

The deal with foams

Today: intro to sl_n -foams

Next time: HOMFLY-PT foams, approach to Hochschild homology, etc.

1. How to get a link invariant from a braided category.

Let \mathcal{C} be a monoidal category with duals (e.g. $\mathcal{C} = \text{Rep}_\mathbb{Z}^{\text{fd}}$, or $\mathcal{C} = A\text{-mod}$, A Hopf algebra)

Example: let A be a Hopf algebra (bialgebra + antipode), such as $U(\mathfrak{g})$

$\Delta(x) = x \otimes 1 + 1 \otimes x \quad x \in \mathfrak{g}$
 $\epsilon(x) = 0 \quad x \in \mathfrak{g}$
 $S(x) = -x \quad x \in \mathfrak{g}$

We say that \mathcal{C} is braided if it has a 2-morphism $c: \otimes \rightarrow \otimes^{\text{op}}$ s.t.:

- $c_{X,Y}: X \otimes Y \rightarrow Y \otimes X$ invertible, inverse $c_{Y,X}^{-1}$

- Depict $c_{X,Y}$ as and $c_{Y,X}^{-1}$ as so = =

$\leftrightarrow \text{crossing} = \text{crossing}$

$\leftrightarrow \text{crossing} = \text{crossing}$

Note: this introduction is not chronological

Q: how to make A -mod braided?

(A Hopf algebra)

$$C_{XY} := X \otimes Y \rightarrow Y \otimes X$$

$$\begin{array}{ccc} & & \\ & \searrow & / \\ R \cdot & & \text{swap} \\ \cap & & \\ A \otimes A & & X \otimes Y \end{array}$$

Conditions on R : $\text{swap} \circ \Delta(a) = R \Delta(a) R^{-1}$

"Universal R -matrix"

$$(\Delta \otimes \text{id})(R) = R_{13} R_{23}$$

$$(\text{id} \otimes \Delta)(R) = R_{13} R_{12}$$

Key example: $A = U_q(\mathfrak{g})$, $R = \sum_{a_i \text{ basis of } U(\mathfrak{b}_+)} a_i \otimes a_i^c$. Such Hopf algebras are called **quasitriangular**.

(technically infinite, take completion and restrict...)

Theorem (Reshetikhin-Turaev, 1990):

Braided monoidal categories with duals yield invariants of colored oriented links. (technically framed...)

↓
by objects in \mathcal{C}

Construction (Reshetikhin-Turaev):

Example: Take the full subcategory of $U_q(\mathfrak{gl}_n)$ -mod \otimes -generated by $\Lambda^0 V, \dots, \Lambda^n V$ and their duals $\Lambda^0 V^*, \dots, \Lambda^n V^*$

So $P_{\mathfrak{gl}_n}(\text{link}) = p(q)$

If we color every component by V , we get HOMFLY() $(q, t = q^n)$

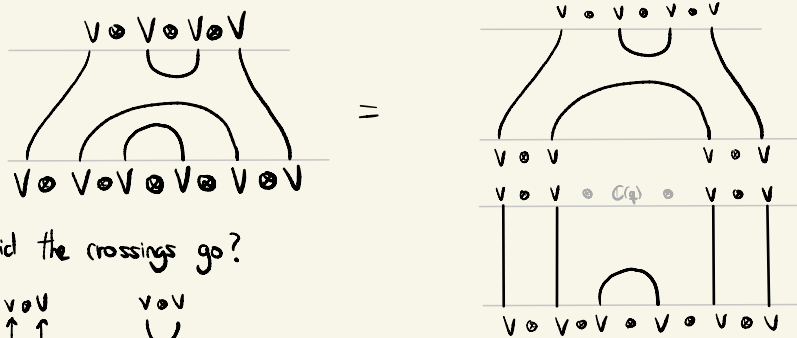

2. Webs (MOY calculus)

For some categories, hom spaces have nice combinatorial bases.

Example 1: $\mathcal{C} \subseteq U_q(\mathfrak{sl}_2)$ full subcategory \otimes -generated by $V (= \mathbb{C}q^{\frac{1}{2}})$

\otimes, \circ -generate all Hom spaces, i.e. all morphisms are linear combinations of things like:

Wait... where did the crossings go?

Remark 1: these diagrams are the morphisms of the Temperley-Lieb category for $\delta = -[2]$

Remark 2: $\text{Kar}(\mathcal{C}) = U_q(\mathfrak{sl}_n)$ -mod so morally this controls all of it

Example 2: Take again $\mathcal{C} =$ full subcategory of $U_q(\mathfrak{gl}_n)$ \otimes -generated by $\wedge^a V, \dots, \wedge^n V$ and their duals $\wedge^a V^*, \dots, \wedge^n V^*$

Then every morphism is \otimes, \circ -generated by:

Example 2: Take again $\mathcal{C} = \text{full subcategory of } U_q(\mathfrak{gl}_n)$ \otimes -generated by $\Lambda^0 V, \dots, \Lambda^n V$
 and their duals $\Lambda^0 V^*, \dots, \Lambda^n V^*$
 (continued)

For instance:

Such combinations are called webs, or MOY graphs:

A web (= MOY graph)

A closed web

Note: $\downarrow \uparrow = \downarrow \uparrow \uparrow$

Example 2: Take again $\mathcal{C} = \text{full subcategory of } U_q(\mathfrak{gl}_N)$ \otimes -generated by $\Lambda^0 V, \dots, \Lambda^N V$
 and their duals $\Lambda^0 V^*, \dots, \Lambda^N V^*$

(continued)

We have more relations:

$$\begin{aligned}
 \langle \bigcirc_k \rangle &= \begin{bmatrix} N \\ k \end{bmatrix} & \langle \begin{array}{c} 1 \quad m \\ \leftarrow m+1 \quad \leftarrow 1 \\ \leftarrow m+1 \quad \leftarrow 1 \\ 1 \quad m \end{array} \rangle &= \langle \begin{array}{c} \uparrow \\ 1 \\ \downarrow \\ m \end{array} \rangle + [N - m - 1]_q \langle \begin{array}{c} 1 \quad m \\ \swarrow \quad \nwarrow \\ m-1 \\ \swarrow \quad \nwarrow \\ 1 \quad m \end{array} \rangle \\
 \langle \begin{array}{c} i \quad j \quad k \\ \swarrow \quad \searrow \\ j+k \\ \uparrow \\ i+j+k \end{array} \rangle &= \langle \begin{array}{c} i \quad j \quad k \\ \swarrow \quad \searrow \\ i+j \\ \uparrow \\ i+j+k \end{array} \rangle \\
 \langle \begin{array}{c} m+n \\ \uparrow \\ m \\ \downarrow \\ m+n \end{array} \rangle &= \begin{bmatrix} m+n \\ m \end{bmatrix} \langle \begin{array}{c} \uparrow \\ m+n \end{array} \rangle \\
 \langle \begin{array}{c} m+n \\ \uparrow \\ m+n \\ \downarrow \\ m+n \end{array} \rangle &= \begin{bmatrix} N-m \\ n \end{bmatrix} \langle \begin{array}{c} \uparrow \\ m \end{array} \rangle \\
 \langle \begin{array}{c} l+n \quad m \\ \leftarrow n \quad \leftarrow m-n \\ \leftarrow n-1 \quad \leftarrow m+l-1 \\ 1 \quad m+l-1 \end{array} \rangle &= \begin{bmatrix} m-1 \\ n \end{bmatrix} \langle \begin{array}{c} l \\ \leftarrow l-1 \\ \leftarrow 1 \\ 1 \quad m+l-1 \end{array} \rangle + \begin{bmatrix} m-1 \\ n-1 \end{bmatrix} \langle \begin{array}{c} l \quad m \\ \swarrow \quad \nwarrow \\ l+m \\ \swarrow \quad \nwarrow \\ 1 \quad m+l-1 \end{array} \rangle \\
 \langle \begin{array}{c} m \quad n+l \\ \leftarrow n+k-m \quad \leftarrow m+l-k \\ \leftarrow k \quad \leftarrow m+l \\ n \quad m+l \end{array} \rangle &= \sum_{j=\max(0, m-n)}^m \begin{bmatrix} l \\ k-j \end{bmatrix} \langle \begin{array}{c} m \quad n+l \\ \leftarrow j \quad \leftarrow n+l+j \\ \leftarrow n+j-m \quad \leftarrow m+l \\ n \quad m+l \end{array} \rangle
 \end{aligned}$$

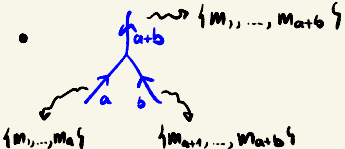

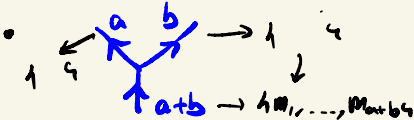

Theorem (Murakami-Ohtsuki-Yamada, 1998): these relations suffice to evaluate any closed web.

Theorem (Caotis-Kamnitzer-Morrison, 2014): the functor $\text{Web}_n \rightarrow \mathcal{C}$ is in fact an equivalence.

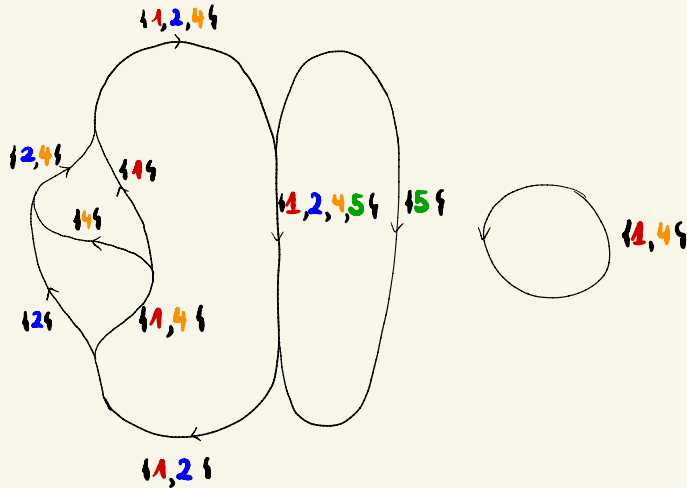

Coloring formula for web evaluation:

Let Γ be a closed web.

Definition: A coloring of Γ is an assignment of the edges to subsets of $\{1, 2, \dots, n\}$ such that:

- $|k| \leq m_k$
- 
- 

Example:

Let c be a coloring. For a pair of pigments $i, j \in \{1, 2, 3, \dots, n\}$, let

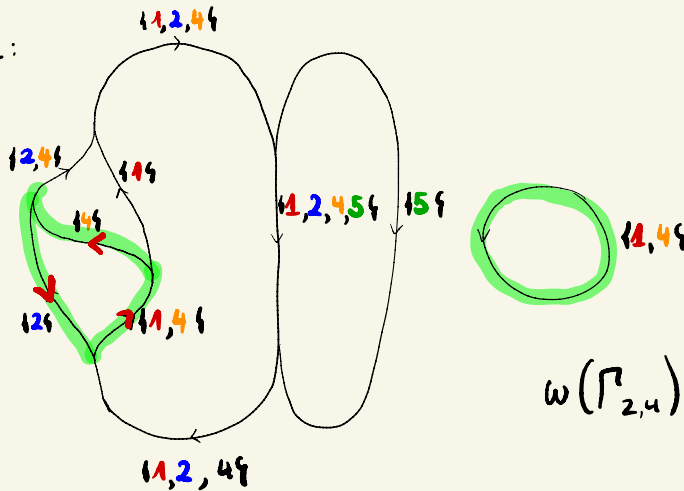

$$\Gamma_{ij}(c) = \{ \text{edges colored by } j \} \Delta \{ \text{edges colored by } i, \text{ reversed} \}$$

Define $w(\Gamma_{ij}) =$ signed # circles in Γ_{ij}

$$w(c) = \sum_{1 \leq i < j \leq n} w(\Gamma_{ij})$$

Write $\langle \Gamma, c \rangle = q^{w(c)}$

In the example:

$$w(\Gamma_{2,4}) = 2$$

$$\langle \Gamma, c \rangle = \sum q^c$$

Theorem (coloring formula for web evaluation)

$$\langle \Gamma \rangle = \sum_{c \in \text{col}(\Gamma)} \langle \Gamma, c \rangle$$

Corollary: $\langle \Gamma \rangle \in \mathbb{Z}_{\neq 0}[q, q^{-1}]$.

Clear for knots,
not so for webs

Categorification?

Specifically: $L \rightarrow H_*(L)$ s.t.

$$\langle L \rangle = \sum_i (-1)^i q^{\dim H_i(L)}$$

??

3. Foams (via Robert-Wagner evaluation)

Foams can be thought of as cobordisms of webs. More precisely:

A gl_n -foam is a finite 2-dimensional CW complex embedded in \mathbb{R}^3 with a thickness function $\{2\text{-cells in } F\} \rightarrow \{1, \dots, n\}$ such that the neighborhood of a point is homeomorphic to one of the following:

on a facet

on a binding

singular vertex

+ orientation condition
facets \leftrightarrow bindings

Examples:

Remark: facets may have "decorations", symmetric polynomials in (thickness)-many variables.

They behave multiplicatively:

$$\boxed{\begin{matrix} i \\ \cdot \\ i \end{matrix}} = \boxed{\begin{matrix} i \\ \cdot \\ i \end{matrix}}$$

Some motivation for what follows:

To a link we will associate a complex $C_*(\text{link})$ of graded modules over $\mathbb{Z}[x_1, \dots, x_n]^{\mathbb{S}_n}$

Inspiration comes from the sl_3 case, worked out by Khovanov. Khovanov's choices were in turn inspired by the sl_2 case (Khovanov homology).

• sl_2 : $C(\text{unknot}) = \text{TQFT}(\text{unknot}) = \mathbb{Z}[x] / (x^2) = H^*(\mathbb{C}P^1)$ after shift, graded rank is $q^{-1} + q = [2]$

• sl_3 : $C(\text{unknot})$? It should have graded rank $[3]$ so take $H^*(\mathbb{C}P^2) = \mathbb{Z}[x] / (x^3)$

$C(\frac{1}{2}\text{-twist})$? • It should have graded rank $\langle \frac{1}{2} \rangle_n = [3] \cdot [2]$

• It should have three $\mathbb{Z}[x] / (x^3)$ -module structures:

Take $H^*(\mathbb{F}P_3)$

$$H^*(\mathbb{F}P_3) = \mathbb{Z}[x_1, x_2, x_3] / (x_1 + x_2 + x_3, x_1 x_2 + x_2 x_3 + x_1 x_3, x_1 x_2 x_3)$$

Foam evaluation provides the "denominators" of these graded modules.

Define colorings as with webs:

Observations:

- $F_i = \bigcup$ facets containing i is an oriented surface
- $F_{ij} = \bigcup$ facets containing i XOR j is an oriented surface (take orientations of the facets containing i reversed)
- $F_{ij} = F_i \cap F_j \sqcup F_j \cap F_i$, and these meet at circles which inherit an orientation:

Dense Θ_{ij}^+ for the number of positive circles in F_{ij}

Degree of a foam:

Choose any coloring c and define $\chi_n(F) = \sum_{1 \leq i < j \leq n} \chi(F_{ij})$. "Weighted Euler characteristic"

Define the degree of F as $\deg(F) = -\chi_n(F) + 2 \sum_{\text{facets } f} \deg(P_f)$

↳ decoration on f

Foam evaluation

Foam $F \rightsquigarrow \langle F \rangle \in \mathbb{Z}[x_1, \dots, x_n]^{S_n}$

Robert and Wagner's idea: take inspiration from the coloring formula for web evaluation.

Denote $X = \{x_1, \dots, x_n\}$ and given $S \subset \{1, \dots, n\}$, $X_S = \{x_i : i \in S\}$.

$$\text{Define } \langle F, c \rangle = \frac{(-1)^{s(F,c)} \prod_{f \text{ facet}} P_f(X_{c(f)})}{\prod_{i < j} (x_i - x_j)^{\chi(F_{ij}(c))/2}}$$

Remark: $s(F,c)$ is given by $\sum_{i=1}^n i \frac{\chi(F_i(c))}{2} + \sum_{1 \leq i < j \leq n} \theta_{ij}^+(F,c)$

and finally: $\langle F \rangle = \sum_{c \in \text{col}(F)} \langle F, c \rangle$

Example: $n=3$,

$$c = \{1\} \Rightarrow \langle F, c \rangle = \frac{-x_1^3}{(x_1 - x_2)(x_1 - x_3)} \quad s(F,c) = 1$$

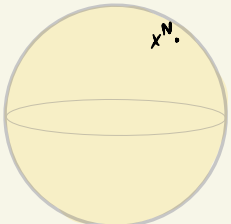

$$c = \{2\} \Rightarrow \langle F, c \rangle = \frac{x_2^3}{(x_1 - x_2)(x_2 - x_3)} \quad s(F,c) = 2$$

$$c = \{3\} \Rightarrow \langle F, c \rangle = \frac{-x_3^3}{(x_1 - x_3)(x_2 - x_3)} \quad s(F,c) = 3$$

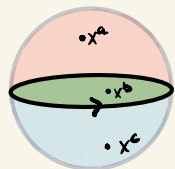

$$\langle F \rangle = \frac{-x_1^3(x_2 - x_3) + x_2^3(x_1 - x_3) - x_3^3(x_1 - x_2)}{(x_1 - x_2)(x_1 - x_3)(x_2 - x_3)}$$

$$\begin{aligned}
 \langle F \rangle &= \frac{-x_1^3(x_2-x_3) + x_2^3(x_1-x_3) - x_3^3(x_1-x_2)}{(x_1-x_2)(x_1-x_3)(x_2-x_3)} \\
 &= \frac{-x_1^3x_2 + x_1x_2^3 - x_2^3x_3 + x_3x_2^3 - x_3^3x_1 + x_1x_3^3}{x_1^2x_2 - x_1^2x_3 + x_2^2x_3 - x_2x_3^2 + x_3^2x_1 - x_3x_1^2} \\
 &= -(x_1 + x_2 + x_3) \quad (!)
 \end{aligned}$$

Example:

$$\begin{aligned}
 \left\langle \text{Sphere} \right\rangle &= \frac{-x_1^N(x_2-x_3) + x_2^N(x_1-x_3) - x_3^N(x_1-x_2)}{(x_1-x_2)(x_1-x_3)(x_2-x_3)} \\
 &= \frac{-\det \begin{pmatrix} x_1^N & x_1 & 1 \\ x_2^N & x_2 & 1 \\ x_3^N & x_3 & 1 \end{pmatrix}}{\text{Vandermonde}} = -S_{n-2,0,0}(x_1, x_2, x_3) = -\sum_{i+j+k=n-2} x_1^i x_2^j x_3^k
 \end{aligned}$$

Remark:  $\langle \text{Sphere} \rangle = S_{a-1, b-1, c}$, among many combinatorial relations.

It is almost immediate that $\langle F \rangle$ is a symmetric rational function

Fact: $\langle F \rangle$ is in fact a **polynomial**. Proof relatively painless but omitted.

4. A foamy link homology

We first define a functor $\mathcal{F}: \text{Foam}_n \longrightarrow \mathbb{Z}[X]\text{-gmod}$

\downarrow \downarrow
 (webs, foams between them) $\mathbb{Z}[x_1, \dots, x_n], \deg x_i = 2.$

On objects:

$$\Gamma \longmapsto W_n(\Gamma) / \text{Ker}(\ell \cdot, \cdot)_n$$

where: $W_n(\Gamma) =$ free module with basis foams with boundary $\emptyset \rightarrow \Gamma$

$$W_n(\text{ellipsoid with 3 points}) = \mathbb{Z}[X] \cdot \{ \text{cup}, \text{cup with bubble}, \text{cup with 3 foams} \}, \dots \{$$

and $(F, G)_n = \langle \bar{G} \circ F \rangle$

On morphisms: $F : \Gamma_1 \rightarrow \Gamma_2$ gives $W_n(\Gamma_1) \rightarrow W_n(\Gamma_2)$
 $G \mapsto F \circ G$

Note if $L \in W_n(\Gamma_2)$ is in $\text{Ker}((\cdot)_n)$ then $F \circ L \in \text{Ker}((\cdot)_n)$

This is the so-called **universal construction**. \rightarrow Works in much greater generality.

Theorem: $\mathcal{F}_n(\Gamma)$ is a free graded $\mathbb{Z}\langle X \rangle$ -module of graded rank $\langle \Gamma \rangle$.

Proof: We denote grading shifts as: $q^a \cdot M = M(a)$. One shows using the evaluation that:

$$\mathcal{F}_n(\emptyset) = \mathbb{Z}\langle X \rangle$$

$$\mathcal{F}_n(\bigcirc^a \sqcup \Gamma) = \mathcal{F}_n(\bigcirc^a \sqcup \Gamma) = \begin{bmatrix} n \\ a \end{bmatrix} \mathcal{F}_n(\Gamma).$$

$$\mathcal{F}_n \left(\begin{array}{c} \nearrow a \\ \diamond \\ \searrow b \\ \hline \nearrow \\ \searrow \\ \hline a+b \end{array} \right) = \begin{bmatrix} a+b \\ a \end{bmatrix} \mathcal{F}_n \left(\begin{array}{c} \uparrow \\ \hline \uparrow \\ \hline a+b \end{array} \right),$$

$$\mathcal{F}_n \left(\begin{array}{c} \nearrow a \quad \nearrow b \quad \nearrow c \\ \hline \searrow \\ \hline a+b+c \end{array} \right) = \mathcal{F}_n \left(\begin{array}{c} \nearrow a \quad \nearrow b \quad \nearrow c \\ \hline \searrow \\ \hline a+b+c \end{array} \right),$$

$$\mathcal{F}_n \left(\begin{array}{c} \uparrow \\ \hline \uparrow \\ \hline b \\ \hline \uparrow \\ \hline a \end{array} \right) = \begin{bmatrix} n-a \\ b \end{bmatrix} \mathcal{F}_n \left(\begin{array}{c} \uparrow \\ \hline \uparrow \\ \hline a \end{array} \right),$$

$$\mathcal{F}_n \left(\begin{array}{c} \begin{array}{ccc} \nearrow 1 & \nearrow a & \nearrow 1 \\ \hline \nearrow a+1 & \leftarrow & \searrow a+1 \\ \hline \nearrow a & \leftarrow & \searrow a \end{array} \\ \hline \end{array} \right) = \mathcal{F}_n \left(\begin{array}{c} \uparrow \\ \hline \uparrow \\ \hline a \end{array} \right) \oplus [n-a-1] \mathcal{F}_n \left(\begin{array}{c} \nearrow 1 \\ \hline \leftarrow a-1 \\ \hline \searrow a \end{array} \right),$$

$$\mathcal{F}_n \left(\begin{array}{c} \begin{array}{cc} \nearrow a & \nearrow b \\ \hline \nearrow a & \leftarrow 1 & \searrow b \\ \hline \nearrow a & \leftarrow 1 & \searrow b \end{array} \\ \hline \end{array} \right) = \mathcal{F}_n \left(\begin{array}{c} \begin{array}{cc} \nearrow a & \nearrow b \\ \hline \nearrow a & \leftarrow 1 & \searrow b \\ \hline \nearrow a & \leftarrow 1 & \searrow b \end{array} \right) \oplus [b-a] \mathcal{F}_n \left(\begin{array}{c} \uparrow \\ \hline \uparrow \\ \hline a \end{array} \right) \oplus \left(\begin{array}{c} \uparrow \\ \hline \uparrow \\ \hline b \end{array} \right).$$

Now any web reduces to \emptyset using finitely many of these relations. At each step we obtain a projective module.

Projective modules over $\mathbb{Z}\langle X \rangle$ are free.

The relations are those for web evaluation so we get $\text{grk}(\mathcal{F}(\Gamma)) = \langle \Gamma \rangle$. \square

What about the knots ?

Recall: we can rewrite the crossings as:

$$\langle \text{crossing} \rangle = \langle \text{crossing}_2 \rangle - q^{-1} \langle \text{parallel} \rangle, \quad \langle \text{crossing} \rangle = \langle \text{crossing}_2 \rangle - q \langle \text{parallel} \rangle$$

As in Khovanov homology, we categorify this as complexes, using \mathcal{F}_n as a sort of TQFT:

$$\mathcal{F}_n(\text{crossing}) = \mathcal{F}_n(\text{crossing}_2) \xrightarrow{\text{deg}-1} q^{-1} \mathcal{F}_n(\text{parallel}) \quad \mathcal{F}_n(\text{crossing}) = q \mathcal{F}_n(\text{parallel}) \xrightarrow{\text{deg}-1} \mathcal{F}_n(\text{crossing}_2)$$

So the complex associated to an oriented link diagram is

$$C(L) = \bigotimes_{\text{crossings } x} (\text{Complex at } x)$$

Theorem: This is an invariant of oriented links that categorifies the sln link polynomial.
(up to overall grading shift) (It's considered up to homotopy)

A generalization for free

In fact we can express any crossing as:

$$\langle \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \rangle = \sum_{k=\max(0, b-a)} (-1)^{k-b} q^{k-b} \langle \begin{array}{c} \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \\ \begin{array}{c} \xrightarrow{b-k} \\ \xrightarrow{k} \\ \xrightarrow{b-k} \\ \xrightarrow{k} \\ \xrightarrow{b-k} \\ \xrightarrow{k} \end{array} \end{array} \rangle$$

So we can form the more general **Rickard complex**:

$$\begin{aligned} \mathcal{F}_n \left(\begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \right) &= \mathcal{F}_n \left(\begin{array}{c} \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \\ \begin{array}{c} \xrightarrow{b} \\ \xrightarrow{b-a} \\ \xrightarrow{a} \\ \xrightarrow{b-a} \\ \xrightarrow{a} \end{array} \end{array} \right) \rightarrow q^{-1} \mathcal{F}_n \left(\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \\ \begin{array}{c} \xrightarrow{a-1} \\ \xrightarrow{b-1} \end{array} \end{array} \\ \begin{array}{c} \xrightarrow{a} \\ \xrightarrow{b-1} \\ \xrightarrow{a} \\ \xrightarrow{b-1} \end{array} \end{array} \right) \rightarrow q^{-1} \mathcal{F}_n \left(\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \\ \begin{array}{c} \xrightarrow{a-2} \\ \xrightarrow{b-2} \end{array} \end{array} \\ \begin{array}{c} \xrightarrow{a} \\ \xrightarrow{b-2} \\ \xrightarrow{a} \\ \xrightarrow{b-2} \end{array} \end{array} \right) \rightarrow \dots \\ \dots \rightarrow q^{1-a} \mathcal{F}_n \left(\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \\ \begin{array}{c} \xrightarrow{a} \\ \xrightarrow{b-a} \end{array} \end{array} \\ \begin{array}{c} \xrightarrow{a} \\ \xrightarrow{b-a} \\ \xrightarrow{a} \\ \xrightarrow{b-a} \end{array} \end{array} \right) \rightarrow q^a \mathcal{F}_n \left(\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \nearrow \\ \searrow \\ b \quad a \end{array} \\ \begin{array}{c} \xrightarrow{b-a} \\ \xrightarrow{a} \end{array} \end{array} \\ \begin{array}{c} \xrightarrow{a} \\ \xrightarrow{b-a} \\ \xrightarrow{a} \\ \xrightarrow{b-a} \end{array} \end{array} \right) \end{aligned}$$

(Similarly for negative crossings)

$$C_*(L) = \bigotimes_{\text{crossings } x} (\text{Complex at } x)$$

Theorem: This is an invariant of colored oriented links that categorifies the colored sln link polynomial.
(up to overall grading shift) (It's considered up to homotopy)

5. A cool application

Fact: $H_T^*(Fl_n) = \frac{\mathbb{Z}[T_i, X_i]}{P(X_i) - P(T_i), P \text{ sym poly}}$

and $H_T^*(Fl_n(a_1, \dots, a_n)) = H_T^*(Fl_n)^{S_{a_1} \times \dots \times S_{a_n}}$
 $\mathbb{C}^{a_1} \subseteq \mathbb{C}^{a_1+a_2} \subseteq \dots \subseteq \mathbb{C}^{a_1+\dots+a_n}$

Proposition (Robert-Wojnow):

$$H_T^*(Fl_n(a_1, \dots, a_n)) \cong \mathbb{F}_n \left(\begin{array}{c} \text{Diagram of a flag manifold } Fl_n(a_1, \dots, a_n) \end{array} \right)$$

The isomorphism is given by:

$$\prod_{i=1}^k s_{\lambda_i}(X_{a_i+1}, \dots, X_{a_{i+1}}) \mapsto$$

This can be used to compute the structure constants for $H_T^*(Fl_n(a_1, \dots, a_n))$ as a ring:

Thank you!
