

12. When two structures are secretly the same

We will be assigning

Just like we had a notion of equivalence of links:   $\cong$  

we have a notion of **isomorphism** of groups

For example, take  $G = (\mathbb{Z}, -1, \cdot)$  and  $H = (\{\text{True}, \text{False}\}, \text{XOR})$

$$\begin{array}{c|cc} & 1 & -1 \\ \hline 1 & 1 & -1 \\ -1 & -1 & 1 \end{array} \xleftrightarrow{\cong} \begin{array}{c|cc} & T & F \\ \hline T & T & F \\ F & F & T \end{array}$$

intuitively the same

How to make this mathematically precise?

## Sets

Definition: an isomorphism of sets is a function  $f: X \rightarrow Y$  such that

1. Different elements get sent to different elements  
if  $x \neq y$  then  $f(x) \neq f(y)$

Injectivity

2. Every element of  $Y$  is the image of some element of  $X$ .  
for all  $y \in Y$ , there exists  $x \in X$  such that  $y = f(x)$

Surjectivity

Example:  $f: \{1, 2, 3\} \rightarrow \{A, B, C\}$

$$f(1) = A$$

$$f(2) = B$$

$$f(3) = C$$

• Injectivity:

• Surjectivity:

We conclude that  $\{1, 2, 3\} \cong \{A, B, C\}$  and we say they are isomorphic as sets

Important observation: take a finite set, for instance

$X = \{ \text{members of this class} \}$

Then we can find an integer  $N \geq 0$  and an isomorphism

$$\{1, 2, 3, \dots, N\} \longrightarrow X$$

Definition: the number  $N$  above is called the **cardinality** of  $X$ , and is denoted  $|X|$ .

In other words: every finite set is isomorphic (as sets) to one of:

$$\{1\}, \{1, 1\}, \{1, 2\}, \{1, 2, 3\}, \{1, 2, 3, 4\}, \dots$$

Thus we have reached a **Classification of finite sets** (high brow counting)

# Groups

What does an **isomorphism of groups** look like?

Running example:  $\text{Sym}(\text{rectangle})$  and  $C_2 \times C_2$

Recall that we had

$$\text{Sym}(\text{rectangle}) = \left\{ \begin{array}{c} \text{D} \quad \text{C} \\ \text{---} \text{---} \\ \text{A} \quad \text{B} \\ \text{---} \text{---} \\ \text{A} \quad \text{B} \end{array} \right\} = \left\{ \begin{array}{c} \text{D} \quad \text{C} \\ \text{---} \text{---} \\ \text{A} \quad \text{B} \\ \text{---} \text{---} \\ \text{A} \quad \text{B} \\ \text{id} \end{array} \right\}, \left\{ \begin{array}{c} \text{A} \quad \text{B} \\ \text{---} \text{---} \\ \text{D} \quad \text{C} \\ \text{---} \text{---} \\ \text{D} \quad \text{C} \\ \text{V} \end{array} \right\}, \left\{ \begin{array}{c} \text{C} \quad \text{D} \\ \text{---} \text{---} \\ \text{B} \quad \text{A} \\ \text{---} \text{---} \\ \text{B} \quad \text{A} \\ \text{H} \end{array} \right\}, \left\{ \begin{array}{c} \text{B} \quad \text{A} \\ \text{---} \text{---} \\ \text{C} \quad \text{D} \\ \text{---} \text{---} \\ \text{C} \quad \text{D} \\ \text{R} \end{array} \right\} \right\}$$

$$C_2 \times C_2 = \{(0,0), (1,0), (0,1), (1,1)\}$$

They have the same cardinality, so they are **isomorphic as sets** (good start)

How about the operations?

Operation tables:

Sym (  )

|    | id | V  | H  | R  |
|----|----|----|----|----|
| id | id | V  | H  | R  |
| V  | V  | id | R  | H  |
| H  | H  | R  | id | V  |
| R  | R  | H  | V  | id |

$C_2 \times C_2$

|       | (0,0) | (1,0) | (0,1) | (1,1) |
|-------|-------|-------|-------|-------|
| (0,0) | (0,0) | (1,0) | (0,1) | (1,1) |
| (1,0) | (1,0) | (0,0) | (1,1) | (0,1) |
| (0,1) | (0,1) | (1,1) | (0,0) | (1,0) |
| (1,1) | (1,1) | (0,1) | (1,0) | (0,0) |

Sending

|    |                   |       |
|----|-------------------|-------|
| id | $\xrightarrow{f}$ | (0,0) |
| V  | $\xrightarrow{f}$ | (1,0) |
| H  | $\xrightarrow{f}$ | (0,1) |
| R  | $\xrightarrow{f}$ | (1,1) |

the tables "agree", in other words:

$$f(x * y) = f(x) * f(y)$$

We arrive at:

Definition: Let  $G$  and  $H$  be groups. A function  $f: G \rightarrow H$  is an **isomorphism of groups** if

1)  $f$  is an **isomorphism of sets**

2) For all  $x, y \in G$ ,  $f(x*y) = f(x)*f(y)$  " **$f$  respects the operation**"

If such an isomorphism exists, we say that  $G$  and  $H$  are **isomorphic** and we write  $G \cong H$ .

A fundamental question in Group Theory is:

Classify groups up to isomorphism

This is a monumental task, unlike the case of finite sets

We can, however, take on more modest tasks.

Question: Classify all groups of cardinality 2

Step 1: We have  $C_2 = (\{0, 1\}, +)$

Step 2: It seems that those are all the possibilities, so let's prove it.

Take some other group of cardinality 2. Say  $G = \{a, b\}$ .

Step 3: By the axioms, there is an identity element, let's say it's  $a$ . So we know:

$$a * a = a$$

$$a * b = b$$

$$b * a = b$$

Step 4: What are the possibilities for  $b * b$ ?

$$b * b = a \quad \text{or} \quad b * b = b$$

Then the map  $0 \mapsto a$   
 $1 \mapsto b$

is an isomorphism

Impossible:

**Conclusion:** there is exactly one group of cardinality 2 up to isomorphism

Exercises : classify up to isomorphism groups of small orders.
