_w V E(\phi(\lambda), w\lambda) \quad (\in \mathcal{M}(V))$$
is holomorphic for \( \text{Re} \, \lambda = 0 \) and

\[
\theta_\phi = \sum_V \int_{\text{Re} \, \lambda = 0} \text{Res}_{wV} \sum_w E(\phi(\lambda), w\lambda)
\]

The map

\[
p[V] \theta \phi = \sum_{V \in [V]} \int_{\text{Re} \, \lambda = 0} \text{Res}_{wV} \sum_w E(\phi(\lambda), w\lambda)
\]

is a spectral projection (commutes with \( G(\mathbb{A}) \)), and we can identify the image with \( L^2 \)-sections in a Hilbertian stack over \( o(V) + \text{Im} \, V \). In particular, the discrete spectrum corresponds to \( V = pt \).

\( GL_n \) (Jacquet, Mœglin-Waldspurger) Discrete spectrum appears for \( M = GL_m \times \cdots \times GL_m \) (\( k \) times) and \( \pi \otimes \cdots \pi \). The singular point is \( \lambda_0 = (\frac{k-1}{2}, \ldots, -\frac{k-1}{2}) \). The residue is given by

\[
\lim_{\lambda=(s_1,\ldots,s_k) \to \lambda_0} \prod_{i=1}^{k-1} (s_i - s_{i+1} - 1) E(\varphi(\lambda), \lambda)
\]

classical groups:
$G_2$ example: Recall roots: $\alpha$ (long), $\beta$ (short), $\alpha + \beta$, $\alpha + 2\beta$, $\alpha + 3\beta$, $2\alpha + 3\beta$. $M = T_0$. In addition to $\rho = 3\alpha + 5\beta$, the two short roots $\alpha + \beta$, $\alpha + 2\beta$ are also singular. There is an intertwining operator (not surjective). $N = \otimes N_p : I(\alpha + 2\beta) \to I(\alpha + \beta)$. Let $J = \otimes J_p$ be the image.

$$(\text{Res } E(\phi_1), \text{Res } E(\phi_2)) =$$

$$[(\phi_1(\alpha + \beta), N_p\phi_1(\alpha + 2\beta)), (\phi_2(\alpha + \beta), N_p\phi_2(\alpha + 2\beta))]$$

$p\phi$ depends on the germ of $\phi$ at the point. where $[\cdot, \cdot]$ is the inner product on $I(\alpha + \beta) \oplus J$ given by

$$((f, g), (f', g')) = ((1 + E/2)N_2(f + g), f + g)$$

The image of $N_2 = \otimes (N_2)_p$ is $\otimes (\pi_p^+ \oplus \pi_p^-)$, $\pi_p^+$ unramified, $E = \otimes E_p$ acts as $1$ on $\pi_p^+$ and as $-2$ on $\pi_p^-$. Thus, we get $\bigoplus_{\varepsilon} = (\varepsilon_p) \otimes \pi_p^{\varepsilon_p}$ the sum is over all $\varepsilon$ such that $1 \neq |\{p : \varepsilon_p = -1\}| < \infty$. 

Fourier coefficients of Eisenstein series

Producing cuspidal representations from Eisenstein series (Ginzburg-Rallis-Soudry)

Example: Let $\pi$ be a cuspidal representation of $GL_{2n}(\mathbb{A})$ such that $L(1, \pi, \wedge^2) = \infty$. By the general philosophy this “means” that $\pi$ is a functorial lift from $SO_{2n+1}$. (Reason: in the $L$-group side $\pi$ is a lift from a subgroup of $GL_{2n}(\mathbb{C})$ on which $\wedge^2$ has a fixed vector, i.e. from $Sp_{2n}(\mathbb{C})$. Note that $L SO_{2n+1} = Sp_{2n}(\mathbb{C})$).

Consider the Eisenstein series on $SO_{4n}$ induced from $\pi |\text{det}|^s$. It has a pole at $s = \frac{1}{2}$. Let $\Psi$ be the residue. The Fourier coefficient with respect to the character $\psi(x_1,2 + \cdots + x_{n-2},n-1 + \frac{1}{2}(x_{n-1},2n + x_{n-1},2n+1))$ on the unipotent radical of the parabolic with Levi part $L = GL_{1}^{n-1} \times SO_{2n+2}$ defines an automorphic form $\Phi$ on
$SO_{2n+1}$ which is the stabilizer of this character in $L$.

Example: $n = 2$

$$
\Phi(h) = \int_{(F \backslash \mathbb{A})^6} \psi \left( \begin{pmatrix} 1 & v & * \\ h & v^* & 1 \end{pmatrix} \right) \psi(v) \, dv \quad h \in SO_5(\mathbb{A})
$$

for an appropriate character $\psi : (F \backslash \mathbb{A})^6 \to \mathbb{C}$.

It turns out that the $\Phi$’s obtained this way form an irreducible cuspidal representation $\tau$ of $SO_{2n+1}(\mathbb{A})$ which is generic (has a non-zero non-degenerate Fourier coefficient) and whose functorial transfer to $GL_{2n}$ is $\pi$. That is, if $\tau = \bigotimes_v \tau_v$ and $\tau_v = \text{Ind}(\cdot|^{s_1}, \ldots, \cdot|^{s_n})$ at a place where $\tau_v$ is unramified then $\pi_v = \text{Ind}(\cdot|^{s_1}, \ldots, \cdot|^{s_n}, \cdot|^{-s_n}, \ldots, \cdot|^{-s_1})$.
