If arXiv (which grew during its Los Alamos days, beginning in the early 1990s, to have an effective world-wide monopoly on distribution of contemporary theoretical physics information among the physicists of the world) censors possibly useful ideas such as (but not limited to) Peter's possibly very useful K-theory ideas, then the loss to physics is IMMEDIATE and SERIOUS, and should not be minimized as "things that are much like politics".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Peter, thanks for the Happy Holidays wishes. I am also celebrating Holidays through next week and the calendar New Year, and I join you in wishing everybody Happy Holidays of whatever kind they prefer.

December 24, 2005

Merry Christmas everyone!

-drl

17. **Not a Nobel Laureate**
December 25, 2005

Dr. Woit – thank you for your efforts in running this blog.

Wishing everyone a Merry Christmas and a Happy and Productive New Year.

18. **andy s.**
December 25, 2005

Why not approach the matter scientifically? You have a theory, namely that arxiv has a bug up its collective ass on the subject of Peter Woit.

Test this hypothesis by having someone other blogger make the same comments you do and see if they get deep sixed as well.

19. **Juan R.**
December 25, 2005

FP Said,

> Maybe it is a problem that arXiv has a quasi-monopoly as pre-print storage?
> Some competition is always healthy, but apparently nobody outside Cornell wants to do the job.

Perhaps you would click on the two links that i provided above. The quasi-monopoly of ArXiv administrators is explained in the letter recently published in Nature journal. Whereas that the Nobel laureate and some other people has launched an free alternative to ArXiv without censure (it is the reader who decides what is 'good' and what is not).

Juan R.

Interesting proposal. Do you believe that Peter Woit is exagerating?

I doubt it, but if your own reply is affirmative, please read first the material contained on links that i provided before obtaining your conclusions. For example the Nobel Prize for physics Brian D. Josephson (University of Cambridge) says in Nature

> The exclusion of particular individuals
> and particular ideas from arXiv appears
> to me to be deliberate.

Curiously some scientists have done experimental studies on ArXiv administration policies proving the premise. One of most interesting i know is the submiting of identical preprints to ArXiv from two different e-mails. Curiously the works submitted from *black listed* e-mails are automatically erased from the ArXiv at few minutes, whereas their copies were stored during days (until manually detected and erased). How can a preprint service reject works on function of e-mail. Would not works be rejected just in basis to scientific issues? For example if a preprint is flagrantly wrong (e.g. Lynds preprint) then would be erased.

Some empirical studies show a correlation coefficient of near 1 for the thesis of deliberate exclusion.

In this intersting blog i know at least three (if i count now to Woit) authors suffering 'censure' from ArXiv.

Juan R.

21. **D R Lunsford**
December 25, 2005

Why not just sue them? Something should be done to rein in those petit-Napoleons. Suing is the best option.

-drl

22. **anon**
December 25, 2005

Lunsford, a turkey breeding (or string theory) community can't afford a diversity that would make the most popular theory (strings/turkeys) look silly. I suggest you give up on trying to reform dictators; they just try to suppress all criticism and shoot the messengers. Instead of telling them what they don't like to hear and having them doing the shooting, you need to adopt more sturdy methods and go on a turkey cull. So I suggest you try building on alternatives to strings until one succeeds in doing more than string theory, then shoot, stuff and slowly roast the turkey.

Merry Christmas

23. **andy s.**
December 25, 2005

Juan R. I have no idea if it's going on or not, which is why I suggested the experiment.

Looks like somebody already thought of my idea. Story of my life.

24. **woit**
December 25, 2005

Danny and others,

I'm not the litigious sort, and this trackback issue is not one of great importance anyway, so I'm not about to sue anyone.

I don't think I should need to try to run experiments on their system to try and figure out what decisions it is making. The arXiv administrators and their advisory board have every right to decide that the kind of commentary that I've requested they post trackbacks to isn't part of legitimate professional discussion and that links to it should not be allowed on the arXiv. All I'm asking is to be informed about whether that's the decision they have made and if so to be assured that they take responsibility for and stand behind such a decision.

If that is their decision, I have a perfectly good venue here for saying what I think about it, and the rest of the community that is familiar with these matters can draw their own conclusions about what this means for the current state of one of the most important institutions in particle theory these days, and by implication, for the health of the field in general.

25. **D R Lunsford**
December 25, 2005

Peter,

I basically don't care what they do – as far as I'm concerned, they have about as much credibility as tachyons. I'm happy to be dissociated from them and have no plans to submit future work there.

But the stories are too similar to be discounted – e.g. what happened to Paul LaViolette happened to me as well (and my paper was *already* published), just as he stated – no answers, no explanations. Being unable to answer any questions, physics or administrative, must be habit-forming.

-drl

26. **Adrian Heathcote**
December 25, 2005

I think it's obvious that the reason they provide no explanation of their reasons for rejection is precisely that they fear being sued. If they don't explain then they provide no ammunition for a skilled attorney. I think it's unlikely that you will ever get anything out of them other than pro forma comments to the effect that 'the decision of what to accept is entirely in the hands of the administrators, blah blah blah'.

Merry Christmas to all

27. **ObsessiveMathsFreak**
December 25, 2005

When you were young, you assummed that scientists were a magnamous, logical and rational bunch. You had great faith in their ability to be imparital and to discern the truth through the application of scientific rigour. You also thought they had great integrity and were above petty actions as they aspired to the greater goal that was The Truth.

Then you grow up and hear about things like this and see that scientists are just as human as everyone else, pettiness included. It's still very disappointing though.

28. **Jose**
December 26, 2005

I've visited sciprint.org, a pretenended competence to arxiv.org, and there are very few papers. I've seen those of the mathematical physics section and none of them can be called a scientific paper, the authors expalin his theories in words, not with mathematics as should be for a physical theory.

29. **Alejandro Rivero**
December 26, 2005

Please note that we are not speaking in this thread about ArXiv articles, but about an ArXiV comment feature. As far as I understand, the comment feature has been suggested if not since the origins, at least since the web doorway of the ArXiV. It is only via Distler that it has been finally incorporated, and it is partial, experimental &c. We do not know how favourable to comments the rest of the ArXiV management are.

30. **woit**
December 26, 2005

Adrian,

The peculiar part of this story is the fact that I've been unable to get out of the arXiv even the sort of pro forma rejection that you describe.

ObsessiveMathsFreak,

I never had any great illusions that scientists were above human pettiness. But I must say that the lengths certain people are willing to go to avoid acknowledging the failures of string theory continues to surprise me, even now.

31. **anon**
December 26, 2005

Once they define string theory as being such a beautiful piece of genuine science, they are actually defending science by censoring out criticism. You have to see this from their warped perspective!

32. **D R Lunsford**
December 26, 2005

It all sounds like groupthink (make up your own examples):

1) Having an illusion of invulnerability
2) Rationalizing poor decisions
3) Believing in the group's morality
4) Sharing stereotypes which guide the decision
5) Exercising direct pressure on others
6) Not expressing your true feelings
7) Maintaining an illusion of unanimity
8) Using mindguards to protect the group from negative information

8) is particularly relevant.

Groupthink seems to be at the bottom of much of our (USA) current dysfunction. Countless examples could be adduced. The Shuttle Columbia and World Trade Center disasters come to mind immediately. (Iraq? New Orleans? the list is endless…)

-drl

33. **Dumb Biologist**
December 27, 2005

Sorry to see this blog has been excluded, though not surprised.

A totally shameful event in the field of biology has been the revelation of fraud in the human embryonic stem cell field, which everyone has heard about already. Amid all the legitimate beating of breasts and rending of garments shall come, I hope, a grateful recognition of the fact that the fraud was revealed, and corrective measures could be taken. Nature being the final arbiter, and all, the truth will aways out. I'm not sure if the fact the outing took place essentially outside of the conventional system of peer review (which appears to have completely broken down, and in Science, of all journals) is something to be happy or unhappy about. Again, I guess it's nice to know smacking into the "real world" will eventually correct for the failings of human investigators, if and when no human mechanism is up to the task.

Unfortunately, at least in some branches of theoretical physics, it seems investigators have forged ahead so far away from attainable real-world checks and benchmarks that the system of peer review is all they've got, or perhaps will have, for a very, very long time. How could the tyranny of groupthink not prevail in such an environment? It's functionally equivalent to a church. Very sad.

34. **Jose**
December 27, 2005

A question:

does http://www.physcomments.org/ pertain to arxiv.org?

I ask this question because there appears a link to this blog, so perhaps censorship is not an appropriate word.

35. **Alejandro Rivero**
December 27, 2005

Jose,

No, it does not pertain to the ArXiV. I pay from my pocket money both the domain and the hosting, as it is explained in the About…

The status of PhysComments about trackbacks has been evolving. It started bad, because of my so-called "spam" to people in the references of each preprint, and because this system included the possibility of anonymous commenters. I have agreed to identify the people commenting in the blog (this is the goal of the line "A comment by…" and now it seems I am allowed to send trackbacks. Of course, one never knows when this permission can change again.

36. **MathPhys**
December 27, 2005

Peter,

While I agree with you that Jacque Distler's behaviour is petty (he's normally a nice man, actually), the current status of string theory is serious business to certain academics: It makes it very hard to apply for promotions, get grants, students, etc, things that materially affects people's lives. I can understand the bitterness (but not condone it).

37. **Peter Wilson**
December 27, 2005

Peter,

After privately censoring me three times (before the cock's call, I might add), you lambast the powers-that-be for censorship.

Nice work!

38. **woit**
December 27, 2005

Peter Wilson,

As I wrote in another comment, I'm not opposed to censorship per se, and some sort of moderation (or censorship if you will….) is necessary in many contexts to maintain a useful forum for information and discussion. The difference here is that I take full responsibility for what I am doing, and will respond to any polite request asking to know why I've deleted a certain comment. I don't remember yours in particular. I do delete a sizable number of comments submitted here, virtually all on the grounds that they are off the topic of the posting. If I don't do this, experience shows that such off-topic posting overwhelm other discussion.

The arxiv has every right to not include trackbacks to my postings. But I believe that they should respond in some way to my polite requests asking what is going on. I have been having a hard time finding out even whether they have decided not to include my trackbacks. The only evidence I have at the moment that they have made such a decision is based on private communications from people who have partial knowledge of what is going on, and insist that I not use their names, since this is evidently a highly contentious issue there.

39. **Matthew**
December 27, 2005

"what happened to Paul LaViolette"

Right. What happened to him is that he got ignored, as he deserved to be, after bugging a ninety-three year old to try to get his paper published.

40. **Arun**
December 27, 2005

I would understand a arxiv policy that disallowed trackbacks to any forum that allowed anonymous posting. But whatever the policy is, it should be made explicit.

41. **JC**
December 28, 2005

MathPhys, and others,

(slightly offtopic)

I wonder how much of the "defense" for the legitimacy of string theory these days has to do with maintaining the gravy train of things like funding grants, promotions, etc … I'm sure it would look pretty bad if all the untenured faculty hired to do string theory over the last few years, all suddenly had most or all of their grant funding yanked before tenure decisions are made. Most people don't want to have to "save face" for their bad decisions. For the case of a physics department who hired string folks for assistant professor jobs, I can imagine things would not look too good for them if their "star" string theorists were denied tenure.

For an untenured string person from a more down to earth and/or selfish perspective, I can imagine that maintaining the string gravy train until a "day of reckoning" or falling into obscurity, as more of a "stalling" tactic until most or all of the present untenured string folks are awarded tenure. Then afterwards if the entire string enterprise collapses under it's own anthropic weight, it wouldn't matter anyways since they already got tenure.

42. **Eli Rabett**
December 28, 2005

ArXiv is partially funded by NSF. A call to NSF, or even an Email to ArXiv asking whether their policy conforms to their NSF funding requirements might be a lot more successful. It seems to me that they would be allowed to reject postings and trackbacks but would have to have a stated policy that was applied uniformly.

The most interesting thing to me about ArXiv is that it represents a fundamental change in policy for the US. When I was going to university in the 1960s, several people who were in a position to know told me that after WWII the question arose as to how the government should, could or would encourage scientific publication. Two models were proposed, direct funding of publications sponsored by organizations such as APS or ACS, or providing page charges as part of grants. The latter was adopted because it would encourage for profit publishing organizations as well. ArXiv and PubMed are direct challenges to the previous policy.

43. **Chris W.**
December 28, 2005

Eli,

Speaking of the for-profit publishers, how do they feel these days about arXiv.org? How often (if at all) do preprints get taken offline because a publisher insists upon it? Given the current contention between the big publishers and the library community, and the litigiousness of the AAP, I would think that preprint servers would be as sensitive a topic as ever right now.

(NOTE: I'm not a professional academic, so I'm a bit out of touch with the on-the-ground realities in this area.)

44. **Tony Smith**
December 30, 2005

Since censorship and Cornell both seem to be involved in this thread, here is a quote from the book Cosmos (first edition, Random House, 1980, at page 91) by Carl Sagan, then "Director of the Laboratory for Planetary Studies and David Duncan Professor of Astronomy and Space Sciences at Cornell University":

"… The worst aspect of the Velikovsky affair is not that his hypotheses were wrong or in contradiction to fimly established facts, but that some who called themselves scientists attempted to suppress Velikovsky's work.

Science is generated by and devoted to free inquiry: the idea that any hypothesis, no matter how strange, deserves to be considered on its merits.

The suppression of uncomfortable ideas may be common in religion and politics, but it is not the path to knowledge; it has no place in the endeavor of science.

We do not know in advance who will discover fundamental new insights. …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

45. **Rien**
December 31, 2005

Chris W,
Preprints don't get taken offline, all the relevant publishers allow arxiving. If they didn't, nobody would publish in their journals. Some of them actually say you're not allowed to update the eprint to reflect the published version but I don't think anyone cares about that. At least I don't.

In fact, preprints can't be removed once they're submitted, even if they are withdrawn the older versions are still available.

46. **John Gonsowski**
December 31, 2005

Wonder what former Cornell and current Columbia string theory guru Brian Greene would think about this thread?

47. **FS**
December 31, 2005

There is an International Mafia in Science which controls ideas, awards
felowships and prizes,
and ignores or even boycotts people who have different opinions than theirs.

A Few New Links

December 27, 2005
Categories: Uncategorized

Eckhard Meinrenken has been teaching a course at Toronto on Lie groups and Clifford algebras, and he has lecture notes available. This is beautiful mathematics and brings together several of my favorite mathematical topics: Clifford algebras, spinors, and representation theory of Lie groups. Some of this material is quite new, and very possibly has interesting applications in physics.

Dennis Gaitsgory, a new young tenured member of the Harvard math department, has been teaching a course on Geometric Representation Theory, and also has lecture notes available. These explain the "D-module" point of view on the subject.

My Columbia math department colleague D. H. Phong and fellow ex-Princeton grad student Eric D' Hoker have a new paper on the arXiv called Complex Geometry and Supergeometry. It is based on Phong's recent lecture at this year's Current Developments in Mathematics conference at Harvard last month. D' Hoker and Phong have been able to explicitly write down and show finiteness of superstring amplitudes at two loops, with the problem still remaining open at higher loops.

The arXiv web-site has a new look today. Gone are Paul Ginsparg's "skull and cross-bones" icons like this.

5. **Samuel Prime**
   December 28, 2005

   These Clifford algebra notes look good and are worth having. Thanks for mentioning it. I had a colleague long ago give seminar lectures on them, which i really enjoyed. Admittedly, I have used Clifford algebras only sparingly in relation to K-theory of C*-algebras (through Connes' work). (Particularly, C^{p,q} = R^p + R^q.)

6. **D R Lunsford**
   December 29, 2005

   It's very dry, what? (When did lively style go out of fashion, then?) For physics, this sort of approach is hopeless. He took a lively idea and made it seem dull. That took skill.

   Why (in these papers) is it always about restating the known?

   (Arun: extremely funny 🙂

   -drl

7. **D R Lunsford**
   December 29, 2005

   Siegel has the best line of all time about ST:

   "Cosmology is the opposite of string theory: Instead of starting with 10 or 11 dimensions, and compactifying most of them, you start with no dimensions (except time), and the Big Bang uncompactifies 3 of them."

   ..and a candidate for the best footnote ever:

"500 – No, it's really an exponent, not a footnote. You don't seriously think there could realistically be 500 footnotes, do you?"

-drl

8. **Levi**
   December 29, 2005

   I printed out all 96 pages of the lecture notes by Meinrenken. Nice stuff. Reading them carefully could take a while though…

9. **Tony Smith**
   December 30, 2005

   Peter, you said "… The arXiv web-site has a new look today. Gone are Paul Ginsparg's "skull and cross-bones" icons …".

   Just to be nit-picking historically, the "skull and cross-bones" icons were NOT the ORIGINAL logo/icons of what is now called the Cornell arXiv. IIRC, the first web site was at http://MENTOR.LANL.GOV/ and its logo/icon was the image that I have attempted to preserve for posterity at http://www.valdostamuseum.org/hamsmith/Mentor.gif (as you can see, it is more related to Ancient Egyptian Pyramids than to the more recent ocean pirates).

10. **jeffrey collins**
    January 11, 2006

    String theory offers promsie, but we do have as of yet a fundamentally satisfying way to falisfy it, or prove it true. The LHC will certainly give us some answers, but sheer philosophy about the string is simply not science. Something is missing, and we do not know-yet–what we are missing.

Jerusalem Winter School

December 29, 2005
Categories: Uncategorized

The 23rd Jerusalem Winter School in Theoretical Physics started yesterday. The topic is "String Theory: Symmetries and Dynamics", and it is organized by David Gross and Eliezer Rabinovici.

Some of the talks are already available on-line, with the quality of the video and audio very good, although you need the latest version of Apple's Quicktime player. In his opening talk, Gross mentioned the recent New Scientist article quoting him as admitting string theory was in trouble, saying that the article misrepresented what he said. At the recent Solvay conference he had said something like "In string theory we don't know what we are talking about", and the New Scientist reporter interpreted that as meaning there was trouble, an interpretation Gross disagreed with. He was annoyed by the New Scientist editorial about the sorry state of string theory, and says he has been offered the opportunity to write a rebuttal and may do so. Gross went on to claim that really string theory is a vital subject and that it is in a wonderful period. He didn't mention the Landscape.

Update: Another recent particle theory conference was the Christmas Meeting at Durham. There's a report from the conference by blogger Paul Cook. Evidently Herman Verlinde is taking bets that string theory is the correct unified theory. Those who want to make some easy money might want to contact him. Then again, it's unclear when you would get paid.

Update: The lectures by my Princeton classmate Igor Klebanov on using string theory to study strongly coupled gauge theories are particularly clear and interesting. Near the beginning he mentions this blog quoting it as saying "String theory is not good for anything." I'd like to emphasize that that is not something I wrote or something that I think, I assume he is referring to one of my commenters.

Comments

1. **Alejandro Rivero**
   December 29, 2005

   I had already suggested that it was just a misinterpretation of a very repeated slogan about M-theory.

2. **Chris Oakley**
   December 29, 2005

   I suppose that this means that the plea, "Never, never, never, never give up!" will have to be changed to "Never, never, never, never, never, never, never, never, never, never, never, give up!"

   I am sure that Winston Churchill would have admired their determination, if not their judgement.

3. **garrett**
   December 29, 2005

   And here I thought De Nile was only near Jarusalem, and not actually in it.

4. **Danger**
   December 29, 2005

   NSF crackpot fund.

   Once you realize how many millions are at stake, it's easier to understand the String Theorist's supreme commitment to inceipherable nonesense.

   http://www.nsf.gov/awardsearch/piSearch.do;jsessionid=12140160808182889516AF72BFC8F425?SearchType=piSearch&page=1&QueryText=string&Search=Search#results

5. **Quantoken**
   December 30, 2005

   It doesn't matter what Gross says about super string theory. SST already has the endorsement of the greatest mathematician of all times and greatest physicist since Sir Newton, Einstein notwithstanding, Mr. Edward Witten, it also has the endorsement of the most famous physicist since the invention of Television, Mr. Michio Kaku, and the endorsement of a number of other big guys. Who is Gross to say either way about SST?

   At the end of day, only facts speak the truth. The true is still that SST is in trouble after more than 2 decades, whether Gross agree or disagree with that notion.

6. **MathPhys**
   December 30, 2005

   I think the problem with a web site such as this, is that it attracts more than its share of crackpots. That's probably inevitable.

7. **Tony Smith**
   December 30, 2005

   Danger said "… Once you realize how many millions are at stake, it's easier to understand the String Theorist's supreme commitment to inceipherable nonesense. …" and then cited a search link at http://www.nsf.gov/awardsearch/ for the word "string". I did a similar search for the word "superstring", and here are four large grants on the resulting list:

   0098527
   Theoretical Physics
   PHY CENTRAL & EASTERN EUROPE PROGR, ELEMENTARY PARTICLE THEORY
   08/15/2001
   Smith, John
   NY

SUNY at Stony Brook
$1,552,181.00

0354776
Theoretical Physics
PHY
ELEMENTARY PARTICLE THEORY
08/01/2004
Smith, John
NY
SUNY at Stony Brook
$986,000.00

0098395
Problems in Theoretical Physics
PHY
ELEMENTARY PARTICLE THEORY
08/15/2001
Sugar, Robert
CA
University of California-Santa Barbara
$2,068,257.00

0098840
PHYSICS: THEORY OF ELEMENTARY PARTICLES
PHY
ELEMENTARY PARTICLE THEORY
09/01/2001
Murayama, Hitoshi
CA
University of California-Berkeley
$2,242,047.00

Of course, superstrings get funding from agencies other than the NSF, so these may not be the largest government grants to superstrings, but it seems to me that they indicate that a slogan for present-day physicists might be (to use a word from Danger's comment):

NONSENSE PAYS .

Tony Smith
http://www.valdostamuseum.org/hamsmith/

8. **A.J.**
December 30, 2005

Tony Smith — Nice research finding the grant figures, but your interpretation is a bit off. Please note that none of the grant recipients are actually string theorists. Jack Smith and Hitoshi Murayama are well-known phenomenologists, and Robert Sugar does lattice gauge theories. They might have tossed string theory into their grant applications as a buzzword, but I can guarantee that only a small fraction of that money is supporting string theory research. Most of that money is being spent on down-to-earth particle physics.

(Frankly, if the NSF were dumping as much money into strings as you guys imagine, then there would be far more funding for string theory graduate students. As it is, at all but the wealthiest schools, there's usually not enough to go around.)

9. **woit**
December 30, 2005

A.J. and Tony,

One thing to remember is that many of these grants are group grants: they fund all or most of the particle theory group at an institution. So, even if only part of the group is doing string theory, string theory will appear in the proposal. Even if the P.I. doesn't do string theory, many of these group grants do include string theorists.

If you want to figure out how much is actually going to string theory, you need to get ahold of the detailed budgets and see where the money goes. If you can do that, you have the added bonus of being able to compute the actual salaries of most of the people involved…

10. **Anonymous**
December 30, 2005

Another thing to keep in mind is that these grants generally cover multiple years. Paying the salaries of a few postdocs over a few years adds up to a reasonable amount of money, but it's not as if anyone is making millions each year doing string theory! String theorists earn approximately the same amount of money as other physicists, generally speaking, but their research requires comparatively little money. Most of the money going to physics goes to experiment (as it should!), where the research itself can require astronomical amounts of funding. There is always much more money to support experimental graduate students than theory graduate students (again, this is as it should be!).

Tony, I suggest you think twice about what you label as "nonsense." As A.J. says, much of what is being funded from those numbers is not string theory. Hitoshi is a good example of a particle theorist whose work is mostly guided by experiment. It might be true that much of what comes out of particle theory these days isn't very good, but that's because it's hard to work without experimental guidance. Wait five or ten years for LHC results and then we'll see who's still producing nonsense and who isn't. (Maybe even some of the hardcore stringers will switch!)

Peter, thanks for the link to the Jerusalem school. The lectures are nice and pedagogical, and steer clear of the more dubious parts of recent string theory research. It's interesting that Kutasov speculates there might be different universality classes of string theories and that so far everyone might be focusing on ones that don't describe the real world.

December 30, 2005

MathPhys says:
I think the problem with a web site such as this, is that it attracts more than its share of crackpots. That's probably inevitable.

Hmmm, I wonder if that's true. This anti-string theory site seems to attract a fair number of well-known reputable scientists. I wonder what the mean education level is here and at other science blogs.

12. **Tony Smith**
December 30, 2005

Anonymous suggests that I should "… think twice about what …[I]… label as "nonsense." As A.J. says, much of what is being funded from those numbers is not string theory. …".
That is a point well taken.
Although I do regard much of conventional superstring theory to be nonsense as physics (and all the grants I listed were for funding for physics, and not interesting related mathematics etc), l do agree that any part of those funds going to experiment might be well spent, at least if the experiments are truly fair searches for unexpected new phenomena, and not narrowly focussed by triggers and cuts to look only for those phenomena that are expected by conventional superstring theorists.

I fear that LHC might not turn out to be as useful as it might be if all the cuts and triggers are set by consensus expectations of currently popular theoretical models. I certainly hope that Anonymous is correct in stating "… Wait five or ten years for LHC results and then we'll see who's still producing nonsense and who isn't. (Maybe even some of the hardcore stringers will switch!) …".

I also wish that Anonymous were not Anonymous, so that I would know more about the background of a person whose comments seem reasonable to me. However, anonymity can be interesting – I have often toyed with the idea of submitting comments, etc, through a sock puppet so that I could make a comparison of responses, but I have not yet done so.

December 31, 2005

LHC triggers will find events with high-energy leptons or photons, with large missing transverse energy (a sign of invisible stable particles, as expected in SUSY, but maybe in other things as well), or events with sufficiently many high-energy jets. It's hard to think of new physics that wouldn't be found by decays to high-energy Standard Model particles, so this is pretty flexible. Even more bizarre scenarios with long-lived charge particles have been studied and can generally be found. It's hard to think of how to make the triggers accept more things without overloading the available bandwidth; accepting more low-energy jets is impossible, for instance, because of QCD background. The limitations on the hardware and software for triggering are very strict, so it is pretty highly optimized. Of course, if you have ideas of plausible new physics that wouldn't be found by the triggers, you should start bugging people about it!

14. **Tony Smith**
January 1, 2006

Anonymous said that if I "… have ideas of plausible new physics that wouldn't be found by the triggers …", then I "… should start bugging people about it! …".

My main concern is that observation of T-quark events may limited by cuts to the energy region within a few GeV of the 173 GeV peak that was observed at Fermilab, whereas
it seems to me (in my unconventional opinion) that Fermilab's T-quark event data also shows two other "peaks", or "regions of interest" within 10% or so of about 130-140 GeV and 225 GeV, and therefore I would like to see cuts set so that those regions are also studied at least to some degree.

I think that a set of 3 peaks around 130-140, 173, and 225 GeV might indicate that the Fermilab observed T-quark events are NOT simple decay of an isolated quark, but are due to an interesting 3-element system involving the Vacuum, the Higgs, and a T-quark condensate, described by Nambu-Jona-Lasinio and variants thereof. Some material about those ideas can be found at http://www.valdostamuseum.org/hamsmith/YamawakiCP2KKNJL.html with more details being available on other pages of that web site.

I did present this idea at the APS DPF meeting in Tampa in April 2005 in a session chaired by Joe Lykken, and he seemed to have some interest in it at the time, but I have heard nothing further, so I assume that it is not being pursued.

Unfortunately, my status of being blacklisted by the Cornell arXiv affects my reputation in the physics community adversely, and a probable consequence thereof is that if I were to "start bugging people about it", it might do more harm than good.

Tony Smith

15. **anon**
January 1, 2006

If you don't bug other people, nothine ever gets done.

"… the innovator has for enemies all those who have done well under the old conditions, and lukewarm defenders in those who may do well under the new. This coolness arises partly from fear of the opponents, who have the laws on their side, and partly from the incredulity of men, who do not readily believe in new things until they have had a long experience of them. Thus it happens that whenever those who are hostile have the opportunity to attack they do it like partisans, whilst the others defend lukewarmly…" – http://www.constitution.org/mac/prince06.htm

16. **Anonymous**
January 1, 2006

Tony, the good thing about complaints like yours is that they are issues of analysis, not of triggering. The data are there, you just have to convince someone to analyze the right mass windows. And as anon says, the only way to do that is to bug people in the experiments.

17. **Tony Smith**
January 1, 2006

Anonynmous is quite correct in saying "… The data are there, you just have to convince someone to analyze the right mass windows. …".
Also, Anonymous is probably correct in saying "… as anon says, the only way to do that is to bug people in the experiments. …".
However, my capability of bugging people has severe limitations, including the following:

1 – I have no institutional affiliation through which to "bug" LHC people by contacting them through institutional channels;
2 – I did speak at APS DPF April 2005, but such talks alone seem to be ineffective (most people at such big conferences seem to me to spend almost all their time with like-minded people, lining up support for grants, jobs for their students, etc);
3 – I can speak my mind on a forum such as this blog or on my web site (and as you can see I have done so), but blacklisting prevents me putting a series of papers about the issues on the relevant parts of Cornell arXiv, thus eliminating a very effective way to "bug" LHC people;
4 – The fact that I am blacklisted not only diminishes my reputation in the physics community, it also apparently frightens some in the physics community so much that they seem to be afraid to be associated with me.

As to anon's advice to me in comment 16 hereinabove:

It is sad enough that there has been very little advance in elementary particle theory since the 1970s (when the Standard Model was developed),
but it is far sadder still that
back in 1980, in his book Cosmos, Carl Sagan could say "… The suppression of uncomfortable ideas may be common in religion and politics, but it is not the path to knowledge; it has no place in the endeavor of science. …",
while
now in 2005/2006, Machiavelli is considered to be the teacher who must be followed in order to succeed in elementary particle physics.

Maybe the leaders of today's theoretical particle physics establishment should be asked the McCarthy question:

HAVE YOU NO SHAME ?

involving topics in BOTH string theory and LQG , with back-to-back
lectures in both topics.
http://www.iucaa.ernet.in/~scveu
Hope the slides get archived.

19. **Anonymous**
January 1, 2006

Tony, I have one more suggestion. Your website is somewhat disorganized, full of long quotes, and hard to approach. Also, it advocates a number of very speculative ideas. I, for one, find it hard to isolate the parts of it that I might think are interesting. I hope you will not be offended if I suggest that in part the reason you are not listened to is that you are not effective in communicating in the typical language of physics and physicists.

It is possible for someone to be interested in your ideas about the top quark data without being interested in the bulk of your website. An experimentalist you might convince to take a closer look at the data would likely fall into this class.

Thus, if you could write up a clean (preferably TeX'ed, available as PDF) account *soley of the top quark data*, with general remarks about why one might expect multiple apparent masses to show up in data (top condensates, etc….), and indications of what you think are the hints that these in fact *do* show up in the data, I think you would be *far* more likely to get a response from someone. Divorce your idea about re-analyzing the data from particular ideas about new physics. The RG arguments for a particular heavy top mass are fairly well-known, but the general attitude is that since we found it somewhere else, those models must be too simplistic. You really need to argue from the data, at least partly. Also, reliance on NJL models is not so great; qualitatively they're very interesting, but as non-renormalizable field theories one doesn't tend to trust exact numbers from them, since one tends to view them as effective theories modified by other new physics we don't understand.

If you produced a clean, well-argued document focusing *only* on top quark physics, I think at least a small number of people would read it. If it's *convincing*, one of those people might be able to do something about it.

One last note: you would be wise to not take the tone that you are certain to be right. It grates on the people who have done difficult experimental work over the past decade or more. You should suggest this as interesting, potentially overlooked physics, not as truth. And it would help if you exhibit some willingness to admit you might be wrong and the experimentalists so far might be right. (Even if there are hints of something at other masses, the amount of data is likely too small to say anything definitive at this point. Don't mistake caution on the part of Fermilab experimentalists for conspiracy.)

Best of luck.

20. **Tony Smith**
January 1, 2006

Anonymous is quite correct that my website "… is somewhat disorganized, full of long quotes, and hard to approach. Also, it advocates a number of very speculative ideas. …".
However, I view my web site as my home, containing all sorts of stuff from oil and politics to Jesus and Mary Magdalene to math and physics, and a lot more. It is not intended to be a clear exposition of a single topic (such as LHC cuts for T-quark candidate events).

Anonymous also said that it might be good for me to "… write up a clean (preferably TeX'ed, available as PDF) account *soley of the top quark data*, with general remarks about why one might expect multiple apparent masses to show up in data (top condensates, etc….), and indications of what you think are the hints that these in fact *do* show up in the data …".
That is substantially what I did for my 10-minute talk at APD DPF 2005 in Tampa, and, as I said, the chair (Joe Lykken) seemed interested at the time, and there is a pdf version of that talk on my web site at http://www.valdostamuseum.org/hamsmith/YamawakiNJL.pdf However, it is not in LaTex because I was using the pdf file projected from my computer onto the screen as the basis for my talk. Even if I did convert it to a standard-academic-LaTeX look, there is no place that I can post it where LHC folks can read it (without it being on my web site, which as you point out they might dislike due to it containing a lot of controversial stuff) because I am blacklisted by the Cornell arXiv and the CERN EXT preprint series has been terminated.

Anonymous also said "… reliance on NJL models is not so great … as non-renormalizable field theories one doesn't tend to trust exact numbers from them, since one tends to view them as effective theories modified by other new physics we don't understand …".
That is true of pure NJL (which might decribe one of the 3 peaks from my point of view), but the variants of NJL which might describe the other 2 peaks may include renormalizable structures that would in fact be the "new physics" of which pure NJL is a corresponding effective theory, as has been indicated by the work of Yamawaki in hep-ph/9603293 and of Hashimoto, Tanabashi, and Yamawaki in hep-ph/0311165. All this is work in progress, but a lot of work has been done including some numerical calculations that can be compared with experiment, and I find it sad that some people who advocate conventional superstring theory (which seems to me

obviously to be far more incomplete) might attack Yamawaki-type models because they may not yet be completely perfected.

Anonymous also said that I "… would be wise to not take the tone that you are certain to be right. … Don't mistake caution on the part of Fermilab experimentalists for conspiracy. …".
If I have ever said anything to the effect that I am "certain" to be "right" about ANYTHING, I apologize and retract it. My whole life and everything I do is only a work in progress, and I NEVER expect to achieve "certainty" in this lifetime.
However, at any given time I do have a certain amount of enthusiasm for the ideas that I hold in the moment, and it is hard to suppress that enthusiasm, but over the years I have always been happiest when I found a flaw in a model and then reworked it, either correcting it and making it better, or finding that the model was irreparably flawed, and thereupon throwing it out and not worrying with it any more. I do apologize if that enthusiasm appears to be certainty.

As to "conspiracy" of "Fermilab experimentalists", I think that "conspiracy" is not a correct description, but, based on years of personal experience, and also on the book The Evidence for the Top Quark: Objectivity and Bias in Collaborative Experimentation, by Kent W. Staley (Cambridge University Press 2004), I feel that the organizational structure of Fermilab has produced some results that might, from the outside, reasonably be perceived as conspiratorial, although they were actually probably produced by dysfunctional aspects of Fermilab bureaucracy.

I don't think that Peter's blog is the place to go into any further detail on such things, but I would be willing to participate in e-mail discussion of further details.

January 2, 2006

Tony,

(I'm not saying this to be belligerent).

Most folks seem to already have a lot of stuff on their plates, and don't really want anymore stuff to deal with. Whether it's from physical and/or mental exhaustion, there's only so much stuff which can be done in a day. In some fields, such as string theory, just keeping up with the current literature is almost equivalent to a full time job.

For many folks when they are young and full of enthusisam, it's easy to want to read a lot of books and papers, and working out a lot of calculations. When the same folks get older and into academic (ie. professor) type jobs, there's a lot more stuff on their plates such as teaching, bureaucratic, etc … type duties. With all kinds of stuff on their plates, there's only so much time which can be allocated to reading new papers, that one has to pick and choose and be more selective. There isn't enough hours in the day to still work like a grad student or postdoc, especially if one also has more outside commitments like a family.

Whether somebody's research is right or wrong in the long term, is largely irrelevent when it comes to short term funding issues. (Just have to ask some older professors who worked on analytic S-Matrix theory in the 1960's). It's unfortunate the system works this way, with funding issues governing the direction of research and the "herding" mentality which comes with it.

22. **D R Lunsford**
January 2, 2006

I love Tony's website, it's full of interesting things. The 3-d diagrams of various polytopes alone are worth the time spent visiting.

-drl

23. **John Gonsowski**
January 3, 2006

Some experiments seem to have low signal to noise ratios that make them easy targets for the "herding". I would not want to have my bets on physics decided by "herded" experiments.

Those A-D-E series polytopes (and the associated Triality) are the main reasons I became certain Tony is right. Not actually being Tony, I'm allowed to say that, right? I'll finish making my own page about this some time soon but it's hard to put intuition into words so hopefully the pictures talk well.

One visitor to Tony's site told me he found the linear organization of Tony's downloadable e-book easier to use. I think you can get the same effect by using the outline you get to through Tony's "Keywords" link.

What Is Your Dangerous Idea?

January 2, 2006
Categories: Uncategorized

John Brockman's Edge web-site has an annual feature where he asks a wide array of scientists and others how they would answer a hopefully thought-provoking question. Last year the question was What Do You Believe Is True Even Though You Cannot Prove It? This year it's What Is Your Dangerous Idea?

There are responses to this question from 117 different people, a large fraction of them psychologists or cognitive scientists. Among the responses from physicists, several deal with the Landscape as a dangerous idea. Susskind takes credit for it, noting "I have been accused of advocating an extremely dangerous idea", and that some of his colleagues believe it will lead to the end of science, leaving no way to defend physics as a truer path to knowledge than religion. He proudly describes the anthropic Landscape idea as "spreading like a cancer."

On the opposite side of the issue, Brian Greene emphasizes the dangers of the Landscape philosophy:

When faced with seemingly inexplicable observations, researchers may invoke the framework of the multiverse prematurely — proclaiming some or other phenomenon to merely reflect conditions in our bubble universe — thereby failing to discover the deeper understanding that awaits us.

Paul Steinhardt is more emphatic about these dangers:

I think it leads inevitably to a depressing end to science. What is the point of exploring further the randomly chosen physical properties in our tiny corner of the multiverse if most of the multiverse is so different. I think it is far too early to be so desperate. This is a dangerous idea that I am simply unwilling to contemplate.

He also has his own "dangerous idea", about a cyclic model of the universe explaining the small size of the cosmological constant. Lawrence Krauss gives his own version of an explanation of the danger that the Landscape will lead to an end-point for theoretical physics:

… all so-called fundamental theories that might describe nature would be purely "phenomenological", that is, they would be derivable from observational phenomena, but would not reflect any underlying grand mathematical structure of the universe that would allow a basic understanding of why the universe is the way it is.

Some other interesting contributions from physicists come from Philip Anderson, who has some speculative comments about dark matter and dark energy, Lee Smolin, who discusses the possibility of natural selection having something to do with fundamental laws, and Carlo Rovelli, who remarks that we have still not completely absorbed the revolutionary ideas of 20th century physics:

I think that seen from 200 years in the future, the dangerous scientific idea that was around at the beginning of the 20th century, and that everybody was afraid to accept, will simply be that the world is completely different from our simple minded picture of it. As the physics of the 20th century had already shown.

What makes me smile is that even many of todays "audacious scientific speculations" about things like extra-dimensions, multi-universes, and the likely, are not only completely unsupported experimentally, but are even always formulated within world view that, at a close look, has not yet digested quantum mechanics and relativity!

Comments

1. **Adrian Heathcote**
   January 2, 2006

   I think Carlo Rovelli is right on the money. Physics moved ahead too quickly in the last century, without properly understanding the mathematics of quantum mechanics. The big advances in understanding QM came after 1960 when QFT had more or less been finalised. Parables about building on quicksand come to mind.

   Happy New Year

   The String Landscape, Black Holes and Gravity as the Weakest Force
   Nima Arkani-Hamed, Lubos Motl, Alberto Nicolis, Cumrun Vafa
   20 pages, 5 figures (hep-th/0601001)

   > If true, our conjecture shows that gravity and the other gauge forces can not be treated independently. In particular, any approach to quantum gravity that begins by treating pure gravity and is able to add arbitrary low-energy field content with any interactions is clearly excluded by our conjecture. Of course in string theory all the interactions are unified in a way that makes treating them separately impossible. In particular, if we take the standard model gauge (augmented by SUSY or split SUSY or other particles leading to precision gauge coupling unification), we have perturbative gauge couplings at a very high energy scale, and our conjecture then implies that there must be new physics at a scale beneath the Planck scale, given by …. which is close to the familiar heterotic string scale [of order] 1017 GeV.

   January 2, 2006

   Susskind offers this curious remark:

> Another danger that some of my colleagues perceive, is that if we "senior physicists" allow ourselves to be seduced by the Anthropic Principle, young physicists will give up looking for the "true" reason for things, the beautiful mathematical principle. My guess is that if the young generation of scientists is really that spineless, then science is doomed anyway. But as we know, the ambition of all young scientists is to make fools of their elders.

I say curious inasmuch as this remark suggests that Susskind has been concealing his motivations. Perhaps he anticipates being deemed not crazy, but rather crazy-like-a-fox, at some point in the not-too-distant future. More precisely, perhaps he has decided that the best way to promote the intellectual independence of the post-1990 generation of theoretical physicists in the face of these deep problems is to convince them that their erstwhile mentors have become depressed, foolish, demented, or outright raving lunatics.

5. **Kasper Olsen**
   January 3, 2006

   Adrian quoted Rovelli as of saying:

   > Physics moved ahead too quickly in the last century, without properly understanding the mathematics of quantum mechanics.

   This is a really odd statement; you cannot blame physics for moving too fast, but maybe rather Rovelli for not having understood quantum mechanics; what math is it which is so complicated? Hilbert spaces? Linear equations? Or matrices?

6. **hack**
   January 3, 2006

   "But as we know, the ambition of all young scientists is to make fools of their elders."

   Susskind is an old scientist, who wishes to be forever young, therefore it is his ambition to make a fool of himself.

   Mission accomplished!

7. **D R Lunsford**
   January 3, 2006

   It's interesting the see Carroll go apoplectic over a supposed attack on the holy balance of gender, while he calmly entertains the most absurd and twisted physical ideas.

   Here's my "dangerous idea" (what a load of dung for a topic) – Western man is committing intellectual suicide by allowing the entire estate to be tended by such hysterical stewards.

   -drl

8. **D R Lunsford**
   January 3, 2006

   Bravo KO!

   -drl

9. **Charles Daney**
   January 3, 2006

   Greene, Steinhardt, and Krauss all make reasonable arguments against Susskind's Landscape idea, or similar ideas associated with any concept of a "multiverse", eternal inflation, etc. The arguments are generally of the form: It's a cop-out to accept that the important physical constants are simply random variables. It would discourage continuing efforts to find fundamental principles that explain the values of these constants. And it's not a testable or refutable idea anyhow.

   But then I'm reminded of another theory which posited that fundamental aspects of reality are random variables — quantum theory. That has turned out OK, even though Einstein didn't like it.

   And further, I don't see how the idea that there are basic principles determining the fundamental constants (as Einstein and many others have supposed) is refutable either. The idea that there really is a scientifically sound "theory of everything" may be testable if/when we have a candidate to test — but not before.

   And what if we did happen to find a satisfactory theory that fully determined all the fundamental constants, as Einstein expected? Then we would have to face a rather striking conclusion — that the fundamental principle(s) together with pure mathematics require that all the physical constants have specific values which just happen to allow our kind of life to exist. Wouldn't that itself be a conclusion which demands an explanation?

   Just asking.

10. **Chris Oakley**
    January 3, 2006

    > Another danger that some of my colleagues perceive, is that if we "senior physicists" allow ourselves to be seduced by the Anthropic Principle, young physicists will give up looking for the "true" reason for things, the beautiful mathematical principle. My guess is that if the young generation of scientists is really that spineless, then science is doomed anyway. But as we know, the ambition of all young scientists is to make fools of their elders.

    I wonder what exactly Susskind expects young researchers to make of this?
    Currently, the academic system rewards obedience and punishes independent thought, unless the thinker in question is already well established (Susskind or Weinberg, for example). Young researchers who are prepared to snub their noses to the fashionable trains of thought do not tend to last more than a year or two, unless they have obtained a permanent job by some fluke. Even then, they will be ostracised. Although elderly gentlemen like Susskind may say that they relish the prospect of being proved wrong by some 24-year-old, they are in fact conveniently forgetting that the hierarchical structure they sit on will silence most dissenting voices long before they get a chance to be heard.

11. **Adrian Heathcote**
    January 3, 2006

    Kaspar said

    "what math is it which is so complicated? Hilbert spaces? Linear equations? Or matrices?"

Unbounded self-adjoint operators with their domain restrictions (see Reed and Simon vol 1); State spaces of operator algebras (see Alfsen and Schultz, 2 volumes); Hyperfinite Factors; Gleason-Kochen-Specker proofs; C^* Algebras and Information theory; etc.

Time to update beyond your Dirac or von Neumann texts from the 1930s. A lot has happened. (The Copenhagen interpretation really did chloroform the physics community! I think that is what Rovelli is complaining about.)

12. **Tony Smith**
January 3, 2006

Chris Oakley et al quoted Susskind as saying that "… if the young generation of scientists is really that spineless …[as to]… give up looking for the "true" reason for things, the beautiful mathematical principle … then science is doomed anyway … ".

Since Susskind himself is, by advocating his Landscape, "… … giv[ing] up looking for the "true" reason for things, the beautiful mathematical principle … ",
it seems to me that he himself is advocating that "science" be "doomed", and
that his comment seems to be an attempt to shift the blame for any resulting Dark Age from himself to the "spineless … young generation".

As one who has a model that does allow calculation of the fundamental constants, which model is therefore testable, I find the questions of Charles Daney:

"… what if we did happen to find a satisfactory theory that fully determined all the fundamental constants, as Einstein expected? Then we would have to face a rather striking conclusion – that the fundamental principle(s) together with pure mathematics require that all the physical constants have specific values which just happen to allow our kind of life to exist. Wouldn't that itself be a conclusion which demands an explanation? …"

to be interesting.

Unbounded Ignorance…
Ups! This is of course something which I should have known about, sorry. But I'm sure Adrian will help me. For starters: what is an unbounded operator? One without boundaries? (It's hard for me to imagine what this could mean). How can such an OP have domain restrictions when it is unbounded? What is a state space of OP algebras? (I've never heard about an operator being in some specific "state"). And C^* algebras? What does the C stand for – and more interestingly the * – is it ultimatively related to cosmology? And Information Theory? Does that apply both to modern quantum mechaincs and the media? Seems like I've go a lot to learn…

14. **Adrian Heathcote**
January 3, 2006

Hi Kaspar

Yes, it looks like it's going to be a long winter over those books. Enjoy! 🙂

A.H.

"what is an unbounded operator? One without boundaries? (It's hard for me to imagine what this could mean). How can such an OP have domain restrictions when it is unbounded? What is a state space of OP algebras? (I've never heard about an operator being in some specific "state"). And C^* algebras? What does the C stand for – and more interestingly the * "

An unbounded linear operator on a normed vector space (e.g. Hilbert or Banach space) is a _not necessarily continuous_ linear operator that is _not necessarily_ defined on the whole space! Bounded (= continuous) linear operators are then (confusingly) a special case of unbounded linear operators! Domain restrictions are a big thorn in the analysis of unbounded operators, which is why some mathematicians feel physicists are a bit dodgy in their calculations. See the nice paper:

F. Gieres, Mathematical surprises and Dirac's formalism in quantum mechanics (quant-ph/9907069)

for a discussion of the sutleties of unbounded ops in QM.

For a more basic general discussion see the Wikipedia article:

http://en.wikipedia.org/wiki/Unbounded_operator

As for C*-algebras, see: http://en.wikipedia.org/wiki/C%2A-algebra

The * stands for the involution or "adjoint" operation on a C*-algebra (which plays the role of a generalized "conjugate transpose" from matrix theory). Physicists tend to use a "dagger" symbol for adjoints, while mathematicians use a "star" symbol. There is also the C*-identity: ||T*T|| = ||T||^2. Thus, a C*-algebra is a normed algebra, which is complete with respect to the induced norm topology, with an involution operation * that happens to satisfy the C*-identity.

A "state" on a C*-algebra A is a positive linear functional f : A -> C from A to the complex numbers C. (Thus, the "state space" of A is a subset of the dual space A* of all bounded linear functionals, but that is another use of *…) When A = B(H) is the C*-algebra of bounded linear operators on a Hilbert space H, every unit (= state) vector v gives a "state" for B(H) by the "expectation" formula:

f(T) = (T(v), v)

for T in B(H), where (v , w) denotes the inner product. By the Gelfand-Naimark-Segal (GNS) construction, every state on an abstract C*-algebra A can be (essentially) viewed in this way.

Hope this helps,
Jody

16. **Kasper Olsen**
January 3, 2006

Sorry guys – but it was obviously a joke from begining to end 😉 Of course I know these things very well indeed.

The point here is, that for many applications of quantum mechanics (for example if you are doing atomic physics) you don't need to know what an unbounded self-adjoint operator is. Or what a C^* algebra is. Or what Information Theory is.

So, it was not *unbounded ignorance* from *my* side…

17. **Lee Smolin**
January 3, 2006

HI everyone.

Carlo Rovelli did not say or imply that "Physics moved ahead too quickly in the last century, without properly understanding the mathematics of quantum mechanics." Kasper, this comment was made by Adrian. Please read what he actually said, http://www.edge.org/q2006/q06_9.html#rovelli. Rovelli's point was entirely different.

What Rovelli is complaining about is clear from his last sentence. It has nothing to do with the math, it is the extent to which string theory has become a study of cataloguing solutions to classical or at best semiclassical equations, ignoring both the background independence of general relativity and the challenges of understanding what a spacetime is within quantum mechanics. His point, with which I sadly have to agree, is that those who think of themselves as doing fundamental physics but have avoided wrestling with the implications of combining the principles of GR and QM have not appreciated the radical conceptual and technical innovations imposed on us just by those principles.

Best wishes to everyone for the new year, Lee

ps To avoid the inevitable misunderstanding, I do NOT imply here that the Einstein equations are fundamental, only that the principles of GR are.

18. **Aaron Bergman**
January 3, 2006

And, yet, Rovelli was still condescending and wrong.

19. **rof**
January 3, 2006

We must understand that Carlo has his own interpretation of quantum mechanics, the so-called relational interpretation, and his statement that others have not understood quantum mechanics simply means that others don't share his interpretation.

(Incidentally, his interpretation is that which we should say that a thing is in one state "relative to" something else, rather than saying that a thing is in a particular state. He doesn't answer the question: Can a cat be dead relative to one person and alive relative to somebody else? If the answer is yes, his interpretation is just many worlds, and if the answer is no then there's nothing relational about it – the cat is absolutely alive or dead. Consequently, his interpretation is incoherent.)

The remarks about background independence are more widely known, and have more justification, although the appeals to Leibniz's theory of space should not be made, since Leibnizian space was disproved by Kant in the 1780's.

Aaron, would you care to say which of Rovelli's statements you consider to be wrong and whether it is just your opinion or whether it's an established fact?

20. **Anonymous**
January 3, 2006

Rovelli said:

What makes me smile is that even many of todays "audacious scientific speculations" about things like extra-dimensions, multi-universes, and the likely, are not only completely unsupported experimentally, but are even always formulated within world view that, at a close look, has not yet digested quantum mechanics and relativity!

rof asks:

Aaron, would you care to say which of Rovelli's statements you consider to be wrong and whether it is just your opinion or whether it's an established fact?

I don't presume to speak for Aaron, but the quote above seems wrong to me, and it's *Rovelli* who needs to justify the opinion. A perusal of the literature on extra dimensions, for instance, will reveal plenty of both relativity and quantum mechanics. It is, as Aaron said, condenscending of Rovelli to claim that other physicists do not understand these things. They are the bread and butter of all of high-energy physics.

21. **Aaron Bergman**
January 3, 2006

Aaron, would you care to say which of Rovelli's statements you consider to be wrong and whether it is just your opinion or whether it's an established fact?

The idea that people don't understand background independence, the lessons of general relativity, yadda, yadda, yadda. People are quite capable of understanding the metaphysics and still rejecting Rovelli's favorite theory.

22. **Dumb Biologist**
January 3, 2006

Has anyone of the "bigwigs" (a scientist of stature on the order of a Weinberg, say) proposed the dangerous idea that if quantum gravity theorists can't figure out how to formulate a falsifiable theory, they should either make the ethical leap to mathematics*, where their imagination need not be fettered by external referents, or abandon quantum gravity models altogether for fields that contain problems which are testable, at least in principle?

(*This is not to denigrate mathematics, being perhaps the only worthy "philosophy", to which the greatest human minds contribute, just to acknowledge there's a difference, and that difference can be important.)

23. **Lee Smolin**
January 3, 2006

Aaron and Anonymous,

Let's lower the temperature and discuss the substance of what we disagree about. You say, "People are quite capable of understanding the metaphysics and still rejecting Rovelli's favorite theory." But, as Carlo makes clear, his favorite theories are general relativity and quantum mechanics. He claims that the principles of these are ignored by approaches to unification that study only semiclasical effects in fixed classical spacetime backgrounds.

You make it clear that you disagree, i.e. you reject the view that a quantum theory of gravity should be background independent. This is a substantial disagreement. So lets discuss why we disagree.

Certainly, no insult is intended. But it is hard to avoid the impression that some people who reject the case for background independence have not thought carefully through the issues in the interpretation of general relativity that lead us to adopt it. Perhaps this is not true of Aaron, but it is true of many who confuse the methodlogy used to interpret very symmetric solutions to GR with the very different issue of describing observables for the generic solution.

The issue is not about knowing how to write the Einstein's equations down or find simple solutions. It is about the interpretation of observables on the space of solutions. Untill one has struggled through the issues raised by the hole argument, or the problem of specifying diffeomorphism invariant observables, you cannot have absorbed the full meaning of general relativity. My impression is that once people have absorbed this it changes their taste as to what kinds of solutions to the problem of quantum gravity they are willing to entertain. Specifically it seems impossible to have understood these things and still to believe in the possible viability of any background dependent approach to quantum gravity.

Of course the equations of general relativity are used in Kaluza-Klein inspired higher dimensional unifications. But, because of these subtle interpretational issues, this is not the same thing as taking the princiiples of the theory seriously.

A related issue is that all the higher dimensional unifications require that some degrees of freedom be frozen. Otherwise, as Penrose argues in his recent book, there are instabilities that lead quickly to collapse to singularities. These are to some extent avoided by the flux compactifications but, as we know, the cost is the need to appeal to anthropic arguments.

But the point is that from a background independent point of view, any result that requires the specification of a specific solution rather than a generic prediction of the theory seems unreliable exactly because the symmetric solutions are in many ways non-generic.

Even Einstein saw this was a potential trap, when he commented, ""It is anomalous to replace the four dimensional continuum by a five dimensional one and then subsequently to tie up artificially one of those five dimensions in order to account for the fact that it does not manifest itself"

Thanks,

Lee

24. **woit**
January 3, 2006

Dumb biologist,

There seems to be a misconception that if what string theorists are doing isn't falsifiable and thus not physics, it must be mathematics. Not so. Some sorts of work in string theory involves non-trivial new mathematics that is of interest to mathematicians, and there already are some people doing this successfully working in mathematics departments. But most of the non-falsifiable stuff going on in string theory does not involve any new mathematics, and mathematicians want even less to do with this kind of thing than physicists.

25. **Dumb Biologist**
January 3, 2006

Ah, I see.

Well, that's kind of depressing…

26. **Moshe**
January 3, 2006

Lee, back to that story. I believe you are talking about string perturbation theory when you claim we expand around a classical solution, which are very symmetric, and all the rest. I would call it lack of *manifest* BI., but never mind that.
\
Since it is already 2006 we don't have to have that conversation. We have, since 1997, a background independent formulation of quantum gravity in spaces with negative cosmological constant. Yes, it is not quite as BI as you would like it to be, but as I mentioned before there are good reasons, independent of string theory, to believe that is the best one can do. Indeed, one of them is precisely the struggle to define diffeoemorphism invariant observables, which at least so far require one to have appropriate asymptotia.
\
Finally, not too get too deeply into that, but lowering the temperature seems like a good idea if one is to have a useful conversation, derogatory or misleading statements about each other's research are not helpful in that.

27. **woit**
January 3, 2006

Since I kind of started all this by posting the material from Rovelli, let me say a bit about why it struck a little bit of a chord with me and I included it. I suspect that my own ideas about this are quite different than Rovelli's, but perhaps there is some overlap.

As everyone in the field is aware, combining QM and special relativity inescapably leads us to quantum field theory. My version of Rovelli's comment that our picture of the world is too simple-minded and that we haven't fully absorbed the implications of QM and special relativity would be not that physicists don't understand the standard formalisms of these two subjects, but that the full implications of QFT have yet to be fathomed or absorbed. Starting in the late 1970s, people have found some very deep new mathematics by thinking about QFT, and I suspect there's a lot more of this to be uncovered, with major implications both for mathematics and physics. 200 years from now, people may very well see the late 20th century as a period when we were just starting to get a clue about what QM+SR=QFT really was, with a large part of the field ignoring the very challenging issues posed by trying to get to the bottom of this, instead spending its time on ideas about multiverses and extra dimensions that turned out to be shallow and besides the point.

28. **Aaron Bergman**
January 3, 2006

You make it clear that you disagree, i.e. you reject the view that a quantum theory of gravity should be background independent.

I have made absolutely no such claim whatsoever. We've covered this ground *ad nauseum* on Cosmic Variance, so I'm not going to repeat myself here.

After all of that discussion, that you still don't understand my position is inexplicable to me.

29. **Lee Smolin**
January 3, 2006

Dear Moshe,

Thanks. Two small points. You say, "there are good reasons, independent of string theory, to believe that is the best one can do." No, we know that one can do much better and get results from genuinely background independent methods. This is shown by recent results in causal dynamical triangulations and LQG in both 2+1 and 3+1 dimensions. Indeed, the recent results are based on methods which deal successfully with the problems of diffeo invariant observables (read Rovelli's papers leading up to the recent results on the graviton propagator-as that was their purpose.)

As for AdS/CFT, let me insist again that except for special cases where BPS symmetry is used, the evidence supports a weak form of the conjecture-which is the one in WItten's 97 paper. This conjecture gives a map between CFT's on the boundary and classical or semiclassial field threories on fixed backgrounds that are asymptotically AdS. Most of the very impressive results in this subject support this weaker form of the conjecture. This is far from sufficient to support the much bolder conjecture of Maldacena that there is an equivalence between a string theory in the bulk and the boundary CFT. Given that there is not even a complete formulation of free string propagation on AdS5 X S5 one cannot claim that there is strong evidence for Maldacena's form of the conjecture-except again in very special cases where BPS symmetry allows constructions to be done that may not otherwise exist.

Given this, I see little support for the even stronger form of the conjecture that posits that results of the boundary CFT are equivalent to a fully background independent (except for asymptotic boundary conditions) quantum gravity theory in the bulk. There are many papers that assume that the conjecture is true and deduce consequences, but the only evidence I know of that supports a strong as opposed to a weak form of the AdS/CFT conjecture makes strong use of BPS symmetry, which means it may not be reliable outside of a tiny sector of the Hilbert space.

So I do not agree that "We have, since 1997, a background independent formulation of quantum gravity in spaces with negative cosmological constant." I cannot object if you personally believe this strong form of the conjecture, but I do object if you write as if it is an established fact.

thanks, and happy new year, Lee

30. **Lee Smolin**
January 3, 2006

Aaron, I'm sorry, but I looked on CV and you say there that: "… to say that any quantum theory of gravity must be background independent smacks of hubris….Nature is going to work how it's going to work." And, "If a nonperturbative formulation of string theory exists, we should find it. If it's background independent, that's great. … But, if the nonperturbative formulation isn't background independent, then so be it."

If these are representative then you appear to " reject the view that a quantum theory of gravity SHOULD be background independent". which is what I said.

Thanks, Lee

31. **Aaron Bergman**
January 3, 2006

Again, Lee, look at the paper of Berenstein, Maldacena and Nastase and the **795** papers the cite it.

32. **Aaron Bergman**
January 3, 2006

I reject there the idea that a quantum theory of gravity **needs** to be background independent. But, as the whole rest of that thread points out, string theory looks background independent. Nobody's rejecting the "case for background independence". You continually set up this straw man, and it's tiresome.

33. **Moshe**
January 3, 2006

Lee, Aaron reminds me there was a reason for my deja vu… Let me just say I strongly disagree with your characterization of AdS/CFT as applying just to the BPS sector, or only in the supergravity limit, this is just wrong. I also think a conjecture that faced thousands of attempts for refutation over 8 years is as established as we will ever acheive in this business, just my opinion. If you prefer we can refer to anything that was not rigorously proven as a conjecture…
\
Peter, interesting interpretation of Rovelli's remarks, I am afraid though that he refers to general and not special relativity… I have to say that this struck a chord with me as well, the thing I find most useful about string theory is that it is a quantum mechanical model which naturally incorporates general relativity at large distances. So maybe we don't fully incorporate the deep ideals of QM and GR, but at least we incorporate the theories themselves, that is a good start.

34. **Lee Smolin**
January 3, 2006

The pp waves studied by BMN are an extremal limit of the theory. While these are very impressive results they are special cases that rely on special structures and so do not prove the general conjecture.

And Aaron, please clairfy: you reject the idea that a quantum theory of gravity NEEDS to be background independent. But you say nobody rejects the case for background independence. Isn't this a contradiction? My reading of the "case" is that it consists of arguments that REQUIRE background independence.

I am sorry if this is tiresome, but you claim that "string theory looks background independent." What is meant by background indepedence is a formulation of the theory that makes no reference to any classical background geometry. Even granting the strong Maldacena conjecture, it would not do this because there is a fixed Minkowksi geometry on whcih the SYM theory is defined.

Were there in fact a backgound independent formulation of string theory it would have a Hilbert space and observable algebra whose specificaion made no reference to any classical metric. There simply is no such formulation of string theory. All the matrix models considered to be part of string thoery, including BMN and BFSS have a fixed metric in their Hamiltonian. There were a few attmepts to make a truly background independent formulation of string theory, but not enough is known about them to claim success.

Lee

35. **Aaron Bergman**
January 3, 2006

Lee, you said “As for AdS/CFT, let me insist again that except for special cases where BPS symmetry is used, the evidence supports a weak form of the conjecture”. Now, when presented with such evidence, you say “they are special cases that rely on special structures and so do not prove the general conjecture”. This strikes me as goalpost shifting.

In general, I reject metaphysics. You can make all such arguments you want, but nature is the ultimate arbiter. I don’t think we can ever ultimately learn anything about nature except through experiment.

As for the rest, pretty much everything I want to say has already been said in the CV thread, but “Even granting the strong Maldacena conjecture, it would not do this because there is a fixed Minkowksi geometry on whcih the SYM theory is defined.” is really a very strange statement. You’re complaining about background independence for a nongravitational theory?

36. **Anonymous**
January 3, 2006

You know, there is always the possibility that quantum gravity *really does* depend on asymptotics. Background independence will be nice, but we just don’t know for sure if it is a necessary feature of quantum gravity. I think Banks has argued that it cannot be a feature of quantum gravity, for instance.

Lee, is the following true from your perspective? Every known attempt to start from background independence and construct a theory of quantum gravity relies on the *assumption* of a UV fixed point for gravity. It’s true of all the examples I know, but I know of no convincing reason for that underlying assumption.

So if we have to choose a starting point, either a UV fixed point and background independence, or a lack of a UV fixed point and a lack of manifest background independence, I would go with the latter. But string theory, though lacking *manifest* background independence, certainy appears to have *at least some degree* of background independence. It would certainly be nice to clarify the exact status of background independence in string theory, but the lack of manifest background independence is no reason to scrap string theory in favor of other approaches starting from much shakier foundations.

37. **Adrian Heathcote**
January 3, 2006

Hi Peter

Since Kasper pulled my leg by asking me ”which new mathematics” for QM, can I ask you to ‘fess up and say what new maths for QFT you have in mind?

(I’ve long been curious what happened to the Glimm and Jaffe program. At a certain point I just no longer heard of it. Did it face some insurmountable problem or did people just drift on to other things? For a while there it looked like it was the bomb.)

happy new year to you

38. **Peter**
January 3, 2006

Adrian,
Some of my speculations about the kind of mathematics behind quantum gauge theory is in the paper about QFT and representation theory I wrote a few years ago that is on the arXiv.

I haven’t heard much in recent years about the kind of rigorous constructive QFT that Glimm and Jaffe were working on. Not sure whether there just are very few people working on it, or really insuperable problems. My own guess is that trying to rigorously construct very general classes of QFTs is too hard, you need more structure to make the theory tractable. If one really could better understand the relation between QFT and representation theory I was writing about, for certain specific QFTs one might be able to do much more in terms of understanding the theory rigorously.

39. **Lee Smolin**
January 3, 2006

Hi Anonymous,

Thanks, your statment about background independence and UV fixed points is interesting but does not agree with my understanding of the results. Ambjorn and Loll, who have good results which show the emergence of geometry from a background independent theory, SHOW in detail that fixed points exist, they don’t assume it. As for the LQG results, the theory is shown to be uv finite, in both the hamiltonian and path integral formulations. So there is no uv scale invariance at all.

As to the role of asymptotics: in GR, which is a background independent theory, the phase space splits into disconnected sectors, depending on the asymptotics. I see now reason the same should not be true in
the quantum theory. The evidence, for example, from 2+1, is that it is.

To Moshe, I don’t dispute there is an AdS/CFT relation, I am just trying to find out precisely which possible version is true. Don’t you agaree this is a good thing to do, given that there are different possible conjectures? I am following a basic rule of logic which is that if two conjectures explain some evidence, only the weaker of them can be considered to have support from that evidence. Especially in a subject that has been well explored, where, as you say, there have been thousands of papers over 8 years, isn’t it reasonable to believe the weakest conjecture that I need to explain the evidence in all those papers?

I can easily imagine results that would support a stronger conjecture, given the subject is well studied, their absence is also at least indicative.

But perhaps we should agree to disagree till there are fresh results,

Thanks, Lee

40. **Moshe**
January 3, 2006

Lee, I am curious about your statement about the phase space of GR having disconnected pieces, do you regard that as evidence for weaker form of BI such that asymptotics are kept fixed?
\

As for AdS/CFT, all I am saying there is lots of evidence for much stronger form of the relation than the form you presented (only BPS objects in the supergravity limit).
\
I also think that the mode of operation of physicists tend to be taking whatever seems to work as a hint and try to apply it to further interesting problems (for example in the present case gravity in deSitter space), we don't tend to stick around and sharpen and prove conjectures, maybe that is regrettable but this is the way things are.

41. **Tony Smith**
January 3, 2006

I pretty much agree with Aaron about the tiresomeness of objections to superstring theory based on lack of background independence.

If you go back to the days of N=8 supergravity, IIRC the gravity sector got the Einstein-Hilbert action from a MacDowell-Mansouri process applied to the anti-deSitter group Sp(2) = Spin(2,3), and IIRC people back then were not attacking supergravity based on lack of background independence.
IIRC, the attacks back then were based on fears that UV finiteness would not be maintained at high orders.
Was the idea back then that somehow "enough" background independence for GR would probably "emerge" through the MacDowell-Mansouri process (a la Deser-type formulations)?
Since such supergravity might be a low-energy limit of some superstring formulations, could it be that a similar "emergence" of "enough" background independence for GR might occur?

Doesn't that mean that, unless and until such an "emergence" is conclusively ruled out (which I do not think has been done or is likely to be done in the near future), it is silly to attack superstring theory on the basis of lack of background independence?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – If my recollections above (designated by IIRC) are seriously flawed, then, as Gilda Radner used to say, "Nevermind".

42. **D R Lunsford**
January 3, 2006

Lee Smolin said:

The issue is not about knowing how to write the Einstein's equations down or find simple solutions. It is about the interpretation of observables on the space of solutions.

This is absolutely not the issue! and it is flat wrong for you to annouce it as such. I think you people are not very bright – you completely miss the point about GR, which is how you end up abusing it so much.

The issue is the measurement problem without assuming an apparatus = a background. This does honor to both GR and QM. You will instantly understand if you think for 10 minutes that the entire ethos of the measurement problem is antithetical to the idea of background independence. Any attempt to go farther than this is doomed. You must either change one, or the other. Your crowd ignores the actual physical import of GR because it is easier to hide one's canoe in the metaphyical tributaries of the of "interpretation".

"Wave function of the universe" – case closed!

The only people who take both GR and QM seriously are Finkelstein, Dirac, Einstein, Pauli, and Schroedinger. The very people who get ingored now.

-drl

43. **Chris W.**
January 4, 2006

(..and the actual physical import of GR is…)

Are you saying that assuming a background is equivalent to assuming that measurement apparatuses are physical realizable, which is obviously an essential precondition for doing physics, hence the demand for background independence is self-defeating and pointless?

44. **Chris W.**
January 4, 2006

[correction: *physically* realizable]

45. **Anonymous**
January 4, 2006

Lee,

OK, it sounds like we are in agreement that asymptotics are potentially important.

You say "Ambjorn and Loll, who have good results which show the emergence of geometry from a background independent theory, SHOW in detail that fixed points exist, they don't assume it. As for the LQG results, the theory is shown to be uv finite, in both the hamiltonian and path integral formulations. So there is no uv scale invariance at all."

I'm puzzled by the Ambjorn/Loll result, but I have to admit to only having skimmed the relevant papers. It doesn't seem the lattice theory is known to have a good continuum limit, which is what I would think you mean by "SHOW" that fixed points exist. Are you saying they have definitively established such a limit? In which papers?

As for LQG: you're saying the theory is UV finite but there is no UV fixed point? How does this mesh with the nonrenormalizability of GR? What's the extra structure that fixes the infinitely many independent constants one naively expects in quantum GR?

One last question: in all of these non-string theoretic approaches, quantum gravity is proposed to be just a *quantum field theory* in the usual sense, yes? If so the claims conflict with my field-theoretic intuition, but if you can answer or give references for answers for my questions above it should help me understand exactly what you're claiming. Maybe others have the same confusion? (I, for one, thought LQG was predicated on assuming a UV fixed point of some sort.)

Thanks!

46. **Lee Smolin**
January 4, 2006

Hi Moshe,

Yes, GR satisfies a weak form of BI (background independence) in which several things are kept fixed including dimensions, topology and asymptotics. So hence does any direct quantization of GR. We might posit a deeper theory that dispenced with these background structures, which takes us beyond the strict quantization of GR. Several people in the BI quantum gravity world have advocated doing so, for example, Markopoulou and Freidel both advocated forms of spin foam models in which there is no fixed embedding space for the spin foams.

I agree also its regrettable that at least some people don't dig in and sharpen and prove conjectures. We can certainly do something about this, for example make sure that people who do so, like Berkovits, are honored and rewarded.

Hi Anonymous, for Abjorn and Loll, you can see clearly the demonstration of a fixed point in their 1+1 dimensional case, hep-th/9805108. Another way to see it is in the paper of Ansari and Markopoulou, hep-th/0505165. There are results also in 3+1 but those are numerical, whereas in 1+1 they are analytic and clean. As for LQG I tried to explain in an intuitive way for quantum field theorists the basics in my review hep-th/0408048. It evades perturbative non-renormalizability because there simply are no excitations with wavelength below the planck scale.

But there was an intuitive idea which indeed was motivational for LQG at the very beginning, which is that one expected from the ideas of asymptotic safety that a uv fixed point would require a scaling dimension of 2. This suggested that when you probe to Planck scales you should see a distribution of 1+1 dimensional excitations on a background where the metric vanished. Crane and I studied this heuristically in 84-85. This suggested initially looking at states made by finitely distributed WIlson loops, which was adopted then to the Ashtekar connection. But the actual results indicated there is just a uv cutoff rather than a scaling with reduced dimension.

However it is interesting to note that both Amborn and Loll and recent works on asymptotic safety see evidence for a reduction in scaling dimension to 2.

Thanks,

Lee

47. **rof**
January 4, 2006

DRL,

Can you elaborate a bit about GR and measurement? It is a project of mine to take GR as it is presented at the moment (namely, as an ontological theory – "There exists a manifold, with this and that tensor and these geometrical properties") and reword it so that it makes mention only of experimental results and their relationships from the points of view of observers. Have you attempted something similar?

48. **Moshe**
January 4, 2006

Lee, just to clarify my opinion, I think that proving conjectures is not a particualrly effiecient search startegy. Sure, once the correct language and issues are identified this should be done. I am glad for example that the people who developed the standard model did not stop to prove their points. Many of the ingredients going into that theory, such as confinement and the existence of chiral gauge theory, remain on shaky mathematical ground to this day. But, of course this is just a matter of judgement, though this view I think is wide-spread among theoretical physicists of all stripes.
\
And about background independence, I am a fan of the weak form, which fixes the asymptotics, at least for now. I take it as another encouraging sign that Einstein's classical gravity obeys precisely this form.

49. **Fabien Besnard**
January 4, 2006

I would like to go back to what Rovelli said in the first place. I have heard him say something similar, and he also talks about it in his book : it's the need to be conservative to open the way for a scientific revolution. What Rovelli says, and he's surely right about it, is that finding a quantum theory of gravity is not just a very difficult technical problem but a conceptual one that will involving a complete reinterpretation of our old ideas about the world. Perhaps even the words "quantum theory of gravity" are inappropriate for what will come out. But that does not mean that new concepts need to be introduced by hand before solving this problem : Rovelli also argues in his book that it had never worked that way. The only thing we can do is taking seriously the theories we have, without any wild guess about additional structures, and follow the thread until something appears that need to be understood in a new way. This is exactly what Einstein did with special relativity : he took Mawxell theory and galilean relativity seriously, and follow the thread until the Lorentz transformations followed. What's interesting is that these were already around, but no one understood them, no one took them really seriously. Einstein did because they followed logically from two well established facts : the invariance of c and the relativity of inertial motion. Thus he was compelled to take them seriously, and it led him to a new conceptual framework. Before that, wild theories about how the way aether interacted with matter had been made, but of course they couldn't get anywhere. Now suppose string theory is the right direction to follow to quantize gravity. To what conceptual revolution does it hint to ? This is not only a rhetorical question, I am frankly curious about that. As far as I can see, Maldacena conjecture if it turns out to be true seems to me the only candidate for a change in concepts, but I don't know enough to be sure about that. On the other hand, the disappearance of time in LQG does really sound like a conceptual revolution to me. But what makes the difference between a new concept and what is just a clever idea ? Can several very clever ideas lead to a new concept ? I don't know for sure, but perhaps one could say that a clever idea is an answer to a specific question (how many dimensions does spacetime has ? what is the shape of the universe ? what do particles look like at very small scales ?), even one that has never been put forward, whereas a new concept does not answer any question but tells you what questions you are allowed to ask.

50. **Juan R.**
January 6, 2006

Rovelli exactly says:

> We still haven't digested that the world is quantum mechanical, and the immense conceptual revolution needed to make sense of this basic factual discovery about nature.

That is not true and perhaps it is the basis of the typical "*we do not understand quantum mechanics*". Maybe people who claim to be doing fundamental physics would revise their knowledge of basic stuff.

As brilliantly highlighted by Bohr -a century ago- there is two visions of the world. At the one hand, the quantum vision, mainly applicable to atomic scale. At the other, the classical vision, mainly applicable to macroscopic scale. Both are complementary between them and none view can be *reduced* to the other.

Precisely, that is the reason that Schrödinger equation is totally inefficient when dealing with macroscopic phenomena, and that the old quantum measurement problem is not solved still. This is reason that Gell-Mann/Hartle 'histories formalism' [1] has not predictive power. It is the reason of great failure of the decoherence approach to solve measurement problem (far from P. W. Anderson unjustified claims [2]), this is reason that multiple-worlds Weinberg 'interpretation' sounds (see for example Penrose's criticism on why multiple-worlds is wrong in both philosophical and technical details in one of his last books [3]) to joke for people doing serious stuff (i.e. people who is doing top-research in quantum measurement), etc.

All **realistic** models of quantum measurement published in specialized literature are based in generalizations of the quantum: axiomatic generalizations of QM (e.g. Martingale models based in Lindblad semigroups that permit us *derive* Born rules), nonlinear equations violating superposition principle at large scales (e.g. 'Caldeira-Leggett' ones), LPS systems outside of Hilbert space (Austin-Brussels School Rigged-QM), etc.

Simple equations of the kind Rovelly loves (H phi = 0 or ADM or similar ones) are rough approximations valid just in certain specific situations.

Probably, the general misunderstanding about quantum mechanics is the explanation for the four decades futile effort about geometrodynamics, LQG, and so. I agree that superstring theory does rather poor our approach to quantum gravity, but LQG is not better. One can agree that both are complementary approaches. LQG does mistakes A, B, and C, whereas superstrings incorrectly deals with D, E, and F points.

Unfortunately, Rovelly (as many others LQG theorists) does not understand time and this is the reason of his last decade unfounded claims on a pure relational structure for the universe.

Of course, the superstring perturbative series around a fixed classical spacetime background is wrong and really trivial (one can use elementary R-QFT techniques); I agree with the LQG philosophy here. However, sorry to say this Lee Smolin, the principles of GR are not fundamental.

Lee Smolin said:

> Yes, GR satisfies a weak form of BI (background independence) in which several things are kept fixed including dimensions, topology and asymptotics. So hence does any direct quantization of GR. We might posit a deeper theory that dispenced with these background structures, which takes us beyond the strict quantization of GR.

I do not agree. We might posit a deeper theory explaining available (present and future) experimental data. Only that!

There are no single experimental data suggesting us that topology of spacetime may change at Planck scales even if anyone in quantum gravity community think so. Therefore, you (as Rovelli) are expressing how you want universe was…

Nekrasov on String Perturbation Theory

January 3, 2006
Categories: Uncategorized

Nikita Nekrasov is giving a very interesting series of talks at the Jerusalem Winter School on the topic of "Introduction to modern covariant superstring theory." The first of his talks was yesterday and is now on-line. In it he outlined the two main formalisms for superstring theory and discussed their advantages and drawbacks, while also giving a beautiful discussion of the quantization of the superparticle, and the use of twistor and pure-spinor methods in 10d super-Yang-Mills.

One of these two formalisms, the NSR formalism, uses supersymmetry on the world-sheet, with target space a usual (bosonic) space (i.e. 10d space-time). The advantage of this is that amplitudes are computed using a linear theory, supergravity on the worldsheet. One disadvantage of this is that spacetime supersymmetry is not manifest, only recovered after GSO projection. A very serious technical problem is that, while one ultimately wants to construct amplitudes by summing over spin structures and integrating over the moduli space, the formalism gives one for each spin structure an amplitude on the super-moduli space, not the moduli space (and these super-moduli spaces are different for different spin structures). In recent years D'Hoker and Phong have been able to deal with this problem for genus 2 (and they have some results for genus 3), but for higher genus how to consistently get amplitudes on moduli space remains an open problem. Note that the problem with these multi-loop amplitudes is not only that you aren't sure they are finite, but you aren't sure that they are even well-defined. Presumably this is purely a technical problem, not evidence of an inherent inconsistency problem with such amplitudes, but one can't be sure of this until someone finds a way of resolving the problem.

The other formalism, the so-called Green-Schwarz formalism, uses a bosonic worldsheet, but takes the target space to be a supermanifold. This has the advantage of making space-time supersymmetry manifest, and avoiding the problem of integrating over super-moduli space, but it carries its own disadvantages. The world-sheet theory is now a highly non-linear, constrained theory, with both first-class and second-class constraints, constraints that Nekrasov describes as "hard to separate in a covariant way". No one knows how to quantize this theory preserving super-Poincare invariance, so one typically uses a non-covariant gauge-fixing like light-cone gauge, something that runs into trouble at genus 2 or higher.

In recent years, Berkovits has been developing an improved version of the Green-Schwarz formalism, sometimes called the Berkovits formalism, and this is the main topic of Nekrasov's lectures. Presumably Nekrasov will be discussing in his next two lectures how this works and some of the interesting problems with it, problems that he wrote a paper about a couple months ago, one which was discussed here. In his talk, Nekrasov seemed rather nervous that he would get into trouble because people might think he was raising the possibility of superstring perturbation theory being inconsistent. At one point he said that his "policy statement" was that he hoped that things could be made to work at any genus. He also seemed concerned in his talk yesterday about how his remarks might be reported today, saying:

There are really conc… well… I don't want to call them conceptual problems because these days everything is recorded. If I say something is a conceptual problem, tomorrow there will be a blog on that, or a paper. So, there are some technical difficulties….

Comments

1. **MathPhys**
   January 3, 2006

   I think that this website has helped educate more people about the most recent developments in string theory (while keeping a sober view of its problems and shortcomings) more than any other resource on the internet, excluding Ginsparg's archives.

   I think that this website is doing string theory as a discipline a great service. I doubt more than a fraction of the readers of this website read J Distler's blog (for example).

2. **woit**
   January 3, 2006

   Thanks MathPhys,

   I've certainly noticed that a sizable fraction of the traffic here comes from machines at academic sites with "string" part of the machine name, and have also heard from several string theorists that, while they disagree with my point of view, they do find a lot of interesting material here.

   Recently there have been roughly 5000 people a day looking at this weblog, a number that really astounds me.

3. **Luboš Motl**
   January 3, 2006

   Dear Peter and MathPhys,

   try to guess what error you have done that allows an intelligent reader, after going through all occurences of "MathPhys" on this blog, determine that you are the very same person. 😉

   All the best
   Luboš

4. **MathPhys**
   January 3, 2006

   Dear Lubos,

   Would you be willing to put your money where your mouth is and bet anything above US$1,000 that Peter Woit and I are the same person?

   If not, would you be willing to apologize in public for insinuating that Peter Woit lacks the integrity that puts a stunt such as you proposed below him?

   I am willing to accept any method of verification by independent observers. I do not accept any bets below $1,000 because that makes them not worth my time.

   Thank you.

5. **Luboš Motl**
   January 3, 2006

Dear Peter or MathPhys,

no, I don't intend to make a bet with you because I don't believe that you would pay me the money.

All the best
Luboš

6. **Peter**
   January 3, 2006

   Lubos,

   You really are mad as a hatter, I can't begin to guess what you have in mind here, do tell. I do know who MathPhys is, and no he's not me. From his previous comment he has less of a sense of humor about your antics than I do.

7. **MathPhys**
   January 3, 2006

   Peter, Please! I can use the money!

   Lubos, It shouldn't be too difficult to find someone that both of us accept who can administer the bet. I know at least one person right here that both of us trust. Or you can nominate anyone from your side that I know.

8. **Arun**
   January 3, 2006

   Looking forward to hearing about the technic-conceptu-al problems.

9. **WorldRen**
   January 3, 2006

   Luboš Motl
   I visited your blog before using the link woit provided. But I don't think I would visit your blog again.

10. **Peter**
    January 3, 2006

    Enough about Lubos, please! Unless he has an entertaining explanation of why he is sure I am MathPhys, I don't want to hear any more about it. Further comments should be about higher order calculations in superstring perturbation theory.

11. **Luboš Motl**
    January 4, 2006

    Dear "WorldRen",

    indeed, I would appreciate if you'll never come closer than 5 miles from my blog because I have roughly 10 times more of such WorldRens visiting the blog than what would be appropriate and their market value is heavily negative. Thanks! 😉 Incidentally, it is not hard to see that this is the first time that "WorldRen" appears in the physics blogosphere. What do you think is the conclusion?

    Peter,

    your comments about the stringy perturbative expansions are pathetic. I have explained you why it works in such a transparent way that a better than average high school student must have already understood the proof of the finiteness.

    Nikita is trying to get people's attention and attract the people into the worldsheet because it is his world. Of course he will never say that there are conceptual problems with string perturbation theory because he knows that such a statement is unjustifiable, and if he said such a thing, everyone would be asking him what he means (and he would have nothing to answer) because – as we correctly observe – everything is recorded these days.

    Best
    Luboš

12. **David**
    January 4, 2006

    Peter, it creates a strange impression when on the one hand you bemoan the current dominance of string theory in particle physics (or at least the formal theory end of it) and on the other hand use your blog to publicise the work of string theorists. I can understand it when the purpose is to point out and discuss major problems with the program (landscape etc), but that doesn't seem to be the case here. The admiring tone of your discussion of Nekraskov's "very interesting series of talks" is hardly offset by the mention of the "conc-technical difficulties" bit at the end. Are you a closet string theory fan? (Perhaps analogous to a homophobe whose homophobia is really a reaction to doubts about his own sexuality…)

    In a previous post/comment you said that you thought LQG is advancing much more than string theory at present and that research efforts should be shifted from strings to LQG. Why is it then that you write admiring posts on string theory work but have never done the same for LQG work? (I know you mentioned the talks at Loops 05 but that isn't the same.) Another area where interesting developments have occured in recent years, and which would have been natural for you to mention given you background in it, is lattice gauge theory. E.g. one of the developments in this area made the AIP's `Top stories of 2005′ (www.aip.org/pnu/2005/split/731-1.html); other developments include index theory on the lattice and have led to major progress on the very topic of your PhD work (see, e.g., hep-lat/0108009, hep-th/0407052). Is the reason why you don't mention work in these areas that the people doing it are not high-powered or illustrious enough for your liking?

13. **Alejandro Rivero**
    January 4, 2006

    Well I can think of three justifications for Lubos first comment here:
    1) A naive "social engineering" attemp to discover (for free) the identity of MathPhys

    2) A misread of an early intervention of MathPhys, where he appears as first commenter of a post titled "Hiding in the Mirror". Lubos could had missed a previous

apparition of this commenter some days before and thought that this one was the first one, then being a subtle play of Peter.

3) I really thought a third reason, but I have forgotten it while I was writting this note.

14. **hobgoblin**
January 4, 2006

The issue is about finiteness, and the arguments on one side seem to consist of statements like 'There's no evidence that it isn't finite and no reason to suppose that something magical will step in at higher orders and ruin everything,' while the argument on the other side is 'There's no proof that we have finiteness at all genera and the assumption that we do have it without further evidence is wishful thinking.'

A lot of the debate in theoretical physics seems to be like this lately. There's an awful lot of politicization and taking sides going on, and that isn't healthy for science. In fact, most of the side-taking seems to relate specifically to string theory (either 'string theory is the best achievement of the human race since speech' versus 'string theory is a massive waste of resources that are better spent elsewhere', or 'the landscape is stupid' versus 'the landscape is the best achievement of the human race since string theory').

As for Lubos, he has been diagnosed as a narcissist.

15. **WorldRen**
January 4, 2006

Peter,
In your posts, you try to publicize the most recent development in string theory and modestly criticize it at the same time. Well, the key problem with string theory is, of course, that there is no experimental evidence to prove it or disprove it yet. So string theory is special. I suggest everyone should be careful when making posts and comments in case not to mislead people. Maybe we need some humility in string theory.

Dear Luboš Motl,
You seems to be confident. But if one becomes too confident, he/she may ignore others' existence and may somewhat reluctantly trusts anything.

16. **Ben Compson**
January 4, 2006

Lubos, presumably you are going to apply for a faculty position at some point, then hope to be awarded tenure. Have you thought of the consequences of having written so many nasty comments and ad hominem attacks on this career path?

Or do you think yourself so smart that that all your online activities will be overlooked?

17. **secret milkshake**
January 4, 2006

hobgoblin: I have a problem with what you wrote:
1) such a diagnose requires some experienced psychiatrist
2) who needs to be at least as smart as the patient.
3) and who does carefull examination of the case history + interviews + tests with the patient.

The results are not likely to be posted on a blog. To the point 1) and 2): I am not sure you can find somebody qualified, Dr. Lecter has been travelling.
You better re-phrase your statement to something like this: "Lubos has been widely conjectured to be a piece of work".

Also, check out the most recent Motl, Vafa paper on arXiv; they are trying to drasticaly narrow the permisible lansdscape by introducing a new condition (by hand). If you ask me, the new hand-drawn line between the landscape and swampland on Fig.1 looks a lot like map of Czech Rep…

18. **woit**
January 4, 2006

Hi David,

You're probably right that I take too great an interest in following exactly what string theorists are up to. One justification I can give is that if I'm going to criticize them I should at least understand what they are doing, but sure, that's not sufficient.

I should try and make more clear what this blog is and what it isn't. It's my own take on what I for one reason or another take an interest in, it's not in any way an attempt to make uniform judgements about what is or isn't worth pursuing in theoretical physics. The fact that I don't take enough of an interest in something to write much about it doesn't mean it's not interesting, it just means that for one personal reason or another it's not something I've spent much time thinking about, virtually always simply due to a lack of time. There are many, many, many topics I wish I had more time to look into and think about.

About LQG: I have written some about it, but one of the main reasons I haven't written more is that it is an active, healthy subject that already has some really excellent expositors (such as Smolin and Rovelli). I encourage people to read what they have to say, and if quantum gravity is your main interest, you should be paying close attention to what is going on in LQG. But quantum gravity is not my main interest, particle physics is, so I'm mostly spending my time thinking about other things than LQG. While I think what the LQGers are doing is great and should be encouraged, I also want to draw attention to ideas closer to my own interests that are getting virtually none.

About lattice gauge theory: Again, this is an important, healthy subject, with a lot of good work going on. But it's not something I actively think much about these days. Some of my current interests grew out of first thinking a lot about spinor geometry in an attempt to find better ways to put spinors on the lattice. This is a problem I keep hoping to find time to come back to. If I ever do, I'll probably be writing more about lattice theories here.

As for my interest in string theory. First of all, while I do bemoan endlessly its current dominance, the formal theory end of it is actually the part that I think is worth paying some attention to. What seems to me really a complete waste of time are some of the phenomenological ends of the subject. Unlike "string phenomenology", the more formal, mathematical ends may very well lead somewhere, at least in terms of producing spin-offs of good new mathematics or new ideas about quantum field theory. The Nekrasov talks are a good example. If you look at his second talk, which I just watched, it's all about an interesting 2d qft, one with target space one of great geometrical significance, the space of pure spinors (=space of orthogonal complex structures). This is a nice QFT story, involving some spinor geometry that deserves to be much better known. Ignoring the string perturbation theory context, on its own it's a nice piece of work on quantum field theory. Some of the other topics Nekrasov discussed in his first lecture involve again some beautiful ideas that are independent of string theory, especially the use of twistor methods to study Yang-Mills.

One of my reasons for taking an interest in the multi-loop issue is purely idiosyncratic: I have friends and colleagues who have worked on this, and have enjoyed discussing their work with them and follwing this story over the years. Finally, I think it is also an excellent example of what's wrong with how string theory is often being pursued. Instead of honestly evaluating what is known and what isn't, and trying to push forward and learn more (as Nekrasov, D'Hoker, and Phong are doing), string theory partisans loudly make untrue claims and personally attack anyone who disagrees with them. Lubos is just the most extreme case, others like Distler aren't much better.

19. **anon**
January 4, 2006

Lubos is symptomatic of the bigotry of many theoretical physicists.

In a way you could say it is refreshing honest to see a person behaving so outrageously instead of quietly suppressing opposition.

Lubos loudly proclaims without a fig leaf of evidence that string theory must be right, and that alternatives are a waste of time.

This in my opinion is more honest than the usual "conspiracy of silence" which theoretical physicists use. Without people like Lubos, there wouldn't be much evidence of the misery caused!

20. **Michael**
January 4, 2006

"[…] if I'm going to criticize them I should at least understand what they are doing […]"

Peter, do you believe you do understand what string theorists are doing? May I quote you as saying that you believe you understand recent developments in string theory?

Thanks,
Michael

21. **secret milkshake**
January 4, 2006

since the Bogdanov affair, it is clear that that some PhD comitees and article editors do not have much clue about string theory. (At least at one minor French university and several less-known journals, they were accepting/publishing 100% balooney stringy thesis + several articles. This was done on the face value of the summary of this bogus work – because the comitees/referees were unable to understand the gibberish.)

22. **woit**
January 4, 2006

Michael,
I have no idea who you are, but from your behavior I'm quite sure that I understand a lot more about recent developments in string theory than you do. And yes, you can quote me on that.

23. **shantanu**
January 4, 2006

Peter , what about neutrino physics. It is one field in particle physics in which
there have been lots of exciting developments in the past 7 years both in
experiments (neutrino mass discovered, solar neutrino problem solved,
direct evidence for tau neutrino, etc.) IS it something which can impact rest of particle physics and what do you think?

24. **MathPhys**
January 4, 2006

Michael,

If Peter Woit had no clue what he's talking about and/or what's going on in string theory, people like you (and most notably Motl) wouldn't even bother to log onto his web site, let alone take the trouble to write comments on it.

I just don't see what your problem is with someone who says that the formal/technical aspects of string theory are great, but that the theory has made no contact with physics.

It seems like a very reasonable point of view (also made by people like 'tHooft, and in different ways by Witten) and one that any of us may wish to disagree with but can also live with.

Logging onto this site simply to write insulting comments anonymously is something that doesn't become a scientist.

25. **woit**
January 4, 2006

Shantanu,

There certainly has been a lot of progress in neutrino physics in recent years, and it looks like there will be more in years to come (MiniBoone and Numi-Minos should soon be reporting results). It's one piece of particle physics where the limitations on the energy to which we can accelerate particles is not very relevant.

But the problem is that we still have no idea where the entries in fermion mass matrices come from, neither the ones we already knew about, nor the new ones we're learning about in the neutrino sector. So what is being discovered about neutrinos is just adding a new puzzle to solve, pretty similar to one we've already failed at solving for quite a while now. Maybe there will be some hint hidden in the structure of these new numbers that gives an important clue…

26. **dan**
January 4, 2006

Peter,
Does theory predict neutrinos travel at a constant speed (presumably less than c due to mass) at all times, or can they vary, and can gravity slow down (or accelerate) their speed?

i wonder if dark matter is nothing else but slow moving neutrinos?

does string theory have anything to say about neutrinos?

27. **woit**
January 4, 2006

Dan,

I don't want to get into a discussion of this here, it's off topic. But very quickly: yes, neutrinos travel at variable speed less than c, string theory says nothing about neutrinos, and dark matter doesn't seem to be just neutrinos (their mass is too small).

28. **hobgoblin**
January 5, 2006

Dr. Milkshake,

You're right about needing a qualified psychiatrist to make a diagnosis, but you don't need a psychiatrist to see that something is abnormal. Psychiatrists have crazy people brought to them by non-psychiatrists – they don't have to prowl around the population looking for candidate crazies who others just aren't qualified to spot.

I'll have a look at the landscape paper today. Best of luck to everybody for 2006 from the goblin.

29. **David**
January 5, 2006

Hi Peter,
Thanks very much for your detailed, balanced reply to my somewhat knee-jerk comment. I understand your points. The problem I have with the original post, while sympathising with the reasons you gave in your comment, is that it adds to the impression that string theory is where the action is and that if someone wants to make an impact in particle physics then that is what they should be working on. I know this wasn't really your intention, but still, it's an impression that someone reading it could easily get.

More generally, when attempting to counter the "sociological" problem of string dominance I think it is crucial to emphasise and discuss breakthroughs and interesting developments taking place in other areas. I do understand though that there is only so much that you as an individual can do in finite time. And for what it's worth I think you have generally been doing an excellent job of pointing a critical spotlight on string theory. There was a real need for someone to step in and counter the string hype, and you have been performing this role admirably imho. It's too bad there aren't other people to help you out with this. (Sure there are other string critics but as far as I can tell no one else has been prepared to immerse themselves in the details in the way that you have done.)

Best wishes,
David

30. **Arun**
January 5, 2006

I had technical difficulties in getting to Nekrasov Lecture 2, and I wouldn't understand most of it anyway. Was there anything that throws new light on the superstring perturbation expansion?
Thanks in advance!

31. **woit**
January 5, 2006

Arun,

Nekrasov's second and third lectures were rather technical, mainly about the sigma model discussed in his recent paper. Unfortunately the video cut off at the end of his third lecture while he was about to answer questions from the audience. He describes his approach as a more geometrical version of that of Berkovits, I don't think he has actually used it to do multi-loop calculations himself. He did say that Berkovits claimed to be able to use his formalism to reproduce some of the 2-loop results of D'Hoker-Phong and even come up with some new ones. But nothing in his talk that I noticed dealt explicitly with the issue of what happens at higher order than 2-loops.

32. **mathjunkie**
January 7, 2006

Peter appeared as MathPhys to attack the stringy guys?

Outrageous Fortune

January 4, 2006
Categories: Uncategorized

There's an article in this week's Nature by Geoff Brumfiel entitled [Outrageous Fortune] about the anthropic Landscape debate. The particle physicists quoted are ones whose views are well-known: Susskind, Weinberg, Polchinski, Arkani-Hamed and Maldacena all line up in favor of the anthropic Landscape (with a caveat from Maldacena: "I really hope we have a better idea in the future"). Lisa Randall thinks accepting it is premature, that a better understanding of string theory will get rid of the Landscape, saying "You really need to explore alternatives before taking such radical leaps of faith." All in all, Brumfiel finds "… in the overlapping circles of cosmology and string theory, the concept of a landscape of universes is becoming the dominant view."

The only physicist quoted who recognizes that the Landscape is pseudo-science is David Gross. "It's impossible to disprove" he says, and notes that because we can't falsify the idea it's not science. He sees the origin of this nonsense in string theorist's inability to predict anything despite huge efforts over more than 20 years: "'People in string theory are very frustrated, as am I, by our inability to be more predictive after all these years,' he says. But that's no excuse for using such 'bizarre science', he warns. 'It is a dangerous business.'"

I continue to find it shocking that the many journalists who have been writing stories like this don't seem to be able to locate any leading particle theorist other than Gross willing to publicly say that this is just not science.

For more about this controversy, take a look at the talks by Nima Arkani-Hamed given today at the Jerusalem Winter School on the topic of "The Landscape and the LHC". The first of these was nearly an hour and a half of general anthropic landscape philosophy without any real content. It was repeatedly interrupted by challenges from a couple people in the audience, I think David Gross and Nati Seiberg. Unfortunately one couldn't really hear the questions they were asking, just Arkani-Hamed's responses. I only had time today to look at the beginning part of the second talk, which was about the idea of split supersymmetry.

Update: One of the more unusual aspects of this story is that, while much of the particle theory establishment is giving in to irrationality, Lubos Motl is here the voice of reason. I completely agree with his recent comments on this article. For some discussion of the relation of this to the Intelligent Design debate, see remarks by David Heddle and by Jonathan Witt of the Discovery Institute.

Comments

1. **JoseIRS**
   January 5, 2006

   I don't understand how string theorists don't realize that the idea of the landscape go against of the former philosophy of his theory: "standard model contains multitude of adjustable parameters, etc…". With the landscape we don't need string theory: we live in a multiverse and in each pocket universe the parameters of the standard model take different values, so we don't need to explain that particular values of our universe.

   It's a shame for people that, like me, had some hopes in string theory, to see how it is transformed in a ridiculous sci-fi story by Susskind and company.

2. **MathPhys**
   January 5, 2006

   I think David Gross is a hero.

3. **anon**
   January 5, 2006

   "I continue to find it shocking that the many journalists who have been writing stories like this don't seem to be able to locate any leading particle theorist other than Gross willing to publicly say that this is just not science."

   This is called the "tactiturn problem":

   "An old Cambridge story, concerning a person who found himself sitting next to the taciturn Prof. X (X being variously named as Dirac, Stokes ..) at dinner.

   "Person sitting next to X: "someone has bet me I won't get more than 2 words out of you tonight"

   "Prof. X: "You lose!"

   – Josephson, see http://electrogravity.blogspot.com/

4. **Dumb Biologist**
   January 5, 2006

   I just don't get it.

   During the course of a conversation at Cosmic Variance, I've learned of something like four or five testable hypotheses for extending the SM, some even involving extra dimensions with or without strings/branes, most very difficult to distinguish from one another, and it seems like in a decade or so there will be plenty of new stuff about our own universe to argue about. Stuff we've actually *seen*, because we *can*. Once we've seen what we will see, we'll build a bigger machine to pin down some of the observed "BSM" physics. It'll take time, but it looks like particle theorists have their hands very full already just preparing to interpret the LHC's discoveries.

   I just don't understand why, in a universe so full of unsolved, yet conceivably tractable problems, a scientist would not recoil from a path that leads inevitably to the unobservable. I don't understand the arguments for exploring the landscape because "it might be right" when one cannot *ever* assay causally isolated regions of the putative multiverse. What's even more bizarre is the apparent notion that String Theory can incorporate all the plausible hypothetical models of TeV physics that have been constructed in anticipation of actually doing that TeV physics. Little Higgs? Well that's just this version of String Theory with d branes on orbifolds. Low energy SUSY? String Theory predicts it. High energy SUSY? Same thing! (why not? there's a landscape, after all…) UED? My guess is since it's got a KK tower and extra dimensions, naturally it's just a facet of string theory…

   It's everything, it's everywhere, it's bigger than we can ever know. Whatever you think it is, it's strings. It can't be killed!

   Must be fun doing calculating God…

JoseIRS wrote:
"With the landscape we don't need string theory: we live in a multiverse and in each pocket universe the parameters of the standard model take different values, so we don't need to explain that particular values of our universe."

I understand that some find this disappointing or irritating, but what is the objection to the possibility that this happens to be exactly the way things are?

10. **Adrian Heathcote**
January 5, 2006

EF says "what is the objection to the possibility that this happens to be exactly the way things are?"

What is it that "makes" the values of the parameters take on different values?

11. **woit**
January 6, 2006

Elmer,

The objection to this possibility is not that it is inherently impossible or inconceivable, but that there is no scientific evidence for this at all. No one has a consistent theory that makes some predictions that can be checked and also predicts this kind of multiverse. What is going on here is that string theory has failed as an idea about unification, and instead of acknowledging this, its proponents are giving up on the standard idea of how to do physics. They are turning theoretical physics into a pseudo-science whose only purpose is to come up with untestable explanations for why string theory should be believed, despite the lack of any evidence for it, and the impossibility of ever getting any evidence for it.

12. **Anonymous**
January 6, 2006

I suggest you check out Nima's talk "Possible and Impossible In Effective Field Theory (2)." He gives field-theoretic arguments (to appear in a paper soon, I gather) that certain effective field theories used in phenomenological models are sick. They have a secret inconsistency with Lorentz invariance + causality + unitarity, which is only visible when you turn on a nontrivial background (so in that sense, it is a nonperturbative problem). This together with the recent paper by Nima, Lubos, Alberto Nicolis and Cumrun Vafa seem to be very interesting directions. They're ruling out huge classes of effective field theories all at once, based on very solid general arguments. We can hope that continued study along these lines might reveal hidden inconsistencies in string vacua as well, but even if it's limited to effective field theory this is powerful stuff. I have a feeling that a fairly large class of extra-dimensional models are ruled out on similar grounds.

13. **Chris W.**
January 6, 2006

> I understand that some find this disappointing or irritating, but what is the objection to the possibility that this happens to be exactly the way things are?

Haven't we had enough of this particular line of bullshit? The reason that so many people have come to accept the strangeness of quantum mechanics, notwithstanding its challenges to our intuitions and pre-existing philosophical prejudices, is that it is supported by a vast array of *empirical evidence*, and it has been extremely difficult to find empirically viable alternatives that are any more palatable. Do you remember what "empirical evidence" means? It means confirmation by actual observations that *could easily have contradicted the theory*, but once made, were found to be consistent with it.

If you want the Multiverse to *deserve* to be taken seriously as a scientific hypothesis then you have to do a hell of a lot better than saying, "well, after all, that *could* be the way things are". You might object by pointing out that we were led in the first place to inflation, and then eternal inflation and the multiverse, by attempting to apply quantum field theory and general relativity to the whole universe. (I'm acknowledging the argument that a form of the multiverse predates the string theory 'landscape', although the landscape can be [and should be??] interpreted as an even bigger and messier multiverse.)

Well, to the extent that this has led fundamental physics into its current quandary, we ought to be questioning the theoretical (and philosophical!) assumptions that got us here, rather than just saying, "that could just be the way things are" in the total absence of genuine empirical evidence that they are that way. We could have settled for such a pseudo-solution to any number of problems in the last 350+ years. It's as much of a copout now as it ever was. It's like saying, "well, the ether could exist, and the properties of matter and electromagnetism could just happen to conspire to make its presence undetectable by any means we have been able to imagine. In fact, thanks to H. A. Lorentz and others, we have models for this. So let's keep right on creating mechanical models of the ether itself and try to understand it better."

— Peter: The above is little more than a polemical elaboration on your comment, but I felt the need to post it anyway. I too have felt for quite a while that the “things could actually be that way” argument is about as worthless as assertions that astrological influences *could* be real.

14. **Adrian Heathcote**
January 6, 2006

”What is it that ‘’makes’’ the values of the parameters take on different values?”

Maybe that was putiing my point too rhetorically. So to be clearer: I doubt that there is *any possible explanation* of how, or why, the free parameters assume the values that they are meant to assume. They can’t be taken as eigenvalues of some operator—which would be the QM path—for there would be no explanation of how the operator came to act; and it would not constitute an explanation to say that they can’t be taken as the solutions to some equation—the classical way: this would not tell you how any particular universe has the properties that it does. So the landscape idea is an explanation-free idea posing as an explanation.

15. **island**
January 6, 2006

Peter: The above is little more than a polemical elaboration on your comment, but I felt the need to post it anyway. I too have felt for quite a while that the “things could actually be that way” argument is about as worthless as assertions that astrological influences could be real.

I really am ashamed to say that neo-darwinists do the same thing on a regular basis. They think that speculative theories are fair game in origins science just because they’re popularized.

17. **Urs**
January 6, 2006

If we forget for a moment string theory, the landscape speculation, our disdain for string theory or the disdain for the way some of it is being performed, then what remains is the following trivial fact.

Fact: We have *no clue* if the final theory, whatever it is, will fix the parameters of the standardmodel uniquely.

Claiming that we do know that the parameters should be unique solutions of some equation is just as much astrology as claiming the opposite.

The problem with the landscape discussion is not that it is a priori pointless to think about a theory in which the parameters of the standard model are not uniquely specified.

18. **Who**
January 6, 2006

I think I agree with Urs here:

The problem with the landscape discussion is not that it is a priori pointless to think about a theory in which the parameters of the standard model are not uniquely specified.

The validity of Urs position was demonstrated by Smolin in “Scientific Alternatives to the Anthropic Principle” which exhibits an EXAMPLE of a falsifiable theory in which SOME of the parameters are locally optimal for black hole formation.

Urs seems to be saying “it is not a priori pointless to think about” theories in which some of the parameters are variable.

In fact one can be more definite than Urs was, and say it can be entirely POINTFUL to think about such theories—because the set of such theories that are predictive and falsifiable is non-empty.

Smolin CNS is a kind of “existence proof” example showing that one can have a theory in which perhaps some of the parameters are uniquely determined but where others are variable and assume values near local maxima for black hole formation. Then if some astronomer or experimentalist ever happened to observe that one of the variable parameters of this theory is NOT near-optimal for black hole abundance, this would be evidence against the theory.

To elaborate on what Urs said: I think maybe what IS the problem with landscape discussion (Urs says what it is not) is that when one does science one has a MORAL OBLIGATION TO USE TESTABLE THEORIES because the scientific community depends for its unity on the possibility of resolving differences of opinion by empirical methods.

(rather than by rhetoric or showbiz or war or burning-at-the-stake, or all the other ways people have of arriving at consensus)

19. **Tony Smith**
January 6, 2006

Anonymous says that Nima gives “… field-theoretic arguments (to appear in a paper soon …) that certain effective field theories used in phenomenological models are sick. They have a secret inconsistency with Lorentz invariance + causality + unitarity, which is only visible when you turn on a nontrivial background … I have a feeling that a fairly large class of extra-dimensional models are ruled out on similar grounds. …”.

How “sick” do the “ruled out” effective field theory models appear to be?
Can they me “cured” by modifying them in some reasonable way, just as some unifications of gravity plus standard model were “cured” of “inconsistency” with Coleman-Mandula by using Lie superalgebras instead of ordinary Lie algebras ?

Even if “a fairly large class” of models were to be conclusively “ruled out”, wouldn’t that still leave the landscape subject to the same type of objections that are being made now, because the landscape after removal of such a “ruled out” part might still be a very large landscape,
unless
the “ruling out” process were able to “rule out” all but one unique physically realistic model ?
Is that the goal of Nima et al in that line of work?

What about, instead of starting with a landscape full of models that may or may not, as Urs says, “fix the parameters of the standard model uniquely”,
approach the situation by spending some time and effort studying models that do “”fix the parameters of the standard model uniquely”, no matter how unconventional they might appear at first glance. At least one such model (mine) can be formulated in terms of (non-supersymmetric) string theory.
Since it is not supersymmetric, would it not be included in the landscape in which Nima et al are searching?

Tony Smith

20. **woit**
January 6, 2006

Urs,

I’m not claiming at all that one has to believe that a final theory will fix the standard model parameters. Maybe it will, maybe it won’t, maybe it will fix some and not others. The problem with the anthropic landscape is that it not only predicts absolutely nothing whatsoever, it does not even come with a remotely plausible idea about how it will ever be able to predict anything. The best people like Susskind can do is say that if we devote thousands of physicist-years to investigating the landscape, maybe we’ll find some way to make a prediction, even though there is zero evidence so far of any such thing. As far as I can tell, the justification for doing this is pure wishful thinking and desire to avoid admitting failure. This isn’t science.

The issue of whether or not certain parameters are environmental is a red herring. Right now, we don’t know and our job as scientists is to figure out what determines them. If we’re successful at that, then we’ll know whether they are uniquely calculable or not. The real issue here is one of scientific ethics: we’re faced with the shocking phenomenon of leading figures in the field abandoning honest science. What do you do about this? Just say that maybe they’re right, and this has to be done? People like my commenter David Heddle and the Templeton foundation, who would love to mix religion and science together, think what is going on is great. I think it’s appalling.

21. **David Heddle**
January 6, 2006

Peter,

This is the second time (once on a previous post) you mischaracterize my view. You claim I think it is “great.” I do not. In terms of the landscape similarities to ID, I think it is *amusing*, not great. I don’t spell that out in my posts, but I don’t think you have Fellini to figure it out.

If I promoted ID as science, then I might find it great. But I take no pleasure, as a physicist, that some of the brightest in HEP are telling us, in effect, that physics as we know and love it is, ultimately, a fool’s errand.

22. **woit**
January 6, 2006

Anonymous,

I did look at Arkani-Hamed’s talk you mention, as well as his recent paper. It’s the same idea as Vafa’s “Let’s investigate the Swampland”, and I have the same objections. If one manages to show that some sorts of exotic brane-world scenarios can’t be embedded in our current understanding of string theory, so what? There’s zero evidence for either them or string theory, and our understanding of string theory is so primitive one can argue that when we understand it better it will accomodate even these exotic scenarios.

Amidst the swampland hype, you’re missing the main point. This has nothing to do with the problem of the landscape. The infinite number of known vacuum states of the landscape are still there and those mucking about in the swampland have nothing to say about them. You are attributing to this work some interesting possiblities that even its promoters don’t claim.

23. **woit**
January 6, 2006

David,

Sorry for mischaracterizing your views. Sounds like we’re more in agreement than I thought, although “amusing” is not quite my reaction to Susskind.

24. **island**
January 6, 2006

David Heddle said:
If I promoted ID as science, then I might find it great…

Ah, but you do, (make an unfounded leap of fath to) promote the anthropic principle as scientific evidence for the existence of god, so you must, (like me, but for different reasons), be happy to see that Lenny has admitted that these special implications do exist if there is no multiverse?

25. **David Heddle**
January 6, 2006

island,

This is a great blog and I don’t want to be a troll so I’ll clarify my position just once. In the sense that Susskind is motivated by the problem of fine-tuning I am pleased because he has provided a service. I have spent so much time arguing that there is fine-tuning that I admit Susskind has been helpful in demonstrating that it is real and requires an explanation. You have no idea how many of the Panda’s Thumb folks have argued with me that only religious wingnuts claim there is fine tuning, and that the cosmological constant is off by 120 OoM only because the calculations are naïve (or because of the units one uses). I am now sensing, thanks in part to Susskind, fewer objections along those lines. For that you can't fault Susskind—after all there really is a fine tuning problem.

But two points are obvious:

1) If Susskind is correct, then fine-tuning is an illusion
2) If Susskind is correct, it's a dark day for physics

Still, if there were a way to test the landscape, I'd be all for it.

Similarly, if black-hole natural selection is correct, then once again fine tuning is an illusion–but hey, let's do the science and see how it plays out.

I am always for doing the science. If it ever explains the fine-tuning, then I'll stop talking about cosmological ID. Strangely, the best way to preserve the fine-tuning and to preserve cosmological ID would be a fundamental theory that explains the constants. That is where I hope progress in HEP is forthcoming. If no progress is ever made, I fear we'll reach a point where undetectable multiverses are accepted as self-evident. That would be very bad.

This period we are in now–where cosmology is so metaphysical and really smart folks are ready to redefine science–well that's not good news for anyone.

26. **island**
January 6, 2006

I just want to say that I do not think that David is a troll, and I actually have a fair amount of respect for the man as a mostly honest with themselves), scientist, regardless of our departure.

You have no idea how many of the Panda's Thumb folks have argued with me that only religious wingnuts claim there is fine tuning,

Yes, I do, because I've done the same, myself, and I've made your point to this group on numerous occassions, without pulling any punches as to how I feel about their willfully ignorant, Devil's-advocate approach.

I make this point so emphatically because it is so relevant to this whole mess that it isn't even funny!

This attitude goes well beyond neodarwinians… and it is killing science!

27. **Leon Hart**
January 6, 2006

It seems to me that (finally) scientists, string theorists in this case, are reaching the limits imposed by Godel's theorem (the Godel Wall). One can get arbitrarily close to the wall, but it takes an infinite amount of time to actually touch it. The closer you get, the larger the number of Lanscapes you see. I find this debate extremely interesting indeed.

With respect to a "final theory" (perhaps maybe it should be called "next model" because there might be further and even better ones), Peter said:
"… Maybe it will, maybe it won't … fix the standard model parameters …
… our job as scientists is to figure out what determines them …".

How should scientists figure that out?

As to any parameters that might be unfixed by a "next model", maybe the anthropic/landscape approach is the only way to go.

As to parameters that might possibly be fixed, what methods might be used to fix their values? Here are some possibilities that come to my mind (not necessarily in order of how useful they might or might not be):

1 – Renormalization techniques – For example, Alvarez-Gaume, Polchinski, and Wise (Nuclear Physics B221 (1983) 495-523) said "… Weak interaction breakdown occurs for top-quark masses between 100 and 195 GeV … The renormalization group equation … tends to attract the top quark towards a fixed point of about 125 GeV …".

2 – Volumes and measures related to symmetry groups – For example, Wyler's calculation (see his IAS papers at http://www.valdostamuseum.org/hamsmith/WylerIAS.pdf) of the fine structure constant.

3 – Combinatorial methods – For example, in their book Combinatorial Physics (World Scientific 1995), Bastin and Kilmister offer an extension of Eddington-type calculations.

4 – Chaotic structures of quantum fields – For example, the work of Christian Beck in hep-th/0207081and other publications.

5 – P-adic structures – For example, the work of Matti Pitkanen.

6 – Algebraic structure of quantum field theory – For example, the work of Connes and Krein in hep-th/0201157.

7 – Phenomenological structures in string theory – For example, the work of Lust in hep-th/0401156 (since this is a part of string theory and is well-funded, there are many other examples of this).

8 – Clifford algebra structures – For example, the works of Traying and Baylis in hep-th/0103137 and of Chisolm and Farwell in J. Phys. A: Math. Gen. 20 (1987) 6561-6580.

I am not saying that the above list is exhaustive, nor that all the examples are the best that might have been chosen, and I am not saying that any or all of the listed methods may or may not be useful (in fact, I use more than one of the listed methods in my model, which does fix the parameters of the standard model).

I am saying that it would be a good idea if some funding and support were available for work on all such methods (not just the "popular" or "superstringy" ones) and that none of them should be banned, or people who work on them blacklisted, just because some influential people don't like them.
If any of them produce calculations, then comparison with experiment can determine how useful they are.

Tony Smith

30. **Chris W.**
January 6, 2006

Kind of off-topic, and kind of not: Sharon Begley of the WSJ has this to say about recent experiments in nano- and mesoscale quantum mechanics:

> But I confess that interests me less than what producing cat states and entangled particles says about the world. In an essay at the Web site Edge.org, astrophysicist Piet Hut of the Institute for Advanced Study muses that quantum advances are making conventional understanding about what exists and what is real start "to melt away." With "avant-garde insights" such as entanglement, he writes, the next scientific revolution "could be a dissolution of the strict distinction between reality and fiction."
>
> To which Dr. [Dietrich] Liebfried* adds, "I'm with Niels Bohr [a founder of quantum physics]. If you're not outraged by the implications of quantum physics, you don't understand it."

(* of NIST)

31. **Urs**
January 7, 2006

I feel like listing more trivial facts.

Fact: If you don't fully understand your theory yet, it is speculative to talk about its space of solutions.

Fact: Interesting speculations tend to play an important role in the development of physics (like conjectures do in mathematics).

Fact: Debate over speculations tends to be fruitless unless concrete substantial questions can be addressed with non-philosophic means.

Once we agree on these fact we can move on with the really interesting questions. (That was my optimistic statement for today.)

32. **Who**
January 7, 2006

David Heddle 6 January 1:18P
Similarly, if black-hole natural selection is correct,…–but hey, let's do the science and see how it plays out.

the science IS being done whenever the mass of a neutron star is measured.

the theory is empirically testable and it is being tested—-although more could be done by way of working out detail and deriving other predictions (other means of testing the theory).

Urs 7 January 8:57A

Fact: If you don't fully understand your theory yet, it is speculative to talk about its space of solutions.

I don't think this is right. A famous counterexample is Darwin's theory of evolution by natural selection. In the mid-1800s, genes were not known—the mechanism of heredity which allowed for small variations in offspring was not understood—but one could still test the theory.

If a theory makes a prediction, then one can test the theory, and "address substantial questions" by empirical (non-philosophic) means even though the theory is not completely understood.

**…
Fact: Debate over speculations tends to be fruitless unless concrete substantial questions can be addressed with non-philosophic means.**

I believe what you say here is true and it implies that discussion of black hole natural selection is NOT speculative, since the theory can already be addressed by empirical (nonphilosophic) means.

As reminder, a core prediction of black hole natural selection is that you cannot point to any parameter of the standard model which, if it were changed slightly, would lead to a greater abundance of black holes.

33. **Juan R.**
January 7, 2006

I wonder why there is debate about nonsense (i.e. Landscape).

It remember me ancient discussions about the sex of angels…

Perhaps people would take again a course on scientific methodology:

> A scientific hypothesis is one can be scientifically tested.

The 'Landscape' is not pseudo-science as Gross admits. It is pure philosophy or best religion (since God appears in the debate of some 'stringers').

The problem of particle physics and string theorists is that do not understand the world we can see. But is is **their** problem…

I am a bit tired of all this nonsense; that Landscape here, that Landscape there; that the cosmological constant only can be undertood via antropic reasoning [arXiv:hep-th/0511037], etc.

Stop nonsense, I am a scientist!

34. **Who**
January 7, 2006

there's a danger that I'm being misunderstood and need to clarify. If you disagree with these please correct me:

BH natural selection has nothing to do with the "Landscape" of string vacua.

BH natural selection has nothing to do with "God" or "cosmological ID"

BH natural selection is not a "Multiverse" theory in the usual sense.

Essentially this is meant to respond to what Peter said:

woit 6 January 12:12P
The issue of whether or not certain parameters are environmental is a red herring. Right now, we don't know and our job as scientists is to figure out what determines them. If we're successful at that, then we'll know whether they are uniquely calculable or not.

BH natural selection does not assume the cosmology/standard model parameters are apriori environomental. If I understand correctly, it is an appeal to the usual principle of MEDIOCRITY.

We live in a part of the universe that is not atypical

There is a single connected universe—-all part of the same uniform process. Some parameters are allowed to vary slightly during a BH bounce. These will evolve to favor BH formation. A TYPICAL region of the universe will have values of those constants which are at or near local maxima. The **prediction** is, since we live in a typical region, **we will not be able to find any parameter which could be varied slightly so as to make BHs more abundant.**

Because this theory is simple, explanatory, and testable, I am arguing that it should be examined FIRST before imagining multiple (causally disjoint) universes, or anthropic selection effects, or the Landscape of 10^500 string vacua, or intentional manipulation by a conscious "Fine Tuner".

Given that this theory may explain simply some of the parameters in question, for Occam Razor reasons, the research priortiy should be to determine WHICH of the parameters affect BH abundance and then TEST whether their values local optima. This offers a chance to invalidate the theory, whereupon more complex and far-fetched theories could be considered. Basically I am saying that the "Landscape" discussion is out of order until this simple matter has been cleared up.

35. **Juan R.**
January 9, 2006

Who,

> BH natural selection has nothing to do with the "Landscape" of string vacua.

I would not say "nothing to do". Thecnically both are different, but both are related in a conceptual way. In some sense both deal with a multiverse.

> BH natural selection has nothing to do with "God" or "cosmological ID"

It may depend of author. I do not remember Smolin specific arguments but i believe that you are right.

> BH natural selection is not a "Multiverse" theory in the usual sense.

What do you mean by 'usual sense'? Multiverse means "more than one universe" and if i remember correctly, Smolin dealed with multiple universes, each child being more optimized than previous one for the generation of BH. If i remember correctly, Smolin even explicitely used the term multiverse in his writtings…

> We live in a part of the universe that is not atypical

What is the definition of "atypical"? If by atypical i mean far from mean values then i (personally) live in a very atypical region of universe:

– typical temp, 3 K. Vigo temp today, 288 K.

– typical dens, 10^(-25) kg m^(-3). Earth dens. 5,52 kg m^(-3)

> There is a single connected universe—-all part of the same uniform process.

Nobody know anything of that. That is pure speculation (as string landscape)

> Some parameters are allowed to vary slightly during a BH bounce. These will evolve to favor BH formation. A TYPICAL region of the universe will have values of those constants which are at or near local maxima.

Idem

> The prediction is, since we live in a typical region, we will not be able to find any parameter which could be varied slightly so as to make BHs more abundant.

That is not a prediction, no scientifc one at least!

> Because this theory is simple, explanatory, and testable, I am arguing that it should be examined FIRST before imagining multiple (causally disjoint) universes, or anthropic selection effects, or the Landscape of 10^500 string vacua, or intentional manipulation by a conscious "Fine Tuner".

I do not call simple a theory with a landscape number of **unobserved** universes in a great cosmological evolutionary family. 'That' has explained nothing of *this* world. I think that it would be ignored like the rest of nonsense you cite next.

—

Juan R.

Center for CANONICAL |SCIENCE)

36. **Who**
January 9, 2006

Juan thanks for your response. Smolin's hypothesis saves the idea of the universe as a single connected deterministic process evolving everywhere by the same laws.

This is not the usual idea of Multiverse. The usual idea involves many DISCONNECTED causally disjoint items.

The usual Multiverse is not encompassed in a a single uniform evolution.

So there is a clear difference, even if you or Smolin wishes to call his picture a "multiverse".

I think it was simply a bad choice of word on Smolin's part, to call his picture a "multiverse", because it is distinct from the usual in so many basic ways.

I do not know whether BH natural selection is correct or not—-I do not even know if the "Bigbang" event was actually a bounce, with a prior contraction (as some approaches to QG suggest). But the prior contraction should be regarded as JUST AS OBSERVABLE as the first instants of expansion because it is connected to us by a lawful progression.

In the same sense that we can infer things about the first three minutes (of expansion) using independently testable theory, we could also in principle infer things about the final stages of contraction prior to the bounce again using independently testable QG theory.

All observation (at least in cosmology) requires assuming some theoretical model, which must be independently tested, in order to interpret and only in this sense can one say that one can observe the early stages of our expansion—it is an extrapolation of causality.

Granted that **we do not yet have an independently testable model of a BH bounce!** and so I can only say that the prior stage is IN PRINCIPLE observable.
At the present time we cannot infer back because we have no model of what occurs during the bounce.

I disagree with you here:

W: The prediction is, since we live in a typical region, we will not be able to find any parameter which could be varied slightly so as to make BHs more abundant.

JR: That is not a prediction, no scientifc one at least!

It is clearly a prediction which is able to falsify the hypothesis of BH natural selection. If one can find a parameter of the standard model which could be varied in such a way as to make BHs more abundant it would shoot down BH natural selection. The hypothesis is highly exposed to falsification and it amazes me that it has survived for over 10 years without serious challenge.

Thanks again for your critique,

Who

Who wrote:

> If one can find a parameter of the standard model which could be varied in such a way as to make BHs more abundant it would shoot down BH natural selection.

Why? Why could you not counter that our present universe is merely good at producing black holes? Maybe there haven't been many generations. Why does it have to be *optimal*? No, I don't think your falsification test is legitimate.

38. **Who**
January 9, 2006

good objection Heddle,
what I said needs qualification with some vague words like "substantial" and there is a judgment-call involved

if a parameter were found to be within ONE PERCENT of local optimum then I personally would not discard the BH natural selection hypothesis.

but if it were discovered that a gradual change in some parameter by as much as TEN PERCENT

39. **Who**
January 9, 2006

sorry, I struck the wrong key while typing the above, so it got entered prematurely. Here's what I was trying to say: If it turned out that you could vary some parameter gradually and get a steady monotone improvement in BH abundance until the parameter was changed by some ten percent or more, then I would consider BH natural selection refuted and forget about it.

So less than ONE percent from a local maximum seems to me IMHO to be all right, and more than TEN percent from a local maximum would seem in my opinion to be fatal.

In between seems to me to be a grey area and I would listen to expert opinion arguing pro and con. It is a judgment call and I wouldn't try to make up my own mind about it.

It has to do with the primitive (partly intuitive) idea of MEDIOCRITY. I picture a typical region as having gone through enough iterations to get to within one percent of local maximum—-if this process has been going on at all.

if parameters are not within one percent, then my feeling would be that there is something wrong and maybe this process has NOT been occurring. But I would still listen to experts if they disagreed about it—maybe they know something I haven't thought of. And if it is a worse than ten percent fit, then forget it.

thanks for your critical response Heddle. I hope you see the falsification test as legitimate (as qualified) now, or can give me some more definite reasons why you think it isn't.

40. **David Heddle**
January 9, 2006

Well I can see a couple objections.

One is that falsification of BHNS should ultimately be related to an experiment, not to consistency with the standard model.

Second, I don't think one can tweak the parameters of the standard model and reliably calculate the resulting density of black holes.

41. **Who**
January 9, 2006

…falsification of BHNS should ultimately be related to an experiment, not to consistency with the standard model.

to experiment, that is, OR astronomical observation.
For that, see
http://arxiv.org/abs/hep-th/0407213
and also references therein going back to 1994

… I don't think one can tweak the parameters of the standard model and reliably calculate the resulting density of black holes.

Must take up that with Lee Smolin. See the discussion of neutron star mass in the same paper
http://arxiv.org/abs/hep-th/0407213

The paper gives several examples where a few percent change in some standard model parameter is argued to reduce BH abundance

42. **David Heddle**
January 9, 2006

Who,

Thanks for the references. Perhaps my assertion was incorrect. I'll read the papers

43. **Leon Hart**
January 10, 2006

… so the Theory of Everything will be a Web Page where anybody – the Inteligent Designers – will be able to build Toy Universes by guessing the 31 or so parameters (I bet the final number will be 42) that according to Tegmark and coworkers define the Laws of Physics. The rest of science will continue feeding technological innovation as usual to feed. Perhaps research in Extra Dimensions will even lead to spaceships capable of populating the Landscape of all the anthropically valid Universes constructed by the Inteligent Designers.

44. **Juan R.**
January 10, 2006

I am sorry to say this but Lee Smolin paper [http://arxiv.org/abs/hep-th/0407213], even ignoring several thecnical mistakes and acepting (as true) several unproved premises, is NOT a scientific paper.

In no way, the S premise our universe is optimized for production of BH is scientific one. In fact, i ask,can even Smolin rigorously prove the existence of BH?

Question: is S from Smolin?

—

Juan R.

Center for CANONICAL |SCIENCE)

45. **Who**
January 10, 2006

Juan, ***S*** is not a premise, but a statement which Smolin challenges us to show is false—-by empirical means.

S is defined on page 29 of the paper

section 6.3 (page 33) is
"How a single heavy pulsar would refute ***S*** "

section 6.4 (page 34) is
"How observations of the CMB could refute ***S*** "

section 6.5 (page 35) is
"How early star formation could refute ***S*** "

Smolin challenges us to make astronomical observations and find a neutron star above a certain mass, which will falsify the hypothesis he has offered us.

Some people believe that science is done this way, can you explain why you think this is not the case?

——————————

Peter, I want to emphasize the aspect of falsifiability to support and elaborate your quote from David Gross. You wrote:

> The only physicist quoted who recognizes that the Landscape is pseudo-science is David Gross. "It's impossible to disprove" he says, and notes that because

> we can’t falsify the idea it’s not science.

I believe you and others have pointed out that it is unethical for anyone calling himself or herself a scientist to traffic in unfalsifiable suppositions (as do the Landscapers) because the community of scientists depends in an essential way on the ability to resolve differences by empirical test. Scientists a moral obligation to propose only testable theories. David Gross is saying that the Landscapers are not behaving as morally responsible members of the community.

This theory ***S*** may very well be wrong—that is a secondary issue. I think it is being offered, in some measure, to SHOW WHAT A SCIENTIFIC THEORY WOULD LOOK LIKE as an implicit criticism of Landscapery. This supports David Gross’ objection by illustration. It shows that one can have a theory with some explanatory power as regards the values of fundamental dimensionless constants, which nevertheless is not in any sense anthropic and which is highly (one might say almost indecently) exposed to refutation.

thanks,
Who

46. **Juan R.**
January 11, 2006

Who,

Thanks by your opportunity to explain better my point.

In my opinion Smolin Natural selection view is a camouflaged version of anthropic arguments.

About the nomenclature for S, simply to state that, in logic, a premise is “*One of the propositions in a deductive argument*.”

For people who has not read cited Smolin preprint, S is defined as follow

> If p is changed from the present value in any direction in P the first significant changes in F(p) encountered must be to decrease F(p).

where P is the ‘phase’ space of dimensionless parameters of the standard models of physics and cosmology, and the ‘phase’ point characterizing our universe is denoted by p. F(p) is a fitness function which is equal to the average number of descendents of a universe with parameters p.

Yes, it is true that Smolin propose certain observations for the refutation of S and this would be an advance over the untestable anthropic reasoning of stringers, but i continue to say that *S is not a scientific premise*. In fact, i think that Smolin misunderstand the measuring of certain observables *with* the scientific testing of his premise S.

Take, as illustration, the next hypotetical J premise

> Child universes are optimized for 10^(5) value of Lambda(x)

where Lambda(x) is the value of the cosmological constant for our universe.

Then, following with this hypotetical example of a ‘theory’ of “natural cosmological evolution” we could imagine that each universe generates baby universes via a process similar to Linde chaotic inflation.

Now well, could the J premise be refuted?

Reply is negative.

If we measure the actual value for Lambda in OUR universe (order of 10^(-52)) and it is not the value J ‘predicted’, we am **not** refuting J. Imagine now a hypotetical premise J2 claiming a value of 10^(-52). Any measuring of Lambda for OUR universe does **not** verifies or refutes J2.

To your question

> Some people believe that science is done this way, can you explain why you think this is not the case?

I may say that i practice a very strict definition of science and, as many people, I consider that cosmology is not a pure scientific discipline since is based more in observation that in experiment.

I agree with George F.R. Ellis when says that the core of cosmological questions form more a metaphysical discipline that physical one.

Moreover, even if Smolin Cosmological Selection was a scientific theory, I would still wait that Smolin presents us an astrophysical BH.

Each x time all of us heard of a confirmation of a BH, but all previous candidates failed in more detailed test…

In view of the possibility of alien life somewhere out there, isn’t the use of the term anthropic a bit anthropomorphic? Why not generalize it to “panthropic”?

48. **Jack Lothian**
January 12, 2006

I read this month’s Discovery & followed this story here. Very interesting BLOG. I have been hearing about BLOG’s for a while but this is the first BLOG I have visited. Really interesting – more interesting than the last 10 years of Scientific American.

It has been 25 years since I left physics (my field was statistical mechanics – very far from this debate) so I am a bit rusty but I would like to comment.

First – Who:

You say, “S is not a premise, but a statement which Smolin challenges us to show is false—-by empirical means” and then you say “Some people believe that science is done this way, can you explain why you think this is not the case?”

Proving a negative is a high bar to jump – much more difficult than proving a positive. This has the appearance of being a reasonable request but in reality it puts the onus on the refuter to disprove any claim made by the author rather than having author show that the theory suits our reality. These so-called empirical tests seem very fuzzy to me. Most of the tests build on measurements, assumptions and theories that can be challenged – thus ultimately they are false tests.

Secondly in economics they distinguish between “empirical facts” and “stylized facts”. Empirical facts are facts that can be verified in repeatable and controlled experiments while stylized facts are observed consistencies that are observed in non-repeatable and non-controlled systems. Often stylized facts are observed in a limited number of data sets. I believe what you are calling empirical facts are actually stylized facts.

Thirdly as a general comment on the issue. I am avid reader of sci-fi & in the last few years I observed a phenomena that troubles me. More & more sci-fi writers are claiming their fictional ideas are supported by current physics theories. To support these scientifically outlandish ideas they usually point to articles or talks from well-known string or landscape theorists. When the line between sci-fi & science blurs I worry about where science is going.

Lastly, for over 30 years I have been an avid reader of Scientific American and my impression is that starting in the 80s, outside of genetics, fundamental breakthroughs and discoveries have really slowed down in many sciences, especially in physics. Where there use to be 1 or 2 really interesting and thought provoking articles each months, recently 1 or 2 a year is the average. I personally don’t think the decline is due to a decline in the quality of the writers – rather it is a reflection of a decline in the quality of the science being produced.

A layman’s thoughs.

49. **woit**
January 12, 2006

Hi Jack,

Glad you like the blog. I certainly share your perception that fundamental breakthroughs in physics have slowed down (although there are some subfields like astrophysics and cosmology, which have been very active). In particle physics, the problem is that the field has been a victim of its own success. The standard model, developed by 1973-74, is just too good, and addressing some of its remaining problems requires energies that are technologically very hard to reach. As a result, things have gotten strange in particle theory…

50. **Thomas Larsson**
January 13, 2006

Jack,

It has been 25 years since I left physics (my field was statistical mechanics – very far from this debate)

If you had stayed on for another five years, the gap would have been much smaller. In 1984, conformal field theory, which counts as stringy math, was applied to 2D phase transitions, certainly a subfield of statphys. Unlike the situation in string theory, this application of CFT has been experimentally confirmed beyond reasonable doubt. But that something is relevant to 2D statphys does not mean that it is relevant to 4D gravity, or even 3D statphys.

51. **Who**
January 13, 2006

Hi Jack,
I will explain why showing S to be false is not as complicated as you might think.

for starters, in his paper Smolin explains why simply observing a neutron star above a certain mass would falsify S.
Just take a look at the paper
http://arxiv.org/hep-th/0407213
around page 33

he has worked out one way of falsifying the theory, saving us the trouble.

but more generally, look at what S actually says and you will see that it is rather straightforward to falsify it by empirical observation

——here’s part of your comment—-
You say, “S is not a premise, but a statement which Smolin challenges us to show is false—-by empirical means” ….

Proving a negative is a high bar to jump – much more difficult than proving a positive….
——–endquote———

I will explain that in THIS case proving the negative of S is NOT a high bar to jump! It is more like proving a positive.

Here is what S says:

> If p is changed from the present value in any direction in P the first significant changes in F(p) encountered must be to decrease F(p).

P is the parameter space—-if there are 31 dimensionless constants going into the standard models of particle physics and cosmology then P is just a 31 dimensional space —-a point p in P is a list of 31 numbers.

F(p) measures the abundance of black holes. To falsify the statement all you need to do is FIND ONE DIRECTION IN WHICH TO CHANGE p SUCH THAT F(p) INCREASES.

The statement says that changing p (from the measured value) in ANY direction will cause the abundance of BH to DECREASE.

To refute that you just need to find ONE direction in which a change will make it INCREASE. Just find **one uphill direction**
and you’ve done it! The theory is toast!

The changes involved have to be significant in the sense of exceeding noise or measurement uncertainties, that is discussed somewhat in the paper, but this is the broad outlines.

52. **Juan R.**
January 14, 2006

Who,

> F(p) measures the abundance of black holes. To falsify the statement all you need to do is FIND ONE DIRECTION IN WHICH TO CHANGE p SUCH THAT F(p) INCREASES.

It appears that you are misunderstanding direction in usual 3D with any direction in Smolin P space which is very, very different.

Directions, gradients, etc. in P space cannot be measured, therein Smolin premise is so not scientific as antrophic string.

Juan R.

Center for CANONICAL |SCIENCE)

53. **Who**
January 14, 2006

I thought someone might be amused by the suggestion that Smolin's parameter space is R^31. The dimensionality is taken from the yearend 2005 paper **Dimensionless constants, cosmology and other dark matters** by Tegmark, Aguirre, Rees, and Wilczek.
http://arxiv.org/astro-ph/0511774
There was some discussion of that paper here at Peter's blog including posts by Smolin, Aguirre, and Tegmark.
http://www.math.columbia.edu/~woit/wordpress/?p=310

Smolin doesn't say how many independent fundamental constants there are in the combined standard models of particle physics and cosmology—naively speaking the number of knobs on the universe-machine. But Tegmark et al give a list of 31 dimensionless numbers.

Anyway, suppose ***P*** is that space of dimensionless parameters, and suppose ***p*** is the list of parameters which we measure. Then the statement of the theory that you have to falsify—-the hypothesis—is this:

you can't find a small change in *p* that makes F(*p*) increase

(as in all such situations, there is the usual need for reasonableness and good-faith because measurement and calculation involve uncertainty, you would have to show that F(p) increases *significantly* as some parameter is varied)

The most puzzling objection to Smolin's proposal which I have seen so far is the one offered by Anthony Aguirre in posts #101 and #105 of the thread referred to above. They are easy to find because the thread has 107 comments.

Here is Aguirre's main point from #105:

> …Now, the questions of how *generic* eternal inflation is, is I think an interesting one: are there non-fine-tuned inflation models that explain the observations and are not eternal? I don't know of any decent study on this question (and may well undertake one myself). In the context of CNS, however, even the *possibility* of eternal inflation is very dangerous, however, because unless eternal inflation is *forbidden* by the 'meta' laws that govern which types of inflation are possible in the landscape of possibilities, it must only be realized once to 'take over' the ensemble by creating an infinite number of black holes out of one. The only escape from this, it would seem, would be to have other channels to create infinitely many black holes from one 'parent' — but then you would be in the same extremely thorny boat of comparing infinities…

Surprisingly, since this comes from Aguirre, I do not see that the objection is relevant. Aguirre argues that SOME black hole might accidentally have an infinite number of offspring, but he does not contend that this is TYPICAL. On the other hand, Smolin's hypothesis concerns a local maximum, assuming mediocrity. It is not affected by rare instances of "eternal inflation", should they occur. So Smolin's fitness function F(p), the number of black holes in a single generation, is typically finite. The hypothesis is that it evolves towards a local maximum and (rare instances of eternal inflation notwithstanding) will typically BE at a local maximum. But this can be CHECKED. So the challenge stands: **can you show a change in some parameter which would result in our spacetime having more black holes?**

54. **Jack Lothian**
January 14, 2006

Who

Thanks for your comments. I downloaded the paper. I will read it but I suspect it will take me a week or two to get through it.

55. **Who**
January 14, 2006

Hi Jack,
I am glad you have downloaded the paper and intend to have a look at it. I may be able to save you time by giving some specific page references.

Only a part of the paper is about Smolin's black hole natural selection idea and the opportunities to test it. We can narrow the focus some.

To recap, the paper I referred you to is:
http://arxiv.org/abs/hep-th/0407213
[b]Scientific alternatives to the anthropic principle[/b]
(Contribution to "Universe or Multiverse", ed. by Bernard Carr et. al., to be published by Cambridge University Press)

The section on cosmological natural selection begins on page 28
with the section "5.2 Natural Selection"

Section "6 Predictions of Natural Selection" begins on page 30
and runs through page 36.

So I believe that everything relevant is contained in pages 28 thru 36. I look forward to any comments you have, particularly about the testability.

The testability issue speaks to the main point made by David Gross in the remarks which Peter quoted at the beginning of this thread.

> The only physicist quoted who recognizes that the Landscape is pseudo-science is David Gross. "It's impossible to disprove" he says, and notes that because we can't falsify the idea it's not science. He sees the origin of this nonsense in string theorist's inability to predict anything despite huge efforts over more than 20 years: "'People in string theory are very frustrated, as am I, by our inability to be more predictive after all these years,' he says. But that's no excuse for using such 'bizarre science', he warns. 'It is a dangerous business.'"

"It's impossible to disprove" he says, and notes that because we can't falsify the idea it's not science."

Smolin has offered an hypothesis with some potential for explaining the values of key constants which, however, IS subject to disproof. So it IS science by David Gross standards. This testable hypothesis ought to be mentioned along with the prospect (which Weinberg and Wilczek appear willing to contemplate) of GIVING UP amid string landscape's welter of possible vacua. The hypothesis may indeed be incorrect and it may be possible to falsify it—perhaps that should be first on our list of things to do.

56. **Juan R.**
January 15, 2006

Each time the discussion becomes more interesting,

Who said,

> F(p) measures the abundance of black holes. To falsify the statement all you need to do is FIND ONE DIRECTION IN WHICH TO CHANGE p SUCH THAT F(p) INCREASES.

and now adds

Anyway, suppose P is that space of dimensionless parameters, and suppose p is the list of parameters which we measure. Then the statement of the theory that you have to falsify—-the hypothesis—is this:

you can't find a small change in p that makes F(p) increase

Therefore, I admit now that you are informed that P is not 3D space. Then the you may aware that experimental methodology would be:

1) Measure the number of BH in our universe (or region). So far i know still nobody measured one and, however, Smolin curiously talk how if we found BHs each day.

2) Take p_1 = G for our universe. Then [i]vary[/i] the value of G in our laboratory and the point p in 'phase' space changes to p'.

3) Now measure again the number of BH in this new universe

4) Repeat 1)-3) for rest of parameters from p_2 to p_31

5) If our universe is optimized for the production of BH then the S premise is correct.

May I continue with this nonsense?

—

Anthropic nonsense: universe is optimized for human life.

New 'BHolic' nonsense: universe is optimized for BHs.

—

Juan R.

Center for CANONICAL |SCIENCE)

57. **Who**
January 15, 2006

Hello Juan, you say

> Anthropic nonsense: universe is optimized for human life.
>
> New 'BHolic' nonsense: universe is optimized for BHs.

I am not sure you have correctly stated the Anthropic position (defeatists like Susskind may not actually claim "optimized for", they may merely be asserting "compatible with") human life.

The point made by Peter, in quoting David Gross at the beginning of this thread, is that whatever they are claiming is not science because it is not falsifiable. There is no way to demonstrate that the universe is NOT compatible with human life.

By contrast the BH natural selection conjecture IS FALSIFIABLE. This is the significant difference, and the main point I am stressing here.
I am waiting for you to read and comment on pages 28-36 of the paper because several ways to falsify it are discussed there.

The proposed tests of BH natural selection depend on some established physics that has been independently confirmed by experiment, such as Gen Rel, QED, QCD. I trust that you will grant that it is legitimate to use older well-established branches of physics in designing ways to test new theories.

58. **Who**
January 15, 2006

> 5) If our universe is optimized for the production of BH then the S premise is correct.

the aim in not to prove that the theory is correct, by testing for optimality in every direction

the aim is to show that the theory is INCORRECT, by finding just ONE direction in which one can vary the parameters so as to increase BH abundance.

Scientific theories are never proven to be correct because they can never be tested in infinitely many cases. In 1919 when Eddington tested Gen Rel, he did not prove that Gen Rel is correct. He made an unsuccessful effort to show that it was incorrect. If he had observed the Pleiades to be in a substantially different position this would have falsified Gen Rel.
But apparently he didn't and Gen Rel survived that test. And continues to survive. That is what scientific theories do: they CONTINUE TO SURVIVE.

And that is what Smolin's BH natural selection theory is doing today. It continues to survive astronomical testing. The theory predicts that you cannot have a two solar mass neutron star—because if you could, then the topquark mass could be revised so as to make neutron stars more apt to collapse (this is discussed in the paper). But astronomers are constantly finding neutron stars and measuring their masses. Some day they may find one which can be reliably shown to have a mass of 2 solar or more. That would invalidate the BH natural selection theory.

This is only one of what I suspect are a great many possible ways to test, and potentially falsify, the theory.

Just as people have thought of several different ways to test Gen Rel itself, so they can invent a variety of ways to test this theory, and i hope they do 🙂

Your steps 1) through 5) are essentially an argument that optimality can never be proven and that BHNS can never be shown to be correct. Right! you can't show that. This is not the issue. The point is that there are ways to show that BHNS is incorrect.

59. **Who**
January 19, 2006

Urs,
I want to make sure I understand the sense of what you said in this thread earlier
http://www.math.columbia.edu/~woit/wordpress/?p=321#comment-7237

"The problem with the landscape discussion is not that it is a priori pointless to think about a theory in which the parameters of the standard model are not uniquely specified."

I think this means that there IS a problem with the landscape discussion. But the problem is NOT that it involves considering a theory in which the standard model parameters are undetermined.

As I interpret (please correct me if I misunderstand) this rather complicated sentence it suggests that it is OK and quite scientific for a theory not to determine the fundamental constants.

Maybe this is is drifting towards a kind of "apologia" for string theory that says "hey string theory is OK and quite scientific, don't criticize it because it fails to determine the fundamental constants! Lots of other OK theories do not do that!"

In the Susskind NYT Book Review thread,
http://www.math.columbia.edu/~woit/wordpress/?p=329#comment-7668
you blurred the distinction between testable scientific theories and string thinking by arguing that having an infinite space of solutions is GENERIC, so what is especially deficient about string?

Urs 18 Jan 3:28P
"I tried to point out how a theory generically has infinitely many solutions. So it's not clear to me why it should be a problem if some theory has only finitely many."

I think the message is: why should string be considered unscientific if theories generically have an infinite space of solutions?

It helps to keep examples of alternatives in mind. General Relativity is an example of a theory with instant falsifiability. If it had happened to predict the wrong light-bending angle, checked in 1919, then it is simply wrong. If it predicted the wrong clock speeding with altitude, constantly checked by the GPS, then it is simply wrong.

As you pointed out, Gen Rel has an INFINITE SPACE OF SOLUTIONS—I believe these are associated with different possible initial conditions and the key point is SO WHAT? because that does not affect the instant falsifiability. The theory can still make predictions that refute it if they are not observed.

Maybe we are dealing with a sort of apologetics here and some of this could be smoke or red herring. What matters is the testability/falsifiability and not the "infinite solution space" or the "undetermined parameters"

A theory can have infinite solution space and undetermined parameters and still commit to decisive predictions. If string is non-committal and accomodating to any future experimental result then that is probably the problem. And it doesnt help, or is at best only a distraction, to point out that other scientific theories have undetermined parameters and infinite solution spaces.

Basically this amplifies the David Gross quote in the original post.

60. **Urs**
January 19, 2006

> General Relativity is an example of a theory with instant falsifiability.

Only once you have detectors that are sensitive enough to see the required effects.

61. **Who**
January 19, 2006

Only once you have detectors that are sensitive enough to see the required effects.

I am not sure how to interpret this, Urs. I think that when Gen Rel was published in 1915 there WERE already detectors able to see the effects.

Or, if there were none already sitting on the shelf, one could see a clear way to build them. One could say in good faith that it was reasonably practical to test—it was in actual practice VULNERABLE to empirical disproof.

I see a moral obligation for theoreticians to make their theories be vulnerable. Because the unity of the scientific community depends on the ability of members to settle their differences of opinion by empirical means.

If a theoretical construct is not vulnerable, it does not seem like proper science to me. This depends on people being reasonable and discussing in good faith. If one can see how to build an instrument within reasonable time and cost, then as long as one can see the way to do it then it does not have to be already available when one makes the theory. One wants to see that the theoreticians are at least sincerely TRYING to make their theory vulnerable to practical tests.

At this point it would help to compare string with some other QG approaches—because it involves a judgement call of what is reasonable to expect. Currently my testcase example is Laurent Freidel paper hep-th/0512113. It looks to me that if the result is extended to 4D then it is falsifiable with instruments that are planned or underconstruction. Please say if you disagree, since i would value your point of view on that very much.

the reason for considering alternatives is because one has to judge what is reasonable to expect (pure logic outside the context of alternatives does not seem to make for a successful discussion)

best wishes

62. **Urs**
January 19, 2006

> I think that when Gen Rel was published in 1915 there WERE already detectors able to see the effects.

Sure. But in 1815 there were not.

Today, entire high energy physics is suffering from the lack of good detectors. Theory is far ahead of experiment, unfortunately.

63. **anonymous**
January 19, 2006

"Theory is far ahead of experiment, unfortunately."

Indeed! I thought it was the other way round, with theory being unable to catch up with experiments. Perhaps I've missed a paper on arXiv.org that predicted the masses of quarks, coupling constants, and other Standard Model parameters. How careless of me.

Categories: Uncategorized

An assortment of interesting things I've run across recently:

There's something called Multiversal Journeys that seems to organize lecture series on theoretical physics, with a special interest in the multiverse (at least to the extent of using it as an inspiration for the organization's name).

UC Davis particle physicist John Terning has a weblog. Also a new graduate-level text book on supersymmetric field theories, entitled Modern Supersymmetry: Dynamics and Duality, soon to be published by Oxford.

Ever since 2001, the physicists in Paris have been running a Seminaire Poincare, modeled after the mathematicians famous Seminaire Bourbaki. The latest Seminaire Poincare was on the topic of Quantum Decoherence, and texts from the older meetings are available.

Harvard philosopher Hilary Putnam has an updated version of his 1965 article "A Philosopher Looks at Quantum Mechanics" in the latest issue of the British Journal for the Philosophy of Science. It is entitled A Philosopher Looks at Quantum Mechanics (Again). Part of my misspent youth involved taking several philosophy courses as an undergraduate at Harvard, including ones from Quine and Putnam.

In November, Joe Lykken gave a particle physics seminar at Princeton entitled Is particle physics ready for the LHC? His talk explains some of the challenges particle physics will face at the LHC. The next-to-last slide is a none too subtle dig at the lack of any particle phenomenology going on at my alma mater. It is entitled "is Princeton ready for the LHC?", and lists the titles of the particle theory seminars going on at Princeton during the period before his talk.

The International Committe for Future Accelerators (ICFA) has a new web-site.

The Tevatron has recently achieved new luminosity records, both for peak luminosity and integrated luminosity over a week. You can follow the status of the Tevatron here.

A beautiful new paper by Greg Landweber and Megumi Harada has just appeared. It is entitled A comparison of abelian and non-abelian symplectic quotients and uses equivariant K-theory methods to get the relation between the K-theories of the symplectic quotients M//G and M//T, here T is the maximal torus of a compact Lie group G.

Update: One more. Slate today is advertising Meaning of Life TV, where various people, including some physicists, do things like promote the idea that the anthropic principle shows religion has a lot to do with science. This site has been around for a while, but just now has affiliated with Slate. Looking at it I thought "funny, this is the only thing like this trying to inject religion into science that doesn't seem to be a Templeton Foundation project." Then I saw the About Us link.

   January 6, 2006

   THAT IS A RATHER NICE PAPER AT THE END. I FIND GIT VERY DIFFICULT BECAUSE THE SURJECTIVITY ARGUMENTS ARE A LITTLE BIT SUBTLE.

   APOLOGIES FOR GOING VERY SLIGHTLY OFFTOPIC, I AM PRONE TO DO THIS OCCASIONALLY AND HOPE YOU WILL NOT THINK LESS OF ME FOR IT.

   I HEREBY DECLATE THAT I, QWERTY, SUPPORT ISRAEL GELFAND FOR THE ABEL PRIZE 2006. I WAS APPALED AND DISGUSTED WHEN PETER LAX WON IT LAST YEAR. I THINK GELFAND DESERVES IT BECAUSE HE IS VERY CLEVER.

   PS I HAVE NAMED MY PET HAMPSTER GELFAND IN HIS HONOR.

   PPS I THINK YOU SHOULD TALK MORE ABOUT MATHEMATICS AND LESS ABOUT PHYSICS

3. **MathPhys**
   January 6, 2006

   Peter,
   Why do you consider your time attending Putnam's and Quine's classes misspent? I have my own ideas about that, but I wish to hear yours.

4. **woit**
   January 6, 2006

   I took a class from Quine on mathematical logic, which mostly was him reading from ancient lecture notes (the notes were on cards from what I remember). I don't remember as much about Putnam's class, I think I was just auditing it.

   When I started college I was quite seriously interested in philosophy, especially philosophy of science and mathematics. While, outside of his class, I greatly enjoyed reading some of Quine (and to a lesser extent Putnam), and found his view of how physics fits into philosophy quite congenial, in the end it seemed a lot more interesting to deeply study math and physics themselves than to study "philosophy of" math or physics. The deepest questions about these subjects seem to me not the ones that are addressed by philosophers, but ones that our lack of sufficient knowledge of these subjects still leaves us unable to answer.

   For example, the current debates over whether the multiverse is science, falsifiability, etc. aren't truly deep problems in these subjects. They are coming up because people are refusing to honestly go after the real problems. Philosophers may be useful in getting people to think clearly and honestly, and they may contribute to these issues now.

But they can’t help much in creating the kind of new math and new physics needed to make progress on fundamental problems.

5. **secret milkshake**
January 7, 2006

Feynman: “Physicists are explorers, philosophers are tourists.”

6. **Sakura-chan**
January 7, 2006

"“A Philosopher Looks at Quantum Mechanics” in the latest issue of the British Journal for the Philosophy of Science. It is entitled A Philosopher Looks at Quantum Mechanics (Again).”

Hmmmm, I think there’s like five people in the world who have subscribed to The British Journal for the Philosophy of Science Online, and I’m sure not one of them. =D Is it worth my $$$?

7. **mgimo**
January 7, 2006

While agreeing essentially with Woit, I’d say that mathematical logic provides an interesting blend of philosophical and mathematical questions which can be studied from a mathematical point of view. As tools of mathematical logic develop, one hopes that they enable to answer philosophical questions by meaningful mathematical theorems. For example, now there are meangful (mathematical) tools to tackle the question why “why we study what we study”…

8. **logopetria**
January 7, 2006

“Philosophers may be useful in getting people to think clearly and honestly, and they may contribute to these issues now. But they can’t help much in creating the kind of new math and new physics needed to make progress on fundamental problems.”

In most periods of science, this is probably true. When we have lots of data, and multiple theories competing to explain it, with new theories and variations being spun off and explored all the time, there’s probably little that a philosopher can add to the party. But high-energy physics generally isn’t in a period like that at the moment. Not least in quantum gravity, new experimental data is relatively sparse, and progress is mostly in pure theory.

That (arguably) means that new developments will come from two sources: new mathematical techniques and ideas, and new ways of thinking about and understanding our old theories. There’s a decent chance, then, that some of the useful new ideas that will help move the field forward might come out of philosophy of physics, rather than physics alone.

Of course, philosophers can only be helpful in these areas when they have relevant knowledge of the subject in question. Fortunately, there are quite a few researchers in philosophy departments who have a very solid background in physics as well. A good cross-section of this work is given in the book “Physics Meets Philosophy at the Planck Scale” edited by Craig Callender and Nick Huggett (many articles from which can be found online: click on “logopetria” above).

9. **woit**
January 7, 2006

Sakura-chan,

I mentioned the Putnam article because I think it is historically interesting: Putnam is one of the more well-known philosophers in the US and his 1965 article was often-cited as influential. Like the old one, the new article is very clearly written, and it also has some interesting asides about Einstein’s views and those of an unidentified “world-famous physicist” (I’m guessing Feynman, may be wrong). But I don’t think the article is especially good or original in terms of getting at the real problems of the interpretation of quantum mechanics (e.g. decoherence is not even mentioned).

10. **Juan R.**
January 7, 2006

secret milkshake said,

> Feynman: “Physicists are explorers, philosophers are tourists.”

From what perspective?

Well, Feynman was a physicist, one great but only was that. Feynman philosophical insight was very superfitial. For instance his “Character of physical law” and similar works are often cited in philosophical courses as an example of superfitial approach to serious epistemological and ontological stuff.

Therefore,

Physicists are explorers, philosophers are tourists in the physical land

AND

Philosophers are explorers, physicists are tourists in the philosophical land

“A Philosopher Looks at Quantum Mechanics” again 🙂 has no real interest for science. In fact, one can easily see many ideas about scientific hot topics launched by philosophers are completely wrong. For instance, one can read all nonsense published by philosophers about quantum measurement, irreversibility, absence of time in last decades.

I agree with Gell-Mann that philosophers would do just philosophy and leave physics (and probably epistemology) for physicists…

The Templeton Foundation never stops trying to buy a stairway to heaven…

14. **Adrian H.**
January 8, 2006

Well, I can't resist a moderate defence of philosophers.

It is true that some philosophers of science have done little more than add noise to the debates, but some others have also contributed very usefully. It was philosophers who were the primary sceptics about the Copenhagen interpretation through the 40s and 50s. It was philosophers who were the main enthusiasts for the quantum logic approach of Birkoff and von N. and it was they who were the primary sceptics when it looked like it wouldn't work. And now that physicists are rushing as one (the herd instinct seems quite well developed!) to think of decoherence as the solution to the measurement problem it is philosophers who are trying to point out to them that it just won't work.

Physicists are often condescending about philosophers but when they attempt to to do philosophy themselves (because they think they can do it with their eyes closed, with no training at all) it is often embarassingly sophomoric. Witness Susskind, Weinberg, etc.

When philosophy of science is done well it is done by people who know the maths, know the physics, and look at the theorems as external scrutineers. They are trying to answer the question "Yes, but what does it all mean?" in a more sceptical and frank way than physicits often manage unaided. Philosophy is (as some politician once said) there to keep the bastards honest. And in quantum mechanics it has been remarkably effective, particularly over the last thirty years.

I wouldn't expect much from Quine or Putnam. Putnam I think has never kept up with the literature. He listens to his friends, puts together his ideas from conversations with the *people who matter*. His ideas veer all over the map because he thinks quickly but no longer particularly well. Quine had the same arrogant attitude—but gave the impression of having even less contact with the outside world.

I should add that I think Peter W. is an exception here: his philosophical instincts seem judicious and right, to this writer anyway. Maybe those few courses he audited had a salutary effect. 🙂

Philosophers, it is true, have largely ignored string theory. But that also is to their credit. I think they can tell vapourware when they see it.

15. **j**
January 9, 2006

As a student looking to grad school, the contentious/complementary relationship between modern science and philosophy is both fascinating and troublesome. To pursue a more humanisitic approach to physical science or a more rigorous bend in philosophy? I'm pleased to see the topic arising here (if only tangentially) and that Prof. Woit faced similar considerations as an undergrad.

Out of curiousity, can anyone cite examples of philosophers [of science/math] that appear to "get it"? Is anyone familiar with the work being done by Hans Halvorson at Princeton?

16. **Adrian H.**
January 9, 2006

Yes, I'm familiar with Halvorsen's stuff. And he's good. Very good. So also is Jeff Bub at Maryland. N.P. Landsman is a very philosophically astute mathematical physicist in Holland. Michael Dickson of Sth Carolina is good. Guido Bacciagaluppi of Paris is good (they seem to have quite a few good people in Paris—go figure?) John Earman of Pittsburgh is also good—and interested in quantum field theory.

But I don't agree that there is a "contentious/complementary relationship between modern science and philosophy"—mostly the relationship (at least from the philosophers' side) is good. Philosophers who b*tch about science are an ignored minority, mostly social constructivists of one kind or another.

17. **j**
January 9, 2006

Adrian, I appreciate the list of names.
I didn't mean to imply a signficant rift between the two disciplines or any fundamental tension, but rather my recurring experience with the cliche of the specious philosopher and the myopic physicist. (The opinion(s) of Feynman and Gell-Mann cited above being superficial, if not outdated examples.)

18. **Juan R.**
January 9, 2006

Echeverría and Rábade Romeo in general theory of knowledge, Kleene in metamathematics.

Personally, i am very influenced by Prigogine (not by thecnical details of his theory); Scerri in philosophy of chemistry…

Etc.

I do not know Jeff Bub work but i do not agree with him in [http://carnap.umd.edu/philphysics/bub_research.html]. In fact, he appears to have a serious misunderstanding of basic issues of both quantum and classical mechanics.

I do not agree with some Landsman's work, specially his 'wavefuntions of universe' in quantum gravity. He has not adressed the problems of WdW and ADM quantum gravity in detail.

I think history of philosophy is the history of continuous loosing of fields of aplication in favor of rival: science. In some sense, current philosophy is the study of those fields cannot be *still* studied in a scientific manner.

—

Juan R.

Center for CANONICAL |SCIENCE)

19. **Adrian Heathcote**
January 9, 2006

Hi j—just a little more information. Halvorson at Princeton seems to have the aim of reviving a Bohrian philosophy of QM, partly tied to the idea that QM is "really" about information. A number of people are riding this horse at present, including Jeff Bub. Personally I'm pretty unconvinced, and I think many people share that scepticism. But Halvorson seems to be exerting a strong influence at present.

From a different direction N.P. Landsman also seems to be looking to resuscitate Bohr. I think his 100 page essay Between Classical and Quantum is one of the best surveys around at present. Look for it on arXiv for 2005 as quant-ph/0506082.

There are many other good philosophers around that I didn't mention: Craig Callender at UCSD, van Fraasen at Princeton, harvey Brown at Oxford, David Albert at Columbia(!) and many more.

On Feynman: apparantly he had a run-in with the neo-Wittgensteinians at Cornell in the 50s and couldn't stand philosophers ever after.

20. **Juan R.**
January 10, 2006

I do not think that N.P. Landsman seems to be looking to resuscitate Bohr in his recent quant-ph/0506082.

In fact, i think that he is ignoring the main premise of Bohr the classical is not reducible to the quantum.

Moreover his analysis of the situation is not rigorous (there are several sound technical errors in the h-limit, N-limit, decoherence, and histories sections) and he just forget the most realistic and fascinating option in his 'review'; the third way: that both quantum and classical are two sides of a more complex nature.

Precisely this third way is taken by Martingale models, Penrose, Prigogine theory, etc.

I myself have done some recent advance in the topic. In brief, i will publish a **derivation** of Martingale models and Born rules from first principles. Prigogine theory for example appears like a special case of a more general model. No other model (e.g. the popular decoherence) has done similar things.

January 10, 2006

Since the title of this post is "Yet More Links", I hope this isn't considered off topic. There is an interesting new paper out today by Connes and Marcolli entitled "A walk in the noncommutative garden". It's a long survey paper consisting mostly of an exploration of examples. Some of the examples are from physics, including string theory. The final section sketches the function field approach to the Riemann Hypothesis that Peter is fond of. The link is

http://arXiv.org/abs/math/0601054

22. **Adrian H.**
January 12, 2006

Juan

"I do not think that N.P. Landsman seems to be looking to resuscitate Bohr in his recent quant-ph/0506082.

In fact, i think that he is ignoring the main premise of Bohr the classical is not reducible to the quantum."

In his use of Raggio's therem on p. 20–1, he is certainly defending Bohr's response to Einstein, and is using the idea that the classical is fundamentally different from the quantum realm (it has a commutative C^* algebra rather than a noncommutative one). However this is all much more explicit in his other 2005 article on arXiv (quant-ph/0507220) and there the resuscitation of Bohr is the central aim of the paper rather than a side issue. Again Raggio's theorem is the primary technical result.

Follow-Ups

January 8, 2006
Categories: Uncategorized

Follow-Ups to two recent postings:

Michael Duff has written a letter to New Scientist complaining about their recent editorial Physics' greatest endeavour is grinding to a halt. Duff begins by claiming:

History has shown that rapid confirmation by experiment is a poor guide to the eventual value of a physical theory

but backs this up in a rather bizarre way. You might think he would list some physical theories whose experimental confirmation took awhile, instead he lists various theoretical ideas that have been around for a long time, still haven't been experimentally confirmed, although lots of people are still working on them. Evidently for Duff the value of a physical theory is how many people are working on it (he also points out that about 500 people go to Strings 200X), not whether there is any experimental evidence for it. The examples he gives range from cases where there is zero experimental evidence, and probably never will be any (extra dimensions, supersymmetry) to ones that it is very plausible we will soon see evidence of (Higgs boson, gravitational waves) to ones that arguably we already have some evidence for (cosmological constant).

He notes that gravitational waves were predicted in 1916 and have yet to be confirmed, that string theory is more ambitious than GR so it should take longer to confirm, and that one should only really start counting in 1995, when M-theory came along. So I guess his prediction is that by 2074, we still won't yet be anywhere near confirming string theory. Like many string theorists, he make highly tendentious claims about the relation of the standard model to experiment, writing:

decades required to knock the standard model into a shape that could be confirmed by experiment

I assume he's not talking about the QCD part of the standard model, which was born in 1973, already making verifiable predictions, and within ten years had accumulated a huge amount of evidence in its favor. The electroweak theory was first written down by Weinberg and Salam in 1967, and by ten years later the evidence for it was overwhelming. I suppose you could try and argue that the history of attempts to put together the standard model go back to Glashow in 1960 or Yang-Mills in 1954. Even using 1954, it was 19 years later that the full standard model was in place with a lot of experimental evidence already there and more pouring in. And that period would quite likely have been shorter if most of the theory community hadn't given up on QFT and been working on the bootstrap, dual models or string theory during that time. In the case of string theory, taking Veneziano in 1968 as a starting point, nearly 4 decades later there is not a glimmer of a piece of experimental evidence for string theory. Comparing the history of the standard model to the history of string theory is just absurd.

On another recent topic, the New York Times finally today carried an obituary for Raoul Bott.

Comments

1. **Wolfgang**
   January 8, 2006

   Peter,

   the example of gravitational waves is not so bad in my opinion.
   If experiments are difficult for classical gravitation it is no surprise that
   quantum gravity is even more difficult.

   But I would make a different point: We may already have some evidence for new physics, e.g. the Pioneer anomaly or perhaps in a few years deviations from Newton's potential at small distances.
   The problem is that string theory currently makes no concrete statements about such effects.

2. **JK**
   January 8, 2006

   The slow down in orbital period of binary pulsars constitutes good evidence for gravitational waves (Taylor et al. 1978). I would put gravitational waves in the same category as the cosmological constant, "arguably we already have some evidence".

3. **woit**
   January 8, 2006

   Wolfgang,

   Yes, the problem is that after almost 40 years, string theory predicts nothing. This is very different than the case of GR, where precise predictions about gravitational waves were there from the beginning (and, as JK points out, we already have indirect evidence).

   Sure, true quantum gravitational effects may always be beyond the reach of observation, but string theory is supposed to include all other interactions too. The fact that it can't actually predict a single thing about those after almost 40 years is what conclusively shows it is on the wrong track.

4. **dan**
   January 8, 2006

   "Yes, the problem is that after almost 40 years, string theory predicts nothing. "

   String theory does predict SUSY, which may turn up at LHC ca 2010

5. **A.J.**
   January 8, 2006

   String theory does predict SUSY, which may turn up at LHC ca 2010

   It's probably more accurate to say that string theory _assumes_ or perhaps _requires_ supersymmetry. It's a necessary part of the theory rather than a consequence of it.

   Now with that said, the discovery of supersymmetry among the elementary particles would constitute indirect evidence that our universe can be described by a string theory. Coupling a supersymmetric gauge theory to gravity more or less requires us to consider supergravity, and supergravity theories basically all arise as low energy limits of string theories.

The reasoning above isn't iron-clad, so take it with a grain of salt. For one thing, it might well be that susy appears in particle physics, but only as an approximate symmetry, indicating further substructure. (Something like this actually happens in nuclear physics.)

6. **Peter**
January 8, 2006

Dan,

The problem is that supersymmetry is broken and string theory doesn't tell you how or even at what energy scale. If it's broken at very high scale (which landscapeologists seem to prefer), it's indistinguishable from a non-supersymmetric theory at any energy scale we can ever hope to access, and you certainly won't see anything at the LHC. I don't see many string theorists these days willing to stand behind the idea that string theory implies supersymmetry at the LHC scale.

7. **Anonymous**
January 9, 2006

A.J. says:

It's probably more accurate to say that string theory _assumes_ or perhaps _requires_ supersymmetry.

To what extent is this clear? The type 0 theories, for instance, have worldsheet SUSY but not spacetime SUSY. True, they have a tachyon, but in at least some cases it's pretty clear that the tachyon condenses and doesn't really cause problems. Example: whatever the dual of pure Yang-Mills theory is 😉

Of course, these things probably can't describe a realistic universe with gravity and all of the other fields we know about, but I'm not sure there's an airtight case that realistic string theory backgrounds require SUSY….

8. **Fabien Besnard**
January 9, 2006

Peter, I think you would not complain against string theorists if they were a small community and made more humble claims about what their theory has achieved so far and about how promising it is. Duff is right when he says that "rapid experimental confirmation" is not a good guide : what is a good guide is the own prejudice of gifted researchers about the way nature works. Well it's a good guide only 1 percent of the time so what we need is a diversity of ideas. The academic institution should encourage such a diversity as long as no theory has won the competition… and as long as no theory destroys the rules of the competition, that is scientific method.
I develop a little bit more here .

9. **Chris Oakley**
January 9, 2006

Mike Duff is just digging his own (and his fellow Superstringers') grave by making these comments. To adapt the kamikaze motto: The requirement to understand the physical world is as heavy as a mountain, but individual theories as light as a feather.

If you had invested in a company that failed to make a profit after 40 years of trading, would you put up with being told by one of the directors that all of this is your fault for not being patient enough? I think not.

10. **Fabien Besnard**
January 9, 2006

"If you had invested in a company that failed to make a profit after 40 years of trading, would you put up with being told by one of the directors that all of this is your fault for not being patient enough? I think not. "

Do you really think science should be "managed" like a company ?

11. **anon**
January 9, 2006

Physics already is managed like a company. It is big business: compare the costs of particle accelerators to other business costs.

Outsiders passionate about science are written off automatically as amateurs. The professionals are those who make money out of it.

12. **Chris Oakley**
January 9, 2006

> Do you really think science should be "managed" like a company?

They need our money to operate, so why should they not be accountable?

There is in any case nothing wrong with operating like a company. In my experience research in companies is better managed than academic research. More emphasis on results, less on personalities, and much more willingness to give up on things that are leading nowhere.

13. **Quantafyzyx**
January 9, 2006

Wanting definite experimental predictions from a theory is so twenty-first century! Knowledge itself has a quantum behavior, like electrons and photons. Without 24th century mathematics, it is hard to explain but a rough analogy can be provided. Please remember, these are analogies only.

A definite theory with predictions that can be compared to experiment is roughly analogous to a quantum system with close-to-classical behavior (see Schrodinger's cat). Low Energy Physics is classical – there is a definite theory and definite experiments. However for physics of 1000 TeV and above, theory is in a quantum state. This analogy is rough, too, but the theory of physics is (in your language) a wavefunction over the space of string theory landscapes. Without knowledge that you all don't have right now, the best LHC can do for you is collapse the theory wavefunction onto one of two branches of the landscape – roughly those with low-energy SUSY and those without. Even a rough estimate of amplitudes is currently beyond you.

Now, knowledge of physics itself being quantum is extremely inconvenient and virtually intractable. Therefore the effort is to make it as "classical" as possible (the so-called incoherent regime where theories do not interfere with each other). Rough analogy again- there are two ways of collapsing the theory wavefunction – the first is by suitable experiment, and the second is by suitable theoretician. The cost of education, salary and retirement benefits for a theoretician is four-to-five magnitudes cheaper than any conceivable experiment, and therefore, we must produce more theoreticians. All this is dealt with in the Theory of Incoherence, though the upper bound on reduction of the landscape per theoretician is still undetermined upto a multiplicative constant. One of the important open questions, this is.

On the practical side, The Harvard Breeding Program of 2316 has been instituted to optimize production of theoreticians.

Clearly, more string theorists the more rapidly we approach the Incoherence regime, and Peter, your blog has been identified as a key blocker to production of such.

Please consider this a polite request from the 24th century to cease and desist.

14. **Chris W.**
January 9, 2006

Actually, business itself is considerably messier and hard to manage than investor newspeak* would lead one to believe, especially when technology is involved. The analogy is forced only because nobody would invest in high energy physics as a pure business proposition. If one tried to turn it into a business one would end up selling snake oil to dupes.

(* intentional reference to *1984*)

15. **dan**
January 9, 2006

I recall Lubos expecting to see SUSY @ LHC. I agree with you that if no SUSY is found, it would not falsify string theory as it now understood, but if SUSY is found, then the question is not where it breaks (obviously at TEV scale) but how. it would provide strong experimental support to string theory i think.

" I don't see many string theorists these days willing to stand behind the idea that string theory implies supersymmetry at the LHC scale."

16. **Fabien Besnard**
January 9, 2006

"I recall Lubos expecting to see SUSY @ LHC. I agree with you that if no SUSY is found, it would not falsify string theory as it now understood, but if SUSY is found, then the question is not where it breaks (obviously at TEV scale) but how. it would provide strong experimental support to string theory i think."

So it's a game where you can't lose. Cool !

If you can't kill a theory isn't it a strong indication that this theory is not alive ?

17. **Chris Oakley**
January 9, 2006

Hi Quantafyzyx,

You are probably right, but for the majority of the contributors to this blog, bringing ourselves round to your point of view would just cause too much distress.

Is there any chance of you developing and marketing brain implants that would enable us to to see the beauty of the Landscape without painful electric shock treatment?

18. **Chris W.**
January 9, 2006

The dialogue with experiment, Multiverse/Landscape edition:

"The answer is yes. What was the question?"

(This is an exaggeration, but not as much as one would hope.)

19. **AJ**
January 9, 2006

Hi Anonymous,

As you say, it's not entirely clear that string theory really requires supersymmetry for its formulation. But I think this supports my claim, that strings don't really predict SUSY, except in so far as one includes SUSY from the start.

Out of curiosity, is there really any evidence that pure YM theory has a gravity dual?

20. **Urs**
January 9, 2006

> But I think this supports my claim, that strings don't really predict SUSY, except in so far as one includes SUSY from the start.

But if you don't include SUSY from the start, you get something which seems to be incompatible with observation, namely the bosonic string. One is tempted to say that the bosonic string is ruled out by experimental data, namely by the observed existence of fermions.

So from the available string models only those with SUSY are not immediately excluded by observation. In this sense (high energy) SUSY is a prediction.

Of course it might still be that the endpoint of closed string tachyon condensation is nothing but the superstring. I suppose nobody can yet decide this one way or another.

If true, we'd have an even more robust implication of supersymmetry from the assumption of strings.

But certainly, as noted by others, worldsheet SUSY and hence SUSY of 10D flat space does not imply much about the SUSY we might hope to actually observe…

21. **anon**
January 9, 2006

SUSY is required for a hypothetical unification at an energy beyond that which can ever be measured. The 1-1 boson:fermion superpartners are no more scientific a prediction than predicting aliens, because no specific energy is predicted, there is no detailed dynamics, no numbers to be tested.

If you don't want precise calculations and numerical predictions that are testable scientifically, you find that religion can be interpreted as making many "testable predictions" about the afterlife, heaven, the day of judgement, etc.

As Lunsford would say, it's not science, it's horseshit even before you start looking at the landscape of 10^500 universes in ST.

22. **Marty Tysanner**
January 9, 2006

So from the available string models only those with SUSY are not immediately excluded by observation. In this sense (high energy) SUSY is a prediction.

I don't think I will easily understand this reasoning, unless the word "prediction" is redefined in just the right way. If I understand your comment correctly, you have a set of possibilities (the space of all string models) that can be grouped into two subsets: one depending on something that gives you the bosonic string, and another that includes SUSY. So far, there is no prediction. Then you add experimental input (i.e., that the first subset is incompatible with observation), and claim that what now remains is a prediction. A naive counting indicates that the ratio of outputs to inputs is less than or equal to one.

That doesn't look like a prediction to me.

23. **woit**
January 9, 2006

Marty,

Urs is just giving you an argument that unification inherently requires the superstring, not the bosonic string, which is a not unreasonable argument. There are lots of reasons to rule out the bosonic string. The problem is that even if you just look at the superstring, in the simplest version it has unbroken space-time supersymmetry. So it predicts exact supersymmetry, which is a very bad prediction, since we don't see that in nature. You can break this supersymmetry in various ways, but the problem is that the theory doesn't tell you what the energy scale of the supersymmetry is. Urs is being slippery when he says "(high energy) SUSY is a prediction", because "high energy" can be any thing: 1 Tev, an intermediate scale, the GUT scale, the Planck scale. For all I know maybe it can even be way above the Planck scale.

So what is bogus is saying that "SUSY is a prediction" when you know (from experiment) that it is broken, but string theory has nothing at all to say about how it is broken, not even at which scale.

24. **A.J.**
January 9, 2006

Hi Urs,

But if you don't include SUSY from the start, you get something which seems to be incompatible with observation, namely the bosonic string.

Right. Experimental results rule out the non-supersymmetric string theory. That's not quite the same thing as saying that supersymmetric string theory predicts supersymmetry.

25. **dan**
January 10, 2006

Peter,
Do you think though that with enough researchers and enough intelligence and studies thrown at the problem, that string theory could come with a mechanism of how it is broken, and at what scale? or do you think that the problem is insurmountable, even for string theorists?

So what is bogus is saying that "SUSY is a prediction" when you know (from experiment) that it is broken, but string theory has nothing at all to say about how it is broken, not even at which scale.

26. **Tony Smith**
January 10, 2006

Urs said "… if you don't include SUSY from the start, you get something which seems to be incompatible with observation, namely the bosonic string. One is tempted to say that the bosonic string is ruled out by experimental data, namely by the observed existence of fermions. …".

However, Englert, Houart, and Taormina said, in hep-th/0106235:
"… supersymmetric and nonsupersymmetric ten-dimensional fermionic closed string theories stem from the compactified closed bosonic string theory. … Space-time fermions … arise from bosonic degrees of freedom … Compactification must generate an internal group SOint(s) admitting spinor representations … the spinor representations of SOint(s) describe fermionic states … the highest available space-time dimension accommodating fermions is … s + 2 = 10 … the truncation … to SOint(8) + ghosts transfers modular invariance from the 26-dimensional bosonic string to ten-dimensional fermionic strings …
a manageable non-perturbative approach to the bosonic string is mandatory. An attempt towards formulating such an approach in a classical limit has been recently proposed … G.T. Horowitz and L. Susskind, Bosonic M Theory , hep-th/0012037 … and the present analysis suggests that such efforts should be further pursued. …".

In hep-th/0012037, Horowitz and Susskind said:
"… We … try to interpret bosonic string theory as a compactification of a 27 dimensional theory. We will refer to this theory as bosonic M theory. …".

In hep-th/0104050, Lee Smolin said:
"… "A new matrix model is described, based on the exceptional Jordan algebra, J3(O). … There are 27 matrix degrees of freedom, which under Spin(8) transform as the vector, spinor and conjugate spinor, plus three singlets, which represent the two longitudinal coordinates plus an eleventh coordinate. Supersymmetry appears to be related to triality of the representations of Spin(8).".

In hep-th/0110106, Yuhi Ohwashi said:
"… … Smolin's matrix model [is] based on the groups of type F4. … the actual world requires complex fermions without doubt. … In accordance with this complexification, the groups of type F4 are upgraded to the groups of type E6. … we consider a new matrix model based on the simply connected compact exceptional Lie group E6 …".

The result, which has much in common with my E6 model described on the CERN preprint server at http://cdsweb.cern.ch/ as EXT-2004-031, is that bosonic string theory CAN be interpreted in a way that is consistent with experimental observations.
As Smolin suggests, Spin(8) triality produces fermion-boson relationships that are a subtle form of supersymmetry in which the familiar fermions of the standard model are the subtle-supersymmetric partners of the familiar bosons.

In short, the bosonic string is NOT "ruled out by experimental data", because fermions emerge naturally in bosonic string theory.
Maybe that is what Urs had in mind by saying "… it might still be that the endpoint of closed string tachyon condensation is nothing but the superstring …" and that Urs supposes "… nobody can yet decide this one way or another …". I think that the above line of work can decide this in favor of realistic fermion emergence from bosonic string theory.

Tony Smith

27. **Thomas Larsson**
January 10, 2006

I recall Lubos expecting to see SUSY @ LHC.

According to himself, Lubos has bet several thousand dollars on the experimental discovery of SUSY by 2006. Unfortunately, I am not among the ones who accepted his bet, but I wonder whether the deadline was January 1 or December 31…

Actually, the deadline might be quite appropriate. When the Tevatron has collected 2 fb^-1 of data, which should happen this summer, it might be able to rule out a light Higgs, and thus indirectly SUSY, at the 95% CL.

But this prediction is of course not watertight. We could be dealing with split (or supersplit) SUSY, which has been intelligently designed to avoid confrontation with experiments forever.

28. **Urs**
January 10, 2006

Tony,

thanks for listing all these references. I know people are trying to see if the closed bosonic string is related to the superstring. One idea has always been that, since it contains a tachyon and is hence instable, it will reduce to the 10D superstring when closed tachyon condensation is over.

I am no expert at all on the state of the art of studying this. The impression I got from hearsay is that it is not really understood yet. But very likely much more is understood than I am aware of.

As a gut feeling, I would *expect* the bosonic string to be related to the fermionic one.

29. **Urs**
January 10, 2006

Some elements on how a theory gives rise to predictions:

Say we have an assumption A about the world. Say we can show that A implies either B or C.

A => (B v C)

Say we find from measurements that in our world B is violated

not B

Then we combine our assumption above the world with our knowledge of the world and deduce

(A /\ not B) => C .

Hence we conclude:

"Given available data, our assumption predicts C".

An example:

Let A be the assumption that the universe on large scales is described well by an FRW model in Einstein GR. As you know, this implies

(C v D v E)

where C is a universe of positive, D one of vanishing and E one of negative curvature.

Now you make measurements. These rule out two of these possibilities.

not C and not E .

(This example might be a little outdated. Modify as you deem appropriate according to current experimental data.)

Hence combining our assumption (FRW universe) with the experimental data allows us to make the prediction

(A /\ not C /\ not E) => D .

And that is in fact a prediction, as everybody knows. The successful standard model of cosmology follows from

– assuming a theory (FRW model of GR)

– excluding solutions which do not match observation at all

– predicting that the only remaining solution is the one observed in nature, which then again implies predictions for further observations (like CMB fluctuations, etc).

Critics of the fact that string theory seems to admit more than one solution should note in this example how one observation about the world reduces the number of candidate solutions which in turn allows to predict outcomes of more observations.

Similarly, one might hope that if there are only a few (or even just a single) string vacuum matching basic properties of the standard model (like gauge group, number of generations, etc), then this would imply predictions on outcomes of other observations, like for instance the existence and configuration of compactified dimensions at high enough energies.

Since string theory is incompletely understood one might feel that this is unlikely to happen, but it is not by itself a procudure alien to science at all.

Finally, to apply the above to the prediction of high energy supersymmetry that we talked about, we have the following:

The assumption A is that strings with the CFT dynamics considered currently in string theory do exist.

This assumption implies B or C

A => B or C,

where B is the bosonic string and C is the superstring.

Say B were ruled out by observation (we have discussed caveats to that).

Since

(A and not B) => C

we get the prediction C of worldsheet supersymmetry. Finally, since

C => D

where D is (generically broken) target space SUSY, we get the prediction of (broken) target space SUSY from the assumption that strings exist at all and that fermions are being observed.

30. **Tony Smith**
January 10, 2006

Urs said: "… As a gut feeling, I would expect the bosonic string to be related to the fermionic one. …".

I agree, and I think that a possibility that is often overlooked when people say things like "SUSY has never been observed" is that, while the superpartners of naive 1-1 fermion-boson supersymmetry have indeed never been observed,
it may be that supersymmetry is more subtle, and related to Spin(8) triality (as Lee Smolin suggests in hep-th/0104050) in such a way that the "ordinary" fermions of the standard model are in fact (subtle) supersymmetric partners of the standard model gauge bosons.

If that is the case, bosonic strings might be "fundamental parents" of a fully realistic model with fermions, and SUSY might be of the subtle-triality type rather than a naive 1-1 correspondence,
and
one might expect that the LHC would see Higgs, more details about the T-quark, etc, but no "new" superpartner particles,
and
that failure by LHC to observe any "new" superpartner particles would not rule out string theory models such as those described by Smolin and others and cited in my previous comment 27. on this blog entry.

Tony Smith

31. **woit**
January 10, 2006

Urs,

You're still completely evading the main point: Saying that you have a "prediction of (broken) target space SUSY" is completely vacuous unless you can say something about how SUSY is broken. This isn't even in any sense a prediction of SUSY since SUSY with breaking scale pushed off to infinity = no-SUSY.

Dan,

I think the supersymmetry breaking problem is the fundamental problem for supersymmetry, both just in QFT, and in string theory. The fact that no one has come up with a way to break supersymmetry which agrees with experiment and doesn't just about completely ruin the ability of the theory to predict anything indicates to me that there is a serious problem with the whole idea as it stands. My own guess is that there is something to supersymmetry, but it will require some major new idea and a serious revamping of how we think about supersymmetry to come up with something that actually works.

32. **Juan R.**
January 10, 2006

Michael Duff said,

> History has shown that rapid confirmation by experiment is a poor guide to the eventual value of a physical theory.

This may be a joke!

> Consider the following theoretical ideas that have yet to be empirically confirmed: gravitational waves (1916); the cosmological constant (1917); extra dimensions (1926); the Higgs boson (1964); supersymmetry (1971).
> All were dismissed in their time by impatient naysayers as theories going nowhere.

Were those 'naysayers' wrong? There is theoretical evidence that gravitational waves are not real (this is focused to the problem of localization of energy in GR). There are experimental discrepancies (order 2%) in last binary pulse tests suggesting longitudinal components cannot be explained via GR-waves and this has open the doors to reevaluation of energy problem of GR again.

There exist serious theoretical evidence that cosmological constant is not one. In some recent works, even the cosmological constant is a geometrical effect with no vacuum interpretation.

There are studies against existence of addittional dimensions, etc.

Precisely, the existence of **alternative** points of view and theories is the REASON for experimental checks selecting the correct theory or view. There are huge collections of beatiful scientific ideas that experiments ruled out from science. String theorists know a lot of that. String theory NEWER worked. For example, Robert B. Laughlin, 1998 Nobel Prize-winning physicist says

> People have been changing string theory in wild ways because it has never worked.

Do you remember string theory fiasco on strong force? They was substituted by QCD.

In SCIENCE, any interesting idea is not true before experimentally verified. But string theorists have introduced the non-scientific idea of a 'beatiful' idea is true even if there is no more basic experimental evidence for it. They believe are Good…

> String/M-theory is much more ambitious and far-reaching than any of the above ideas. It is a bold attempt to fuse gravity with quantum mechanics and explain all physical phenomena.

Yes! and FAILED. String M-theory does not unify QM and gravity (in fact is even unable to obtain GR equations without appeal to fixed backgrounds) and, of course, being a reduccionist approach string M-theory is UNABLE to explain emergent phenomena. As said P.W. Anderson "More is different".

I already explained that string theory is not a TOE in sci.physics.string. In fact, it is not even a 1% of a realistic TOE.

> The debate is not between those who believe that string/M-theory should be judged by its agreement with experiment and those who do not. The debate is between those who demand instant gratification and those who recognise that a theory of everything does not happen overnight.

No! The debate is between those (scientists) who study the world as it is and those (stringers) who want that universe was as they want. Stringers want that universe was 10-11D, supersimmetric, quantum, reduccionist, and formed by dozens and dozens of unobserved 'particles': 0-branes, 1-branes(strings), 2-branes, … 5-branes, … (and some even claim that may be background dependent and that GR may be ignored!)

They claim all of above (and more) even if SCIENTIFIC disciplines experimental data, and theories claim and prove the contrary.

For example, there is well studied cases in complexity theory and published in specialized journals that prove that reduccionism does not work in complex systems as biological societies due to nonlinear features. It has been proven in very recent articles published in the journal *Foundations of chemistry* that chemistry has been **not** reduced to microphysics and that discipline is emergent one, with own concepts and theories *cannot be reduced* to ontological objects of lower class, e.g. atomic physics.

People who has worked in complexity problems (e.g. Anderson, Laughling, Gell-Mann in Santa Fe institute) has expressed the point that string theory is NOT a theory of everything even if was correct.

Stringers simply ignore data and proofs and continue to call to a 'theory' of microscopic strings a theory of everything…

That is not a scientific attitude and remember to me classical physicists searching for a TOE whereas ignored the new QM.

> Many pioneers of the incredibly successful standard model of particle physics, including Nobel laureates Murray Gell-Mann, Abdus Salam, Steven Weinberg and David Gross, turned their attention to superstring theory and continued to pursue its ramifications notwithstanding its lack of empirical support.

And by each one of those scientist we can cite another smart scientist (including lot of Nobel laureates) rejecting string theory.

Do you remember Feynman evaluations of string theory? Yes he used the word nonsense.

Moreover the scientists supporting string theory did some mistakes in the past. Take the example of Gell-Mann or Weinberg. Weinberg has done several wonrg stuff on gravitation, and unification. He openly claimed that QM and Coulomb forces is "all one requires for chemistry" and he failed. Today, we have electroweak quantum chemistry. If the 'father' of eletroweak theory was unable to understand all details theory he did. How can we are sure of his evaluation of string theory.

Take Gell-Mann case, ignore the errors he did in the past and focus in his evaluation of string theory. I have an early work where he clearly explain why heterotic superstring is the *only* serious candidate to unified theory of elementary particles and others string versions being incorrect. In one of his last works, he now carefully talk about the action of M-theory since *now* he know that all string theories are related via dualities.

If Gell-Mann failed then to understand string theory how do you know that now he is understanding M-theory?

> They no doubt recalled the decades required to knock the standard model into a shape that could be confirmed by experiment – for example the 25-year time lag between the prediction and discovery of non-Abelian gauge bosons upon which the standard model is based.

How many alternative theories were rejected in those 25 years? Yes a huge number…

> M-theory solves, among other things, the 1974 puzzle posed by Hawking concerning the microscopic origin of black-hole entropy.

No! There is a mathematical conjeture in brane theory, not a verified scientific explanation.

> Nor is M-theory incompatible with an accelerating universe as your article implied.

Of course, since M-theory is a misnomer because M-theory is not formulated!

Nobody know it but stringers use the term 'theory' how if really exited a theory. In fact, nobody has proven even that the theory exist. We use the term "M-theory conjeture" for refering to those conjetures extracted from non perturbative studies of string theory suggesting existence of a full theory for different values of parameter g.

Some candidates to M-theory as Matrix model violate previous asumptions of string theory. For example, Banks formulation is based in pointlike particles, when during decades all stringers attempted to convice us as stupid the concept of pointlike partiles of the standard model was. Anyone in the street has heard about small unidimensional object (the famous string) but practically nobody heard of 0-branes.

> This is hardly deserving of your description as a theory in "a sorry state". The annual international string theory conference continues to attract an increasing number of participants, now about 500.

Perhaps do you misunderstand between state of theory and state of the community? The community is rather well, the theory is in a sorry state with lot of no-go theorems and zero advance in fundamental issues in the last two decades.

—

Juan R.

Center for CANONICAL |SCIENCE)

33. **Urs**
January 10, 2006

Peter,

I don't think I am trying to evade any point. I am trying to state the obvious elementary facts in a hope to increase the productivity of the discussion.

If your point is that the prediction of SUSY by strings is vacuous for almost all conceivable practical purposes then I fully agree.

I just went through this little exercise in order to show that susy is not really put in by hand in string theory, but follows from assumption A (when stated with all due qualifications).

This is true, albeit not very useful. That happens…

34. **Urs**
January 10, 2006

One more thing: When talking about 'breaking of SUSY in string theory' one is mostly thinking of spontaneous breaking in the effective 4D theory obtained by compactifying 10D on M^4 x CY6.

But, as far as I know, there is no known mechanism that would favor compactification on CY. I'd expect the generic string vacuum 'breaks' susy by not being of the form M^4 x CY6.

What remains true, however, is that flat 10D space will look supersymmetric. So in as far as on small enough scales (i.e. above the compactification scale) spacetime looks locally flat, perturbative string theory would seem to predicts it to look supersymmetric. If it still applied there, that is…

But I am obviously not anywhere near being an expert on this.

35. **Urs**
January 10, 2006

Tony,

this sounds all very interesting. I wish I would better understand the ideas on algebraic patterns that you have (and be able to safely distinguish them from your more voodoo-like ideas, if you know what I mean).

36. **Tony Smith**
January 10, 2006

Urs, about your comment 36. on this blog, here is an effort to describe in voodoo-free terms some aspects of my view of SUSY:

Start with Smolin's hep-th/0104050 statement: "… Supersymmetry appears to be related to triality of the representations of Spin(8). …".

Spin(8) has three 8-dim representations:
two mirror-image half-spinor representations; and
one vector representation.

Half-spinor representations naturally correspond to fermions, so it is natural for one 8-dim half-spinor rep to correspond to fermion particles and for its mirror image 8-dim half-spinor rep to correspond to fermion antiparticles.

Vector representations naturally correspond to vectors.

Triality shows that each half-spinor representation is isomorphic to the vector representation.

So, for Spin(8), triality gives a 1-1 correspondence between half-spinor fermion particles and vectors.

Since gauge bosons come from bivectors, or antisymmetric pairs of vectors, and since there are 8/\8 = 8×7/2 = 28 bivector gauge bosons for Spin(8),
the triality SUSY for Spin(8) is NOT a 1-1 fermion-boson correspondence, but is rather a correspondence between 8 fermion particles and 28 gauge bosons, which is a 2 to 7 ratio, NOT a simple 1 to 1 ratio.

Since I like voodoo, and Spin(8) is natural for voodoo, if I were to advocate my voodoo stuff here I would say in detail how those fermions and gauge bosons look realistic and how the dimensionality of factors in the Lagrangian density in 8-dim spacetime works out to be nice, and how a quaternionic calibration breaks the 8-dim spacetime into 4-dim spacetime plus 4-dim internal symmetry space, etc.
However,
I promised here to stay away from voodoo, so I will do so as follows:

Many people in string theory like to use gauge groups with Lie algebras such as Spin(10), E6, Spin(16), E8, and products thereof, so please note that each and every one of those Lie algebras contain a nice Spin(8) subalgebra with triality, and (calculation details vary with whichever algebra is your favorite) roughly you can find a subtle-supersymmetric correspondence in each case such that the fermions are related to gauge bosons by using the triality of the embedded Spin(8), which means that:

The natural SUSY of such string theory models is NOT naive 1-1 requiring unobserved stuff like selectrons and gluinos.

The natural SUSY of such string theory models is not only more subtle, but, very importantly, THE WELL-KNOWN STANDARD MODEL FERMIONS CAN ACT AS THE SUBTLE-SUPERSYMMETRIC PARTNERS OF THE GAUGE BOSONS,
so that
A FAILURE OF THE LHC TO FIND SELECTRONS, GLUINOS, ETC WOULD BE IRRELEVANT WITH RESPECT TO (actually, supportive of) THE VALIDITY OF SUCH STRING THEORY MODELS.

This may be the "new idea and … serious revamping of how we think about supersymmetry" that Peter mentioned in his comment 32.

I thank you for the opportunity to say this here, because I used to wish that some group somewhere would let me participate in a seminar or workshop etc about such stuff, but I guess my status (being blacklisted by the Cornell arXiv) made me an outlaw-persona-non-grata to be shunned by all decent physicists, and I guess as of now I just have to live with that.

Although I do like the voodoo = Clifford algebra / generalized hyperfinite II1 von Neumann factor / Wyler geometry / strings-as-world-lines model that I use (and I do hope that someday others might come to like the voodoo stuff),

I also hope that it is clear from the above that some parts of it might be very useful in non-voodoo string theory models, and that I am quite happy to discuss such parts in non-voodoo contexts.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

37. **Alejandro RIvero**
January 11, 2006

Just a note: any revamping of supersymmetry should contemplate the hierarchy problem, just as usual susy does; cancellation of fermionic and bosonic loops and all that.

Of course the simplicity of the 3-familiy standard model is amazing, 12 spin 1/2 particles (and another 12 antiparticles thus) and 12 spin 1 particles seem to be claiming for some special symmetry or a cancellation mechanism, or perhaps even a Galoisian justification. But here comes just the same thing we are critiquising in this thread: to build an structure needing these particles is not the same
that to predict the existence of these particles; exactly as to build a metatheory needing susy is not the same that to predict susy.

38. **Urs**
January 11, 2006

Tony,

thanks for the response.

It is certainly true that triality of SO(8) has a lot to do with supersymmetry.

The fact that the superstring has to live in 10 dimensions (to cancel the Weyl anomaly) is closely related to this. Precisely in 10 dimensions does a string (a 2D worldsheet) have precisely 8 transverse directions and its fermionic and bosonic transverse oscillations a chance to be related, thnaks to SO(8) triality.

This is particularly manifest in the procedure which relates the Green-Schwarz formulation of the superstring (the one which is bosonic on the worldsheet and manifestly susy in target space) with the Ramond-Neveu-Schwarz formulation (which is manifestly susy on the worldsheet but not manifestly so in target space).

In order to show that these two formulations are in fact equivalent one rewrites the worldsheet spinors of RNS as worldsheet bosons ("bosonizing" them) and checks that the result is the GS string. This procedure only works due to triality and hence only in 2+8 dimensions.

Similarly the 11 dimensions of "M-theory" arise as 3-dimensions of the worldvolume of a supermembrane plus 8 transverse ones.

So in this sense there is a relation between triality and supersymmetry which is well-established.

But it seems that you are arguing for a different relation.

I am not sure yet if I follow the details, though. Let me see: are you arguing that any system with a spin(8) symmetry has bose/fermi symmetry?

Certainly this is not true without further qualifications. The point of triality above is rather along the lines that in 8 dimensions Weyl spinors have the same number of components as vectors. But the spin(8)-representation still acts inside the spinor space or the vector space seperately.

Maybe I am missing the obvious. Could you maybe sketch the form of one of these Lagrangians that you seem to have in mind which contains 2x fermions and 7x bosons such that it is invariant under a symmetry operation which mixes these 7x-bosons and the 2x-fermions?

39. **Urs**
January 11, 2006

> voodoo = Clifford algebra / generalized hyperfinite II1 von Neumann factor / Wyler geometry / strings-as-world-lines model

I should clarify what I meant by "voodoo" in a previous message. I don't consider Clifford algebra and von Neumann algebra theory as voodoo at all.

I assume what you have to say on your website concerning algebras etc. is correct and often interesting. What looks like voodoo to me are some of your more liberal free associations of structures with physics. It might be that there is deep truth hidden there, but then it is not easy to see.

Hoping that you don't mind me being honest, I have to say that much of what you present (and certainly the style in which you present it) looks like an extremely sophisticated version of numerology.

Maybe it's not. But I bet the reason why you are encountering problems with the arXiv is due to that.

40. **Urs**
January 11, 2006

> strings-as-world-lines model

If you had said "worldsheets as planar Feynman-diagrams" I would agree that there is something very deep about it.

41. **Santo D'Agostino**
January 11, 2006

Hi Urs,

You said about predictions:

"… Hence combining our assumption (FRW universe) with the experimental data allows us to make the prediction

(A ∧ not C ∧ not E) => D .

And that is in fact a prediction, as everybody knows. The successful standard model of cosmology follows from

– assuming a theory (FRW model of GR)

– excluding solutions which do not match observation at all

– predicting that the only remaining solution is the one observed in nature, which then again implies predictions for further observations (like CMB fluctuations, etc). …"

This is, to me, an unusual use of the word "prediction." Sticking with the context of GR, consider the prediction of the perihilion shift of the orbit of Mercury, or the prediction of the bending of distant starlight by the sun. In these two cases, one can derive formulas from GR, then one substitutes experimental values for independently-measured constants (such as the gravitational constant), and the formulas then produce definite, numerical values for the desired quantities. These definite numerical values can then be compared to the corresponding observed values. To my mind, this is what is meant by prediction.

Contrast these predictions with the curvature of spacetime in the FRW models, as you discuss. The curvature of spacetime cannot be calculated by GR, and so does not qualify as a prediction of the theory. True, any experimentally measured value of the curvature is consistent with GR, but that does not make any particular measured value a prediction of the theory.

Using such a traditional interpretation of the word "prediction," are there any predictions of string theory?

Best wishes,
Santo

42. **Urs**
January 11, 2006

Santo D'Agostino,

the example you describe is indeed a special case of what I
sketched in

http://www.math.columbia.edu/~woit/wordpress/?p=323#comment-7364

(There seems to be something wrong with hyperlinks here, at least in the comment preview.)

In your example "A" is the assumption that Einstein GR describes gravity.

Your statement that "one can derive formulas from GR" is the implication

A => (B1 or B2 or B3 or …)

where the Bi for all i in some set I are all the solutions of these equations.

Your statement "then one substitutes experimental values" is precisely the important point which I tried to emphasize in my post. It eliminates classes of the Bi, those that do not fit these experimental values, so that we have

for all j in a subjet J of I : not Bj .

Given sufficient experimental input (large enough set J) we obtain a small enough set

K = I without J

of candidate solutions and
then your statement is true that "the formulas then produce definite, numerical values".

In my notation this was the logical deduction

(A and not Bj for all J in J)
=>
Bk_1 or Bk_2 or … for k_i in K

Please read again carefully through what I wrote to see this.

So the point is this: We make an assumption about the world. This usually is compatible with more than one state of the world. Hence we look at only those consequences of that assumption which do not contradict known facts about the world. Then we check what our assumption implies on the remaining set of solutions.

It's a very simple fact. I stated it because in the heat of string-theory-bashing some simple facts tend to be forgotten. 🙂

String theory is based on an assumption A which says that perturbative scattering amplitudes are given by evaluating certain 2D CFTs over Riemann-surface diagrams.

You can work out consequences of this assumption and go through the above procedure sketched above.

So in particular, you can take experimental input (like the gauge group of the standard model or the number of generations) and use this to exclude certain a priori possible consequences of assumption "A", i.e. certain "string vacua"

Unfortunately, the set K of remaining candidate solutions is thus far still too large to say almost anything definite about it.

Another problem is that assumption "A" itself may not be sufficiently well understood yet.

So, that's how it goes in science. Assumptions are made, checked, reworked, etc. The problem with string theory that Peter is fond of pointing out is not that assumption "A" is by itself an assumption without any chance of being useful. If we perfectly understood the consequences of "A" (say at the level at which we understand the consequences of the assumption that GR describes gravity) we'd be all much happier.

It makes sense to complain about the progress that has been achieved in understanding “A” and to urge people to look at other viable assumptions “A1”, “A2”,…

43. **Santo D'Agostino**
January 11, 2006

Hi Urs,

Although the traditionally standard use of the word “prediction” may indeed logically be a special case of the process you describe (and also call by the name “prediction”), the two processes are sufficiently different in character that they ought to be labelled by different names to prevent confusion.

To clarify the difference in character between the two concepts, consider this passage from your previous message:

“In your example “A” is the assumption that Einstein GR describes gravity.

Your statement that “one can derive formulas from GR” is the implication

A => (B1 or B2 or B3 or …)

where the Bi for all i in some set I are all the solutions of these equations.

Your statement “then one substitutes experimental values” is precisely the important point which I tried to emphasize in my post. It eliminates classes of the Bi, those that do not fit these experimental values, so that we have

for all j in a subjet J of I : not Bj .”

Suppose that the Bi are possible values for the perihelion shift of Mercury. Then by substituting experimental values INDEPENDENT of the perhilion shift, one eliminates possible values of Bi and obtains a single value, called the predicted value of the perihelion shift, which then one can compare to the observed value.

Contrast this with the situation of curvature. That is, suppose that the Bi represent possible values of the curvature of spacetime. If one had a formula for the curvature of spacetime, and substituted experimental values into the formula that were INDEPENDENT of the curvature, then once again one could say that the theory predicts the curvature. However, using observed values of the curvature itself to select values of Bi, which are also values of the curvature, is a process that you refer to as prediction, but which I would not call as such.

With your usage of the word “prediction,” it seems that one could say that GR predicts the curvature of spacetime no matter what its observed value is. This represents a departure from the traditional use of the term, and it would be better to coin a new term for the process you describe.

Best wishes,
Santo

44. **Urs**
January 11, 2006

> With your usage of the word “prediction,” it seems that one could say that GR predicts the curvature of spacetime no matter what its observed value is.

No. Please read what I wrote. In the example of cosmology the observed curvature of space on large scales is experimental input. Only given that input can we select out of all available FRW models the one which we then use to make further predictions.

The whole point is that the assumption GR+FRW model does *not* predict the curvature of space. There is a “landscape of solutions” to GR+FRW which contains precisely three solutions. We pick the one not excluded by experiment and use it to predict further observations.

45. **Santo D'Agostino**
January 11, 2006

Hi Urs,

I’m relieved to read that you agree that experimental input cannot be considered a prediction of a theory. But your usage of the word prediction in an earlier post is still unjustified if we stick to the traditional meaning of “prediction.”

Quoting you:

“Let A be the assumption that the universe on large scales is described well by an FRW model in Einstein GR. As you know, this implies

(C v D v E)

where C is a universe of positive, D one of vanishing and E one of negative curvature.

Now you make measurements. These rule out two of these possibilities.

not C and not E .

(This example might be a little outdated. Modify as you deem appropriate according to current experimental data.)

Hence combining our assumption (FRW universe) with the experimental data allows us to make the prediction

(A $\wedge$ not C $\wedge$ not E) => D .

And that is in fact a prediction, as everybody knows.”

I am not arguing with the validity of the methodology you describe. I am only saying that D should not be referred to as a prediction of the theory, since D is observational input, as you seemed to agree with in your immediately previous post. In other words, I am disputing your sentence, “And that is in fact a prediction, as everybody knows.”

A prediction of a theory is a definite thing, and is not contingent on experimental or observational data. What if in the future, more acceptable measurements rule out D and E, but not C. Would you then say that the theory now predicts C?

Santo

46. **Urs**
January 11, 2006

Ah, now I see what you mean. That was sloppily formulated. The point is, once you have fixed D this implies other things

D => D1 and D2 and …

(like details of nucleosynthesis, CMP spectra, etc.) and *this* are the predictions.

47. **Santo D'Agostino**
January 11, 2006

Hi Urs,

Agreed.

All the best wishes,
Santo

48. **John Gonsowski**
January 11, 2006

Urs, Tony's model uses E6 much like the E6 GUT one gets from the E8xE8 heterotic string. I think for both Tony and the heterotic string the two half-spinors of D4 relate to E6 orbifolding. The difference may be in the use of the D4 vector part of the Triality. If you think of D5 in between D4 and E6 or the SO(10) GUT in between the SU(5) GUT and the E6 GUT. That SO(10) as John Baez mentions in his recent paper is a nice way to see a 10-dim spacetime. That 10 is a D5 vector and is a nice way to see why Tony uses the 8-dim vector of the D4 Triality as spacetime. The two extra dimensions Tony has for an SO(10) spacetime makes the spacetime complex. D5/D4xU(1) has 16-dims or the 10-dim has 2-dim added to the 4 big dimensions to get a 6-dim CP3 twistor. So Tony has spacetime as a substructure of the String. That Gross comment about space and time needing to go away (as the superstructure of the string) seems related to this. Gross asks what then replaces spacetime. For Tony it's the Clifford algebra. Kind of makes sense to think of Lie Algebras as a substructure of Clifford algebras. It kind of bothers me that so many people seem to have trouble with the general idea of Tony's model, it's not that complicated. If you were looking at something like Tony's Lagrangian after dimensional reduction I could see where a discussion is needed, there are tons of places I just take Tony's word for it, he seems rather good at math. As for Tony giving credit to ancient civilizations for finding Clifford Algebra and Lie Algebra patterns, lots of the patterns like D-series root vectors are rather simple and it is not so hard to imagine ancient people noticing them. I personally believe like Tony that some ancient people were quite good at noticing patterns that aren't all that easy to see.

49. **Tony Smith**
January 11, 2006

Urs asked (in comment 39.) "… are you arguing that any system with a spin(8) symmetry has bose/fermi symmetry? … Could you maybe sketch the form of one of these Lagrangians that you seem to have in mind which contains 2x fermions and 7x bosons … ? ..".

No, I am not arguing that ANY system with a spin(8) symmetry has bose/fermi symmetry, but I am arguing that some interesting systems do have what I call subtle supersymmetry due to the spin(8) triality.

The 7/2 boson/fermion ratio stuff is peculiar to my voodoo stuff, so I don't want to say much about it here, but (since yesterday (10 Jan 06) was National Voodoo day in Benin – see the BBC article at http://news.bbc.co.uk/1/hi/world/africa/4599392.stm) I will mention that the key is that in a Lagrangian density over 8-dim spacetime, the dimension of fermion/spinor PSI is 7/2 (as opposed to dimension 3/2 over 4-dim spacetime), and 8 fermion particles x 7/2 dimension = 28 = 28 gauge bosons x 1 dimension.

For a non-voodoo point of view, I will quote from Lee Smolin's hep-th/0104050:
"… the local structure of a 9+1 dimensional spacetime may be expressed in terms of J(O,2), which is the Jordan algebra of 2×2 hermitian matrices of octonions
z1 O0
J(O,2) =
O0 z2
… Similarly, the relevant Spin(9,1) spinors may be parameterized as 2 component octonionic spinors, which we may write as,
O2
PSI =
O1
… The main idea of supersymmetry, in the context of a theory of spacetime, is that there should be some fundamental unification of the spacetime geometry with the fermionic degrees of freedom which live in the spinor representations of the local invariance group.
…to unify the coordinates of the tangent space of a 9 + 1 dimensional spacetime with its spinor degrees of freedom, in a way that naturally includes an eleventh spatial coordinate z3 … incorporate all of them in the algebra of 3×3 hermitian matrices of octonions, which is called the exceptional Jordan algebra. This is given by
z1 O0 O2*
J = O0* z2 O1
O2 O1* z0
… sixteen of the dimensions of bosonic string theory are transmuted from bosonic to fermionic by a dynamical mechanism that involves the decay of the tachyonic degree of freedom … the exceptional Jordan algebra is exactly the unique mathematical structure we seek. … The automorphism group of J is known to be F4. This group has several Spin(8) subgroups, one of which acts on the components of J in the following way: the za are scalars,
O0,O1,O2 are, respectively, the 8 dimensional vector, spinor and conjugate spinors. …
One way to … make an action … is to construct a cubic action … which we will call the exceptional cubic matrix model … Spin(8) acts differently on each of the three slots of the cubic product. … The three particular Spin(8) subalgebras that act on each slot are related to each other by triality …
It is interesting to conjecture that the supersymmetries … can be understood as arising from the components of F4 that live in the 8 dimensional spinor and conjugate spinor representations S and Sc. These act bosonically on the degrees of freedom in J however it is possible that after the compactifications that turn the …[O1 and O2]… into fermions they may imply a fermionic symmetry of the reduced action …".

I hope that the quote is extensive enough to give Lee Smolin's basic idea, and not too extensive as to be burdensomely long in a blog comment.

As you can see from language like "conjecture", full calculations were not done at the time of hep-th/0104050, and, as far as I know, they have yet to be done.

I am sort of puzzled (and disappointed) that both Lee Smolin and Lenny Susskind, authors of papers about such stuff (hep-th/0104050 and hep-th/0012037) seem to spend most of their energy nowadays on other matters, even though they both doubtless have grad students / postdocs /etc who could be assigned some of the calculation work that remains to be done.

Lee's Jordan algebra approach lends itself to LQG / spin foams with the exceptional Jordan algebra at the spin foam nodes,
while
Lenny's matrix model lends itself to string theory models with Lie algebras that are related to that exceptional Jordan algebra,
and
it would be nice (in my opinion) to work on both approaches, and maybe it would result in showing that the two approaches are equivalent (sort of like Heisenberg and Schroedinger quantum models were shown to be equivalent). Maybe they might even also be equivalent to my voodoo model.
Therefore,
I am somewhat saddened that Lee seems to mostly run around talking about relatively general topics such as background independence and Lenny seems to be running around Lost in his Landscape. Such topics are easy to use as PR hype for the public and funding agencies, but in my opinion they are nowhere near as useful as the hard work of doing some detailed calculations about triality and subtle supersymmetry.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Urs, I am quite OK with your honest expression of opinion (in comment 40.) that "… much of what …[I]… present (and certainly the style in which …[I]… present it) looks like an extremely sophisticated version of numerology. …".

As to style, if you are referring to my web site, it is not intended to look like a standard-format physics paper, and it is true that it contains a lot of associations (IFA divination = Clifford algebra, etc) that some people might find unusual.
However,
my pure-physics papers that were put on the XXX archives before Cornell blacklisted me might look a bit less unconventional. For example: hep-th/9302030 deals with Jordan algebras and force strengths and hep-ph/9501252 is a model overview. Although those older papers contain some ideas that I have changed/corrected as of nowadays, they were written in conventional LaTeX format, and I tried to make them look conventional in style. If you find them to also look strange, then I can only apologize for my limited expository ability.
As to some of the associations that I make seeming strange or unusual, that is one of the topics that I discuss in therapy with my psychiatrist. So far, his diagnosis seems to be that the unusual associations are not problematic, although depression is a problem for which I am undergoing therapy.

50. **Urs**
January 11, 2006

> I will mention that the key is that in a Lagrangian density over 8-dim spacetime, the dimension of fermion/spinor PSI is 7/2 (as opposed to dimension 3/2 over 4-dim spacetime), and 8 fermion particles x 7/2 dimension = 28 = 28 gauge bosons x 1 dimension.

If this is really more than numerology it might be interesting. It's hard to say, for me.

> sixteen of the dimensions of bosonic string theory are transmuted from bosonic to fermionic by a dynamical mechanism that involves the decay of the tachyonic degree of freedom

That's what one would hope. What concrete evidence do we have?

> I am somewhat saddened that Lee seems to mostly run around talking about relatively general topics such as background independence and Lenny seems to be running around Lost in his Landscape. Such topics are easy to use as PR hype for the public and funding agencies, but in my opinion they are nowhere near as useful as the hard work of doing some detailed calculations

Well said. We definitely agree on that.

It's not that there is nobody out there looking hard for new grand (algebraic) structures. P. West and H. Nicolai come to mind with their attempts to integrate everything into E10 and E11. Judging from the abstracts of Nicolai's papers there seems to be slow but steady progress and mounting evidence that indeed all of 11D supergravity is (a small subset) of the geodesic motion on something like exp(E10/K(E10)).
(http://golem.ph.utexas.edu/string/archives/000353.html)

But things like that are certainly, and unfortunately, in the minority at the moment.

P.S.
If you make John Gonsowski write a comprehensive and coherent pdf exposition of your ideas, I promise to take a detailed look at it. More importantly, others might, too.

51. **ksh95**
January 11, 2006

> If you make John Gonsowski write a comprehensive and coherent pdf exposition of your ideas…

I second that, especially the part about **coherent**.

> As to some of the associations that I make seeming strange or unusual, that is one of the topics that I discuss in therapy with my psychiatrist. So far, his diagnosis seems to be that the unusual associations are not problematic, although depression is a problem for which I am undergoing therapy.

Whoa, slow down there Tony…Way to much information. You were on a roll, why didn't you quit while you were ahead? You wrote one paragraph to many.

52. **woit**
January 11, 2006

This discussion of Tony Smith's ideas is way off topic, and this kind of thing gives lots of people the idea that this is a forum for discussion of their own work. I then have to spend increasing amounts of my time deleting people's comments in order to keep this comment section from turning into sci.physics. Please continue this discussion with Tony privately or in some other forum.

53. **Tony Smith**
January 11, 2006

Urs, "… sixteen of the dimensions of bosonic string theory are transmuted from bosonic to fermionic by a dynamical mechanism that involves the decay of the tachyonic degree of freedom …" is a direct quote from Lee Smolin's paper at hep-th/0104050, so he would be the one for you to ask: "… What concrete evidence do we have? …". It could probably be answered with some of the hard calculations that in older times would be assigned by someone like Lee to his grad students / postdocs / etc.

Maybe (and this is just speculation from one who has been out of academia for a long time) grad students / postdocs / etc nowadays don't see doing such assigned hard work as "the" way to advance, but instead just write a lot of relatively shallow "me-too" papers, or even follow the example of Lubos and advance by acting as mindless advocates (a la talking head political spin-masters on Fox News etc) of whatever the powers-that-be say.

As to writing a “comprehensive and coherent pdf exposition of …[my]… ideas”, I wouldn’t demand that of anyone, much less a friend like John Gonsowski. The closest thing to such a single pdf file might be the one on my web site at http://www.valdostamuseum.org/hamsmith/TQ3mHFII1vNFadd97.pdf which is about 550 KB, and about 65 pages, in size. It has my ideas up to around 2003, but it is not in LaTeX, and it does not cover my more recent calculations of neutrino masses and mixing angles and of the Dark Energy : Dark Matter : Ordinary Matter ratios observed by WMAP.

Photos of Mathematicians

January 8, 2006
Categories: Uncategorized

For many years C. J. Mozzochi has been taking photographs of mathematicians, primarily at mathematics conferences and lectures in Princeton or in the New York City area. With help from Mark Goresky, he now has a web-site where you can view and download many of his photographs. The site will be periodically updated with additional photographs.

Comments

1. **C. J. Mozzochi**
   January 9, 2006

   Thanks Peter!

2. **Dissident**
   January 9, 2006

   I'm surely missing something really obvious, but… what's the point? Ogling supermodels I might understand, but mathematicians?

3. **woit**
   January 9, 2006

   Dissident,

   As I've said before, the interests of this blog are pretty idiosyncratic. Lots of places to go on the internet if you want to ogle supermodels. Those that want to ogle mathematicians need a much more specialized site like this to point them in the right direction….

4. **Rob Scott**
   January 9, 2006

   Sigh, if there were only supermodel mathmaticians!

5. **MathPhys**
   January 9, 2006

   There are.

6. **John Gonsowski**
   January 9, 2006

   Just got my February Discover magazine and it has a mathematician photo. Is Columbia's math department interested in having a 2nd TV/movie star?

7. **woit**
   January 9, 2006

   Hi John,

   No, I think one of those is enough. I still haven't seen the magazine yet, will write something about it soon.

8. **Chris Oakley**
   January 9, 2006

   Maybe Mozzochi should have three sets of photos: mathematicians in casual attire, mathematicians in their national costume and mathematicians in swimwear, like the Miss World pageant. The latter would not necessarily be a pretty sight, but one could always just make one's excuses and leave at that point.

9. **Robin**
   January 10, 2006

   Andrej Bauer also maintains a collection of photos of mathematicians; mainly people working in category theory and/or logic.

Discover Interview

January 9, 2006
Categories: Uncategorized

The February issue of Discover Magazine contains an interview of me by writer Susan Kruglinski. I haven't seen the magazine itself, and it's not yet on the newsstands here, but a friend who subscribes was kind enough to send me a copy of the article. There's a picture of me sitting underneath the blackboard outside my office taken by a photographer. The day he came I had a migraine headache, so was looking rather grim, not my usual cheery self.

Comments

1. **mathjunkie**
   January 10, 2006

   So, what was the interview about?

2. **MathPhys**
   January 10, 2006

   What do you think it's about?!

3. **woit**
   January 10, 2006

   String theory and the blog, mainly. The title is "The Dean of Debunkers"….

4. **MathPhys**
   January 10, 2006

   Great title, Peter. Could you please make it accessible here?

5. **Dumb Biologist**
   January 10, 2006

   Perhaps the mantle can be shared with James Randi?

6. **woit**
   January 10, 2006

   Sorry MathPhys, but I think Discover wouldn't want me putting up their copyrighted content on my web-site.

7. **John Gonsowski**
   January 10, 2006

   Peter, your photo seems pensive as well as stern and it kind of goes with the folded arms and title. Discover seems to like slightly surreal photos of people. For the interview, you must not have had a migraine or too many off topic comments that day cause it was great. Respectful and understanding of why the field went in the direction it did, but very clear that more people need to be thinking in more directions. I feel like I'm giving an opinion on a movie while not wanting to give away too much.

8. **Quantoken**
   January 10, 2006

   Peter:

   It is **NOT** true that just because it's Doscover copyrighted material you can not re-produce it here on your blog. You have a right to **fair use** of copy-righted materials, persuant to the law, **Title 17 U.S.C. Section 107**

   As a matter of fact, you and your colleagues are already routinely exercise your title 17 section 107 rights, by photo copying published articles without having to contact the publisher.

   The law says: "Notwithstanding the provisions of sections 106 and 106A, the fair use of a copyrighted work, including such use by reproduction in copies or phonorecords or by any other means specified by that section, for purposes such as **criticism, comment, news reporting, teaching (including multiple copies for classroom use), scholarship, or research**, is **not** an infringement of copyright."

   Clearly if you quote the article here for purpose of education and discussion, and not for making money, you qualify for the fair use clause.

   Quantoken

9. **Quantoken**
   January 10, 2006

   Peter:
   All you need to do for such fair use, is attach such a declaration note, in its exact format as below:
   In accordance with Title 17 U.S.C. Section 107, this material is distributed without profit to those who have expressed a prior interest in receiving the included information for research and educational purposes.
   As a matter of fact, if you search on the web that **exact sentence**, you find many occurances.

10. **woit**
    January 10, 2006

    Quantoken,

I'm not completely convinced by your legal argument, and in any case I'd rather just not get involved in this. There's nothing much in the interview that isn't already said many times elsewhere on this blog. The Discover people, the writer, the photographer are all trying to make a living by putting together pieces like this, hoping someone will pay some money for them. I'd rather encourage people to support them by at least buying a copy of the magazine every so often. It would be a shame if magazines like this all go out of business because their market dries up as everyone expects everything to be freely available on the internet.

11. **Thaed**
January 10, 2006

I loved the Discover article, but I'm a lawyer, not a math guy, so I was curious what the equation is on the blackboard above your head?

Michael Crichton is also fond of the expression "Not even wrong." I first read that phrase in an interview with him in some magazine.

12. **Peter**
January 10, 2006

Thaed,

The photographer asked me to write something on the blackboard, that was the best I could come up with at short notice. The top line is just the path integral for a quantum field theory like the standard model. The bottom line is the integration map in equivariant K-theory. What I've been working on is understanding the relation between this physics and this math, can't say that I've figured it out yet, but there's something there….

13. **MathPhys**
January 11, 2006

Some of us have seen a photograph of a very well known physicist standing facing a blackboard, arm extended with a piece of chalk in hand, chalk touching blackboard, blackboard is covered with equations. Looks very impressive. A great physicist in action. Too bad the handwriting on the blackboard is that of a longterm collaborator.

14. **Chris Oakley**
January 11, 2006

What – so were the Feynman Lectures a put-up job then? I know that Leighton and Sands helped write the books, but this is a revelation. So were the students looking at a hologram of the great man navigating around Leighton's equations while the real Feynman was playing bongos or testing out cheesy chat-up lines in hostess bars … ?

15. **woit**
January 11, 2006

Chris,

I asked MathPhys privately what he was referring to (no, despite what Lubos thinks, I'm not MathPhys). It wasn't Feynman, but a more obscure picture of a more obscure physicist, one I wasn't aware of. I'll respect his desire to keep his comment nearly a private joke, but thought I'd mention that it wasn't about Feynman (which would have been my guess too).

16. **MathPhys**
January 11, 2006

Definitely not Feynman. Besides, Feynman never had long term collaborators, let alone any scientific collaborators in any sense (I don't think of those who wrote his books on the basis of his lectures as collaborators). Only those who personally knew the man that I have in mind will recognize him from my comment, so I'll leave it as a private joke.

17. **Thomas Love**
January 12, 2006

We on the West Coast get the magazine late so I just read the article last night. I agree that string theory is not even wrong, but I said that about the standard model years ago (unpublished) so I don't understand your love affair with it. I was at the AMS summer meeting in Salt Lake City in 1987 when Witten gave a week long series of talks on string theory. I laughed out loud, it was so absurd. Another phrase I like: It's crazy, but is it crazy enough? In a letter to the editor of Physics Today I wrote: Nature comes with no strings attached.

18. **anon**
January 12, 2006

Nature has no strings attached! How does that translate into Latin? It should be adopted as the motto of objectivity. 🙂

19. **Thomas Love**
January 18, 2006

In describing string theory to a friend, with thousands of little strings wiggling around, I realized "This is a bucket of worms."

Current Science

January 10, 2006
Categories: Uncategorized

Mathematician David Goss wrote to tell me about the latest issue of the journal Current Science, which contains quite a few articles on Einstein's legacy, including an interesting one on Einstein and the search for unification by physicist David Gross. Perhaps I'm being a bit churlish, but surely I'm not the only person who is at least a bit happy that 2005 is over and done with, so that attention can begin to be paid to some other topic than that of Einstein. He was a true giant, but I bet he'd be pretty tired of the hoopla by now.

Gross discusses Einstein's goal of finding simple universal laws from which all physics can be deduced, and tells about how this inspired him at the age of thirteen to decide to become a theoretical physicist. He tells about Einstein's failed attempts to find particle-like solutions to the non-linear equations of GR, unified in various ways with electromagnetism, and notes that in the early 80s, with Malcolm Perry, he found magnetic monopole solutions that were a bit like what Einstein was looking for.

Getting to topics of current interest, Gross talks about "The discovery of supersymmetry, which we all hope and some expect in a few years from now at the Large Hadron Collider…" I don't think I'm the only one hoping not for this, but for something more interesting. I'd also be curious whether Gross puts himself among those who "expect" to see this at the LHC. There's the usual string theory propaganda, including the incorrect claim that string theory provides "a consistent and finite quantum theory of gravity" (no, the sum of the perturbation series is not finite, and Gross is one who often says we don't know what the theory even is). Gross also as usual stresses that he thinks we need to give up on space and time, but doesn't know what will replace them. He concludes that Einstein was wrong to refuse to accept quantum mechanics and to ignore nuclear and particle physics, but that he was right to try and unify gravity with the other forces, saying "this we know today is the central issue in fundamental physics", something I don't really agree with (I'd go for understanding electroweak symmetry breaking).

This issue of the journal also contains interesting articles by Michael Atiyah on Einstein and Geometry, and by Abhay Ashtekar on The winding road to quantum gravity. There's also a completely uncritical piece of string theory propaganda by Ashoke Sen entitled String theory and Einstein's dream that could easily have been written ten years ago.

For more uncritical promotional material on string theory, here are two things from UC Davis. They have something there called the "High Energy Frontier Theory Initiative (HEFTI)", and on their website you can read a report written by an external committee for the Dean at Davis promoting the idea of hiring more string/brane theorists of the phenomenological sort. The report is a few years old, but shows exactly what the consensus thinking of just about the entire high energy theory community has been for the past few years about what is the hot area to hire in. They promote the idea that particle theory is doing extremely well, so much so that

The last period of comparable experimental and theoretical ferment occurred in the early 1970s, swiftly culminating in the development of the Standard Model of particle physics.

and that the "pace of new developments is accelerating" in both theory and experiment.

Also from UC Davis is a new paper entitled Space and time from translation symmetry by Albert Schwarz. It starts off by claiming "In some sense string theory today is in very good shape", but seems to be empty of content.

Finally, there's a new paper out tonight reviewing the status of the string theory Landscape. It looks like landscapeologists are now ready to abandon even the idea that the number of phenomenologically viable vacua is finite, and the last part of the paper contains some impressive contortions about why this isn't necessarily a bad thing. They also seem to have given up on Douglas's idea of making predictions by counting vacua. They're still counting the vacua, but now the reason given is not to make predictions, but to see if there are enough to be sure that one of them will reproduce the standard model.

Comments

1. **MathPhys**
   January 10, 2006

   I hope that when putting the world together, God had more imagination than to attach a superparticle to every particle, then push it to very high energies.

2. **anon**
   January 10, 2006

   "… He concludes that Einstein was wrong to refuse to accept quantum mechanics and to ignore nuclear and particle physics,…"

   I don't this well represents the concerns Einstein was expressing. It is possible to accept the mathematics of quantum mechanics and particle physics as being a useful working approximation without religiously proclaiming that it is infallible.

   Einstein's reservations were not directed towards the validated empirical equations of QM, but towards Bohr's brainwashing philosophies which sweep inconsistencies between classical and quantum theories under the carpet.

   It is not good science to invent philosophies that make questioning look heretical or silly (complementarity and correspondence principles), although it had to be done back in 1927 to overcome the charge that QM was incompatible with classical physics.

3. **Juan R.**
   January 10, 2006

   A bit of history,

   Einstein was not the father of the idea of unification. This one of multiple miths. In fact, as historically proven, Hilbert already was working in an unified field theory before Einstein. In fact, Einstein contacted with Hilbert before the formulation of GR expressing his interest in Hilbert axiomatic unified field theory.

   Einstein rejected QM as pure nonsense and wait that some alternative equations (e.g. somewhat in the spirit of Bohmian mechanics) could REPLACE Schrodinger one. Einstein become a member of continuum guys, whereas Heisemberg, for example, was member of quantum school.

   Einstein rejected the math of QM (as most of classical physicists who found repugant the new mathematical tools). Einstein durely critized Dirac formalism as a kind of 'nonsense' when was presented to him.

   Einstein completely ignored nuclear physics advances since he waited that nuclear forces would be a kind of combination of EM + gravity. Somewhat as he waited that QM would be explained via some 'modification' of classical mechanics. He was not alone, some physicists (e.g. Stark) waited that a chemical bond could be explained via classical EM forces, for example.

In fact, when physicists said Einstein that via relativistic-QFT, they had obtained the highest precision in experimental predictions never seen, Einstein said “Bah that is not impressive for me”.

January 10, 2006

Juan,

OK, so Einstein had his own share of crackpotism…

5. **Ugo**
January 10, 2006

@ anon :

Einstein’s crackpotism is excusable since he developped a correct theory of gravitation.
It was not a small endeavour, and even if he didn’t accept QM and Bohr’s interpretation of quantum mechanics so what ?
It doesn’t diminish at all all the great discoveries he did : in statiscal mechanics, brownian motion, special and general relativity etc….

6. **Chris W.**
January 10, 2006

Einstein rejected QM as pure nonsense …

This is, to put it mildly, a gross overstatement. Also, to characterize Einstein’s views on quantum mechanics in the 1930s and later as crackpotism strikes me as ludicrously ahistorical and revisionist. (I suspect Anon was just throwing Juan R a bone.) Were his views in several respects wrong, or at least questionable and self-defeating? Undoubtedly, although they stimulated a level of critical examination of quantum mechanics that might not have occurred otherwise.

Before criticizing Einstein for his deeply held positions in the mid-20th century the current generation of physicists should consider how their own views might appear with the benefit of hindsight several decades from now.

From Richard Feynman:

> We have a habit in writing articles published in scientific journals to make the work as finished as possible, to cover up all the tracks, to not worry about the blind alleys or describe how you had the wrong idea first, and so on. So there isn’t any place to publish, in a dignified manner, what you actually did in order to get to do the work.

7. **QWERTY**
January 10, 2006

THE FEBRUARY NOTICES OF THE AMS ARE FULL OF DOO-DOO TOO.

THERE IS NO MATHEMATICAL CONTENT WHATSOEVER. THE INTERVIEW WITH LAX IS ODIOUS AND VILE. REMARKS LIKE “INCIDENTALLY, I HAVE A VERY GOOD MEMORY” ARE SELF-SERVING AND CRASS.

8. **Who**
January 10, 2006

Dear QWERTY
to save me having to walk over to the math library, since i don’t have a subscription (not an AMS member), could you say very briefly what the articles are about that you are objecting to?

Based on impressions gathered in the 1970s I have a very high regard for Peter Lax. It would be amusing and surprising to find him guilty of making doo-doo with no mathematical content whatsoever, though less astonishing if he were merely odious crass and vile, since that is a familiar part of all our human makeup.

Anyway please be a little more specific for the edification of all us AMS non-members. Unless you are totally out to lunch, what are you talking about?

9. **woit**
January 10, 2006

Qwerty and Who,

Peter Lax and the Feb. AMS notices is off-topic, discuss this elsewhere. The AMS site does require you to set up a web-account to access it, but I believe much of the content (like the Notices) can be accessed even if you are not an AMS member.

10. **Who**
January 10, 2006

I stand corrected, Peter. I should never have inquired of QWERTY what in the world he was talking about (so pungently and with such feeling.)

11. **Haelfix**
January 10, 2006

Actually Einstein liked Dirac's formalism, particularly when it was boosted into field theory. What he hated was vanilla quantum mechanics with no special relativity and the collapse principal, he felt that limit was very poorly defined.

People often say he was off on a island, yet very often great physicists would go to see him to talk about interpretational issues in QM (this years after Copenhagen was well entrenched) and he could still with the power of his mind alone convince them otherwise (see Bohm for instance).

Note, he was one of the first people to be supportive of the path integral approach, this near the end of his life when everyone was praising Schwingers methods

12. **StrungOut**
January 10, 2006

A bird once whispered in my ear that the Gross-Perry monopole solution was first found by Sorkin.

13. **MathPhys**
January 10, 2006

That's a bird with a good memory. 1982? 1983?

14. **Fabien Besnard**
January 11, 2006

"Einstein had his own share of crackpotism… "

Geniuses and crackpots share an enormous amout of self-confidence that allow them to keep on following their ideas when everyone else tell them it's a dead end. In fact I see two main differences : the first is that geniuses try to overcome the difficulties, where the crackpots generally just ignore them.

The second can be seen in what Feynman said :

"We have a habit in writing articles published in scientific journals to make the work as finished as possible, to cover up all the tracks, to not worry about the blind alleys or describe how you had the wrong idea first, and so on. So there isn't any place to publish, in a dignified manner, what you actually did in order to get to do the work."

Crackpots can't go through this cleaning process. Their ideas tend to remain muddy.

So what I would like to convey is this : someone is not a crackpot because he has this idea that sounds crazy, like Einstein's ideas about QM or nuclear interactions, but because of his behaviour in case he is opposed to a counterargument or an empirical difficulty. Did Einstein push his own ideas against empirical evidence ? You can't accuse him of crackpotism just because he felt the urge to follow his inner track, his "good passions".

15. **anon**
January 11, 2006

"We have a habit in writing articles published in scientific journals… to cover up all the tracks, to not worry about the blind alleys or describe how you had the wrong idea first, and so on. …" – Feynman

"Crackpots can't go through this cleaning process. Their ideas tend to remain muddy.…" – Fabien

So covering up errors en route to success is called "cleaning up"!

16. **Juan R.**
January 11, 2006

Anon, Ugo, Chris W, Haelfix, and Fabien Besnard,

Einstein rejected both quantum and probabilistic nature of QM and becomed a member of the deterministic continuum school togheter Schrodinger. Born, Heisemberg and others belonging to the nondeterministic discontinuum (matric formulation) school. Einstein named QM nonsense, consider the Dirac formal formulation of QM, ugly and irrelevant for the future of theoretical physics, and ignored experimental success of R-QFT, atomic, and nuclear physics.

There is a lof of hype around Einstein figure somewhat comparable to current hype about string theory. Historical facts are very different from current believings…

A bit more of history,

> Einstein never had a good word for the relativity version of quantum mechanics knows as quantum field theory. It successes did not impress him.[41].

[Abraham Pais. Subtle is the Lord. Oxford University Press, New York, 1982.]

> The quanta really are a hopeless mess.

[Albert Einstein, On doing Quantum Theory calculations with Pauli p58]

> Einstein thinks he has a continuous field theory that avoids 'spooky action at a distance', but the calculation difficulties are very great. He is quite convinced that some day a theory that does not depend on probabilities will be found.

[Albert Einstein to Max Born, p158 Mar 1947]

Einstein did not obtain special relativity or general relativity by their own means as more recent historical studies prove. In a recent 2005 meeting at the American Physical Society, Renn was quoted saying

> I had personally come to the conclusion that Einstein plagiarized Hilbert.

[Winterberg, F. On The Hilbert-Einstein Priority Dispute]

Renn is the director of the Max Planck Institute for the History of Science.

In a recent work in the American Mathematical Society

> His books on Maxwell theory contain the germs of special relativity and led him to analyze, correct, and name the Lorentz transformations. Poincaré published in 1905 a note (followed by an extended memoir) on the dynamics of the electron, containing the whole mathematics of special relativity. Historians of science still passionately discuss the priority between Einstein and Poincaré, and if one follows some recent publications, one might conclude that Hercule Poireau might be the only one able to uncover the whole story. Curiously, the mathematician Poincaré reached relativistic kinematics via Maxwell's electromagnetic theory,
> while the physicist Einstein used an axiomatic
> method. But it is unquestionable that Poincaré anticipated
> the so-called Minkowski space-time.

[Mawhin, Jean. Henri Poincaré. A Life in the
Service of Science. NOTICES OF THE AMS (Oct 2005) p1039]

But some very recent historical discoverings suggest/prove that Einstein copied worked of others. From the Wiki

> Many believe that Einstein and his wife were both aware that the famous Frenchman Henri Poincare had already published Relativity, a few months before Einstein.

[http://en.wikipedia.org/wiki/Albert_Einstein]

One of lattest i know is the historian of science Stephen G. Brush who in his recent 2001 Physics Today review of "Einstein, Picasso: Space, Time, and the Beauty That Causes Havoc" recognized that Einstein was not sincere in his priority issues

> Einstein read Poincaré's Science and Hypothesis (French edition 1902, German translation 1904) and discussed it with his friends in Bern. He might also have read Poincaré's 1898 article on the measurement of time, in which the synchronization of clocks was discussed–a topic of professional interest to Einstein as a patent examiner.

All of this is of direct relevance to the understanding of the history the current status of string theory and social issues of stringy community, since there is a great paralellism between Einstein and string theorists. In fact,

1) String M theorists ignore experimental predictions or discrepancies of many orders of magnitude, just as Einstein ignored success of R-QFT.

2) String M theorists ignore any advances in disconected fields just as Einstein ignored nuclear physics by a 'beatiful' idea: search of unification via classical EM+GR

3) It has been denunciated in several sites including this blog that string theorists copy the work of others and after rename it as new. I am not wrong M. Pittaken has said here in ocassions that some of mathematical ideas usually attributed to M theorists were formulated earilier by mathematicians, even if mathematical relevant papers are not cited and names ignored.

And if i remember correctly, Peter Woit has often shown here that mathematical insights usually claimed to be discovered in the string theory field were already known or belonging to the mathematical side.

—

Juan R.

17. **Juan R.**
January 11, 2006

I have an interesting question for you. Woit said,

> He [Gross] concludes that Einstein was wrong to refuse to accept quantum mechanics and to ignore nuclear and particle physics, but that he was right to try and unify gravity with the other forces […]

In [Albert Einstein to Max Born, p158 Mar 1947] one read

> Einstein thinks he has a continuous field theory that avoids 'spooky action at a distance', but the calculation difficulties are very great. He is quite convinced that some day a theory that does not depend on probabilities will be found.

As it is well-known Nobel laureate Sheldon Glashow has compared many times the real failure of string theory to the failure of Einstein unified field theory. Now subsitute in my above Born quote the keywords "Einstein", "continuous field theory", etc. such as

> Gross (or Witten or Kaku…) thinks he 'has' a unified string M-theory theory that avoids 'the ugly standard model more GR', but the calculation difficulties are very great. He is quite convinced that some day a unified theory will be found.

Yes, Einstein was rigth in his attempt to unify forces (a topic that Einstein learned from Hilbert axiomatic attempt to unified theory of gravitation and EM as proved in correspondence Einstein to Hilbert of 15 November 1915) but only on that Einstein was right. In the rest, Einstein was VERY wrong.

Seeing the impressive difference between Einstein UFT and current way of the Standard model or string M-theory, is not the parallelism between above quotes Born original and modified a clear signal that probably a new 'Gross' would say by the 2050 some like next statement?

> 'New Gross' concludes that string theorists were wrong to refuse to accept string theory was wrong and to ignore other alternatives to quantize gravity and explain the Standard Model, but that they were right to try and develop a unified theory of all known phenomena […]

What is your personal opinion?

–

Juan R.

Center for CANONICAL |SCIENCE)

18. **anon**
January 11, 2006

Juan,

Your point is very relevant. People wants to find a unified theory if it exists. How much longer should they try to achieve that goal by flogging a dead (actually stillborn) horse, "string theory".

I agree with the views of many here, namely that it would be more dignified for science to stop flogging string theory in the hope of making it produce numbers, and to focus on other approaches.

19. **Fabien Besnard**
January 11, 2006

Juan R, if Einstein really plagiarized Poincaré and Hilbert, why haven't they protested (as far as I know) ?

20. **woit**
January 11, 2006

Please, enough of the off-topic material about Einstein, e.g. "Was Einstein a Plaigiarist?". I don't know about anyone else, but 2005 has left me thoroughly sick of endless Einstein discussions and I wish that a moratorium on some of this stuff could be instituted for 2006. If anyone has anything new and interesting to say on the topic at issue here, the relation between Einstein's work on unification and current ideas about unification like string theory, that would be great.. But given the immense of amount of attention this topic has had over the last year, I find it hard to believe people can come up with something new to say.

21. **V H Satheesh Kumar**
January 11, 2006

Hi

In fact, it is my first visit to ur site, n seems tht u have got pissed off with all new advances in Physics like Strings,Branes, Supersymmetry, Cyclic universe and kinda stuff. Then wht do u think is relevant to study? Why dnt u suggest something?

22. **dan**
January 11, 2006

Since Universities employ string theorists, and string theorists cite string papers, Witten Greene and others have a high H-index.I personally agree with Peter Woit and string theory critics that alternatives, such as LQG, should be pursued vigoriously, and that Universities should hire more LQG-theorists. Were this to happen, I would imagine the H-index of LQG-theorists would rise.

23. **woit**
January 11, 2006

Kumar,

If you look at my web-site or on the arXiv you'll find a paper by me explaining ideas that I think are a promising way forward. But I have never wanted this to be a site just promoting my own personal research. I do try and mention interesting new ideas when I learn about them, but unfortunately I think the current situation is that there are few good new ideas around. The people pursuing strings etc. are not stupidly doing so despite there being obviously much better things to work on. Under the circumstances, my view is that people need to be encouraged to come up with new ideas, and one thing that is stopping this is the overwhelming hype being used to promote failed ideas and keep people working on them.

24. **anon**
January 11, 2006

"…unfortunately I think the current situation is that there are few good new ideas around. The people pursuing strings etc. are not stupidly doing so despite there being obviously much better things to work on.…"

Loop quantum gravity is the best known alternative, although the physical picture (spin foam vacuum) is less tangible to most people than strings (albeit extra dimensional ones!).

I think you have to accept that to get funding you have to explain physically what loop quantum gravity says, but nobody does that.

25. **Shantanu**
January 11, 2006

Peter what do you think of Narlikar's article in the same issue(especially the last para?) Do you agree that research in non-standard cosmology should also be supported/encouraged even today?
Probably you already know this, but the rivalry/bitterness between steady state theorists and supports of the Big bang model (especially before 1965) was somewhat(actually much worse) than between string theorists and people
pursuing other approaches to QG.

26. **ark**
January 11, 2006

I wonder if somebody was thinking about the fact that mathematics exist for at least 2500 years and is still thriving while physics exist for about 350 years or so and is in swampland already. Is there in physics literature some kind of equivalent of Bourbaki-type style monographs detached from particular individuals? Or physicists-all of them- only like to glorify themself, to listen only to themself, to promote only their own works -just like in any other religious sects. In my opinion, instead of thinking about who did what, when and how, may be one should think about what, after all, will survive, say, 2500 years (e.g. like a Pithagorean theorem) in physics.
David Hilbert asked A.Einstein to become one of the editors of the Annals of Mathematics and Einstein had accepted his invitation. Everybody can find in the library

volumes of Annals which have Einstein as one of the main editors. I suppose, this fact should put to the rest the dispute about relations between Einstein and Hilbert. As for the path integrals, they vere discovered by L. Bachelier in “Theorie de la speculation”, Ann.Sci.Ecole Norm.Sup.17 (1900) pages 21-86. Incidentally, H.Poincare was one of the members of the PhD committee when Bachelier was defending his dissertation, later published in Ann.Sci. Ecole…Hence, one can go on and on about who did what and when…E.g. the paper by Cameron and Martin on path integrals have been published in Annals of Mathematics in 1944 (just take a look at the math.sci net!). Given that Mark Kac was at Cornell at the same time as Feynman, introduction of path integrals into physics later on looks quite natural….. And so on and so forth…

27. **woit**
January 11, 2006

Shantanu,

I'm fundamentally a particle physicist, of a mathematical sort, not at all a cosmologist. So I don't have any definite opinions about what cosmologists should be doing, or about what value there is in "non-standard" cosmology.

28. **Walt Pohl**
January 11, 2006

ark: *Physics* is in fine shape. It's *particle physics* that has run into difficulty. And there are thousands of works where physicists describes the works of other physicists (what do you think is in all of those textbooks?).

29. **Shantanu**
January 12, 2006

Peter, today cosmology is very much intertwined with particle physics
and vice-versa. for example (though all of this has been dicussed here):
1) the most probable candidate for cold dark matter is the supersymetric
neutralino and/or axion. (lots of experiments currently searching for WIMPs
and/or axions would thus solve two problems in particle physics AND cosmology). Also notice the plethora of papers on how one's favorite
model beyond SM leads to a dark matter candidate. I have seen lots of
talks that one of the motivations behind building the linear collider is to investigate the properies of dark matter.

2) the first evidence for number of "active " neutrino flavors came from theory
of big bang nucleosynthesis and observed Helium-4 abundance.

3) Evidence for non-zero neutrino mass implies that amount of density contributed by neutrinos is as much as the visible stars.

4) Concept of cosmic inflation , which is determined by potential energy of
a scalar field governed by particle physics.

I bet that every participating particle physicist must have worked or thought about (1) and (4) above

By non-standard models, I meant models of cosmology based on alternate
theories of gravity (such as B-D theory and others), or alternate theories of
gravity which explain dark matter (such as MOND)., or things like steady-state
theory of cosmology which rely on slightly different points of view.
do you think studying these could lead to insights in particle physics ?

or are you sufficiently confident in current standard Big-Bang picture
of universe consisting of ~ 23 % dark matter (for which there is no laboratory
evidence but lots of candidates from particle physics) ~70 % dark energy
(for which we have no clue), the concept of inflation (for which we have no idea
about the energy density of scalr field which caused it) and 5 % baryons(again
which we have no idea on how they came about) ?

30. **woit**
January 12, 2006

Shantanu,

Sure, I'm aware of the ideas relating cosmology and particle physics that you describe. But having an informed opinion about the kinds of alternatives to GR or to the standard cosmological model that you mention would require knowing much more than I do about exactly what the astrophysical evidence says. I'm just not expert enough in cosmology to know precisely how strong the evidence is for various aspects of the standard picture, or exactly what this evidence rules out and what could still be consistent with it.

From everything I've seen the standard cosmological model looks very solid and there isn't any unambiguous evidence that I'm aware of for alternatives. But what I've read are generally expository articles for non-experts, and I'm well aware from my experience with string theory that such things can sometimes gloss over problems, and it requires a more serious level of expertise to understand exactly what is really known. Since I don't have this level of expertise, my opinions aren't worth much on this topic.

31. **dan**
January 12, 2006

Peter,
as a particle physicist, i am curious as to whether you think dark matter could plausibly be anything other than SUSY-particles such as the axion or neutralino? an alternative to LHC are detectors which hope to detect dark matter passing through earth.

32. **Alejandro Rivero**
January 12, 2006

Re #23, #24, #27: It seems that the problem is not about having new ideas, but about the energy scale where we expect such ideas to be. It is very interesting that the most suggested alternative to strings is LQG, no GUTs. I believe this comes because of the "effective theory" view of particle phenomenology, so that people aspiring to Unification disregards anything near the standard model.

33. **Jackson Riszemoi**

January 12, 2006

LOL, Juan R., you call a wikipedia article "a historical discoverings suggest/prove that Einstein copied worked of others."?

34. **woit**
January 12, 2006

Dan,

Dark matter could be all sorts of things, we know virtually nothing about it.

Looking for dark matter other ways is not an alternative to the LHC. What the LHC is going to be important for is understanding electro-weak symmetry breaking.

Others:

I've just deleted a bunch of comments of people going on about their favorite non-standard idea about cosmology. This is off-topic: I'm no expert on this, and the people writing these comments don't seem to be either. I don't see the point of having an uninformed discussion on this topic here. Again, this is not sci.physics.

35. **nitin**
January 12, 2006

Hi Pete
I have just started a blog (which is going to be a hell of a challenge for me). I am a student in Physics from Mauritius. Maybe, if you are so inclined, you could add a link to my blog (http://pioneerthis.blogspot.com/) on yours. That would be kind.
Thanks
Best,
Nitin

36. **Dissident**
January 12, 2006

For an informed discussion, you could do worse than visiting the astro-ph section at Cosmocoffee:

http://cosmocoffee.info/viewforum.php?f=2

37. **woit**
January 12, 2006

Hi Nitin,

I've added a link. Good luck with the blog!

38. **robert**
January 12, 2006

However off topic pre/re discoveries might be

"EW Montroll, Communs. Pure Appl. Math. 5, 415 (1952)."

merits a quick look.

39. **ark**
January 12, 2006

Robert, I believe, most of Elliot Montroll's papers merit more than a quick look. They are classic examples of how papers should be written. But, again, are you aware of some kind of detached from particular individual Bourbaki-style monograph in physics? As you probably know, in books by Bourbaki there is always some historical short discussion regarding to how this or that particular idea dicussed in the main text had evolved. Sometimes this is done in the form of exercises. I bet that such an idea will newer cross physics community mind since they love themselves too much to share freely ideas with others. Most typically, they cannot agree on anything between each other even without such a free sharing of ideas. The discussions above my comment are good examples. Is this a sociology of theoretical physics or it comes along with the individual who chooses theoretical physics as a profession ? The great Sh.Chern at the begining of his collaborative work with Ellie Cartan (which happened to be at the very height of the physics sucsesses in quantum mechanics, etc) had asked his mentor if it is worthy to do something in physics to which he got a reply : "stay away from this". So Chern stayed away… letting swampland to be developed by others. Any comments?!

40. **anon**
January 13, 2006

"… they cannot agree on anything between each other even without such a free sharing of ideas."

Mathematics is less controversial because the distinction between fact and speculation is clearer. In physics there are always different interpretations of the facts, or a scatter in the data, which leads to controversy before new ideas become accepted. Generally in mathematics, once a theorem is proved, that's it…

41. **ark**
January 13, 2006

Dear Anon, this fact is well known to me as it is known to you. This is what always you can hear from physicists (I am one of those too!!). Fact of the matter is that if you look a bit closer at things, theoretical physics as much a discipline as it contains a meanigful mathematics. Hence, the controversy lies, apparently, in use of this or that mathematics to achieve the same physical goal. But, as you know, you can go from Chicago to Washington DC via Seattle or you can go straight. As far as the final destination is concerned, both ways will lead there. Hence, the intitial task of finding the only ONE right path cannot be achieved. Yes, mathematicians prove theorems and that is it…But then, they pay attention to what had been proven by others. To come to the point, I would like to rase the following question. Suppose, that in physics somebody published an important result in some journal, say X, will this imply that those who submit their papers to journal Y should be aware and comply with the result published in X ? Or should they ignore result published in X and try to push their own agenda in journal Y ? Mathematicians will comply if the result is proven rigorously while physicists will ignore. Othervice, why it is so important to publish things in PRL or Nature ?! etc. If you do not publish your work in the "right" journal it will be ignored by those who manage to publish their works in such journal. Hence, what is the use for the rest of journals which are "wrong" from the beginning ?! Controversy in physics is synonimous with the trend NOT to be precice, NOT to pay attention to work of others (does not matter how rigorous it is), to push ones own agenda without any regard to even one's own prior work which can be easily forgotten, abandoned, etc. Who among respectable mathematicians had published 650 or more papers during their lives? Does all these 650 papers contain rigorous proofs ?! Is it possible for the very same person to ignore its own proven results in mathematics ?

42. **anon**
January 13, 2006

Dear Ark, in physics many accepted ideas and laws at any one time are always controversial, so the mainstream is decided to a far greater extent by the whims of the leaders and by fashions, than by hard proof. Popper even says that a hard proof (such as the physical proof for the law of buoyancy given by Archimedes) is not useful, because mainstream physics should be fallible. This is the source of the bickering in physics. In mathematics, people can be nicer to one another. Physicists are fallible, mathematicians aren't.

43. **ark**
January 13, 2006

Dear Annon, if you've read my previous comments, you've noticed that I have indentified physics(theoretical physics in particular) with various religious sects. I've provided some facts (other than reference to Popper) justifying my claim. However, I should say that mathematicians are also NOT saints whatsoever! We are talking only about the degree to which one can convert science into religion. Mathematics has proven record that the system of values was chosen correctly from the outset. Physics also have proven record of fighting between Newton and Hook, between Newton and Leibnitz, etc… So, physics had deep roots in religion and Newton in some circles known more for his religious writings than for his scientific…Clearly, if you feel that you are religious person, then follow the pre selected leaders thus going to a pre selected sect. But, please, do not make claims that this has something to do with science. I am talking not to you personally but to those who know to what extent the existing system of values is working for their benefits. Surely, unless some REAL emergency appears at the horizon, things will flow as usual non stop.

44. **anon**
January 13, 2006

Dear Ark, the only things I can reply to are those I've some experience of. In mathematics, alternative theories are welcome if they are useful. In physics, alternatives are fought with rigor. One insidious method of suppressing alternatives is to say that the authors must be ignorant of the details and beauty of the mainstream model, while another is to dismiss the alternative as "speculative" (when in fact it is the maintream model that is overly speculative or even untestable, resulting in the newer model which is not so speculative and is more testable). Outsiders would imagine that such hypocrisy is easily exposed, but it isn't, because the media seeks authority on scientific matters, which means only listening to the mainstream. So the farce just goes on.

45. **ark**
January 13, 2006

Anon, I would be cautious talking about farce. One cannot undo the human nature…One cannot fight against what is intrinsic. However, just like with different countries, they are like people-all different and all the same. If there is something proven to be good in one country why not to borrow the idea and not to bring it to another country…Have you seen this ever happen? For the same reason, physics will stay away from mathematics even though all the ingredients of how to make things to work better are actually known.

46. **anon**
January 14, 2006

Dear Ark, yes in the end useful bits and pieces will have to be put together. The mainstream will first resent any interference from "outsiders" who try to change their foundations, then eventually the mainstream will make a big deal out of how "kind and generous and open-minded" they are to eventually allow publication or discussion of a radical suggestion. The farce is the double standards; they publish worthless speculation, but are scared numb (or become "angry") about "radical" ideas which are less speculative than the string theory ideas they already have!

47. **Juan R.**
January 14, 2006

Jackson Riszemoi

Rather irrelevant question. Reply is, of course, NOT!

Fabien Besnard

Correct, as far as YOU know…

Any other comment in my sugestion that string theorists are playing the role of Einstein, i.e. searching in the wrong way?

48. **xpinor**
January 14, 2006

For more uncritical promotional material on string theory, here are two things from UC Davis. They have something there called the "High Energy Frontier Theory Initiative (HEFTI)", and on their website you can read a report written by an external committee for the Dean at Davis…

Now, isn't it rather interesting that Gunion puts **this** report on his website…

49. **xpinor**
January 14, 2006

A while ago someone here suggested a potential analogy between the string theory establiashment and Enron. I have been seeing it this way for quite a while. I wonder whether string theorists might be found legally (and financially) liable for fraudulently soliciting funding if they were to be proven to have known (or not honestly believed) that string theory cannot describe nature. If so, how could this be brought effectively to the attention of prosecutors at the office of the Attorney General or the respective office in other counties ?

50. **ark**
January 14, 2006

xpinor, can you, please, provide an exact web link to HEFTI. I was able to find on GOOGLE 34 entries none of which match what you've said. I assume, you are not referring to L.Randall public lecture…

51. **woit**
January 14, 2006

ark,

I think HEFTI at Davis is more a plan than a reality, see

http://higgs.ucdavis.edu/gunion/theorygroup.html

xpinor,

While I've seen a certain amount of dishonesty and unethical behavior by certain string theorists in regards to how they have responded to criticisms I've been making of the theory, I think the great majority of them honestly believe in what they are doing, or at least honestly can't think of anything better to do. I don't think there's any case for intentional fraud to me made here.

52. **xpinor**
January 14, 2006

ark,

The report I was refereing to is at:
http://higgs.ucdavis.edu/gunion/particle_report.pdf

53. **xpinor**
January 14, 2006

ark and Peter,

Lisa Randall made that remark about the analogy to the
administration not losing credibility by making up evidence. A smoking gun? Sufficient evidence to justify an investigation, maybe?

54. **Aaron Bergman**
January 15, 2006

Yes. That's precisely it.

In fact, we need a congressional committee.

No. This is international. We should get the UN involved.

Oy vey.

55. **Charles Moeller**
January 15, 2006

On first principles, the continuous may contain (a subset which are) the discrete (quantized values) but never the reverse. A strictly quantized regimen can't be modified enough by expansion or subdivision or by any other means to become continuous. Relativity is couched in the Calculus, which is a continuous mathematics, suitable for continuous space and time. QM is, by definition and by practice, a strictly quantized system. So QM will never encompass Relativity, whereas Relativity could encompass QM.

56. **ark**
January 15, 2006

Thank you very much xpinor for a useful link. As to what encomass what, this is very much of the same quality as wether Sun is rotating around mother Earth or Earth is rotating around Sun. Thanks God, hopefully, nobody is going to be burned alive for taking the sides in this futile dilemma.
Physics is NOT about what comes from what but about how new is connected with old. Correctness of General relativity can be proven in many ways as much as correctness of quantum mechanics. When I say "correctness" I mean 2 things: the predictive power and agreement with earlier, older theories.These older theories work well within some known(agreed upon)domain.There were many serious papers in the past in general relativity which questioned existence of gravitational waves and yet if one looks at GOOGLE one finds that gravitational waves are going to be discovered the next day…Keep in mind, that the whole business of quantum gravity (and, hence, string/brane theory) is about how to quantize gravity correctly. But for this, gravitational waves should be solidly discovered ! But they are not ! This is a typical case (characteristic for string theoreticians as well as of others in physics) of sincerely believing in things which may or may not happen ever. If this is not a religion, then what this is ?! Surely, for the progress to exist, one should believe in something strongly. But this is a personal business (e.g. read Einstein) and cannot be a subject of debates. In mathematics also there are conjectures which need proofs. Nevertheless, general public is NOT involved in debates about correctness/validity of mathematical conjectures ! Why then this happens in physics where, some people spread around false ideas that new string theory requires new not yet developed mathematics. My own experience tells me just opposite: whenever there is a serious use of established mathematics in string theory,there are at least some results of some value. In the opposite case we all know what happens…

The First Evidence For String Theory? Not.

January 12, 2006
Categories: Uncategorized

Over the last couple years there has been a large amount of hype about cosmic strings, including press releases from Santa Barbara, and a story in New Scientist about The First Evidence for String Theory?.

The Santa Barbara press release from June 2004 concerned a paper by Polchinski and others about potentially observable fundamental strings of cosmic size. It stated that "LIGO… could provide support for string theory within two years." There are five months left for this prediction to work out.

The New Scientist story was about an astronomical object optimistically given the name "CSL-1" (for Capodimonte-Sternberg-Lens candidate), that supposedly might be a galaxy lensed by a cosmic string, causing it to appear doubled. Of course the much less exotic and much more likely possibility was always that it was just two similar looking neighboring galaxies. Recently the Hubble space telescope was used to take a closer look at CSL-1, and as reported here and here the Hubble image clearly shows that it's not a cosmic string, just two nearby galaxies.

Comments

1. **anon**
   January 12, 2006

   Peter, can't you stop reporting string theory hoaxes?

   O.K. Pauli made a point of exposing the empty claims of Heisenberg's grand unified theory and many others, but we all know string theory doesn't hold water now!

   Just because the string theory band is still playing loudly, doesn't mean anything. (The band on the Titanic continued playing until the end.)

2. **Dumb Biologist**
   January 12, 2006

   It's interesting that the initial hype was over the image being evidence for either cosmic strings OR string theory. Given the Borg-like ability of string reasearch to lay claim to virtually any and all phenomena hinting at new high-energy physics (as low-energy manifestations of some-or-other version of string theory, I guess), I'm surprised CSL-1 wasn't touted as potential evidence of both at once. Then again, maybe it was…

3. **woit**
   January 12, 2006

   Dumb Biologist,

   The hype was for both. It will be interesting to see how much this effect this negative result will have on the hype going on in this particular area.

4. **Quantoken**
   January 12, 2006

   Peter:

   Predictably this negative result will have virtually zero effect on the enthusiasm of cosmic string theorists. The hype will continue on, so will the search.

   One has got to understand the universe is **pretty big** and there are more number of galaxies than the number of sand grains on a beach. You can find anything you are looking for out of this huge collection of samples. Look a little bit harder and I am sure you will find many more of such similar galaxies in close proximity so it's predictable there will be many more CSL-x type of cosmic strings "discovered" and be hyped by string theorists.

   This time in this particular case HST is **JUST** slightly sensitive enough to be able to make a small distinction between the two close by galaxies. Interesting question to ask is what if it doesn't, or what if the CSL-2 or CSL-3 is slightly beyond HST's the ability to resolve. How long will the hype continue on. Or are they going to claim "String Theory Confirmed by HST"?

   Quantoken

5. **Adrian H.**
   January 12, 2006

   anon said "Peter, can't you stop reporting string theory hoaxes?"

   I don't think there is any danger of Peter acceeding to this request, but I'd like to vote for him continuing as he is. It is very useful to have an honest broker in a field where there is so much…well, I guess we've all agreed to call it 'hype'.

6. **matt**
   January 12, 2006

   What's the difference between a "cosmic" string and a "regular" string?

7. **woit**
   January 12, 2006

   Matt,

   Cosmic strings are strings of macroscopic size, perhaps even big enough that you can see them or their effects in a telescope. It turns out that in some kinds of gauge theories with Higgs fields, there are topologically stable string-like configurations of the classical fields (basically solitons). You don't get these in the standard model, but you do get them in some GUT theories. If they were produced in the big bang, they might still be around since they can't decay for topological reasons. But most kinds have been ruled out since if they existed they would have had effects on cosmology that disagree with observations.

The standard fundamental strings are quite different. They are fundamental dynamical variables, not classical configurations of a Higgs field, and their size is generally assume to be the Planck scale (or, if you believe in some extra dimensional models, they could be as big as the TeV scale, but this is still extremely small). In recent years, Polchinski and others have found variants of string theory where the fundamental strings can get to macroscopic sizes, and there has been a lot of hype promoting these models as ones where strings would be experimentally visible. There's no experimental evidence whatsoever that such models have anything to do with the real world.

8. **Luboš Motl**
   January 12, 2006

   Dear Peter,
   half of what you write is a complete nonsense.

   The fact that strings – if they carry enough energy – can be macroscopic has been appreciated for several decades, certainly since the mid 1980s and probably since the early string theory in the late 1960s. It's just you and your naive readers who has infinite problems to realize that the shape and size of a string is a dynamical observable.

   There's a lot of experimental evidence that these models have something to do with the real world because there is a lot of evidence for the Standard Model and gravity which is implied by these models.

   But your comments are addressed to likes of Quantoken – who obviously thinks that all string theorists are really "cosmic string theorists" 🙂 – so the fact that the quality of your comments is 3 orders of magnitude beneath the quality that would be acceptable in science does not really matter.

   Best
   Luboš

9. **woit**
   January 12, 2006

   Lubos,

   What I wrote is obviously not an exhaustive treatment of the subject, but it is perfectly correct. Your delusion that string theory implies the Standard Model is just wishful thinking.

   In the years before 1984, there was quite a lot of discussion of string-like solutions in gauge theories and whether they might be produced in the early universe, discussions which I was well aware of since I was working on topological aspects of gauge theories. No one was talking about fundamental strings in this context, actually virtually no one except Green and Schwarz was talking about fundamental strings at all.

   In 1985, Witten wrote a paper about the possibility of fundamental strings produced in the early universe reaching cosmic sizes as the universe expands, but he identified three problems with the idea. I'm no expert on this, but my understanding is that it is those three problems that Polchinski et. al. claim to be able to overcome.

   Again, there's not a shred of evidence for the particular scenario Polchinski et. al. work with, as far as I can tell it was developed purely in order to overcome the problems Witten identified and allow cosmic size strings to be produced and survive.

10. **Dumb Biologist**
    January 12, 2006

    Oh well. Though I can't quite get my head around the idea of a fundamental constituent of matter blown up to cosmic scales, I have absorbed as much as my pea brain can from sundry popularizations about cosmic strings, and found the idea of some hyper-dense filament of primordial matter/energy floating around out there to be pretty wild and fun. Too bad this ain't it.

11. **Urs**
    January 13, 2006

    There are some statements which are hard to prove, but easy to disprove. Others are hard to disprove but easy to prove.

    A statement of the form

    "For all x in S we have A(X)".

    Is usually harder to prove than to disprove. Proving it requires knowledge about all x of S. Disproving it requires knowledge only about one x.

    A statement of the form

    "For at least one x in S we have A(X)".

    Is usually harder to disprove than to prove. Disproving it requires knowledge over all x of S. Proving it requires knowledge only about one x.

    I gather this is well known to philosophers of science.

    The situation with string theory is currently that it makes statements of the second kind.

    Up to some well-known caveats, the claim of perturbative string theory is something like

    "There exists at least one x in the set of real numbers such that at an energy scale of x eV we see stringy effects."

    As Peter is fond of pointing out, this is hard to disprove. You can check for higher and higher x (and we cannot check really high). But finding nothing at these x does not disprove this statement. Simply because it is a statement of the form "there is at least one x…".

    Proving the statement (if true) would in a sense be much easier. Observe at least one stringy effect and you are done.

    Driven by the desire to make contact with experiment, people like Polchinski began scanning the theory for possibities of such stringy effects that might be observed.

    They argue that one such possible effect could be cosmic fundamental strings.

    It should be noted that nobody is claiming that string theory demands that we observe cosmic strings.

Just like GR does not demand that we observe a Goedel universe, or Einstein's instable static solution.

But if you want to prove an existence statement of the form "there is at least one x in S" what you usually do is scan the space of all elements of S for those that might be candidates which make the statement true.

So people investigating stable cosmic fundamental strings could be said to be studying the claim:

"There is at least one x in the set of stringy effects such that x can be observed with contemporary technology."

Disproving this is hard. Proving it (if true) would be easier. It suffices to find one example.

So people are checking plausible candidates for x. They argue one good candidate is "x = cosmic fundamental string".

I guess one could have a scientific argument about if this is a "good" candidate or not. But the simple fact is that, indeed, if we did observe a cosmic string which could be identified as a "fundamental string" the above statement would be proven.

I don't think this is likely. But I do think it is scientific.

Of course, one can state many existence theorems which are highly unlikely but nevertheless very hard to disprove.

"There exists at least one extraterrestial life form with a genome the same as terrestrial groundhogs", I claim.

You don't believe that? Prove me wrong!

So if you feel the same about the statement that there is at least one observable stringy effect, there is nothing much one can do about it except that you should feel free to study some other theory.

But whoever does see a chance that a certain existence statement is true should, in order to prove it, try to find an example that solves it. That's what people interested in cosmic fundamental strings are doing.

You may feel that it is hopeless and that money should be spent elsewhere. Fine. But it is not non-scientific.

12. **woit**
January 13, 2006

I haven't said that thinking about cosmic strings is non-scientific (that applies to something else Polchinski promotes, the anthropic landscape). What I object to is the way this work has been over-hyped. Working on something extremely speculative, something for which you don't have any evidence and that is very unlikely to really exist is fine, but I don't think you should be issuing misleading press releases about it.

13. **D R Lunsford**
January 13, 2006

I don't know why but this strikes me as being very funny! I couldn't help but think of the Star Trek movie where Kirk dies saving the Universe from a superstring.

-drl

14. **anon**
January 13, 2006

That's sad. I always thought superstrings were at least nice fiction, but horrible murderers!

15. **Urs**
January 13, 2006

> I haven't said that thinking about cosmic strings is non-scientific (that applies to something else Polchinski promotes, the anthropic landscape).

While it is hard to say what "anthropic landscape" really refers to, I could make a similar discussion as the above on cosmic string solutions but with respect to the space of all global solutions. It's not a priori and by itself non-scientific to study the space of solutions of a theory.

But I agree that there tends to be too much hype about things too little understood.

16. **Juan R.**
January 13, 2006

cosmic string = superstring?

Sure? 🙂

DRL wrote: "I couldn't help but think of the Star Trek movie where Kirk dies saving the Universe from a superstring."

Oh my God! The Nexus ín ST:Generations (1994)!

http://www.startrek.com/startrek/view/series/MOV/007/synopsis/87.html

It wasn't a superstring, it was quite clearly a brane intersection. So THAT is where Randall got the braneworld idea!

I hereby nominate writers Brannon Braga and Ronald D. Moore for the Nobel Prize in physics.

18. **dan**
January 13, 2006

Urs, "Driven by the desire to make contact with experiment, people like Polchinski began scanning the theory for possibities of such stringy effects that might be observed."

Wouldn't one of the most impressive way for string theory to do this, would be as Lubos Motl says, to show you can derive most, if not all, of the particles of the standard model from string tension?

BTW: Lubos states it is possible to derive the standard model from first principles of string theory, Peter says it is not. Who is right on this specific issue?

19. **Urs**
January 13, 2006

> Wouldn't one of the most impressive way for string theory to do this, would be […] to show you can derive most, if not all, of the particles of the standard model from string tension?

It would certainly be impressive. It would also be impressive to have a theory which would allow to derive most, if not all, distances of the planets from our sun. We do, however, have no particular reason to assume that such theories exist.

We may hope such theories exist. Kepler hoped a theory exists which explains the distances from the planets to the sun as given by spheres inside perfect polyhedra.

Some people hope that the parameters of the standard model are unique solutions to a theory beyond the standard model. It might be so, or it might not be so. Who knows.

What I am already impressed, by, however, is that string theory is a theory which in principle allows to address this question. String theory may well be wrong. But it is the only theory we have ever known which has solutions that determine these parameters.

On this blog I shouldn't say something like this without giving an example from outside of string theory which illustrates this by analogy:

Analogously, it is impressive how GR is a theory which, while it does not fix the curvature of spacetime, it has solutions which determine it. If we perfectly understand the space of all solutions of FRW-models in GR we can check if it contains any solution which matches the observed structure of the cosmos at large scales. The theory does not predict it, but it puts a structure on the space of all possibilities.

20. **Zelah**
January 13, 2006

Hi Urs,

Does String theory predict the Standard Model from first principles?

The stringy attempts I have seen are adhoc!

An amateur mathematician

21. **Urs**
January 13, 2006

> Does String theory predict the Standard Model from first principles?

No.

22. **Urs**
January 13, 2006

That was the short answer. There is a longer one which mentions how there is an issue of perturbative versus nonperturbative, how things are too little understood to fully answer this question, and so on. But I have to run now.

23. **woit**
January 13, 2006

> What I am already impressed, by, however, is that string theory is a theory which in principle allows to address this question. String theory may well be wrong. But it is the only theory we have ever known which has solutions that determine these parameters.

The problem with this is that the evidence is that there are an infinite number of solutions, enough to give you almost any values of the standard model parameters. If this is really the case, the theory has zero predictive value, can't be falsified, and continuing to pursue it doesn't make any sense. Some string theorists believe the theory is still not well-enough understood and maybe there is some way around this to get a predictive theory. I think they're engaged in wishful thinking, but at least they haven't given up on science. What I really don't understand are those who accept the idea that all these solutions are out there, can't come up with any evidence that there is enough structure on the space of these solutions to allow predictions, and yet keep working on this.

24. **Urs**
January 13, 2006

> ST is great because it places structure on what possibilities exist, you are just cutting out alternatives and introducing prejudice into science.

That prejudice is called a hypothesis. The structure it implies is called a prediction, implied by the hypothesis.

There is every reason to be unsatisfied with the progress string theory has made on the phenomenological side and with some of its sociological aspects. What I find somewhat deplorable is, however, that on this blog the party line has established that "string theory is not science". That's unfruitful anti-hype (co-hype, for the mathematicians) and not suited to bring anyone closer to the truth than the equally unfruitful string hype is.

25. **Urs**
January 13, 2006

> The problem with this is that the evidence is that there are an infinite number of solutions,

This is, by the way, the generic situation for any theory. The irony of history is that the "landscape affair" was ignited by an argument that there are only *finitely* many solutions to string theory (under some conditions).

> enough to give you almost any values of the standard model parameters.

This might be the expectation of some people, concerning an unknown space known as the "landscape". But if you check with those people who actually construct solutions which come close to the standard model, the picture is rather the opposite.

26. **woit**
January 13, 2006

Urs,

I don't think there's a party-line here, except that this blog does reflect my views. I've never said "string theory is not science", but have time and time again made a quite precise point about the particular thing that I see some string theorists doing that is not science: See my review of Susskind's book for the details of this.

By the way, I'm starting to get annoyed by what I have been hearing and seeing in how some quite prominent string theorists are dealing with the existence of this blog and the arguments I have been making. Instead of dealing with my arguments, people have been attributing to me stupid or mean blanket statements about string theory or string theorists that I have never made. I try to be quite clear and precise in what I write here, and I wish that anyone who wants to discuss any of this would make an attempt to deal with what I actually write, not something else.

27. **Urs**
January 13, 2006

> deal with what I actually write

Sure. I think I was engaged in discussion with other commenter's here and certainly had them in mind.

I get the impression that your personal view, while often expressed in a provocative form ("string theory is not even wrong" is the intended provocative title of this blog, no?) is pretty much that people should stick to doing solid research. Nobody could disagree with that.

But it is also true that the comment sections here display a lot the point of view that "string theory is simply plain nonsense", which I would like to see rectified a little.

And I do think it is good to criticize things which ought to be critized. It is, not the least, helpful for those being criticized.

28. **woit**
January 13, 2006

Urs,

The problem isn't that there are an infinite number of solutions, the problem is that there is no evidence that the structure of the set of solutions has any useful predictivity. If there were an infinite number of solutions, all with different CCs, but all with a specific neutrino mass matrix, you would have a highly predictive theory.

Sure, it is hard to construct particular examples that do exactly what you want. The main reason for this is that simple examples that you can analyze all don't look like the standard model. To get something that looks more and more like the standard model, you have to make your construction more and more complicated. This is an obvious clue that you're on the wrong track.

Correct me if I'm wrong, but of the 20 odd parameters of the SM, and its choice of gauge groups and fermion representations, I know of no plausible proposal of a particular piece of structure on the landscape that will allow you to predict a single one of them. The closest thing to an attempted prediction I have seen was the attempt a year or two ago by Douglas and others to predict whether the supersymmetry breaking scale was low or not, and that effort seems to have quickly collapsed in failure.

29. **woit**
January 13, 2006

Urs,

There certainly is a sizable amount of nonsense in the comment section here, including uninformed blanket denunciations of string theory.

I already delete some of this sort of thing, in the future may start deleting more, to keep the noise level down to a more tolerable level.

30. **ksh95**
January 13, 2006

urs said:

> It would also be impressive to have a theory which would allow to derive most, if not all, distances of the planets from our sun.

Yes, it would be impressive. Let me propose such a theory…F=ma… As input we need the position and momenta of the particles comprising the gas cloud surrounding our proto-sun.
-or-
In principal we could use the SM+GR, using the conditions shortly after the big bang, and derive the radii exactly.
The point, of course, being that the planetary radii are not anthropically-determined random parameters and are entirely derivable from other quantities.

31. **JE**
January 13, 2006

Urs said:

"But it is also true that the comment sections here display a lot the point of view that "string theory is simply plain nonsense", which I would like to see rectified a little."

As a noiseless reader of this blog, I'd say what Peter and others mostly do here is criticizing the hype and unjustified funding and support that string theory is receiving from the Establishment compared to its physical achievements. It's this absurdly large imbalance that is often denounced as plain nonsense in this blog, not the whole string theory program.

32. **BC**
January 14, 2006

String theory has always been a joke.

33. **anon**
January 14, 2006

No, let's be clear. String theory provides one possible frame for quantum gravity since it would allow a spin-2 gauge boson (graviton) if that theory could ever be found (like the empty frame which Heisenberg called his grand unified theory), and it provides a landscape of 10^500 vacua, one of which might be real.

Whatever you do, don't laugh. It is not supposed to be a joke.

34. **Juan R.**
January 14, 2006

dan said,

> Lubos states it is possible to derive the standard model from first principles of string theory, Peter says it is not. Who is right on this specific issue?

It is easy. Cite a single paper, manual, talk, etc. where the Standard Model is **derived** from string theory.

Of course, Lubos Motl is not correct. The whole string M-theory framework is very outated and wrong in many technical details.

P.S: "Derived" here means that all mathematical and conceptual structure of the SM is a special case of the axiomatic and conceptual structure of ST. Of course derivation does not mean to know previously the answer and use it as input in the 'derivation', not obtain models simlar but not equal to SM, for example models with certain simetries resembling SM but based in massless states, etc.

35. **D R Lunsford**
January 14, 2006

Even if string theory worked as advertised, the resulting world-picture would be so repulsive that no one would get interested in science. That it fails so thoroughly is evidence that the world is not repulsive, and people will remain curious about it.

-drl

36. **dan**
January 14, 2006

Lubos is on record stating " claim such nonsenses such as that LQG only has the same problems like string theory"

His position as well as Witten Greene Weinberg, is that the alternatives such as LQG suffer from such serious problems that the only research program worth pursuing is string theory. the argument seems persuasive — given a speculative theory, if the alternatives suffer from even more serious problems, work on the one with the least (in this case string theory).

While i cannot answer Lubos' criticisms of LQG, i cannot help but wonder, if the greatest physcists like Witten worked on LQG's oustanding issues for the past 30 years, and abandoned string theory in the early 80's, where would LQG be today?

37. **Nigel**
January 14, 2006

Some kind of loop quantum gravity is going to be the right theory, since it is a spin foam vacuum. People at present are obsessed with the particles that string theory deals with, to the exclusion of the force mediating vacuum. Once prejudices are overcome, proper funding of LQG should produce results.

38. **Lee Smolin**
January 14, 2006

Dear Dan,

Actually LQG and related research programs (such as CDT or programs based on quantum information ideas) are progressing rapidly, see for example the talks at the recent Loops 05 conference: http://loops05.aei.mpg.de/

Lobus's criticisms have been aswered in detail several places, you might look for example at the FAQ section of my review hep-th/0408048 (although this review needs updating in view of some developments since then.)

While we would of course be happy with anyone's contribution to the subject, the fact is that there is a community consisting of about 150 mostly young physicists and mathematicians working in the general area of LQG and other background independent approaches and the results show that many of them are of equal quality scientifically to the best young people in other fields. The only concern I have for the future of quantum gravity is that these people be rewarded for their contributions with positions that will let them continue to contribute; for the present people in these fields have much harder careers than equally accomplished or talented string theorists. This does mean that those who have gone into the field have significantly more courage and intellectual independence, which I believe is one reason so much has been accomplished by relatively few people.

Thanks also to Nigel for those supporting comments. Of course more support will lead to more results, but I would stress that I don't care nearly as much that LQG gets more support as that young people are rewarded for taking the risk to develop new ideas and proposals. To go from a situation where a young person's career was tied to string theory to one in which it was tied to LQG would not be good enough. Instead, what is needed overall is that support for young scientists is not tied to their loyalty to particular research programs set out by we older people decades ago, but rather is on the basis only of the quality of their own ideas and work as well as their intellectual independence. If young people were in a situation where they knew they were to be supported based on their ability to invent and develop new ideas, and were discounted for working on older ideas, then they would themselves choose the most promising ideas and directions. I suspect that science has slowed down these last three decades partly as a result of a reduced level of intellectual and creative independence avaialble to young people.

Thanks,

Lee

39. **matt**
January 14, 2006

Thanks for that description, WOIT

40. **dan**
January 14, 2006

Hi Lee,
Thanks for the response. I do think your suggestion is admirable in principle, but i wonder to what extent it could be realized in practice. For example, Igor and Grichka Bogdanov would be an example of two intellectual creative young people who developed and invented new ideas, but whether they created some kind of Sokal hoax remains disputed. If a young researcher publishes string theory, the value of the article can be appreciated by other sting theorists. If a young researcher publishes an article suggesting a new program, it may be difficult to find qualified individuals to make a proper evaluation.

I am curious: how close is LQG on its semiclassical description, dynamics and contact with standard model particle physics?

41. **Who**
January 14, 2006

Lee,
you say

> Actually LQG and related research programs (such as CDT or programs based on quantum information ideas) are progressing rapidly, see for example the talks at the recent Loops 05 conference: http://loops05.aei.mpg.de/
>
> …there is a community consisting of about 150 mostly young physicists and mathematicians working in the general area of LQG and other background independent approaches and the results show …

I note that this research community does not have much visibility on the Web: for instance there is no QG blog and I don't know of any central bulletin-board for QG news information and comment.

You mention the archived Loops '05 talks as a good indication of current progress. That would be an excellent resource except the recorded talks are now off-line. They were up for a month or so around late-November-early-December but are now inaccessible. One can still download slides in some cases.

I would particularly like to be able to refer people to the video of the talk by Laurent Freidel, which I found quite impressive. But there are no slides and the recording (like the others from Loops '05) is no longer available. I have my own copy, but nowhere to post it for others.

You mention the intellectual independence of the best young QG researchers. It is a strong point. None of them, that I can think of, are merely working on some senior person's program. They tend each to have a definite individual research direction.

I don't see why universities are not scrambling to hire these people in junior faculty positions. It looks like where the future action is, but apparently deans and department chairmen haven't realized this.

It sounds good, in principle, to say that the academic rewards and support should go to those who make independent progress and not be attached to this or that program. However it would probably help to create prospects for the present crop of postdocs if non-string QG approaches were validated in visible ways.

QG could probably use a web-magazine of some kind. Not limited to scholarly papers but open to comment, news items, usual blog-stuff.
And I mean non-string QG.

There isn't a good collective name for it—-simply saying LQG can lead to confusion (people cite Nicolai et al thinking that is a critique of current LQG work)—-and I see that you resort to circumlocutions such as **LQG and related research programs (such as CDT or programs based on quantum information ideas)**

or as you say elsewhere **LQG and other background independent approaches**

and when you even just say LQG you mean, I believe, to include spinfoams—which many people don't seem to realize under that heading. The Nicolai et al paper purported to review LQG but did not discuss spinfoam—or any path integral approach—as i recall.

So there is a bothersome communication problem. To improve prospects for young researchers you need to publically validate the field and point out the rapid progress being made. but you do not even have a NAME for the field!

Much of the progress is in Path Integral approaches but if you say LQG then stringy-people will make a lot of noise about strict canonical LQG (as defined 5 or 10 years ago and reviewed by Nicolai et al) and this will tend to drown out whatever you say about LQG.

You need a name for this allied group of QG approaches which is short and immediately recognizable and which people cannot intentionally or unintentionally confuse with circa 1995 canonical LQG.

Something like QG*

where the asterisk indicates non-string, background independent, non-perturbative, and that spinfoam and other path-integral approaches are included

and you need a blog with a name like QG*, which reports all the progress being made and emphasizes all that is happening in the field, what different postdocs are doing and where they are going, what the most active centers are. (which turns out to be mostly outside the US, so less visible to people in US habituated to think of Harvard and Princeton etc. as where the important physics research happens)
and I think maybe you need to drum into people the message that
if a physics department is not strong in QG* then it is apt to lose standing the next time round.

But agreeing with your point that QG* is not one specific program but a hodge-podge of independent directions which various independentminded individuals have gone in, off the beaten path, just (this is a delicate point) the successful ones who have made a real contribution and real progress by doing that. Because your main point is that support should not be tied to some senior person's research agenda.

No time to edit this and make organized and brief. Hope helpful anyway.

Yes, but how are we going to get there? The relics who run the research establishment are not going to willingly give up power and young researchers are generally streetwise enough to know that however small their chance of getting tenure, it is going to be even less if they follow the Sinatra doctrine.

46. **Lee Smolin**
January 15, 2006

Dear Dan,

It is no problem to assess even very independent and creative young physicists, and distinguish those with promising ideas and results from those of non-professionals like the Bugdanovs. Their work is not in a vacuum, it is based on and uses established physics and mathematics and is aimed at solving long standing problems. The work can be judged both on the quality of the work and presentation and the promise of solving outstanding problems. A good test is surprise, is the idea new and potentially signficant? Is it an idea I wish I'd had, that I would like to work on? Has the person pulled off more than once an original idea that had an impact on the field? These are the kinds of tests we use when assessing the promise of young people in quantum gravity and foundations of quantum theory and we seem to have done well with them.

To Chris, There is no problem getting there. What I described is an ethic which is followed in some fields of physics and mathematics. It was the governing philosophy in what used to be called "the relativity community" which was why there were so many important results from relatively few people from the 1960s on. I would claim that those communities that don't adhear to it are anomalous and suffer from slow progress because of much duplication of effort and "me too" science and not enough risk taken by people trying to solve the hard open issues.

To Who, Thanks for the suggestion of QG*. We generally speak of just quantum gravity. Of course LQG includes spin foam models. There was a LQG email news and debate distribution list run for a few years by Fotini Markopoulou, this could certainly be now web based. Thaniks for the suggestion, Ill pass it on.

To Aaron,

At the level of statements of results, the basic claims of LQG and CDT are generally accepted. I assume you agree with this as no critic has shown a technical error in an important result-such as those listed in my review. There is of course disagreement on their significance.

Let us put the question this way: it is a non-trivial question whether there could be any examples of background independent QFT's. In fact there are some examples. There are of course the TQFT's but there are others including 2+1 gravity with matter, which we now know a lot about and there are a number of rigorous results about 3+1 including the existence and uniqueness theorems, the finiteness results about spin foam models and the CDT results. So you may disagree that nature should be background independent. But you cannot disagree that there is good evidence that such theories exist.

As to what CDT and LQG have to do with each other, they are both background independent approaches. CDT can be seen as very simple spin foam models. A number of people have worked on both.

Thanks, Lee

47. **Moshe**
January 15, 2006

Lee,

I believe the non-trivial question for LQG and similar approaches is whether they are indeed quantum theories of gravity, in other words do they contain semi-classical states and propagating gravitons in 4dim. I think lots of people will become interested in any quantum model that can be shown to contain gravity as we know it, whether it is BI or not. Since there is some progress on this recently, maybe one can be cautiously optimistic.

48. **Aaron Bergman**
January 15, 2006

I'm entirely too tired to go through the usual rigmarole yet again, so I'll just stand by my statement that people disagree on the *merits*.

Who Says:

> I note that this research community does not have much visibility on the Web: for instance there is no QG blog and I don't know of any central bulletin-board for QG news information and comment.

Yes, you are right about that. The fact that I couldn´t find a blog with discussions directly related to what you call QG* was the reason that I myself started one (which includes other matters as well), even though I am quite aware that it will probably take some time (viz. several years) until my blog reaches the level of quality and usefulness that you mention (and that I very much would like to!). BTW, you have been a very nice contributor to my blog and that is what really enriches a blog, useful comments, specially in its initial stages!

> I don't see why universities are not scrambling to hire these people in junior faculty positions.

Life is not like that, unfortunately I know it well.

Best wishes
Christine

51. **Kasper Olsen**
January 15, 2006

Aaron: I think that LQG and CDT are related in the following way; they are both attempts at a "background independent" approach to quantum gravity; and furthermore, they don't appear to pose any restrictions on the type of matter that couples to gravity…

Gravity *is* important – but there is, to be honest, more that Matters 😉

52. **Aaron Bergman**
January 15, 2006

You know, if I never hear the term 'background independent' ever again, my life would be just that bit happier.

As for the types of matter allowable, it's not at all obvious to me that the existence of a UV fixed point would be insensitive to the types of matter allowable. I'm more amenable to the idea than Jacques is, but it's far from an apparent point.

53. **Chris W.**
January 16, 2006

[You'll want to skip this, Aaron.]

The original form of the requirement of background independence was introduced by Leibniz. Closely related ideas and arguments were developed by Mach, and these have arguably been the most influential.

On the face of it, Newton won this argument with Leibniz; the success of Newton's mechanics and theory of gravitation appeared to show that misgivings about the soundness of his assumption of absolute space and time were misguided. Mach's criticisms made clear to Einstein that they were not. What Mach pointed out was that the operational significance of the notion of an inertial trajectory, and by extension an inertial frame of reference, were deeply unclear in the presence of universal gravitation and in light of the unobservability of absolute position in space. There is an operational resolution to this difficulty, but it is inherently dynamical. Julian Barbour has argued persuasively that this is in fact the essence of what Mach was getting at.

All this has been taken as irrelevant to particle physics, where the operational validity of an effectively (if not literally) inertial laboratory frame is taken for granted. The problem cannot be easily evaded however; one cannot dismiss the issue by simply saying, well, some of us may like the *idea* of background independence but it may not be the way nature is. The precedent of Newtonian gravity + mechanics suggests that this is misstating the issue. To say that there is a fixed background spacetime implies that one has found a way to observe it, and has done so. However, we have not done so, and the existence of such a spacetime is fundamentally inconsistent with general relativity.

In particle physics, before we concerned ourselves with quantum gravity, we could say "well, maybe there is a fixed background spacetime, or maybe there is merely an effective background; what difference does it make?" In quantum gravity we must understand the dynamical origin of that effective background. If we simply assume it as an absolute—eg, because we only know how to formulate quantum mechanics in the presence of a fixed background with certain symmetries—then we assume its *absolute* role in the classical limit, and its observability in that limit. But all our experience suggests that this is not possible, and this impossibility is built into the deep structure of general relativity.

If string/M-theory or particle physics in general could squarely confront this issue—say, by showing that a background is used as a formal device in certain formulations, but is irrelevant to the theory's physical interpretation or observational consequences—then I think you could be spared further heated discussion of "background independence".

On the role of matter in all this, I'll simply point out that matter *is* what we can observe, and that all our operational conclusions about spacetime as a physical entity are based on this. So in some sense matter and spacetime are bound to each other. One is tempted to say that one is derived from the other, or a manifestation of the other. String and M-theory incorporate matter, or provide the substrate for effective field theories to arise, but they treat gravity in this context as just another effective field theory in a *background spacetime*—do they not? This is what needs to be clarified. The massively proliferating complications of the last 10 (or so) years certainly don't help matters.

54. **Thomas Larsson**
January 16, 2006

At the level of statements of results, the basic claims of LQG and CDT are generally accepted. I assume you agree with this as no critic has shown a technical error in an important result-such as those listed in my review. There is of course disagreement on their significance.
Let us put the question this way: it is a non-trivial question whether there could be any examples of background independent QFT's.

The technical objection is that polymer representations of the diffeomorphism group are not of lowest-weight type, unless all other representations of symmetry groups in quantum physics. Hence, although there is no doubt that LQG models exist and are background independent, they apparently fail to be genuinely quantum in this respect. It is easy to argue that no locally non-trivial strictly background independent QFT exists at all. Mathematically, the 1D version of this argument is that the only unitary irrep of the centerless Virasoro algebra is the trivial one.

The solution to the problem of QG lies elsewhere: one must introduce an explicit representation for the observer's trajectory in spacetime. This leads to the resolution of three classes of conceptual problems:

1. It resolves various problems of time.
2. It resolves problems with the Copenhagen interpretation, by moving the observer to the quantum side of the Heisenberg cut.
3. It makes it possible to formulate diff anomalies in 4D, which we know must exist in analogy with 2D gravity, because the multi-dimensional Virasoro cocycles are functionals of the observer's trajectory.

For details, see e.g. this post or this forthcoming book. In order not to litter Peter's blog with off-topic material, objections may be posted here.

55. **Aaron Bergman**
January 16, 2006

If string/M-theory or particle physics in general could squarely confront this issue—say, by showing that a background is used as a formal device in certain formulations, but is irrelevant to the theory's physical interpretation or observational consequences—then I think you could be spared further heated discussion of "background independence".

Please read this thread. You can start with my post #70 if you want to skip to the relevant stuff.

The quick summary is that string theory looks exactly as if the background is only an artifact of th formulation. A more interesting question is the dependence on asymptotics and that is dealt with extensively in the above comment thread.

56. **Urs**
January 16, 2006

> urs said:
>
> It would also be impressive to have a theory which would allow to derive most, if not all, distances of the planets from our sun.

Yes, it would be impressive. Let me propose such a theory…F=ma… As input we need […]

[…] the conditions shortly after the big bang

Exactly, that's my point. You cannot derive it from first principles, but you can derive it given specified initial conditions.

Hence it is not, as Kepler once hoped, a unique solution, but one out of an infinite "landscape" of solutions. In the end, the question "why" the earth has the distance from the sun that it has is certainly not independent from the a posteriori fact that carbon-based systems observe it being there. (That's supposed to be an uncontroversial tautology.)

This does not imply that the same state of affairs applies to the parameters of the standard model. But it may help illustrate that it is nothing exotic for a theory to yield unique solutions only after some initial conditions have been specified. It is in fact the generic case.

We may hope for more, but it does not mean to abandon science to expect less.

57. **Thomas Larsson**
January 16, 2006

unless all other representations
unlike all other representations

58. **dan**
January 16, 2006

so given relevant initial inputs, is string theory able to derive other features of the standard model?

"This does not imply that the same state of affairs applies to the parameters of the standard model. But it may help illustrate that it is nothing exotic for a theory to yield unique solutions only after some initial conditions have been specified. It is in fact the generic case."

59. **Urs**
January 16, 2006

> so given relevant initial inputs, is string theory able to derive other features of the standard model?

As you may know, fixing a compactification for strings (heterotic, say), specifies completely a corresponding low energy field theory which is observed as the 'standard model' of the world described by this solution.

So for instance the known compactifications which come close to the standard model all make a prediction for the number and nature of the Higgs fields in these theories.

But most models so far also predict a bunch of massless scalars (moduli). The most recent model by Braun et al, which produces otherwise exactly the structure of the standard model, as far as I understand, has reduced these to a mere 13. But that's still 13 too many to be phenomenologically viable.

Which, incidentally, means that these solutions have been *falsified*.

http://loops05.aei.mpg.de/index_files/abstract_rovelli.html
Carlo Rovelli
GENERAL RELATIVISTIC QUANTUM PHYSICS: Background independent scattering amplitudes, boundary formalism, local particles and partial observables
Abstract: (i) I present some preliminary results on background independent calculations of particle scattering amplitudes. In particular, I discuss the derivation of the graviton propagator, from loop quantum gravity and the spinfoam formalism. (ii) I illustrate the boundary formulation of quantum field theory, its role in a background independent context, and how "particles" emerge in this language. (iii) More in general, I discuss how systematic physical predictions can be extracted from a general relativistic quantum field theory: I illustrate the notion of "partial observable", and discuss the issue of the physical significance of the spectrum of these observables, which controls the interpretation of the area and volume discreteness."

=============
http://arxiv.org/abs/hep-th/0512113
Effective 3d Quantum Gravity and Non-Commutative Quantum Field Theory
Laurent Freidel, Etera R. Livine

"We show that the effective dynamics of matter fields coupled to 3d quantum gravity is described after integration over the gravitational degrees of freedom by a braided non-commutative quantum field theory symmetric under a kappa-deformation of the Poincaré group."

"We will use these results to write down the Feynman graph amplitudes of a massive scalar field evolving in the 3d quantum geometry and we will show how they reduce to the standard Feynman graph amplitudes of the standard quantum field theory in a no-gravity limit G -> 0. On one hand, that solves the problem of the semi-classical limit of 3d quantum gravity, and on the other hand, this formulation allows us to compute explicitly the quantum gravity corrections to the

standard quantum field theory scattering amplitudes and show that the corresponding geometry is effectively non commutative… "

"… In the full quantum gravity regime, l_P and m_P are fixed and finite. The (semi-)classical limit is defined as

62. **Who**
January 16, 2006

Sorry, the preceding got cut off. Here is the rest

"…The (semi-)classical limit is defined as h-bar -> 0
l_P is taken to 0 while m_P remains fixed: we do not expect to recover standard classical flat space-time physics but a modified theory with a universal mass scale m_P as postulated in deformed special relativity.

The no-gravity limit G -> 0 takes l_P to zero and m_P to infinity but

63. **Who**
January 16, 2006

What I am trying to do is give additional substance to some things others have said in this discussion. What Moshe said regarding "some progress recently" on gravitons connects to Rovelli's talk at Loops '05. What Lee said about the 3D case connects to the Freidel Livine paper. And quotes from that paper serve as response to Dan's question about LQG and the semiclassical limit. Freidel's system shows the correct behavior both as G goes to zero ("zero gravity" limit) and also as h-bar goes to zero (semiclassical limit). Recent QG work is tending to include matter and use the spinfoam formalism (as illustrated by these examples.)

64. **woit**
January 16, 2006

Who,

Please, this posting had nothing at all to do with LQG. This has become way off-topic, and I don't think you should keep posting comments about this here.

65. **Who**
January 16, 2006

Hi Peter,
two issues: I was having technical problems. sorry about the multiple posts. the message in the preview kept getting truncated and not going up

second issue: I think the Freidel Livine paper one of the most important LQG papers of 2005. If we are going to discuss progress in LQG at all, we need to be able to talk about the Rovelli paper (which is uses spinfoam formalism) and the Freidel-Livine paper (also spinfoam).

See last paragraph of page 1 of F-L:
"We use the spin foam quantization of 3d quantum gravity provided by the Ponzano-Regge model…"

See Smolin's post 15 Jan 6:49A:
"Of course LQG includes spin foam models."

If you are going to allow a discussion of last year's progress in LQG then you have to allow people to talk about both the Rovelli paper and the F-L paper. Both the Rovelli and the Freidel papers were presented as invited talks at Loops '05 in October. Both are core representatives of current work in LQG.

66. **John Gonsowski**
January 16, 2006

Who, I think Peter is saying his original blog post was not about LQG. If Peter had started an LQG thread your comments would probably be no problem. It can get started by somebody else I know.

John… practicing for my own blog… just kidding

67. **woit**
January 16, 2006

Who,

John is right. This was not a posting about LQG, and while I think the idea of an LQG weblog is great, this is not it. I don't have either the competence or desire to run such a thing. Also, I'm afraid that no matter what the originial topic, you tend to turn the discussion to LQG or cosmological natural selection topics. If you want an in-depth discussion of these topics, you should set up a weblog devoted to them.

The other problem with this is that it gives lots of other people the idea that this comment section is a forum for them to discuss their favorite ideas, even if they're not the topic I'm posting about and have only come up tangentially in the discussion. I then end up having to spend a lot of my time deleting people's comments to stop this, annoying them and wasting my time.

68. **D R Lunsford**
January 16, 2006

Peter – the problem is, there isn't a neutral zone to talk about ideas – in a strange way you've created a neutral zone of sorts, whether you like it or not – this is a credit to you because you are letting physics as it were "speak for itself", and we all admire you for that.

So it's not polite to run on about things here, but we/they/all of us only do it because you have set up fairness as your first principle.

-drl

69. **Who**
January 17, 2006

Thanks for the reactions. DRL mentions courtesy. I apologize for (unintended) impoliteness and will try to be more considerate. My main concern is that the discussion of QG is often clouded by "Nicolai's mistake"—he coauthored a paper purporting to give an outsider's view of LQG and didn't discuss the spinfoam (path-integral) formulation. Peter then posted a letter from Lee responding to Nicolai in which Lee's main point was that for the past (on the order of) ten years the spinfoam approach has predominated in LQG research. Hope I don't overstate here. Most of the quantum gravity researchers I watch use spinfoam formalism, currently including Carlo Rovelli (who has been closely associated in the past with the canonical version of LQG).

In this thread LQG began being discussed by others and I joined the discussion wanting to respond, supplement and clarify what was said. Dan asked about the current status of LQG and it makes an enormous difference whether or not one includes spinfoam research. Including it also makes the close relationship between LQG and CDT obvious, an issue raised by Aaron and by Kasper Olsen.

Thanks for your patience, Peter. You do a great job creating a neutral forum space as DRL says.

70. **anon**
January 19, 2006

String theorist Dr Lubos Motl, who knows about propaganda, has now usefully given the following enlightening viewpoint:

"An important part of all totalitarian systems is an efficient propaganda machine. … to protect the 'official opinion' as the only opinion that one is effectively allowed to have." – STRING THEORIST Dr Lubos Motl, http://motls.blogspot.com/2006/01/power-of-propaganda.html

71. **Who**
January 19, 2006

Hello anon, hi DRL,
string theorist Hermann Nicolai (who seems the opposite of totalitarian and propagandistic—-an honorable member of the majority so to speak)
has come out with a new paper giving an overview of the main non-string QG approaches that this time INCLUDES spinfoam research

hep-th/0601129

this could actually improve the quality of the discussion.

It used to be that string theorists who wanted to defend against a perceived threat would lump all rivals to string under the heading "LQG" and then discuss only the orthodox canonical LQG essentially of the 1990s

but for the past 5 years or so (maybe more), people who see themselves as part of the LQG community have largely been doing spinfoam (as they tell us, and one can see it by sampling arxiv). There has been a gradual shift towards path integral approaches (like spinfoam and CDT)

so in the past a would-be defensive string theorist was often not connecting with reality. And people would quote Hermann Nicolai's earlier paper of just one year ago hep-th/0501114 LQG an outside view
which unfortunately did NOT discuss spinfoam or much of the activity which the LQG community was pursuing.

Now maybe defensive string theorists will direct their attack more on the actual rivals instead of at a mannequin of their imagining. Something good is likely to result, says I.

Who,

Thanks for that link:

'… it is thus perhaps best to view spin foam models as models in their own right, and, in fact, as a novel way of defining a (regularised) path integral in quantum gravity. Even without a clear-cut link to the canonical spin network quantisation programme, it is conceivable that spin foam models can be constructed which possess a proper semi-classical limit in which the relation to classical gravitational physics becomes clear. For this reason, it has even been suggested that spin foam models may provide a possible 'way out' if the difficulties with the conventional Hamiltonian approach should really prove insurmountable.' – hep-th/0601129

Hedge Fund Finances RHIC

January 13, 2006
Categories: Uncategorized

Federal funding for high energy physics in the US has been declining significantly in recent years. The recently completed FY 2006 budget has a 2.7% cut for high energy physics in the DOE budget, which provides the bulk of US funding for high energy physics research. The NSF also provides some support, but its budget for the mathematical and physical sciences is up only 1.5%, significantly below inflation (I don't know what the number is for high energy physics at the NSF by itself).

Over at Cosmic Variance, Joanne Hewett has commented on how depressing and discouraging the budget situation is, describing discussions amongst those charged to plan for the future as "downright scary at times." One of the worst immediate effects of the 2006 budget had been that the Brookhaven heavy ion collider RHIC would only have been funded for 12 weeks of operation instead of the planned 20 due to higher electric power costs.

Today Brookhaven made a remarkable announcement about this. A group led by ex-mathematician Jim Simons, head of the hedge fund Renaissance Technologies (for more about him and his hedge fund, see here and here) has come up with a contribution of the $13 million needed to run RHIC for the full 20 weeks. The group contributing this money includes other partners at Renaissance, which is based on Long Island, not very far from Brookhaven.

I'm sure the significance of this new source of funding for high energy physics will be debated in the community in coming days. My initial reaction is that while it's wonderful that the worst immediate effect of the budget cuts for 2006 has been avoided due to the generosity of Simons and others, this doesn't materially change the long-term problems.

There's more about this at Entropy Bound, the blog of Peter Steinberg, who works on an experiment at RHIC.

Update: More comments about this are from Joanne Hewett at Cosmic Variance and Chad Orzel at Uncertain Principles.

Update: More about Simons from New York Newsday.

   January 13, 2006

   Peter:

   Small corrections. Quote: "In the light of budget constraints, DOE had **planned to fund 12 weeks** of RHIC operations in FY06, but unexpected increases in electric power costs had **made this limited level of operation impossible**. Now, with the $13-million contribution to the Stony Brook Foundation and the planned Work for Others agreement between the Stony Brook Foundation and BSA, the Laboratory will be able to operate RHIC for a full 20 weeks"

   The reading of the statement is that without this donation, even the originally planned 12 weeks of operation would have been impossible. Of course, you can not always rely on such generous donations to be available each time.

   I am glad that people have begun to realize the restraint that **rapidly raising cost of electricity** imposes on high energy accelerators. Expect something even worse in the coming years.

   If you look at it, a 1% or 2% drop in the funding is something un-pleasant, but is still a completely manageable small percentage. But when the electricity cost double or tripple in just a few years, that is a total disaster and completely un-manageable, unless the funding is also drastically increase in similar fashion, which is just not possible at this moment. That's the reality.

   I am taken back by the Brookhaven director's statement that the raise of electricity cost was "unexpected". As head of such a big organization he should have known better and should have expected things like this. I don't want to see that a few years down the road CERN also issue a similar statement about LHC, say that they never factored in the possible large increase of electricity cost.

   Quantoken

   January 13, 2006

   So it's the ones who go to Wall St who end up bailing out those who stay in science.

3. **Tony Smith**
   January 14, 2006

   Quantoken said "… I am taken back by the Brookhaven director's statement that the raise of electricity cost was "unexpected". As head of such a big organization he should have known better and should have expected things like this. …".

   It seems to me likely to me that the Brookhaven director's statement may be no more a statement of true fact than the statement of Captain Renault in Casablanca (from http://www.imdb.com/title/tt0034583/quotes):

   "… Captain Renault:
   I'm shocked, shocked to find that gambling is going on in here!
   [a croupier hands Renault a pile of money]
   Croupier: Your winnings, sir.
   Captain Renault: [sotto voce] Oh, thank you very much. …".

   Such statements seem to me to be socio-political game-playing tactical moves, and to support the assertions in a letter (responding to Lee Smolin's article "Why No New Einstein?") published in the January 2006 issue of Physics Today by Foster Morrison:

   "… Today's scientists are jet-setting, grant-swinging, favor-trading hustlers looking for civil servants who will provide them with a pipeline to the US Treasury. Not only do they get peer pressure to behave this way, they also get arm-twisting from the academic bureaucracy that wants to get its 50% to pay for its bloated overhead. …".

4. **woit**
   January 14, 2006

   Tony and Quantoken,

   You are being extremely unfair to those people who have the thankless task of trying to get new high-energy physics facilities built and working in an environment where the inherent technological difficulties are immense, and budgets are both being cut and often not even known until well into the fiscal year. These laboratories have large fixed costs, so faced with sizable budget cuts they have a limited number of choices on how to deal with them, all ugly. The main ones involve shutting down accelerators to save on power costs and firing good people who have been working there, doing a good job for years.

   Experimental high energy physics in the US is facing some very difficult times, for very real reasons, not because the people involved are incompetent or "jet-setting, grant-swinging, favor-trading hustlers".

   Theoretical high energy physics is a rather different story…..

5. **Eli Rabett**
   January 14, 2006

   It is not clear to me that it would either be allowed or accepted if the labs hedged on electricity. If they bet wrong (say the cost went down) the papers and the politicians would have their guts for garters.

   However, DOE does generate electricity from a lot of dams in the southeast and the northwest. Most of this is sold at fixed cost to hold down the cost of electricity to customers. It might be possible for DOE to guarantee delivery of electricity to its own facilities under similar terms. This would, of course, be political, because that power would not be available for other uses.

   There are interesting possibilities here, since the money goes into the DOE budget on one side (from purchases of electricity by others) and into the DOE budget on the other (from purchases of electricity by the labs)

6. **Tony Smith**
   January 15, 2006

   Peter said "… Experimental high energy physics in the US is facing some very difficult times, for very real reasons, not because the people involved are incompetent or "jet-setting, grant-swinging, favor-trading hustlers".
   Theoretical high energy physics is a rather different story …".

   Although I would like to make it clear that I am in favor of high-energy experimental physics (even though my favorite future-project, the muon collider, has been assigned a low priority by the physics community),
   I am not of the opinion that the negative aspects of the theoretical physics community do not also infect the experimental community.

   It seems to me that each large collaboration in the experimental physics community acts to protect its interests in much the same way the superstring theorists act to protect their interests, whether or not those interests are aligned or opposed to the advance of physics itself.

   The characterization of "jet-setting, grant-swinging, favor-trading hustlers" as not being limited to theoretical high energy physicists was not my language, but was (as I made explicit in my comment) a quote from a letter published by the AIP in Physics Today.

   For another example of similar opinion, see the essay by Ad Lagendijk in Nature 438 (24 November 2005) 429, in which Lagendijk (a physics professor and group leader in the Netherlands) said in part:
   "… my daily experience as a professional physicist …[is that]… When I participate in a scientific conference I see a gathering of aggressive men (and yes, I mean men) fighting for their scientific claims … Successful scientists incessantly travel around the world performing their routines like circus clowns – forcefully backing up assertions over what are their contributions to the latest scientific priorities. …
   A modest Japanese presenter does not stand a chance against a loud, American critic speaking in his, and modern science's, mother tongue. …".

   Further, in the 5 January 2006 issue of Nature, a correspondence from Maria Uriarte (of the Department of Ecology of Peter's Columbia University) et al said in part:
   "… The story told in Ad Lagendijk's Essay … is very familiar to many of us who have chosen to make a living in science. … this value system and associated behaviours have other, far-reaching consequences,.
   First, they can compromise the integrity of the scientific enterprise …
   Second, they may reduce the diversity of the workforce by attracting, rewarding and therefore retaining those who thrive in particular kinds of competitive environments – who are not necessarily those of greatest scientific ability, insight, or creativity.
   Third, they may limit the range … of scientific pursuits …".

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

7. **woit**
   January 15, 2006

   Tony,

   All sciences have plenty of bad behavior and people protecting their interests. But in the case of the big experimental high energy physics projects there is generally something worth protecting. I don't think the situation there is optimal: if one started from scratch and tried to figure out the best possible way of allocating the money being spent, one could probably do better than what we have. But it's nothing like what is going on over on the theoretical side.

   From what I've seen, the technical problems of a muon collider are fearsome, but people are working on them. One problem that may doom the whole idea is that, at the kinds of luminosities one need, a muon collider beam emits such an intense neutrino beam (from the decaying muons) that it poses a significant radiation hazard, one that you can't shield against. If you built a muon collider deep underground at Fermilab, you'd have a neutrino beam of dangerous intensity coming out of the earth some radius away, possibly in Chicago.

8. **Tony Smith**
   January 16, 2006

   Peter said "… the case of the big experimental high energy physics projects … is … nothing like what is going on over on the theoretical side …".

The two biggest differences that I see are:

1 – Superstring theorists have effectively a 90% monopoly position in theoretical high energy physics, while the big experimental high energy physics laboratories have been careful to avoid such monopolies. For example, even though as of now Fermilab has a monopoly on collider experiments at its energy level, there are two independent detectors (CDF and D0) that can produce independent data sets in order to verify results. On the other hand, the superstring theorists can (and do) present their stuff as the only game in town, thus stifling other approaches; and

2 – Experimental laboratories are by definition closely connected with experimental data, whereas the superstring theorists have grown so distant from contact with experimental results that Susskind is quoted in the 5 January 2006 issue of Nature (pages 10-12) as saying that although he finds it "deeply, deeply troubling" that there is no way to test the landscape principle, he goes on to say "It would be very foolish to throw away the right answer on the basis that it doesn't conform to some criteria for what is or isn't science".
At least one superstring theorist seems unwilling to follow Susskind in unsupported belief that the landscape is the "right answer". In the same Nature article, David Gross says "People in string theory are very frustrated, as am I, by our inability to be more predictive after all these years … But that's no excuse for using such "bizarre science".
However, even though Gross has sense enough to see that Emperor Susskind has no clothes, he seems to be unable to admit that lack of predictivity means that superstring theory should no longer be regarded as the only game in town for high energy theoretical physics.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Peter also said "… If you built a muon collider deep underground at Fermilab, you'd have a neutrino beam of dangerous intensity coming out of the earth some radius away, possibly in Chicago. …".
As to that,
the pdf file titled "Muon Collider & Neutrino Factory Studies – R B Palmer MSU 1/27/05" on the web at http://bt.pa.msu.edu/Phy964_muon/aaMSU-coloquium-v2.pdf
says in part:
"… Conclusion: Muon Collider
– Interesting for physics & Smaller than Linear Collider
– Difficult technically
– Neutrino Radiation limits Maximum Energy
…
Radiation proportional to E^3 / length^2 proportional to E^3 / depth
Use: 1/10 Federal limit = 10 mR/year
Negligible problem at 1.5 TeV
E = 3 TeV ok at 300 m depth
E > 3 TeV Requires:
– Beam wobbles, and/or
– Special Locations (eg an island), and/or
– Better Cooling (Optical Stochastic?) …".

Maybe a Pacific Island (Johnston Island?) or Central Asian location might be acceptable for a high-energy muon collider.

I am under the impression that Fermilab has decided to try for the NLC, but that the Japanese are saying things like "you can't see the Pacific Ocean from the Illinois prairie". Even so,
while cut-throat competition for such things as NLC siting might be life-or-death for a single entity like Fermilab, such a death would not be the end of progress in experimental physics (note that despite the death of the SSC, the LHC and its successors can do the physics that might have been done at the SSC).
In contrast,
if landscape superstring theory were to maintain a monopoly position in theoretical high energy physics, that might indeed mean the end of theoretical physics as a scientific enterprise.
Therefore,
it seems to me that Peter has a valid point that the consequences of "men-behaving-badly" behaviour are far worse in today's theoretical high energy physics community than in the experimental world.

9. **Quantoken**
January 16, 2006

Peter said:

"One problem that may doom the whole idea is that, at the kinds of luminosities one need, a muon collider beam emits such an intense **neutrino** beam (from the decaying muons) that it poses a significant **radiation hazard**, one that you can't shield against."

That I don't understand! We know that neutrino is one of the least interactive particles. One claim that you could have neutrinos passing through thousands of light years thick of lead metal, and hardly a significant portion is absorbed. Neutrino beam is certainly virtually impossible to shield, but since it does not interact much with matters it does not cause any harm either. It can penetrate your body without any interaction, thus causes no health problem.

As a matter a fact, billions of solar neutrinos routinely penetrate through every square centimeter of your skin every second silently but we don't worry about it. So why the neutrino beam of the proposed device would be harzadous?

Quantoken

10. **woit**
January 16, 2006

Quantoken,

Yes, this is a surprising problem, because neutrinos interact so weakly. But to get a lepton collider to function usefully at these energies you need huge luminosities, and every muon in the beam is going to decay, giving you neutrinos (and electrons, but those you can shield). The number of neutrinos is just so huge that the interaction rate becomes a problem.

11. **Tony Smith**
January 16, 2006

As Peter said in reply to Quantoken, "… The number of neutrinos is just so huge that the interaction rate becomes a problem. …".

The paper physics/9908017 by Bruce King of Brookhaven gives some relevant equations. Here are some excerpts from King's description of the situation (the full article contains discussion of more details):
"… The potential radiation hazard comes from the showers of ionizing particles produced in interactions of neutrinos in the soil and other objects bathed by the disk. The tiny interaction cross-section for neutrinos is greatly compensated by the huge number of high energy neutrinos produced at muon colliders. … Most of the ionization energy dose deposited in a person will come from interactions in the soil and other objects in the person's vicinity rather than from the more direct process of neutrinos interacting inside a person. At TeV energy scales, much less than one percent of the energy flux from the daughters of such interactions will be absorbed in the relatively small amount of matter contained in a person, with the rest passing beyond the person. … the radiation levels rapidly become a serious design constraint for colliders at the TeV scale and above.
…
Perhaps the most direct way of decreasing the radiation levels is to greatly decrease the muon current. This can be done either by sacrificing luminosity … or, more attractively, by increasing the luminosity per given current through better muon cooling or other technological advances.
Further, one might consider placing the accelerator deep underground so the radiation disk won't reach the surface for some distance.
…
Further speculative options that have been discussed include
(i) tilting the ring to take best advantage of the local
topography,
(ii) placing the collider ring on a hill so the radiation disk passes harmlessly above the surroundings and, even more speculatively,
(iii) spreading out and diluting the neutrino radiation disk by continuously sweeping the muon beam orbit in a vertical plane using dipole corrector magnets.

Even when the preceding strategies have been used, the strong rise in neutrino energy probably dictates that muon colliders at CoM energies of beyond a few TeV will probably have to be constructed at isolated sites where the public would not be exposed to the neutrino radiation disk at all.
This would definitely be required for the 10 TeV and 100 TeV parameter sets …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

12. **Quantoken**
January 17, 2006

Tony:
I carefully read the paper you pointed to, and still do not see why the neutrino could be a radiation hazard. Assume every derivation of the author is correct, look at equation (13). The numerical factor is 2.9×10^-24. The important variable is Nu, the number of muons per second. I do not see it yielding any number close to one. Probably, the author wrongly considered Nu, the count of muons per second, as in the same order of magnitude as the Avogadro constant. If he so considered then he was completely wrong. Should Nu equal to the Avogadro constant, 6.022×10^23, that means a beam current of 6.022×10^23 * 1.61×10^-19 = 1.0×10^5 Amperes. **Ten thousand amperes**. No modern accelerator could even have a beam current any where close to even one ampere.
The beam current is confined by the limit of the amount of input energy. Let's say the machines consumes the same amount of power as the LHC, 200 mega watts (which is half a city's electricity, so not a small number!!!), and 10% of the energy consumed by the machine turn into beam energy. That's 20 mega watts, or 1.243×10^26 eV energy per second. And let say the muon is accelerated to 1 TeV (1×10^12 ev). That leads to 1.243×10^14 muons per second. And that should be the number fo Nu in equation (13).
So the total dosage would be 2.9×10^-24 * 1.243×10^14, i.e., 10^-10, in terms of order of magnitude. That's a **totally negligible** radiation dosage. And that conclusion is certainly in line with the notion that neutrinos penetrate everything virtually harmlessly.

Quantoken

13. **mike dinsdale**
January 17, 2006

Quantoken, N_u isn't defined as the number of muons per second, it's the total number whose decay will give the dose on the LHS of (13). The dosage limits you're comparing to are in Sv/year, so you need N_u to be the number of muons per year, i.e. to scale up your estimate by about 3*10^7. This gives roughly a mSv which is much more consistent with what he's saying in the paper.

Mike

14. **Quantoken**
January 17, 2006

Mike:

Thanks for that explaination. But still we do not know what a reasonable value N_u is. My estimate is way much too optimistic and too high, bounded only by the available electricity power. I assume that 10% of the total power consumed by the machine could turn into beam energy. That's probably too optimistic to be true. Also realistically I do not know how efficient a muon factory could be (how many muons they can manufacture per second). Generating muons and anti-muons is certainly much harder than just ripping electrons from regular matters by ionization. The author also assumed each kilogram mass contains 1000 moles of atoms, which is too high. For typical atomic weights, like carbon, you would be talking about 80 moles or less per kilogram. That's another factor of 10. So the realistic radiation hazard of the neutrino of such a muon collider is probably 3 or 4 orders of magnitude below the natural background radiation level.

The author never really talked about what he thought the N_u out to be. Without that number the whole paper is meaningless since he has not produced a specific result. The point I want to make is you guys are now trying to lobby the public support for a future accelerator like the muon collider. And you do not even have a clear technocal picture how the machine looks like and how many muons it produces, and you start to talk about the environmental hazard and how it hurt the public health. That's NOT an intelligent thing to do to lobby public support for your research enterprise. The smart thing to do would be get the thing onto the agenda of budget talks first and worry about radiation hazard later when it really come to the design and engineering phase.

Quantoken

15. **woit**
January 17, 2006

Quantoken,

The people thinking about muon collider designs do, believe it or not, actually have a good idea of the physics involved. Stop posting comments here criticizing them unless you actually take the time to really understand what they are doing.

They're not making a big deal of the radiation problem, it's something I brought up because I thought it was surprising that there is one. Maybe one can find a way around it, but it definitely is something that needs to be thought about before you can come up with even the outline of a viable design for such a machine.

16. **Tony Smith**
January 17, 2006

Peter said to Quantoken "… The people thinking about muon collider designs do, believe it or not, actually have a good idea of the physics involved. …
the radiation problem … it was surprising that there is one. Maybe one can find a way around it, but it definitely is something that needs to be thought about…".

Here are two more references for anyone who wants to see more about muon colliders:

The paper (with over 100 authors) at physics/9901022. It is also known as BNL-65623, Fermilab-PUB-98/179, and LBNL-41935. Its title is "Status of Muon Collider Research and Development and Future Plans".
If you read it, and look at the list of authors and institutions involved (and yes, Bruce King of physics/9908017 is one of the authors), I think that it will be clear that people working on muon colliders are NOT, to use Quantoken's language, "… guys ..[who]… do not even have a clear technocal picture how the machine looks like and how many muons it produces …".

My second reference is to a very clear presentation with graphics that was given by Gail G. Hanson (one of Quantoken's "guys", and an author of physics/9901022) at an ICFA Seminar on "Future Perspectives in High Energy Physics", CERN, 8-11 October 2002. A pdf file of it can be found at
http://dsu.web.cern.ch/dsu/of/icfapres/hanson.pdf .

Since the muon collider has not yet received huge funding for construction and operation, the people working on it are (in my opinion) primarily motivated because they love the physics involved and the potential for new and interesting observations.

They themselves have raised the issue of radiation in the area, which is not obvious at first glance because the problem is not so much direct neutrino irradiation of a person as it is the person being irradiated by secondary radiation from the person's environment
(as Bruce King said, "… Most of the ionization energy dose deposited in a person will come from interactions in the soil and other objects in the person's vicinity rather than from the more direct process of neutrinos interacting inside a person. …").
Further, they themselves pointed out that, even though a powerful muon collider would be small enough to fit on-site at either Fermilab or Brookhaven, consideration of the health of the people of Chicago or New York City indicates that a muon collider probably should be put in a more remote location.

That these people not only are working on muon colliders mostly for love of physics,
but are also honest and socially conscious enough to recommend that it be sited away from the established facilities at Fermilab and Brookhaven
(in spite of the fact that a lot of the over 100 authors of physics/9901022 have close ties to those institutions)
makes me feel that, even in this day and age, there are still some good people in the world of physics.

Tony Smith

17. **J.F. Moore**
January 20, 2006

Returning to the original topic, I just wanted to make the small point that some fields, particularly medicine, rely partly on donor funding to good success (and importantly, without jeapordizing other funds). I don't think it is unreasonable to develop similar mechanisms in the physics community to reach out to the philanthropists for at least some funding. This news from RHIC sets a precedent. It is not looking likely that US government funding in physics will be increasing or even keeping pace with inflation anytime soon.

Susskind NYT Book Review

January 14, 2006
Categories: Uncategorized

There's a review of Susskind's book The Cosmic Landscape in this Sunday's New York Times book review section. The reviewer does a reasonably good job of laying out what the Landscape controversy is about, characterizing Susskind's attitude as "braggadocio" with "an air of smugness", and noting that "He allows remarkably little doubt about string theory considering that it has, as yet, not a whit of observational support."

This week's Village Voice has a profile of Susskind.

Update: More about this over at Uncertain Principles.

   Have read the review.

   Is it true that ID=anthropic principle, and string theory is an alternative to ID?

8. **D R Lunsford**
   January 15, 2006

   I wonder if Einstein would wear a Susskind t-shirt?

   He would probably wear a Susskind t-shirt if on it, Susskind were wearing an Einstein t-shirt…

   -drl

9. **Juan R.**
   January 15, 2006

   New piece of nonsense.

   .

Question: When stringers will take the next logical step; the multi-multiverse?

Multi-multiverse: Existence unit formed by existence regions called multiverses. In ONE multiverse, string theory is correct in others multiverses string theory is just wrong. Since number of multiverses is greater that number of universes in a single multiverse, the number of universes where string theory is incorrect is far greater that other case.

Therefore, the interest of string theory for understanding more deeply the 'nature of reality' is proportional to epsilon when epsilon tends to universe.

Sorry! 🙂

This all changes if by some miracle the landscape provides string theory with the means to the ToE, right?

I mean that we wouldn't need direct evidence nor falsifiability if this were proven to be the case.

Right?

11. **john baez**
January 16, 2006

mathjunkie writes:

> Is it true that ID=anthropic principle, and string theory is an alternative to ID?

No, it's not true that intelligent design is the same as the anthropic principle!

Intelligent design is the idea that our universe was designed by some intelligent being. The anthropic principle is the idea that some aspects of our universe can be understood starting from the fact that intelligent life exists here.

(In fact there are many versions of [intelligent design] and [the anthropic principle], but let's not get into that here – follow the links if you want more details.)

It's possible for intelligent design and the anthropic principle to
both be true, both be false, or one be true and the other be false.

For example, God could have intelligently designed our universe by running a machine that builds all possible universes – this would be intelligent because then God could avoid bothering with the details. Then our universe would be one of these with intelligent life – and it's possible we could understand some aspect of our universe starting from this fact.

String theory is not an alternative to intelligent design. In fact, all 8 combinations of intelligent design, the anthropic principle and string theory being true or false are possible.

However, the astute reader will note that this discussion resembles medieval theology more than physics.

12. **mathjunkie**
January 17, 2006

Thank you John for answering my question.

It seems I know next to nothing about the differences among intelligent design, anthropic principle and string theory.

I think you are the researcher who favours LGQ more than the string theory, right?

13. **Santo D'Agostino**
January 17, 2006

Dear mathjunkie,

The nature of the intelligent design (ID) idea can be understood by analyzing the structure of their argument, without being distracted by all the details. It is:

1. There are problems with the theory of evolution.

2. Therefore God exists.

ID is therefore seen NOT as a scientific theory, but rather as an argument for the existence of God, in the same spirit as the arguments for the existence of God proposed by certain medieval philosophers and theologians. ID is just as fallacious; one can prove a mathematical theorem, but proofs of the existence of God are not possible.

Every scientific theory has problems; it is not the way of science to throw up our hands in the face of problems and say, "OK. I give up. God must be the only explanation.” The scientific approach is to analyze as clearly as possible what the problems are, and then to either revise the theory or construct a new one that is better.

Responding to island and arnold, it is interesting to compare and contrast the spirit of thought of the IDers with some of the popularizers of string theory. As argued by many people, both on this site and elsewhere, there is a clear difference between ID and string theory. The former clearly has no chance to ever be science, whereas although the latter is not yet a scientific theory, its proponents are striving to construct what one day might become a scientific theory. That is, a theory that makes specific predictions that can be confronted with observational or experimental data.

All the best,
Santo D’Agostino

14. **Steve Myers**
January 17, 2006

On anthropic principle: since any model has to be general to be useful there will be a large — possibly infinite — number of particular solutions. So can you work backwards from particulars to get a model? Not without some leap or guess or postulating a rule outside the set of particulars. You begin with the fact that Lotte has blue eyes and end with ” there is at least one such and such, such that it possess some property.” See Russell’s “Inquiry into Meaning and Truth.” Every math student has to learn that before he can understand what constitutes a proof. Look, you can always find some function (in fact, there are an infinite number) to fit any data. That’s why the curve you choose is based on data predicted. Of course, you run into the same problem again but that’s why science is ongoing, not a finished project. But isn’t all that obvious?

15. **Urs**
January 17, 2006

> are striving to construct what one day might become a scientific theory. That is, a theory that makes specific predictions that can be confronted with observational or experimental data.

I still don’t think this is the right way to put it. I’d say “people are striving to construct a phenomenologically successful theory”. There is nothing unscientific about string theory. It’s “just” phenomenologically unsuccessful. This may be reason enough to abandon it. But let’s keep the facts straight.

Consider a cosmologist who finds himself living in a universe which on large scales is not homogeneous but highly chaotic. By pure thought, he has come up with the theory of general relativity. Now he is trying to see if this theory is phenomenologically viable as a cosmological theory on large scales.

So he searches for solutions of his theory and tries to match them with the observed data.

First he tries FRW cosmologies. Most fail miserably. One, the mixmaster scenario comes closer in capturing the chaos he observes, but is still way too symmetric.

So he constructs cosmological models which are inhomogenous, depending on one, two, three, then a dozen parameters. All of them being exact solutions of GR, all of them coming a little bit closer to the cosmos he actually observes, but none being quite right.

His fellow bloggers challange him. They say “What an unscientific theory you have. Surely you must believe in alchemy and poltergeists if you also believe in your theory.”

But his theory is GR. He just happens to live in a cosmos which is not described by a simple (highly symmetric, low-parameter) solution of GR, but of a highly complex one.

So for him, GR as a cosmological theory is highly unsuccesful, phenomenologically. But it is not unscientific. He could make predictions (say of CMB spectra, of nucleosynthesis, etc.) if only he knew which solution to GR describes his cosmos. But he doesn’t know.

16. **michaeld**
January 17, 2006

Santo D’Agostino, exactly. It seems that many religious people seem to believe that the sum value of science and religion is a fixed constant, and so every failure of science is a success for religion and vice versa.

17. **island**
January 17, 2006

mathjunkie says:
Is it true that ID=anthropic principle…

Some interpretations of the anthropic principle indicate that we are not here by accident, and IDists erroneously latch onto this as evidence for god’s existence.

The Privileged Planet… by Guillermo Gonzalez and Jay Richards, is once such derivation of this sort.

While it is not correct to conclude that just because we’re not here by accident there must be an intelligent agent involved, this is exactly what IDists do, and unfortunately… skeptics are conditioned to buy straight into this hype, and so their automatic response is to try to find ways to lose the implied “specialness”… rather than to look for some good physical reason for why it might be true.

string theory is an alternative to ID?

Stringy theories that use multiverse rationale can lose any implied anthropic specialness in an infinite number of possible universes, since one of them had to be like ours, but there is no “illusion” of intelligent design without an unfounded leap of faith, regardless of what Leonard Susskind would have us believe.

It’s not a matter of either/or, as Lenny claims… either we accept the multiverse scenario, or… “without any explanation of nature’s fine-tunings we will be hard pressed to answer the ID critics.” since “the appearance of intelligent design is undeniable”.

There is no implication for intelligent design, because there is no inferrence of intelligent design from evidence for purpose in nature, without direct proof. Evidence for goal oriented design or structuring in nature does not constitute evidence for intelligent design if there is no landscape.

Lenny also doesn’t appear to know what theories are valid and which are not when it comes to origins science, because “multiverse rationale” isn’t a valid argument against fine-tuning unless and until a multiverse is proven to exist, or if multiverse “reasoning” proves to be necessary to the one true theory of everything. I think… that very last part is correct… but nobody answered my question.

18. **island**

January 17, 2006

FYI: Santo D'Agostino and michaeld are not correct as the anthropic princple applies to this debate. ID doesn't not require the faliure of science to abuse the anthropic principle as evidence for intelligent design.

19. **Santo D'Agostino**
January 17, 2006

Hi Urs,

Thanks for your comments. Your analogy has given me a very helpful perspective on string theory.

My inclination is to adopt fairly strict criteria for what we call a scientific theory. For instance, it should at least be internally consistent and it should make quite definite numerical predictions that can be tested by observations or experiments. Ideally it will predict new phenomena, but that is not strictly necessary.

It seems that based on some such strict criteria, string theory is not yet a scientific theory, although I admit that my criteria may be too strict, based on your nice analogy.

Another analogy: suppose we have a candidate theory of the hydrogen atom, let's call it theory A. In theory A there are a million different ground states for the hydrogen atom, no way to choose among them, and there is no way to predict any of the excited states. So nothing can be calculated about the hydrogen atom, no transition rates, no frequencies of emitted or absorbed radiation, etc. I would not call theory A a scientific theory, but I would admit that the effort of trying to shape it into a theory may qualify as a scientific activity.

Contrast this with another theory of the hydrogen atom, let's call it theory B. In theory B we have millions of ground states too, and no way to choose among them, but this time no matter which ground state is chosen, the theory predicts the relative energies of the corresonding excited states. In theory B at least you can predict the frequencies of emitted or absorbed radiation, and so I would be willing to call theory B a scientific theory. (The frequencies are always the same, no matter which ground state is chosen, so we still have no way of knowing what the actual ground state is in theory B.)

My impression is that string theory is more like theory A, and so I would hesitate to call it a scientific theory yet. If I am wrong, I would value any further clarifying comments that you might like to make. For instance, are there any specific numerical predictions that string theory makes that can be confronted with observations or experiments?

Santo

20. **Santo D'Agostino**
January 17, 2006

Hi island,

I'm not sure why you say

"FYI: Santo D'Agostino and michaeld are not correct as the anthropic princple applies to this debate. ID doesn't not require the faliure of science to abuse the anthropic principle as evidence for intelligent design."

since I said nothing about the anthropic principle.

I agree with your criticism of Susskind's reasoning; as I already mentioned, it is unscientific to argue for the existence of God based on one's inability to cook up a satisfactory scientific theory.

As for your question,

"This all changes if by some miracle the landscape provides string theory with the means to the ToE, right?

I mean that we wouldn't need direct evidence nor falsifiability if this were proven to be the case.

Right?"

How would you know if such a proposed ToE were a good theory? You would have to compare its predictions to observed and experimental data; in other words, you would need evidence and falsifiability.

All the best,
Santo

21. **Urs**
January 17, 2006

Santo D'Agostino

it is a pleasure to be able to have a reasonable discussion.

I would suggest to slightly modify the analogy which you proposed.

The hydrogen atom itself is a solution of a theory. Quantum mechanics itself does not predict anything about atoms. You need to feed in the correct initial data first.

Once you specify that your electron sees precisely the Coulomb potential, for some value of the one parameter describing it, you can derive atomic spectra using QM+choice of potential. You have to choose the form of the potential (~ a 1/r) as well as pick one value of the parameter a.

You fix this by fitting it to a small subset of experimental data. Then you use the fact that *given that input*, QM predicts the rest of the spectrum.

So, if people had discoverd the formalism of QM before having figured out that the H-atom consists of an electron orbiting a nucleus, they could not have used it to predict anything about the spectrum of that atom.

22. **Juan R.**
January 17, 2006

I said,

> Therefore, the interest of string theory for understanding more deeply the ‘nature of reality’ is proportional to epsilon when epsilon tends to universe.

It would say

Therefore, the interest of string theory for understanding more deeply the ‘nature of reality’ is proportional to epsilon when epsilon tends to **zero**.

>
> 1. There are problems with the theory of evolution.
>
> 2. Therefore God exists.

No, that’s not the nature of cosmological ID, which is what Lenny’s book is about.

> How would you know if such a proposed ToE were a good theory? You would have to compare its predictions to observed and experimental data; in other words, you would need evidence and falsifiability

I was asking about falsifiability of the “Landscape”, not testable predictions of a ToE.

24. **Santo D'Agostino**
January 17, 2006

Hi Urs,

Thanks for explaining to me how my hydrogen atom examples are like your cosmology example for the purposes of this discussion.

I suppose that if the formalism of QM had been discovered before it could predict anything specific, I would also say that it were not yet a scientific theory, but a formalism striving to become one. But as you said earlier, this does not mean it is not worth working on.

All the best,
Santo

25. **Santo D'Agostino**
January 17, 2006

Hi island,

I misunderstood you. I assumed you were talking about ID, not cosmological ID. I don’t know exactly what the latter means, since I have not read Susskind’s book.

All the best,
Santo

26. **Adrian H.**
January 17, 2006

Urs and Santo

I think the thing that is missing between you is the concept of explanation, as against prediction. Urs, you have pressed the idea that ‘string theory is science’ very succesfully, using the idea that it *could* make predictions. You stress the idea that prediction is often a matter of finding correct solutions given some initial conditions. As in GR, put in the values for mass-energy distribution, get out a model of space-time structure.

But I think this analogy misses something important about scientific theories that is not equivalent to prediction: scientific theories are explanatory.

Take a bad theory that is maximally predictive in your terms: one that is of the form A & -A for any A. A contradiction in other words. From that contradiction one can predict anything and everything, since any claim logically follows. But even though it will be predictively a TOE, it is obviously not a scientic theory, or if you wish to stretch the term that far, it is a scientific theory, it’s just a very bad one. A makes an infinite number of false predictions along with the true ones.

Finding a solution to the equations of GR is predictive of the structure of space time (if we found we live in the Goedel Universe, that would be an interesting fact!) but it does not explain why the mass energy distribution is the way it is, or why the speed of light has just that value, etc. Finding solutions to equations is not all, or even the main part of, the scientific enterprise.

I think the worry that is being expressed about string theory and the landscape is that—and this is the thing that pulls it closer to ID than is really comfortable—the theory is incredibly low in even potential explanatory power. “Why are things this way, rather than some other.” If the answer is that we can get our universe out (I’m being optimistic) as a solution to some set of equations, by putting in by hand a whole lot of free parameters then it is of diminished interest. Not no interest at all, just diminished.

And on the subject of explanation vs prediction, note that ID is a perfectly predictive “theory”: it predicts the life forms we see around us. We just have to put in by hand a whole lot of free parameters that describe God’s intentions!

But ID is obviously low in explanatory power. And String theory may be closer to ID than it is to GR. That’s the worry.

27. **Adrian H.**
January 17, 2006

I should add that I’m not saying that everything can be explained, just that explanatory power is something that we seek to maximize in scientific explanations.

And perhaps we should really say that ID is retrodictive, rather than predictive. Likewise the Anthropic Principle looks like a case of retrodiction: People exist therefore this universe must be one where people can exist!

28. **Fabien Besnard**
January 18, 2006

Urs, you seem relieved. But I don't think many people on this blog think string theory per se is not a scientific theory. In particular I've never seen Peter make such a claim. If I understood right Peter's mind, what he says is : 1) anthropic attemps to go out of the landscape are unscientific 2) more and more string theorists argue that unfalsifiability is not such a bad thing after all, and this is a sign that string theory has failed to achieve its primitive goals and that some people are getting nervous about this 3) it's time to try something else.
With all this I fully agree.
Peter, please correct me if I'm misinterpreting your mind.

29. **Urs**
January 18, 2006

Adrian,

thanks for the comment.

It is hard to give a precise meaning to the term "explanation". Some people feel quantum mechanics *explains* the spectra of atoms, while others are so dissatisfied with the interpretational issues of QM that they would only acknowledge that it successfully *describes* these observations, with a "real explanation" still to be found.

But besides personal feelings it does not make much of a difference which standpoint one takes.

So I would not want to engage in a discussion whether some theory "explains" enough to be worth of our considerations. A good theory is one that yields a high number of (maybe approximately) correct descriptions from a low number of assumptions.

Consider the following scenario.

Assume perturbative string theory is indeed a good description of physics beyond the standard model. Assume there are heterotic strings which are weakly coupled and spacetime is really compactified on some Calabi-Yau.

Say the currently available modles by Braun, Ovrut and others can be further refined such that one day they find a choice of Calabi-Yau, a choice of gauge bundle over that CY and a choice of "Wilson lines" (these are the sorts of parameters one has to choose) such that the low energy effective theory obtained by strings on such a compactification produces the standard model on the nose, without any extra moduli. Let me call the string vacuum thus defined SV1. Our first candidate solution of string theory which matches observed low-energy physics.

If this happened, one would want to study the postulate that the world is indeed described by SV1 in weakly coupled heterotic string theory.

This would yield quite a number of predictions. For one, it would predict that at energy scales which resolve the size of the compact CY accelerators would see signatures of these extra dimensions, and the precise topology of these extra dimensions would be predicted.

Note that this prediction might turn out to be wrong. You may even feel that it has no chance of turning out to be right. But it is a prediction.

If it should turn out to be correct, we'd have a nice theory of physics beyond the standard model. If not, we'd need to work harder. That's how science works.

Indeed, there are serious reasons to expect that this scenario has little chance of being true. One might suspect that a weakly coupled perturbative description of high energy physics is likely to miss essential physics. That a non-perturbative description will be necessary, one that does not need to expand about a fixed background.

This may be true, and people are working on it. If anyone has a good idea, it will be worth considering. If it helps to reassure people distgusted by the state of affairs in string theory, I might point out that I know a couple of string theorists who took a very close look at the recent results claimed in CDT. I wish I would not have to emphasize this.

Anyway, I would like to point out that even if we had a nonperturbative definition of a theory beyond the standard model, we'd still face the problem of identifying the correct solution of this theory which describes our world!

There is no reason to expect that, once spin foam models, CDT, AdS/CFT-like dualities or any other nonperturbative approach is well enough understood that one can talk about its space of solutions, it will turn out to provide a unique one. I expect the opposite to be true. There will be infinitely many solutions.

So even with a working nonperturbative theory beyond the standard model we'd face the the issue that predictions cannot be made before some parameters in its solution space are fixed. Fixed somehow.

30. **D R Lunsford**
January 18, 2006

Peter – you handled that very well over on the blog "Uncertain Principles". (Is there a rule that blogs have to carry cute names?) The problem is, correct arguments seem to have lost their value. I was looking at the postings to a right-winger's blog the other day – e.g. one guy offers a detailed, fact by fact, unemotional indictment of the Bush admin, and it just didn't make any difference to the dittoheads in the audience – they simply refused to allow themselves to be tied to facts.

Somehow the art of actually paying attention to an argument has gone missing

-drl.

31. **Thomas Larsson**
January 18, 2006

Say the currently available modles by Braun, Ovrut and others can be further refined such that one day they find a choice of Calabi-Yau, a choice of gauge bundle over that CY and a choice of "Wilson lines" (these are the sorts of parameters one has to choose) such that the low energy effective theory obtained by strings on such a compactification produces the standard model on the nose, without any extra moduli.

This could happen, of course, but I think everyone around here agrees that the odds are so small that they can safely be ignored. If so many bright people haven't gotten any quantitative predictions out of string theory in 20 years, why should things change now? Haven't people turned to the Landscape precisely because they have given up hope that any useful prediction will ever come out of string theory?

Moreover, one must not forget that all natural predictions from string theory, like SUSY, extra-dimensions, 496 gauge bosons, new long-range forces, etc., are in apparent disagreement with experiments. A particularly impressive class of experiments seems to be the search for permanent electric dipole moment, which has been blogged about here, here, here, and here. It may seem strange to use experimental results to argue about theoretical physics, but I strongly feel that the by far simplest explanation for this apparent disagreement with observation is that it is due to a factual disagreement with observation.

Besides, didn't we agree that the correct theory of QG in 4D must allow for diff anomalies, as I understand section 6.1 of Nicolai et al.? If string theory does not allow for such anomalies, how could it possibly be right? Even if you dislike my treatment of anomalies, you cannot reasonably deny that the absense of 4D diff anomalies is fatal?

32. **woit**
January 18, 2006

Fabien,

Yes, I'd basically agree with your summary.

Fabien and Urs,

I'm careful not to say things like "string theory is not science". Some things string theorists are doing are science, but some are not. Very specifically what I claim is not science is when string theorists like Susskind say they accept that string theory leads to 10^500 vacua, but then are unable to come up with a remotely plausible idea of how they are going to use the theory to make falsifiable predictions in this case. The only kind of "predictions" he talks about are the anthropic ones that are not falsifiable and aren't really scientific.

Lots of string theorists now seem to be saying that, while they reject the anthropic arguments, even if string theory does have 10^500 vacua, that is no reason to give up on it. My point of view is that anybody who wants to claim this has to come up with a plausible scenario for how this is ever going to lead to predictions. From everything I've seen, no one can do this, so it appears to me they are just defending the indefensible and not doing science.

The problem with Urs's SV1 scenario is that it is exactly what people have been looking for for more than 20 years and not finding. Braun, Ovrut et. al. aren't able to fix the moduli problem without doing something like KKLT which leads to the 10^500 possibilities, and likely complete loss of predictivity. Sure if this problem magically goes away, you'll have something predictive and be doing science, but right now this looks like pure wishful thinking to me, and wishful thinking that deadly problems will just disappear is not how science is supposed to be done.

33. **Urs**
January 18, 2006

Peter,

I tried to point out how a theory generically has infinitely many solutions. So it's not clear to me why it should be a problem if some theory has only finitely many. And this holds for strings only after some conditions have been imposed. The space of *all possible* string vacua (not restricting to flux CY compactifications) is still infinite, as far as I am aware.

I also tried to point out how, generically, from the space of all solutions one has to pick one by matching it to a subset of experimental data. Only then are predictions possible. I tried to give several well-understood examples for this.

Some people are trying to go beyond what can usually be done. They don't want to just find the right solution, but also understand "why" it is the one we observe. As with all "why" questions in science, trying to answer them tends to lead into non-scientific territory.

34. **woit**
January 18, 2006

Urs,

I'm repeating myself, but again, here's the main issue: if you can't predict anything you aren't doing science. If it is true that all these flux vacua really are legitimate string theory solutions, and one can get almost any value of the standard model parameters out of this, how are you going to predict anything? I'm still claiming that there is no plausible scenario in which this line of research leads to a testable scientific prediction. If you know of one, let's hear it. Saying that we'll be able to fix the Calabi-Yau, then make predictions isn't plausible. There's no reason to believe you will be able to fix the Calabi-Yau, to show that one works the (possibly infinite set of) others don't. And "predictions" of Planck-scale stringy effects are dubious for both practical (you can't ever do such experiments) and theoretical (perturbation theory isn't good enough) reasons.

I actually think it is only the people asking "why" questions who are still doing science, since it is not inconceivable that if you could answer the question of "why" a certain vacuum state, then you could make predictions. The people I have a problem with are those like Susskind, who claim that even if you never understand "why" a certain vacuum, you can still do science in this particular context.

35. **Urs**
January 18, 2006

> I'm repeating myself

True. And I would have to, too, if I tried to reply. So I'll leave it at that.

36. **Who**
January 18, 2006

Urs 18 January 4:13 AM
"There is no reason to expect that, once spin foam models…is well enough understood that one can talk about its space of solutions, it will turn out to provide a unique one. I expect the opposite to be true. There will be infinitely many solutions."

Having a space of solutions which is controlled by a few fundamental constants like G and h-bar is qualitatively different from having a huge out of control space of solutions, so we ought to make the difference clear.

Urs, I disagree with what you say as applied to the particular case of the spinfoam model of http://arxiv.org/hep-th/0512113
In that paper Freidel and Livine work out a model of 3D spacetime and matter which has QFT as the zero-gravity limit (as G -> 0) and General Relativity with some quantum corrections as the (semi)classical limit (as h-bar -> 0).

In that paper I do not see other constants which can vary to give a large space of solutions. However they still have to extend their results to 4D spacetime and matter.

Still I think there IS reason to expect that when and if the Freidel Livine result is extended to 4D it WILL turn out to provide a small space of solutions controlled by a small set of parameters—like a few fundamental constants.

Perhaps I am just more of an optimist than you, Urs 🙂

37. **Tony Smith**
January 18, 2006

Urs said "… Say the … modles … can be … refined such that … the low energy effective theory … produces the standard model on the nose, without any extra moduli. Let me call the string vacuum thus defined SV1. …".

Peter said "… The problem with Urs's SV1 scenario is that it is exactly what people have been looking for for more than 20 years and not finding. Braun, Ovrut et. al. aren't able to fix the moduli problem without doing something like KKLT which leads to the 10^500 possibilities, and likely complete loss of predictivity. …".

Urs then said "… from the space of all solutions one has to pick one by matching it to a subset of experimental data. Only then are predictions possible …".

It seems to me that Urs's reply does not deal with what I see as Peter's main assertion:
Even with many very smart people working for over 20 years, nobody has yet produced a concrete conventional superstring model that
1 – has no obvious fundamental flaws (moduli problem etc)
and
2 – agrees quantitatively with a significant subset of the Standard Model parameters (say, for example, ANY ONE of the following: the fine structure constant; or the weak boson mass scale; or some fermion masses; or the relative strength of the color force; etc).

Only such a concrete conventional superstring model could qualify for Urs's SV1.
IF it were to be found, THEN Urs could say that it matched "a subset of experimental data" and therefore use it to make "predictions" a la SV1.

However, since there 20 years of work by many very smart people has failed to find such an SV1, it seems reaonable to me to conclude:
that it is unlikely that further work along the same lines (conventional superstring theory) will ever find such an SV1,
and
that other approaches should be tried.

As to what kind of "other approaches", consider the remark of Pierre Ramond in hep-th/0112261 "… Nature relishes unique mathematical structures. …".
Maybe it might be reasonable to work on the possibility that the "why" question:
whether the observed set of Standard Model parameters might be unique
could be answered by "because that set is determined by a unique exceptional mathematical structure".

Although I disagree with some other positions taken by Ramond, I do agree that exceptional structures might be a basis for construction of unique and testable physics models. Two examples of approaches using exceptional structures are (as I have mentioned in other comments):

hep-th/0104050 in which Lee Smolin said: "A new matrix model is described, based on the exceptional Jordan algebra, J3(O). … There are 27 matrix degrees of freedom, which under Spin(8) transform as the vector, spinor and conjugate spinor, plus three singlets, which represent the two longitudinal coordinates plus an eleventh coordinate. Supersymmetry appears to be related to triality of the representations of Spin(8).".
and
hep-th/0012037 in which Horowitz and Susskind also deal with 27-dim structure that may be related to the exceptional Jordan algebra J3(O), saying: "We … try to interpret bosonic string theory as a compactification of a 27 dimensional theory. We will refer to this theory as bosonic M theory.".

Personally, I am disappointed that now, 5 years after those papers, Smolin and Susskind seem to be working in other directions.

I am particularly disappointed that Susskind describes his current direction in his 2005 book The Cosmic Landscape as:
"… String Theory will almost certainly have Rube Goldberg complexity and redundancy …
I don't know an equation to describe it, only a slogan: "A Landscape of possibilities populated by a megaverse of actualities." …
… [nothing] … in this book diminish[es] the likelihood that an intelligent agent created the universe for some purpose. …".

Another possible "other approach" might be the emergent vacuum picture advocated by Laughlin and Chapline (popularly described in Laughlin's book A Different Universe (Reinventing Physics from the Bottom Down)). Here is Susskind's criticism of Laughlin's approach:
"… Superfluid helium is an example of a material with special "emergent" properties … In a lot of ways, superfluids are similar to the Higgs fluid that fills space and gives particles their properties. Roughly speaking Laughlin's view can be summarized by saying that we live in such a space-filling material. He might even say … space IS such an emergent material! Moreover, he believes that gravity is an emergent phenomenon. …
There are two serious reasons to doubt that the laws of nature are similar to the laws of emergent materials. …
The first … Laughlin himself …[argues]… that black holes (in his theory) cannot have properties, such as Hawking radiation, that practically everyone else believes them to have …
[second]… insensitivity to the microscopic starting point is the thing that condensed-matter physicists like best about emergent systems. But the probability that … there should be one … endpoint … with the incredibly fine-tuned properties of our anthropic world is negligible. …".

It is sad to me that Susskind's first criticism of Laughlin assumes that "practically everyone" believes that black holes have Hawking radiation, when, in fact, even Hawking himself has repudiated (see his Dublin 2004 abstract at http://www.dcu.ie/~nolanb/gr17_plenary.htm#hawking) information loss by Hawking radiation.

It is also sad that Susskind's second criticism of Laughlin assumes that the process of emergence CANNOT produce an "endpoint" with precisely the properties that our experiments observe.
Perhaps a spin foam with J3(O) nodes might produce our observed universe,
similar to the emergence of superfluid helium from helium atoms.
Unless and until the physics community encourages research work along such lines, how will we know the answer?

Dear Urs

"I tried to point out how a theory generically has infinitely many solutions. So it's not clear to me why it should be a problem if some theory has only finitely many."

Is it possible to work backwards, from the standard model, and particles like neutrinos, electrons, quarks, and show how they are solutions to string theory? knowing what we know about electrons, is it possible to show their properties such as charge, spin, mass, etc cetera, be explained in reference to a string theory as one solution among infinitely many?

to use your other examples, while Newton's laws of motion and General Relativity do not predict what distance the sun's planets should be, they include solutions such as acceleration and force, within the framework of newton/Gr. Can the same be done with string theory?

39. **Urs**
January 19, 2006

> IF it were to be found, THEN Urs could say that it matched "a subset of experimental data" and therefore use it to make "predictions" a la SV1.

Yes, and that's what I said. If such a solution were found, it could be used to make predictions. As in: If you have identified which FRW solution matches large scale cosmology, then you can use it to make further predictions.

40. **Urs**
January 19, 2006

> Having a space of solutions which is controlled by a few fundamental constants like G and h-bar is qualitatively different from having a huge out of control space of solutions, so we ought to make the difference clear.

The space of solutions that we are talking about is essentially the space of solutions to the effective field theory equations of string theory, which look like GR+YM+ higher order corrections+this and that. This space is large in precisely the same sense as the space of solutions to the equations of pure GR is large. There are many possible configurations of the system. (Infinitely many, usually.)

This has nothing to do with the freedom in choosing dimensionful constants like G or hbar. And it is the generic behaviour of non-perturbative theories, too. There is no reason to exepect that they allow precisely one single configuration.

41. **woit**
January 19, 2006

> The space of solutions that we are talking about is essentially the space of solutions to the effective field theory equations of string theory, which look like GR+YM+ higher order corrections+this and that. This space is large in precisely the same sense as the space of solutions to the equations of pure GR is large.

The size of the space of solutions is thoroughly irrelevant. What is relevant is their structure: can you use some experimental data to fix the solution, then use it to make falsifiable predictions for the rest of the data or for future data? In GR you have no trouble doing this, in the string theory landscape you can't. The first is a science, the second isn't.

42. **Urs**
January 19, 2006

> The size of the space of solutions is thoroughly irrelevant.

Yup. Because it's generically very large, in any case.

> What is relevant is their structure: can you use some experimental data to fix the solution, then use it to make falsifiable predictions for the rest of the data or for future data?

Exactly. That's what I am saying all along.

> In GR you have no trouble doing this

Yes, GR is much easier to handle.

> in the string theory landscape you can't

I don't know of a theorem that one cannot. But certainly it hasn't been accomplished yet.

> The first is a science, the second isn't.

Are you saying string theory is a science but studying its space of solutions is not?

I think what you really mean is that the particular way this space of solutions is currently "investigated" by Susskind and others is not science.

43. **woit**
January 19, 2006

> Are you saying string theory is a science but studying its space of solutions is not?

"String theory" is lots of different things, some scientific, some not. Studying the "solutions to string theory" is scientific until the point at which you show that there are so many, capable of describing almost everything, that you can't come up with a plausible way you'll ever get predictions. If you keep working on this after that point, you're not doing science, you're just hiding your head in the sand and refusing to admit your theory has failed.

The anthropic nonsense Susskind has come up with to try and evade the implications of not being able to predict anything is one form of non-science. But I also don't think spending your time working out the details of these solutions is science if your only argument for doing this is wishful thinking: "maybe some miracle will happen and this stuff will allow predictions, even though I can't now plausibly see how this could happen".

44. **Alejandro RIvero**
January 19, 2006

It seems as if the "string theory" were now an alternative no to GUT, but to Quantum Mechanics.

45. **Urs**
January 19, 2006

> even though I can't now plausibly see how this could happen

The progress from a large number of moduli to a mere 13 was obtained by understanding the space of possibilities in more detail. Constructing these compactifications requires quite some insight into the geometry and topology of the CY appearing there. There are still simplifying assumptions in these constructions (for instance that the CY is elliptically fibred) which are made only because otherwise current technology would not allow to compute the properties of these beasts (and hence compute the predictions these solutions make).

So it's a matter of understanding the space of solutions, which is quite complicated. Currently, claims that there is a phenomenologically viable solution in that space are just as plausible or implausible as claims that there cannot be any.

46. **Ethan**
January 19, 2006

I have a problem with Urs's analogy to GR, and I think it touches on my difficulties with seeing the landscape as an interesting step to understanding the physics of the universe.

No one ever evaluated GR by comparing cosmological models. What actually happened was that people either constructed satisfactory cosmological models using GR, or using their favorite competing theory of gravity. If an alternative theory was ever discarded on the basis of cosmological observations, I'm not aware of it. GR is validated by relatively local tests, including solar system tests, and that lends credibility to our attempts to do cosmology with it, not vice versa. Our hypothetical cosmologist in a chaotic universe would believe in GR for the same reasons we do, it just wouldn't be a very useful cosmological tool for him/her/it. Understanding the universe in this case would be a lot like trying to understand the weather.

Supposing that some version of string theory is correct, and that our current understanding of the landscape is correct, i.e. that it gives us a finite, but absurdly large number of possible low energy limits. In this case it seems to me that we learn something interesting about our universe only by ignoring the landscape and exploring less ambitious phenomenological models. I can understand pursuing string theory because one hopes to narrow the range of possible low energy states to a usefully small number of choices. What I can't understand is embracing the landscape in its current form as a useful kind of physical theory.

47. **Chris W.**
January 19, 2006

Peter,

On the topic of wishful thinking, I think it's worth quoting your reminiscence about an encounter you had with Philip Anderson when you were at Princeton:

> Phil Anderson has always been somewhat of an intellectual hero for me. He's really the person who discovered the Higgs mechanism, among many other things. Despite a reputation for being a curmudgeon, at one point he was quite kind to me. At some sort of social event at Princeton to mark students passing their generals, he came up to me and told me that he had graded my solid state physics exam. He complimented me on one problem in particular, one I had got wrong. I had realized something was wrong with my solution of that problem, noting on my exam that the result I was getting couldn't be right and explaining why. **He told me that this had impressed him, that one should always *know what the result of a calculation should look like* before attempting it.**
> [emphasis added]

This was something that I recall being emphasized very strongly in my undergraduate education (as a physics major). It would be interesting to discuss where and when this guideline should be applied.

I'm sure some people would argue that it is based on an unjustified faith in physical (or mathematical) intuition, in domains where such intuition can't be relied upon. I would argue that if one's intuition is unreliable, then one should improve it by *testing it* and carefully studying those instances where it fails, ie, by identifying and elucidating the hidden assumptions that led one astray. In other words, instead of looking for a better oracle, learn to think critically—learn to make effective use of trial and error at every level you can.

(Einstein once expressed his exasperation with a certain theoretician by saying that "the man can calculate, but he can't think".)

48. **Urs**
January 19, 2006

I think the analogy to GR applied to cosmological scales is quite good. There, too, we pick a classical solution to some equations of motion, which, once fixed, predicts properties of quantum fluctuations about this solution, e.g. CMB spectra.

The reason that we can test GR locally and perturbative ST not is a matter of energy scales, not of principle.

49. **woit**
January 19, 2006

> The reason that we can test GR locally and perturbative ST not is a matter of energy scales, not of principle.

No, the reason we can test GR is that we have a consistent model of GR low energy behavior that
1. isn't completely incompatible with observations
2. once you choose a few parameters it is unique and makes real predictions.

In the case of perturbative string theory, if you don't turn on fluxes and play the other sorts of tricks KKLT does, you have unstabilized moduli and your theory is incompatible with observations. That's why you can't use the work of the people Urs is quoting to predict things, not the problem of the energy scales. If you do something like KKLT, again you can't predict anything, now because it can lead to just about any low energy physics (and, again, I'm dubious that the theory is under sufficient control at high energies to do reliable calculations).

This problem with the moduli has been around since the beginning, and all attempts I've seen to get around it have had huge problems of one sort or another. One can believe that with more work along the same lines someone will make it go away, but everything I've seen in following this more than 20 year history and looking at what people are doing now leads me to strongly believe that this is just wishful thinking.

50. **Urs**
January 19, 2006

Peter,

the problem you mention is the problem of finding a phenomenologically viable background. The reason why we don't check perturbative ST "locally" (simply by producing strings in the accelerator) is one of energy scales.

51. **Tony Smith**
January 19, 2006

With respect to finding a conventional superstring model that has no obvious fundamental flaws (moduli etc) AND agrees quantitatively with a significant subset of the Standard Model parameters:

Peter said "… This problem with the moduli has been around since the beginning, and all attempts I've seen to get around it have had huge problems of one sort or another. … everything I've seen in following this more than 20 year history and looking at what people are doing now leads me to strongly believe that this is just wishful thinking. …".

Urs said "… Currently, claims that there is a phenomenologically viable solution in … the space of solutions … are just as plausible or implausible as claims that there cannot be any. …".

So,
Peter sees the failure of many very smart people working over 20 years to find a "phenomenologically viable" conventional superstring model as an indication that it might be a bad bet to expect success from similar people doing similar work over the next few decades,
and
even Urs agrees that there is no more reason to expect success than to expect failure from continued work on conventional superstring theory.

Given that,
it seems to me absurd to continue to devote 90% of theoretical physics funding and jobs to conventional superstring theory,
and
it seems sensible to divert half of those funds and jobs to alternative approaches, such as exceptional math structures, emergent spacetime, J3(O) spin foam, etc,
and
it seems to me that such a diversion is exactly what NSF, DOE, and university administrators should undertake NOW.

While I expect that conventional superstring theorists would cry in pain and outrage at losing money and jobs (just look at how rabidly they defend their turf nowadays), why should they be treated any differently from USA manufacturing and IT workers who lost jobs that were outsourced to China and India ?

If conventional superstring theorists are really "the smartest guys in the room", then they should have no trouble retraining and adapting to a new environment.

Tony Smith

52. **Christine**
January 19, 2006

Regarding the reviewer´s comment on Susskind's book, as well as the set of very interesting comments on this post, I´d like to mention that I have recently found this talk from Dr. Andrew Chamblin (dated Feb. 24, 2004). A further (brief) search on the net (arxiv, etc) did not allow me to find a transparancy of his talk or a related paper (if you know about it, please let me know). His assertion (see full abstract from the link above) seems fragile to me because it is as if one is blindly relying on the "reality" of the cosmic acceleration in order to use it as a valid guideline for the correctness of the approach (I would like to wait a lot more to rely on this, see, e.g., astro-ph/0601377 and astro-ph/0511628, as well as the delay on 2nd year WMAP data release; there are several rumors on this). If it turns out that the cosmic acceleration is not confirmed then it seems that string theory can be simply "adjusted" to fit that (negative) observation as well. I think this is just a practical example on some points that are being discussed here.

53. **Dumb Biologist**
January 19, 2006

If I understand things remotely correctly, testing hypothetical GUT-scale physics has typically involved staring (with photomultipliers, of course) at vast quantities of ultra-pure water for years, waiting for the signature flash of light that will reveal proton decay. Presently, no protons have been observed to decay. One could conceivably build a much bigger tank, so maybe there's still some hope for testing some of the GUTs, but the outlook seem less optimistic than it once did, so I'm told.

Testing Planck-scale physics, being the energy realm virtually all agree is where gravity must be just as important as Standard Model forces, is apparently going to be a lot more difficult.

We're told one might *not* need galaxy-sized machines to probe physics relevant to the quantum gravity realm if, and only if, some best-case scenerios of various speculative q.g. approches pan out (e.g., compactified dimensions are a lot bigger than the Planck length, and hence a humanly-constructible accelerator can achieve the energies required to see the new physics such not-so-small extra dimensions give rise to).

It seems what's being said is that experimental contact with quantum gravity might only be possible if we are lucky enough to be living in a universe where things not only aren't what they seem to be, they aren't what they seem to be in a terribly fortuitous way, something perhaps to the tune of tens-of-orders-of-magnitude in terms of a particle's energy.

Otherwise, maybe quantum-gravitational effects only manifest at Planckian energies.

Watching from the seat in the bleachers provided by popularizers of physics, I've come to wonder if Unification is something mere mortals can reasonably aspire to any time in the next millennium or so. Is there presently a rational reason to presume otherwise? When does it become clear this is or is not physicists' predicament?

54. **Chris W.**
January 19, 2006

D. B.,

There is a counterargument that should be mentioned. When modern physics began, atomism lay firmly in the realm of metaphysical speculation, inherited from certain thinkers of antiquity. It gradually became grist for the theoretical mill of early physics and chemistry, and only after two centuries or more assumed an unassailable role in science. This happened because atomism proved to be an extraordinarily fruitful basis for *framing* a great variety of questions about matter, many of which led to the formulation of precise and testable hypotheses. The point is that atomism began to show its value long before we had incontrovertible empirical evidence that the atomic structure of matter was a fact. (You will note strong echoes of this in some central ideas of modern biology.)

I strongly suspect that something like this will happen with many of the problems that currently fall under the headings of quantum gravity, the unification of fields and forces, cosmology, and the foundations of quantum theory (and quantum field theory). To many people string theory feels like—or, at least, used to feel like—such an idea. I rather think it is more like a muddled hint that such an idea exists, but is not the idea itself. Nevertheless, I think such an idea is needed; we can't even clearly identify the relevant observations and paths of experimental as well as theoretical investigation without it. With it, we may see the relevance and importance of questions that the presuppositions of the Standard Model and it close relatives (GUTs) never prompted us to ask. In a number of ways I think this has already begun to happen.

55. **Tony Smith**
January 19, 2006

Dumb Biologist (actually, maybe a biologist, but certainly not dumb) said:
"… Presently, no protons have been observed to decay. …".

That is clearly the consensus view, but it may or may not be correct.
Adarkar, Krishnaswamy, Menon, Sreekantan, Hayashi, Ito, Kawakami, Miyake, and Uchihori, authors of a paper hep-ex/0008074 entitled
Experimental evidence for G.U.T. Proton Decay
say:
"… in Kolar … an experiment to detect proton decay has been carried out since the end of 1980. Analysis of data yielded … the life time of the proton is about 1 x 10^31 years …
A number of other experiments have also looked … The present consensus among these other experiments seems to be that they have not found any evidence for proton decay yet, and that the lower limit on the lifetime of proton is of the order of 10^33 years. …
The apparent contradiction between these conclusions does not mean a complete disagreement between the observations. … In our opinion, there are many points of agreement between the observations in other experiments and ours …
Since the total number of events to be analyzed and discussed is rather small, we have not fixed any special criterion to select the candidates for nucleon decay at the very beginning and we have tried to understand each event as it is. …".

It seems to me that the validity of the consensus view of proton decay rests upon choices made in analysis of the experimental data, which consists of only a small number of candidate events. If the analysis choices made by Adarkar et al were to turn out to be correct, then some types of SU(5) GUT models might not in fact be ruled out by experiment.

As an illustration of how different analysis choices affect results, here is an excerpt from the Adarkar et al paper:
"… The IMB group has reported … that they have found 4 candidate events for e+ pi0 during the observation of about 4 kty. Out of these,
two events have been rejected because of their association with muon decay signals.
The other two events, according to their analysis also have some difficulty to be considered as due to proton decay phenomenon.
One of them has a concentrated Cerenkov light cone which may come from a slow
proton and
the other event has an extra light cone due to a lower energy particle.
However, if these features are ascribed to fluctuations in cascade showers, these two events may remain as candidates for proton decay. Assuming such an interpretation, their observed rate of candidate event becomes close to our results. …".

It is my opinion that the experimental validity of proton decay by SU(5) GUT should remain an open question until all reasonable alternative analysis choices are taken into account.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

56. **D R Lunsford**
January 19, 2006

DB – to risk echoing Tony, the proton may yet decay but the cool theory with proton decay, the SU(5) gauge theory, is ruled out because not enough of them decay in a given interval. It's wrong by something like a factor of 100. I think everyone was surprised by this failure, since the SU(5) theory has a lot of nice features. That it failed, in a sense cast doubt on the structure of the standard model itself, to be sure mostly unspoken. It's just a nagging "physicist's feeling" that if SU(3)xSU(2)xU(1) were really correct, and you assumed that the strong and electro-weak forces are just parts of a whole, then SU(5) should work.

(It may yet work, if say the theory of the electro-weak interaction changes fundamentally, something that is certainly possible, given current neutrino research.)

-drl

57. **woit**
January 19, 2006

About SU(5):

I haven't looked carefully at the argument that the analysis of the proton decay experiment is wrong that Tony mentions, but I'm very skeptical for purely sociological reasons. Georgi and Glashow have a potential Nobel prize riding on this, so I find it hard to believe that they or their collaborators would be ignoring or downplaying evidence that they might be right.

I was never such a big enthusiast for GUTs like SU(5), because they have nothing to say about the big problem, where electroweak symmetry breaking comes from, and they require an even more elaborate Higgs sector. You "unify" things into SU(5), but then you have to break the unified symmetry back down to SU(3)xSU(2)XU(1) by putting in an adhoc Higgs sector. Not aesthetically convincing….

I think D.B. has it exactly right that the problem with quantum gravity is that it looks all too possible that there's no way to measure its effects. My own point of view is that an interesting solution to quantum gravity has to also tell us something about particle physics. That would be real unification and allow testing of the idea, whatever it was. The fact that string theory might potentially do this is why people got so interested in it. Too bad it doesn't work…..

Urs,

Unless you know what the background is, even if you have arbitrarily high energies available, string theory can't predict what will be seen. The problem is that the theory is unpredictive, not that we don't have the energy to check its predictions.

58. **Dumb Biologist**
January 20, 2006

Didn't know there was any controversy about proton decay results. Perhaps a larger detector could resolve it. At any rate, from what I've read, an instrument of that nature also makes a great neutrino observatory, so cosmologists and particle physicists still win, GUTs or no. It's a worthwhile project, and I'd heartily endorse it…

I guess I'd like to say, witnessing the plight of q.g. theorists is hardly a source of schadenfreude, or any other satisfaction, for me. Whether they fail or succeed, I'm at least intelligent enough to recognize their brilliance, and admire them for it. I do admit I get more than a little disturbed when some of them appear to be promoting the idea that experments can wait 1000 years if that's what it takes. It, uh, bums me out, but after my blood pressure returns to normal, I'm inspired to write my congressman and ask him to give these people a pile of money to build yet a bigger machine more than anything.

As for atomism: I thought the idea started to become much more than spurious physics, or a philosphical curiosity, when things like the ideal gas law, and other concepts dependent on statistical mechanics, started doing a very good job of describing what we see…not to mention some earlier insights from the development of stoichiometric rules in Dalton's day, and so forth. Probably there were earlier evidential hints of atomism I'm ignorant of or forgetting, but if we go back in time much further, we're entering a period where what we know as the scientific method was still in its nascent stages, and it seems hardly fair to judge those thinkers by our standards for empiricism. At any rate, many decades, maybe even well over a century before Einstein's paper on Brownian motion, it seems like there were very good, experimentally verified reasons to think matter was composed of "elemental" particles.

Perhaps I'm wrong, but sometimes I look at q.g., and it reminds me a bit of the plight of scientists exploring the origins of life. I mean, really, the entire field is predicated on the notion that there's a naturalistic, and relatively unexotic (compared to, say, aliens seeding the early Earth, or even panspermia) explanation that will rise from the primordial soup, so to speak. Given the alternatives, it's certainly the most attractive bias, and some preliminary results with autocatalyzing ribozymes certainly lend credence to some models of pre-biotic processes. Too bad RNA is so fragile. Whatever came before it (and it's generally thought something self-replicating probably must have), we've nothing but conjecture. At best we can say what, in principle, might have been possible. Beyond that, convincing verification of abiogenesis hypotheses, or, more ambitiously, a bona fide theory about how life arises, seem virtually unattainable. The evidence was lost billions of years ago, and we've only got our own planet to study, with a paltry n=1 informing all of our data about "life". Lots of good, ideas; no definitive way to test them. Fortunately, there's lots of other things to work on.

Anyway, please forgive the wet-and-squishy bio-hijack.

59. **Aaron Bergman**
January 20, 2006

"Didn't know there was any controversy about proton decay results."

There's no controversy. The damn thing just hasn't decayed yet. This pretty much rules out ordinary SU(5), and, IIRC, susy SU(5) is hanging by a thread at best. SO(10) GUTs aren't ruled out yet, as I understand it, and has some attractive features in relation to neutrino masses.

60. **Juan R.**
January 21, 2006

Thomas Larsson said,

> This could happen, of course, but I think everyone around here agrees that the odds are so small that they can safely be ignored. If so many bright people haven't gotten any quantitative predictions out of string theory in 20 years, why should things change now? Haven't people turned to the Landscape precisely because they have given up hope that any useful prediction will ever come out of string theory?
>
> Moreover, one must not forget that all natural predictions from string theory, like SUSY, extra-dimensions, 496 gauge bosons, new long-range forces, etc., are in apparent disagreement with experiments. A particularly impressive class of experiments seems to be the search for permanent electric dipole moment, which has been blogged about here, here, here, and here. It may seem strange to use experimental results to argue about theoretical physics, but I strongly feel that the by far simplest explanation for this apparent disagreement with observation is that it is due to a factual disagreement with observation.

Fantastic resume!

People -specially young one- does not know the history of the field. Since the very beggining of string theory in the strong force (last 1960s) until TODAY, string theory has been a complete failure.

It is often claimed that string theory cannot be tested. This is just untrue. All direct and indirect experimental verifications of string theory (including cosmic strings or mm-range esxtradimensions) in last near 40 years have obligated to string theorists to rewrite the theory in many ways. This has been denunciated by a number of physicists such as Nobel Prize Laugling.

And what is the final outcome?

A theory with hundred of hundred of hundred of **unspecified** parameters (instead of the few experimentally measured parameters of the SM), that cannot explain anything (**it is not predictive**) and in clear contradiction with other well-versed fields of science and with experimental data.

For example:

1) usual world is non-masless, still string theory only can rigorously deal with non-masless states.

2) The only gravity contained in typical superstring is a gravition over a flat classical spacetime. This is not GR, because GR is not a gravition over a flat spacetime with causal structure defined on the background. Precisely this is the main criticism of LQG and the search for one future M-theory…

3) Far from conjetures and half-trues the SM cannot be derived from string theory.

4) String theory requires lot of unobserved things (SUSY) but explain none of oberved things. If SUSY is observed at HLC last years, this is not a predicition of string theory not indicates that string theory is correct.

It is not a prediction because one may introduce the previously known SUSY on the old-stringy framework by pure consistency of the theory, not because was predicted from. Moreover, In nature SUSY, if observed at high energies, is not observed at usual energies.

String theory claims SUSY to all energies and therefore is in clear contradicition with experiment. No string theorists has proved how at high energies universe is SUSY but at low energies it looks non-SUSY and we observed SM of particle physics.

Conclusion: We obtain a theory that is not defined, is not scientific (not predicitive), contradicts our current scientific knowledge, ignores theorems proved on other fields of science (thermal science, complexity, decoherence and quantum measurement, etc.) deals with 10^500 'universes' but none of the hypotetical universes looks like our universe, is mathematically very deficient (math is very outdated in several ways: HSs, Calaby Yaus and G2), and aestetically very ugly (take for example the 'compactification' of the bosonic 26D into the superstring hibrid), etc.

LQG for Skeptics

January 20, 2006
Categories: Uncategorized

An interesting paper appeared on the arXiv yesterday, by Hermann Nicolai and Kasper Peeters, entitled [Loop and spin foam quantum gravity: a brief guide for beginners](). It includes some of the same material as an earlier paper [Loop quantum gravity: an outside view]() that they wrote with Marija Zamaklar.

Nicolai and Peters (as well as Zamaklar) are string theorists, and given the extremely heated controversy of the last few years between the LQG and string theory communities over who has the most promising approach to quantum gravity, one wonders how even-handed their discussion is likely to be. They identify various technical problems with the different approaches to finding a non-perturbative theory of quantum gravity that are often referred to as "LQG". I'm not an all an expert in this subject, so I have no idea whether they have got these right, and whether the problems they identify are as serious as they seem to claim. Their main point, which they make repeatedly, is that

.. the need to fix infinitely many couplings in the perturbative approach, and the appearance of infinitely many ambiguities in non-perturbative approaches are really just different sides of the same coin. In other words, non-perturbative approaches, even if they do not `see' any UV divergences, cannot be relieved of the duty to explain* in detail *how the above divergences `disappear', be it through cancellations or some other mechanism.

What they are claiming seems to be that LQG still has not dealt with the problems raised by the non-renormalizability of quantum GR. They don't explicitly make the claim that string theory has dealt with these problems, but the structure of their argument is such as to imply that this is the case, or that at least string theory is a more promising way of doing so. Their one explicit reference to string theory doesn't really inspire confidence in me that they are being even-handed:

The abundance of `consistent' Hamiltonians and spin foam models … is sometimes compared to the vacuum degeneracy problem of string theory, but the latter concerns different solutions *of the* same *theory, as there is no dispute as to what (perturbative) string theory* is. *However, the concomitant lack of predictivity is obviously a problem for both approaches.*

While they are being very hard on LQG for difficulties coming from not being able to show that certain specific constructions have certain specific properties, they are happy to state as incontrovertible fact something about string theory which is not exactly mathematically rigorous (the formulation of string theory requires picking a background, causing problems with the idea that all backgrounds come from the "same" theory, and let's not even get into the problems at more than two loops).

The article is listed as a contribution to "An assessment of current paradigms in theoretical physics", and I'm curious what that is. Does it contain an equally tough-minded evaluation of the problems of string theory?

It should be emphasized again that I'm no expert on this. I'm curious to hear from experts what they think of this article. Well-informed comments about this are welcome, anti-string or anti-LQG rants will be deleted.

Update:

There's a new [expository article about spin-foams]() by Perez out this evening.

Comments

1. **Robert**
   January 20, 2006

   Just to repeat it in plain English: When Peter says that string theory is not predictive he refers to the fact that there is likely a very large number of possible low energy effective theories (say in terms of particles and couplings). This is in contrast to LQG which according to the experts can be coupled to _any_ particle content (and possibly even anomalous) with any set of couplings. But this is not the problem that Nicolai and Peters address.

2. **Urs**
   January 20, 2006

   Robert,

   indeed. The remarkable thing is that the landscape problem is a problem other theories currently don't see, not because they somehow solve it, but because they are not understood well enough to even formulate this problem.

   For some reason the existence of many solutions to string theory is sometimes referred to a disadvantage over nonperturbative approaches. But, as I tried to say elsewhere on this blog, there is no indication that these non-perturbative approaches, once they work and are understood, will turn out to have a smaller number of configurations. Why should they? We don't expect that of any theory.

3. **Arun**
   January 20, 2006

   In LQG, presumably many different Hamiltonians/spin foam models supposedly lead to the same low energy gravity – isn't this something we know about from the Wilsonian renormalization ideas? – while in string theory the same high energy theory has 10^500 low energy worlds.

4. **woit**
   January 20, 2006

   Robert,

   I wasn't the one writing here about the lack of predictivity of string theory, that was a quote from Nicolai and Peeters. But while LQG lacks predictivity about particle physics (which is why I've never tried to become expert in it), the claim has always been that it can be consistently coupled to the standard model, producing a unified theory of gravity and particle physics. Such a theory would be predictive about quantum gravitational effects, although it is unclear that one has any hope of ever measuring these. Nicolai and Peeters are suggesting that this claim is not true, that LQG inherently contains ambiguities even in the purely gravitational sector. About that it would be interesting to hear from experts who don't have a pro-string axe to grind.

   Urs,

   For the 10^500'th time, the problem with the landscape is not the number of configurations, it's that in such a scenario you can't predict anything at all. If that's really the way the world is, and any unified theory will ultimately run into this problem, thinking about unified theories is completely pointless and the part of theoretical physics that studies these should just be shut down. Some of us would like to see some actual evidence for this before agreeing to it.

5. **Urs**
   January 20, 2006

   Arun,

   you are confusing theories and their solutions.

   > the same low energy gravity

   That is: the same low energy gravity theory.

   > 10^500 low energy worlds.

   These are solutions to such a theory.

6. **Tony Smith**
   January 20, 2006

   Peter said "… Nicolai and Peters [the authors of hep-th/0601129] … are string theorists … it would be interesting to hear from experts who don't have a pro-string axe to grind. …".

   hep-th/0601129 states that it is a "Contributed article to "An assessment of current paradigms in theoretical physics".".

   What is "An assessment of current paradigms in theoretical physics" ?

   Is it a conference or some sort of program that might eventually lead to redistribution of funding and jobs for theoretical physics ?

   Are there other "Contributed article"s that might present other points of view, including those of "experts who don't have a pro-string axe to grind" ?

   Tony Smith

7. **JKowalskiGlikman**
   January 20, 2006

   Hi,

   I am not a LQG theorist either, but I am quite close to these guys, attending their meetings etc. So while I could not really comment on detailed technical questions, I am rather well aware of the general situation.

   The first paper of Nicolai, Peeters, and Zamaklar was widely considered by experts to be rather unfair; this one I think is much better in this respect. What they present is an outside view, with obvious problems spelled out. As such it is much more important for LQG community than to others: it shows what should be urgently addressed/explained.

   The most important one is of course that in both LQG and spin foam the "right" model is not known. I do not think this is a matter of ambiguities. It is not that there are many consistent models to choose between, we are just not able to perform the most basic consistency checks (like closure of the constraints algebra in LQG) on any of them (if I understand correctly.)

   But I do not see what this may possibly have to do with non-renormalizibility of perturbative QG, which is what N&P claim.

   For me the major problem with LQG is if the quantization of area and volume is the real thing, or just an artifact of the formalism. This is the main real result of LQG, and it is used explicitly, for example, in cosmological and black hole applications.

   I would generally agree with N&P that LQG, (by which I mean the loop canonical quantization of gravity, with its particular Hilbert space, etc) has much more open problems than the solved ones and real solid predictions.

   I think however that something extremely interesting happened last year with Freidel and Starodubtsev paper "Quantum gravity in terms of topological observables," arXiv:hep-th/0501191 (built on some earlier ideas of Lee Smolin.) What they managed to show was that in 4d gravity has the structure of TFT + perturbations, with the TFT part very similar to 3d gravity and the coupling constant dimensionless and very small. Since gravity in 3d is reasonably well understood their formalism raise the hope that gravity can be perturbatively quantized, with manifestly diff invariant perturbative expansion. (of course gravitons would be extremely hard to get in this formalism, but who – apart from string theorists – cares about gravitons!)

8. **Arun**
   January 20, 2006

   Urs,

   Yes, I was confusing two different things. Nevertheless, the nonuniqueness of the LQG Hamiltonians that are consistent with the low energy theory is to be expected on general grounds, and should not impact the ability to predict (if any!!!) in the experimentally accessible regime – it is just a lot of irrelevant operators in the effective low energy theory.

   -Arun

9. **fh**
   January 20, 2006

   JKG, I'm similarily studying in the (very) close proximity of LQG, and I concurr with most of what you say. However at Loops05 Perez presented first work towards a deeper study of the ambiguities, I think he said there was a relation to non-renormalizability.

   Furthermore and even more excitingly Freidel has just gotten a further result, the non gravity limit of 2+1 gravity (not with G -> 0 but with gravitational degrees of freedom integrated out) is a non commutative field theory.

Also closure of the constraint algebra has been achieved (as a mathematically rigorous result) in a nonstandard way through Thiemann's Master constraint program.

Giesel one of Thiemann's students reported on a consistency check on the Area operator regularization, also.

So the list of problems there reads to me rather like "what people are currently working on and have been worried about for a while". THese problems are all being systematically attacked.

10. **Who**
January 20, 2006

this will sound like nit-picking
overall it's a GREAT paper, very glad to see a broad spectrum of active non-string lines of QG research being discussed including CDT and Reuter's QEG, and of course spinfoams (omitted from Nicolai's paper of a year ago) BUT

look at this omission: Nicolai Peeters give three citations to work of Laurent Freidel—-their references [47], [71] and [73]—so they came within an inch of mentioning this other one by Freidel:

http://arxiv.org/abs/hep-th/0502106
Ponzano-Regge model revisited III: Feynman diagrams and Effective field theory
Laurent Freidel, Etera R. Livine

"We study the **no gravity limit** G_{N}-> 0 of the Ponzano-Regge amplitudes with massive particles and show that we **recover in this limit Feynman graph amplitudes** (with Hadamard propagator) expressed as an abelian spin foam model. We show how the G_{N} expansion of the Ponzano-Regge amplitudes can be resummed. This leads to the conclusion that the dynamics of quantum particles coupled to quantum 3d gravity can be expressed in terms of an effective new non commutative field theory which respects the principles of doubly special relativity. We discuss the construction of Lorentzian spin foam models including Feynman propagators"

BTW the fact that they found the model must use DSR connects with the work of Jerzy Kowalski-Glikman, who just posted here.

11. **Urs**
January 20, 2006

Arun,

see http://golem.ph.utexas.edu/~distler/blog/archives/000639.html for a reply to your argument.

12. **JKowalskiGlikman**
January 20, 2006

Who says:

"so they came within an inch of mentioning this other one by Freidel" [and Livine].

This is an exciting paper, since it shows that the semiclassical limit of 3d quantum gravity is DSR, and not Special Relativity. This makes me even more excited about Freidel and Starodubtsev story, because it seems that the proof that DSR is a limit of quantum gravity seems to be within reach.

In my comment above I forgot to say that it seems to me that nobody has even slightest clue as to how to get semiclassical limit from "canonical" LQG (this was long stressed by Lee). So another consistency check of possible hamiltonians, provided by that they have to lead to consistent classical limit seems to be not available either.

13. **Who**
January 20, 2006

Hi Jerzy,
like your work on DSR.
Maybe someone should email Nicolai and suggest he add a reference to
http://arxiv.org/abs/hep-th/0502106
before his article goes to publication.

the trouble is when you do a review paper there will ALWAYS be someone who claims something important has been omitted, but
perhaps in this case the work is important enough to warrant
a message.

Freidel just co-authored a paper with Shahn Majid. I don't understand the significance of that paper—-way too technical for me. Can you please give a clue as to its bearing on QG issues?

14. **fh**
January 20, 2006

Urs, the existence of a non Gaussian UV fixed point might or might not hold, but what is not clear to me is why the infinite constants of the perturbative expansion should neccesarily reappear in the nonperturbative framework.
We don't know if the perturbatively treated effective field theory of the Einstein Hilbert Lagrangian plus higher order terms is a valid perturbative expansion of the nonperturbative theory, this is not certain by far. Particularly no field theory in the LQG Kinematical Hilbert space has infinities, Wilson renormalisation logic suggests that it will look like a renormalizable theory at low energies, but we don't have a good implementation of Wilson renormalization in the context of LQG yet. The old tools do NOT carry over flawlessly.

Particularly if you consider the strong gravity regime the causal structure of the theory changes this is not captured in the graviton expansion around a fixed background AFAIK.
In a similar vein we also don't know if for nonperturbative reasons (e.g. the statespace of the full theory, see the recent work by Perez) the couplings/ambiguities are fixed. The ambiguities appear in a rather nicely ordered way in the regularisation of the Hamiltonian constraint, it's not unreasonable to assume that for many choices you get a trivial phasespace.

15. **Wolfgang**
January 20, 2006

> Particularly if you consider the strong gravity regime the causal structure of the theory changes this is not captured in the graviton expansion around a fixed background

AFAIK.

Many are not aware that there is an exact solution of quantum gravity
in the strong-coupling limit. Maybe this ref. helps to clear up some of the issues discussed here:
http://prola.aps.org/abstract/PRD/v26/i10/p2645_1

16. **JKowalskiGlikman**
January 20, 2006

Who said

"Freidel just co-authored a paper with Shahn Majid. I don't understand the significance of that paper—-way too technical for me. Can you please give a clue as to its bearing on QG issues? "

I do not know if Peter Woit would not mind us going slightly away from the main theme, so just couple of sentences.

I did not have time to study this paper yet. As far as I understand it just refines the rather vague mathematics of the Freidel&Livine. On the other hand I suspect that given knowledge and insight of both Laurent and Shahn there might be something really exciting there.

17. **Tony Smith**
January 20, 2006

Nicolai and Peeters, in hep-th/0601129, seem to me to be doing a hatchet job on alternatives to conventional superstring theory.

After dismissing conventional LQG and Regge and dynamical triangulation approaches on the grounds of Hamiltonian difficulties, they proceed to discuss "a fixed spin foam".
Since (as Nicolai and Peeters admit) "a fixed spin foam … differs considerably from both the Regge and dynamical triangulation approaches",
they do not attack it on the basis of Hamiltonian difficulties.
However,
they do attack "a fixed spin foam" by saying that it is afflicted by
"… the true problem of quantum gravity, which lies in the ambiguities associated with an infinite number of non-renormalizable UV divergences …"
and
that "a fixed spin foam … cannot be relieved of the duty to explain IN DETAIL how the above divergences 'disappear', be it through cancellations or some other mechanism …".

However, as Peter discussed in his blog entry "Is N=8 Supergravity Finite?" at
http://www.math.columbia.edu/~woit/wordpress/?p=268 ,
"… If Bern is right, N=8 supergravity may be renormalizable because of a combination of supersymmetry and twistor geometry …
Yes, it's hard to get the standard model out of N=8 supergravity, which is one reason people gave up on it. But this may be a much more fruitful starting point than string theory … working with a well-defined theory instead of a vague hope that a theory exists might also be a good idea. …".

Even if N=8 Supergravity itself might be flawed with respect to getting the Standard Model,
it might be that some other structure with similar symmetries related to UV-finiteness could be used for nodes of a spin foam that could give the Standard Model.
It might even be that such a spin foam should be constructed in a dimension higher than 4, producing the Standard Model through a Kaluza-Klein process.

I wonder whether Nicolai and Peeters would admit that such a possibility is a reasonable alternative to both conventional superstring theory and the approaches that they dissed in hep-th/0601129, and therefore should be given funding and jobs,
or
would they point to their emphatic "duty to explain IN DETAIL how the above divergences 'disappear', be it through cancellations or some other mechanism"
and
thus put anyone proposing to work on such a possibility in the Catch-22 position of having to do the cancellation calculations in order to get funds and jobs to work on the cancellation calculations.

As to the severity of their "IN DETAIL" requirement, consider Peter Woit's remark about N=8 Supergravity:
"… divergences in N=8 supergravity don't occur until at least 5 loops. Ever tried to do a 5-loop calculation in N=8 supergravity? …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

18. **Lee Smolin**
January 20, 2006

Hi Peter, Thanks for mentioning this. After a quick look I can say that there are some statements they make that I agree with (such as about the difficiulties of relating the spin foam to the Hamiltonian constraint theory) and others with which I disagree, such as their statements about uv finiteness.

In particular, the point you quote, "the need to fix infinitely many couplings in the perturbative approach…." seems to disagree with old, well understood results. (Not to mention they don't seem to make a detailed argument for their claim.) In fact, there is a well understood and detailed explanation for how the theory is cutoff. I won't repeat the argument here (see hep-th/0408048) but the key points are that, as a result of the finitess of area and volume, one can show that the Planck length cannot suffer an infinite normalization if the theory is to reproduce the finiteness of black hole entropy,and the appearence of gravitons in perturbations around weave states. Thus, the theory is uv cutoff and the divergences do not have to cancel as they were never there in the first place. The key issue is then how is this finite cutoff length compatible with the symmetry of the ground state, which leads to the expectation that the symmetry is DSR.

But honest criticism based on detailed study is always welcome and I will read the paper carefully before seeing if I have any more substantial reponse to make.

In case anyone is interested, I am teaching a course on LQG, and video's of lectures will be available as they are given at
http://streamer.perimeterinstitute.ca:81/mediasite/viewer/FrontEnd/Front.aspx?&shouldResize=False

Thanks,

Lee

19. **Lubos Motl**
January 20, 2006

This is such an absurd comment, Peter. For example, your ideas about “experts”. Nicolai himself is a much bigger expert in loop quantum gravity than anyone whom you call an “expert”. Their previous paper is, for example, by far the most cited loop quantum gravity paper of 2005.

20. **D R Lunsford**
January 21, 2006

Lubos I see is still arguing by counting footnotes.

“find author einstein”

“read author einstein”

-drl

21. **Aaron Bergman**
January 21, 2006

The fact that you’ve cutoff the theory doesn’t obviate the need to understand the infinite series of couplings compatible with diffeomorphism invariance (and background independence for that matter). Even if you tune them all to zero at some scale, they’ll show up when you flow. Nicolai and Peeters’s claim, it seems to me, is that it is exactly this amibguity that is at least a part of the infinite ambiguity in the choice of a LQG Hamiltonian.

Myself, I still am rather skeptical about the LQG-like quantization procedure given how far it is from how we quantize, well, everything else, but that’s a different story.

22. **Haelfix**
January 21, 2006

Its also troubling, b/c the second you play with your matter content all those infinite couplings that you’ve cut off, would affect whether or not you can even *find* the correct and fundamental master interacting field theory.

Its just another statement about the RG flow, I just dont see how you can escape from the statement that LQG needs to find a nontrivial fixed point at some stage to make sense.

23. **Lee Smolin**
January 21, 2006

On reading NP I am grateful for the hard work that they put in, but I end up feeling that they still miss the point, because they have prejudices about what a quantum theory of gravity should do coming from old expectations. They appear to evaluate LQG and spin foam models as if they were proposed as a unique theory which was a proposals for a final theory of everything. This is in my view a misunderstanding. One should understand these as a large set of models for studying background and diffeo invariant QFT’s. These are based on quantization of a set of classical field theories which are constrained topological field theories. There are three key claims: 1) these theories exist, rigorously. i.e. there are uv finite diffeo invariant QFT’s based on quantization of constrained TQFT’s. 2) there is a common mathematical and conceptual language and some calculational tools which are useful to study such models and 3) there are some common generic consequences of these models, which are relevant for physics.

Nothing NP say questions these key claims. Unfortunately, they do not mention key papers which support these key claims, such as the uniqueness theorems (gr-qc/0504147, math-ph/0407006) which show the necessity of the quantization LQG uses. And while they mention the non-seperability of the kinematical Hilbert space they fail to mention the seperability of the diffeomorphism invariant Hilbert space, (grqc/ 0403047). It is unfortunate that they omit reference to such key results which resolve issues they mention.

A second misunderstanding concerns uv divergences. NP do not discuss the results on black hole entropy, so they miss the point that the finiteness of the black hole entropy fixes the ratio of the bare and low energy planck length to be a finite number of order one. Calculations on a class of semiclassical states they do not discuss-the weave states-lead to the same conclusion (A. Ashtekar, C. Rovelli, L. Smolin, Weaving a classical metric with quantum threads,” Phys. Rev. Lett. 69 (1992) 237.). So there can be no infinite refinement of spin foams and no infinite renormalization. These theories are uv finite, period. This is one of the generic features I mentioned.

Thus, their main claim, that the fact that there are many LQG or spin foam models is the same as the problem of uv divergent is just manifestly untrue. The freedom to specify spin foam amplitudes does not map onto the freedom to specify parameters of a perturbatively non-renormalizable theory. For one thing, few if any spin foam models are likely to have a low energy limit which is Poincare invariant, a property shared by all perturbative QFT’s, renormalizable or not, defined in Minkowski spacetime. In fact, we know from recent results that in 2+1 none do-the low energy limit of 2+1 gravity coupled to arbitrary matter is DSR. So their argument is false.

They do get a number of things right. The following are open issues, much discussed in the literature: 1) whether there is any regularization of the Hamiltonian constraint that leads to exchange moves, 2) whether thus there are any links between the spin foam amplitudes and Hamiltonian evolution, 3) whether the sum over spin foam diagrams is convergent or, more likely, Borel resummmable (although they miss that this has been proven for 2+1 models, hep-th/0211026). I don’t agree with all the details of their discussion of these issues, but these certainly are open issues.

NP seem to argue as if one has to prove a QFT rigorously exists in order to do physics with it, by which standard we would believe no prediction from the standard model. They mention that there are no rigorous constructed, semiclassical states, which are exact solutions to the dynamics, but this is the case in most QFT’s. This does not prevent us from writing down and deriving predictions from heuristic semiclassical states (hep-th/ 0501091), or from constructing reduced models to describe black holes or cosmologies and likewise deriving predictions (astro-ph/0411124), Nor does it prevent Rovelli et al from computing the graviton propagator and getting the right answer, showing there are gravitons and Newtonian gravity in the theory (gr-qc/0502036).

But, someone may ask, if LQG is the right general direction, shouldn’t there be a unique theory that is claimed to be the theory of nature? Certainly, but should the program be dismissed because no claim has yet been made that this theory has been found? To narrow in on the right theory there are further considerations, all under study:

-Not every spin foam model is ir finite.
-Not every spin foam model is likely to have a good low energy limit.
-The right theory should have the standard model of particle physics in it.

In addition it must be stressed that there can in physics be generic consequences of classes of theories, leading to experimental predictions. Here are some historical examples: light bending, weak vector bosons, confinement, principle of inertia, existence of black holes. All of these observable features of nature are predicted by large classes of theories, which can be as a whole confirmed or falsified, even in the absence of knowing which precise theory describes nature, and prior to proving the mathematical consistency of the theory. LQG predicts a number of such generic features: discreteness of quantum geometry, horizon entropy, removal of all spacelike singularities, and I believe will soon predict more including DSR, emergence of matter degrees of freedom.

One reason for this is of course that most of the parameters in such classes of such theories are irrelevant in the RG sense, and do not influence large scale predictions.

Since we know the theory is uv finite this does not affect existence. The lack of a uv unique theory does not prevent us from testing predictions of QFT in detail, and it is likely to be the same for quantum gravity. The old idea that consistency would lead to a unique uv theory that would give unique low energy predictions was seductive, but given the landscape, it is an idea that is unsupported by the actual results.

Having said all this, I hope that NP will put their hard won expertise to work, and perhaps get their hands dirty and do some research in the area.

Sorry to go on so long,

Thanks, Lee

ps to Haelfix, sure, why not work on RG flow in LQG?

24. **Lubos Motl**
January 21, 2006

Dear Lunsford,

the database does not claim to cover the early 20th century physics. Nevertheless, you will still see that Einstein has 33 papers in it – which may in fact be close to the total – and they have over 1150 citations which is more than some of us.

I am certainly using different criteria but sorry to say, having at least some well-known papers is a necessary condition for someone to be expected to have something relevant to say about science.

All criteria I can imagine imply that Nicolai and Peeters are LQG experts.

Best wishes
Lubos

25. **Lubos Motl**
January 21, 2006

Dear Lee,

how are you? Sorry to say but I don't quite understand how Haelfix can work on something that violates the laws of physics. If you would have said "write an upbeat paper that combines the buzzwords from LQG and RG", then it would be a realistic task. And the paper would make no sense much like when one combines LQG and quantum computing or noiseless information theory or any two decoupled pieces of jargon. There are already many papers of this type around.

In physics, it is impossible to make progress just by combining two random buzzwords.

Haelfix has, on the contrary, explained why he already knows that certain things cannot work and why. LQG is not a local field theory and by its very construction and the discrete philosophy, it does not have a UV fixed point (because distances below 0.1 L Planck do not exist). Consequently, the extreme UV physics is not determined (in a theory with a UV fixed point, it could be determined by conformal symmetry). The physics starts at the Planck scale, if ever, and because there is no other organizing principle than the existence of fundamental metric tensor (a wrong assumption for quantum gravity, by the way), it is clear that all higher-derivative and other terms must be considered. That's not surprising because they are of the same order at the Planck scale.

Because there are no "more fundamental" degrees of freedom and no other organizing principle, the continuous coefficients of all these couplings can be anything, rendering LQG infinitely unpredictive – exactly as unpredictive as the perturbative nonrenormalizable GR written as effective field theory.

Maybe you meant that LQG should try to obtain a long-distance limit. Hundreds of people have tried, have not they? I find it manifest today that no one will every find one because it does not exist. Gravity is not lattice QCD, and the failure to choose the correct UV starting point not only destroys the "correctness" of physics. It destroys the very existence of low-energy physics. In string theory, we have a toy model of this possible problem because in the UV, one must choose the right (or even fine-tune by discrete choices) the vacuum energy for large space to exist in the first place.

In LQG, you also have the cosmological constant problem but you also have infinitely many similar problems associated with ever higher-derivative tems that are expected to crumple the space altogether, unless you fine-tune infinitely many terms in the Hamiltonian constraint. The task you are trying to give to Haelfix is not well-defined and even if the definition were completed, it would be guaranteed to fail.

"One reason for this is of course that most of the parameters in such classes of such theories are irrelevant in the RG sense, and do not influence large scale predictions. Since we know the theory is uv finite this does not affect existence. The lack of a uv unique theory does not…"

If you read these lines of yours rationally, they're equivalent to saying that we know the classical limit of general relativity (given by the Einstein-Hilbert term). But the whole point of *quantum* gravity is that we can also say something about higher energies and/or precision experiments at low energies that get loop corrections from quantum phenomena. You can't do it. Moreover, it is not true that you can even derive the leading term of classical general relativity.

What you're saying, Lee, is completely equivalent to saying that nonrenormalizable field theories exist as quantum theories, and it's just manifestly wrong. Whether or not the numbers "look" finite is completely irrelevant. If we choose a cutoff of any sort we like in quantum field theory, we will also get finite numbers. Finiteness is not the problem. The problem is the presence of infinitely many undetermined parameters.

Another approach that can never lead to realistic science is the permanent promotion of complete rubbish papers, being satisfied by the fact that they were written. Rovelli's "graviton propagator" is an example. He incorrectly assumes that physics is dominated by nearly flat space, and then he "derives" that physics is dominated by nearly flat space. The reasoning is completely circular and has nothing to do with LQG whatsoever. Even if there were some truth in LQG, one could never start to make progress in revealing it before the papers are read rationally and critically and before patently false papers start to be neglected.

All the best
Lubos

26. **Zorq**
January 21, 2006

I love the circularity of Lee's argument that LQG must be a finite theory because, otherwise it gets the BH entropy wrong.

But, even accepting the statement that the low-energy G_N and the lattice G_N are related by a finite multiplicative factor does not demonstrate what he thinks it demonstrates. He has imposed a cutoff at the Planck length. G_N is itself of order l_P^2. So an ordinary quadratically-divergent correction to G_N just looks like a finite multiplicative renormalization. Only if he attempted to take the cutoff to zero (which he doesn't) would he be able to distinguish the two.

Besides, there's also the infinite number of other diffeomorphism-invariant, background-independent couplings to deal with. Saying that almost all values of those couplings will not lead to sensible low-energy physics (one of his arguments) is not the same as saying they are IR-irrelevant couplings, so that low-energy physics is independent of what values you choose (another one of his arguments).

27. **Quantoken**
January 21, 2006

Lee and Lubos:

I clearly see your discussions forming a Loop of Quantum Loops since they are not going any where. Each of you accuse the other camp for failure of making predictions. Let's set the score fair and sqaure: Both have failed to make any meaningful prediction so far. So let's start a fair and equal debate that neither one is better than the other so far in predictability.

Lee claims that LQG has made an experimentally verifiable prediction by predicting dispersion of light speed (light speed is not exactly constant, but has a small variation at high energies, depending on the energy level). I disagree. Predictions need to be definite, quantitative and precise. Tiny dispersions may be observed and maybe not, one of the other. it's a 50/50 chance if you happen to pick the right choices out of the two. Unless you have predicted the exactly amount of dispersion, quantitatively, and show that experimental result matches your numerical calculation precisely, it really can't be counted as a credible verifiable prediction just because there happen to be a small dispersion. Especially consider that the space of the universe is not exactly vacuum, but contains some imtermediate material at extreme low concentration, so dispersion of some sort due to condensed matter physics MAY some how occur.

The super string theory camp is equally guity of making such ambiguious "predictions" that amounts to nothing more than chasing a shadow. One case being the CSL-1 business. Lubos made more than a few enthusiastic hypes cosmic string about that two fuzzy little dots in a telescope image, until it's shown by Hubble they are nothing more than two little tiny galaxies far away. Had hubble be slightly less in instrumental precision, they would now all be celebrating with champane that super string theory has made a prediction that is verified by observation. Be a little bit more specific, precise and exact when you make predictions, OK?

There is a fundamental philosophy difference between Lee and Lubos that Lee believes the universe is inheritantly discrete, but Lubos believes it is inheritantly continuous, beyond the discrete phenomenas that we observe in QM. Maybe we can have more discussions between the discrete picture and the continuous one. That would be a more interesting discussion.

I liked Zorq's points.

The Immirzi parameter can indeed be considered as a multiplicative renormalization of Newton's constant between the Planck scale and low energies. By construction, it is finite as long as G_{Newton} stops running at very long distances – which is so if classical GR is reproduced. The finiteness is no consistency check. The finiteness was put in by construction. The precise value is unknown and there are contradictory results for the values which is why Lee will never tell us a trustworthy value of the Immirzi parameter.

However, there are still constants at low energies – starting from Newton's constant – that do depend on the exact higher-derivative terms (or their equivalents, in whatever language we use). If something is IR-irrelevant, it does not mean that the numerical values in the IR won't be affected by these irrelevant terms. They will be affected because the IR-relevant and marginal parameters will run as a function of the irrelevant couplings.

More generally, the obsession with finiteness obscures the fact that the finiteness of some intermediate results is not really difficult to achieve. Any regularization or any scheme of cutoffs will do. The problem is to make a theory whose predictions are independent of the cutoff – which is a part of renormalization governed by the rules of renormalization group (which is NOT the same thing as regularization).

If the predictions depend on the cutoff, then we have just parameterized our ignorance about the singular physics in terms of the details of the cutoff.

In renormalizable QFTs, we obtain physics independent of the cutoff because we can organize the terms into a small number of IR-relevant and IR-marginal operators and argue that the irrelevant ones are suppressed by a higher energy scale. In perturbative string theory, we may obtain the same or better control because the fundamental theory is really living on the worldsheet and it must be conformal which is a strong constraint (and somewhat analogous to the constraint of renormalizability of QFTs mentioned previously).

In AdS/CFT, there are other constraints of the possible form of the physical laws, and all of us would like to know the most general type of constraint that can give us any consistent background of string theory – something that generalizes the conformal symmetry above (and that probably does not allow us to write the full theory in terms of any local quantum field theory or any worldsheet or boundary). But in LQG, we know for sure that these organizing principles are missing.

29. **Lee Smolin**
January 21, 2006

To Zorq, I apologise that the one argument I gave is far from the whole story. I agree that to define a theory you have first to define a regulated theory and then study the limit as the regulator is removed and show that the expressions for observables that result have the symmetries and gauge invariances of the classical theory. The physical parameters are parameters of the resulting theory. But this was exactly what was done in the hamiltonian construction of LQG, the observables such as area and volume are constructed through a limit of regulated operators and then the limit is taken. The result is finite, diffeomorphism invariant observables. The parameters of the finite, diffeo inv. theory include the bare Newton's and cosmological constant-not as coefficients in the dynamics but as coefficients in the algebra of observables. The diffeo invariance is proved restored in the limit. And don't be confused, the bare planck scale was not the regulator, there was another regulator, that has already been taken to zero. Please study the details of the construction.

So what you ask for has been done-the logic is not circular and the theory is finite. I was addressing the proposal to still take a limit of the parameters vanishing, even after the limit of the regulator to zero is taken. This would be non-standard, and it leads to results in disagreement with the semiclassical theory.

To quantoken: obviously it would be better to have precise predictions than generic ones. But generic ones can still distinguish between classes of theories. If GLAST sees an energy dependent, polarization independent speed of light, thus confirming that the symmetry of the vacuum is DSR, this obviouosly kills theories that predicted either broken or naive Poincare invariance and supports the plausibility of theories that predict-even generically DSR.

I can't agree with your equivalanece of LQG and string theory just because of the vast imbalence in how much work has been put into each. For each point about string theory there are dozens of papers, so the ins and outs of each issue have been often thoroughly explored. Key facts about LQG still rest, in many cases on one or a few papers. There are many obvious things to do that have not been tried for lack of people. So there is a lot still do to, for example to turn generic predictions into precise predictions.

And I don't "believe" nature is discrete, we showed this is a generic property of a large class of diffeo invariant QFT's.

I'll reply to the rest later,

Lee

30. **anonymous**
January 21, 2006

Lumos has a long list of publications about speculation on unobservables. So I guess he's well qualified to make vacuous assertions. What I'd like to see debated is the fact that the spin foam vacuum is modelling physical processes KNOWN to exist, as even the string theorists authors of http://arxiv.org/abs/hep-th/0601129 admit, p14:

'… it is thus perhaps best to view spin foam models … as a novel way of defining a (regularised) path integral in quantum gravity. Even without a clear-cut link to the canonical spin network quantisation programme, it is conceivable that spin foam models can be constructed which possess a proper semi-classical limit in which the relation to classical gravitational physics becomes clear. For this reason, it has even been suggested that spin foam models may provide a possible 'way out' if the difficulties with the conventional Hamiltonian approach should really prove insurmountable.'

Strangely, the 'critics' are ignoring the consensus on where LQG is a useful approach, and just trying to ridicule it. In a recent post on his blog, for example, Motl states that special relativity should come from LQG. Surely Motl knows that GR deals better with the situation than SR, which is a restricted theory that is not even able to deal with the spacetime fabric (SR implicitly assumes NO spacetime fabric curvature, to avoid acceleration!).

When asked, Motl responds by saying Dirac's equation in QFT is a unification of SR and QM. What Motl doesn't grasp is that the 'SR' EQUATIONS are the same in GR as in SR, but the background is totally different:

'The special theory of relativity … does not extend to non-uniform motion … The laws of physics must be of such a nature that they apply to systems of reference in any kind of motion. Along this road we arrive at an extension of the postulate of relativity… The general laws of nature are to be expressed by equations which hold good for all systems of co-ordinates, that is, are co-variant with respect to any substitutions whatever (generally co-variant). …' – Albert Einstein, 'The Foundation of the General Theory of Relativity', Annalen der Physik, v49, 1916.

What a pity Motl can't understand the distinction and its implications.

31. **Zorq**
January 21, 2006

Lee,

You seem to make a strange (and nonstandard) distinction between a "finite theory" and an "RG fixed-point" theory. What is the distinction?

N=4 SYM is a finite QFT. It is also a fixed-point of the Renormalization Group. Moreover, it is a fixed point for any value of the gauge coupling.

You claim that LQG, with all (the infinite number of) couplings except for the cosmological constant and Newton's constant set equal to zero is a finite theory (an RG fixed point). Do you want to claim that this is true for ANY values of Newton's constant and the cosmological constant, or just for some special values (as claimed by Reuter et al)?

32. **Lubos Motl**
January 21, 2006

Dear Lee,

what you write about the regulators is internally inconsistent. If the limit depends on the regulator in a diff invariant theory and when the regulator contains as many parameters as a generic effective field theory or more, which is easy to see in LQG, then you cannot guarantee that the 4D results will be diffeomorphism invariant simply because you can see that the 4D nondiff invariant results will be generated.

A subtlety may be that you don't quite distinguish the 3D diffeomophisms from the 4D diffeomorphisms. The latter include the Hamiltonian constraint. In the Hamiltonian treatment, the failure to obtain diffeomorphism-invariant physics will be manifested as the failure of the constraint algebra to close on the kinematical Hilbert space. This failure of the LQG algebra, including the Hamiltonian constraint, to close in LQG was discussed in the previous paper by Nicolai et al.

(This statement has its known counterpart in string theory: in the light-cone gauge, the critical dimension arises from the correct commutators of the Lorentz group.)

When you say that you obtain diff invariant results, you surely mean the 3D diffeomorphisms only, but that's just not enough for gravity. The difficulties to extend some 3D results to the full 4D spacetime is of course related to the general problems with dynamics in LQG and its failure to reproduce any symmetry between space and time, especially not the Lorentz symmetry.

Finally. this statement is really cute:

"And I don't "believe" nature is discrete, we showed this is a generic property of a large class of diffeo invariant QFT's."

What you have shown is that a class of discrete theories (that have no continuous limit or any other relation with physics) has the property that its elements are discrete theories. It is a completely vacuous and circular statement, and it in no way suggest that these theories are interesting as theories that physicists should study.

Best
Lubos

33. **Lubos Motl**
January 21, 2006

Dear Zorq,

surely no one wants to claim that gravity with a nonzero Newton's constant is a conformal field theory. It has a scale because Newton's constant is dimensionful. The same thing applies to the cosmological constant.

Your equivalence between finiteness and UV conformal symmetry is only valid for QFTs in continuous spaces. LQG is not a QFT in this sense. It can be in some sense finite as any other discrete, regulated, or latticized theory. But of course, its continuum limit must behave as an effective field theory for which having a UV fixed point is equivalent to finiteness.

Strictly speaking, we know that LQG can't have a UV fixed point exactly because the spectrum of its areas and eigenvalues of other dimensionful observables is discrete, and therefore it is not scale-invariant. This pretty much kills the hopes of a UV fixed point that are plausible in other, more general candidate theories of quantum gravity.

Because of these reasons, the discrete character of spacetime in LQG is on the same level as with any other generic regulator that someone may invent. The Hamiltonian formalism can guarantee that the regulator is invariant under 3D diffeomorphisms, but it has been shown that it is not invariant under 4D diffeomorphisms. In the Hamiltonian treatment, this fact is manifested as a non-closure of the constraint algebra if it acts on the original full kinematical Hilbert space (see the Nicolai et al. paper 1 year ago).

All the best
Lubos

34. **Zorq**
January 21, 2006

"Your equivalence between finiteness and UV conformal symmetry is only valid for QFTs in continuous spaces."

I didn't say anything about (UV) conformal invariance.

A finite theory gives cutoff-independent answers. An RG fixed-point is one where the coupling constants don't vary as you vary the cutoff. With the normal meaning of these terms, these are the same concept.

As you say, LQG is abnormal in many ways. But if these terms mean the same thing to Lee that they usually mean, then they are still synonymous in LQG. If they mean something different to him, I'd like to know what that is.

35. **Lubos Motl**
January 21, 2006

Dear Zorq, while I agree with nearly everything you write, your usage of the word "cutoff" confuses me. Cutoff independence is something different from conformality. The Standard Model – or a GUT theory to be better – is cutoff-independent but it is not a conformal field theory. It has a conformal UV fixed point (at least in the case of asymptotically free Yang-Mills) but still, one should recognize the dependence on the cutoff from the dependence on the chosen RG scale.

36. **arnold**
January 21, 2006

As a non-expert could anybody clarify to me this doubts?

1.If I understand well, LQG is the quantization program applied to GR (so I don't even know why it has a different name). Right?

(this seems to me the most natural thing to do in order to quantize gravity)

2. why a theory with infinite number of constant cannot be the correct theory?

thanks

Ponzano-Regge model revisited III: Feynman diagrams and Effective field theory
Jerzy K-G says (20 jan 1:57P)
http://www.math.columbia.edu/~woit/wordpress/?p=330#comment-7742

——-quote from Jerzy in this thread——

"so they came within an inch of mentioning this other one by Freidel" [and Livine].

This is an exciting paper, since it shows that the semiclassical limit of 3d quantum gravity is DSR, and not Special Relativity. This makes me even more excited about Freidel and Starodubtsev story, because it seems that the proof that DSR is a limit of quantum gravity seems to be within reach.
————end quote——————–
This illustrates Smolin's point about classes of theories making TESTABLE generic PREDICTIONS

It's an important point and to recognize and emphasize it would help clarify this discussion

As Smolin uses the term, LQG is a CLASS of theories including spin foam models. There is current uncertainty about whether this class generically requires DSR. If it does, then it would tend to refute LQG if the GLAST satellite does not see DSR, when put in orbit next year or so.

It seems to me that to some extent LQG critics waste their time unless they not address LQG as a class of theories (including spin foam models) because when blanket statements are made one often has the impression that the critics lack a clear idea of what they are talking about. They should also be talking about upcoming possibilities for tests—that is how to dispose of a scientific theory, not by quibbling.

Anyway, LQG is a class of theories where in recent years a major focus of research has been spin foam models, I would guess that has been the main focus. One goal the researchers have is to NARROW DOWN the class and extract further generic predictions so that one can TEST. Here is what Smolin says along these lines:
http://www.math.columbia.edu/~woit/wordpress/?p=330#comment-7757

—-Smolin 21 jan 9:51A—
But, someone may ask, if LQG is the right general direction, shouldn't there be a unique theory that is claimed to be the theory of nature? Certainly, but should the program be dismissed because **no claim has yet been made that this theory has been found**? To narrow in on the right theory there are further considerations, all under study:

-Not every spin foam model is ir finite.
-Not every spin foam model is likely to have a good low energy limit.
-The right theory should have the standard model of particle physics in it.

In addition it must be stressed that **there can in physics be generic consequences of classes of theories, leading to experimental predictions.** Here are some historical examples: light bending, weak vector bosons, confinement, principle of inertia, existence of black holes. **All of these observable features of nature are predicted by large classes of theories, which can be as a whole confirmed or falsified, even in the absence of knowing which precise theory describes nature,** and prior to proving the mathematical consistency of the theory. LQG predicts a number of such generic features: discreteness of quantum geometry, horizon entropy, removal of all spacelike singularities, and I believe **will soon predict more including DSR, emergence of matter degrees of freedom.**
—-end quote—

In sum, I think LQG critics' effort would be better spent asking what progress the LQG community is making in narrowing down and making the class of theories testable. It is a waste of time for a critic to pick one representative theory which he imagines to be representative and to quibble over it, and to try to give the impression that "it" (whatever he thinks it is) will never work.

Incidentally I don't think Nicolai and Peeters make this mistake. They are making a constructive effort to shed light on the LQG field of research.

38. **woit**
January 21, 2006

arnold,

1. In general, one doesn't expect what it means to "quantize" a classical theory to be unambiguous. LQG chooses different variables to work with and tries to find a non-perturbative quantum theory whose classical limit is GR. The whole discussion here comes about because this is not the standard quantization one uses in perturbing around flat space, using the metric components as dynamical variables. Because this is a new set-up, there is still a lot that is not well-understood.

2. Unless the infinite number of constants have special properties, one would expect their existence to ruin the predictivity of the theory, since no matter how many constants you fixed by experimental measurements, you still wouldn't be able to predict the results of new experiments, since they would still depend on unknown constants.

39. **arnold**
January 21, 2006

Thanks Peter,

1. I agree with you that there might be ambiguities. It would be interesting to hear something about that from LQG people.

2. I am not sure I agree on that for several reasons:
2.1
how can we know that the correct theory has to be also predictive? Maybe nature knows the value of the parameters, but maybe we humans will never know them all…
2.2 are we sure that a theory with infinite # of paramters is not
predicting anything?
For example by making assumptions on these parameters one could
be able to predict something (and then check if the assumptions are correct by experiments…).
2.3 In some sense the Standard Model has the same problem…but one assumes that all the higher order operators are negligible(or zero)…and then checks the assumption in the lab (and for now the assumption is confirmed)

40. **Zorq**
January 21, 2006

I never used the word "conformality." You did.

All I did was repeat the following standard argument. Consider some physical observable, f. When you compute it in the cutoff theory, it depends both explicitly on the cutoff and on the bare couplings, g_i, of the cutoff theory.

f= f(a,g_i)

The RG tells you how to change the g_i when you vary the cutoff, in order to assure that f does not change.

0 = a df/da = a \partial f/\partial a + \sum_i b_i \partial f/\partial g_i

where

b_i(g) = a \partial g_i/\partial a

are the beta-functions of the theory.

Finiteness is

\partial f/\partial a = 0

An RG fixed-point is b_i(g_*)=0 for all i. These are the same.

Only in a global (non-gravitational) field theory are they related to dilatation (conformal) invariance.

41. **Lubos Motl**
January 21, 2006

Dear Arnold,
you ask:

"1.If I understand well, LQG is the quantization program applied to GR (so I don't even know why it has a different name). Right?"

It is because pure GR in spacetime with dimensions above 3 cannot be quantized. GR is a non-renormalizable effective field theory. A different word is needed for GR and for this direct attempt to quantize it simply because classical GR is serious physics while the attempts called LQG are not serious physics and all serious theoretical physicists understand why it cannot work.

"(this seems to me the most natural thing to do in order to quantize gravity)"

It may seem natural to the laymen but it is impossible in science once the "details" are actually investigated.

"2. why a theory with infinite number of constant cannot be the correct theory?"

It cannot be a correct theory because it cannot be a theory at all. A theory means a finite system of ideas and assumptions that can in principle be determined, written down and used to make predictions, at least approximate ones. A spiritual system with infinitely many important unknowns does not satisfy this definition of a theory. A spiritual system with infinitely many continuous unknowns is just a way to parameterize (complete) ignorance, not a way to gain knowledge.

Best
Lubos

42. **Lubos Motl**
January 21, 2006

Dear Zorq,

sorry for my being slow but I am afraid that you have not yet explained what you mean by an RG flow that is unrelated to a dilatation – regardless whether the theory has gravity ir not – and consequently, how can a fixed point fail to be scale-invariant.

Best
Lubos

43. **Tony Smith**
January 21, 2006

Peter said, about LQG / Spin Foam / etc models:
"… Unless the infinite number of constants have special properties, one would expect their existence to ruin the predictivity of the theory …".

Isn't and example of such "special properties" the "combination of supersymmetry and twistor geometry" mentioned by Peter in his blog entry at http://www.math.columbia.edu/~woit/wordpress/?p=268 about Zvi Bern's work on fineteness of N=8 Supergravity ?

It seems to me that it would be useful to direct substantial funds and jobs to work on models using exceptional structures related to the exceptional structures of N=8 Supergravity in the hope that:
1 – such models might be finite;
2 – at least one such model might include gravity plus the standard model; and
3 – due to the exceptional nature of the building blocks of such models, such a realistic model might be seen to be unique.

An example of a specific proposal for one such model would be a J3(O) exceptional Jordan algebra high-dimensional spin foam. It is just one example so that readers can see that this proposal is neither vacuous nor limited to supergravity models. Of course, I would advocate pursuing many types of models that use such exceptional structures in various ways.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – As I stated earler, I remain (to use Peter's words) "… curious what … "An assessment of current paradigms in theoretical physics" … is …".
Does anyone reading this blog know? Would they care to share their knowledge here?

44. **JKowalskiGlikman**
January 21, 2006

Just to clarify one thing.

Lee Smolin said:

"If GLAST sees an energy dependent, polarization independent speed of light, thus confirming that the symmetry of the vacuum is DSR, this obviously kills theories that predicted either broken or naive Poincare invariance and supports the plausibility of theories that predict-even generically DSR."

Well, there is a long lasting discussion in the DSR community as to whether DSR predicts energy dependent speed of light. I personally do not think so.

Basically the reason being that there are two effects which should be taken into account when calculating the speed: the modified dispersion relation and the modified phase space structure. In the DSR models based on non-commutative space-time both these effects cancel neatly, so that the speed of massless particles is exactly 1, though the expression for velocities as functions of energies for massive particles differ from the standard one. (more details can be found in hep-th/0405273.)

I must stress however that some experts like Lee, Joao Magueijo, and I think also Giovanni Amelino-Camelia do not agree with this.

45. **Aaron Bergman**
January 21, 2006

Before deciding whether to wade into the rest of this discussion, I just wanted to address this:

In general, one doesn't expect what it means to "quantize" a classical theory to be unambiguous. LQG chooses different variables to work with and tries to find a non-perturbative quantum theory whose classical limit is GR. The whole discussion here comes about because this is not the standard quantization one uses in perturbing around flat space, using the metric components as dynamical variables. Because this is a new set-up, there is still a lot that is not well-understood.

The situation is much "worse" than this in my opinion. LQG used a quantization techinque which is fundamentally different than the approach we use to quantize all the field theories we understand. If we apply the LQG-type quantization to theories like QCD, we get an experimentally wrong answer. Now, Lee will say that because he wants thing to be "background independent", the only choice is to use this new quantization technique and that experiment is the only way to resolve the question. The latter part is certainly correct, but that doesn't change the fact that LQG is not the same as quantization-as-we-know-it.

46. **Thomas Larsson**
January 22, 2006

The latter part is certainly correct, but that doesn't change the fact that LQG is not the same as quantization-as-we-know-it.

You don't need to be a string theorist to be worried about this. As I see it, one must cope with two key lessons:

1. The key lesson from GR may be manifest background independence, which I interpret as a action of the **full space-time** diffeomorphism group on the dynamical objects alone.

2. The key lesson from QM is that, well, it is QM in the conventional sense. In particular, the Hilbert space carries a representation of the one-parameter time evolution group, and this representation must be of lowest-weight type, cf. the harmonic oscillator.

How these lessons should be combined is left as an exercise for the reader.

47. **Anonymous**
January 22, 2006

Lee, how do you expect the matter degrees of freedom to emerge?

50. **Lee Smolin**
January 22, 2006

Zorq, the distinction between a finite theory and a uv fixed point is the following: a lattice QFT or condensed matter physics model with a fixed lattice spacing is a finite theory. You can still apply the RG to study the infrared behavior. The point in LQG is that AFTER carrying out the regularization procedure and defining the diffeo invariant states and operators from the limit of the regulator removed, there remains a theory with a fixed, but spatially diffeo invariant cutoff. So it is like a lattice theory in being intrinsically finite, except that all the states are spatially diffeo invariant. So the physical theory has a fixed cutoff. One place this is explained in detail is Rovelli's book, pages 280-282, another is my review hep-th/0408048. To see how this is done rigorously see Thiemann's gr-qc/0110034 or Ashtekar-Lewandowski GR-QC 0404018.

Lubos, the finiteness is achieved kinematically, once the procedure just described is done the theory is uv finite WHATEVER the dynanmics, again just as in a lattice QFT with fixed lattice spaceing. But, to continue with my example of 2+1, which you misunderstood, is that the symmetry of the groundstate is not put in, it is determined dynamically. In 2+1 it turns out to be kappa-Poincare. This cannot agree with perturbation theory carried out as an expansion around Minkowski spacetime, which order by order assumes ordinary Poincare invariance.

I agree there is an issue in the Hamiltonian theory with full spacetime diffeo invariance, which is one of several reasons I always discuss dynamics in the spin foam picture.

Thomas and Aaron, this has been discussed before. For QFT the harmonic oscillator kind of quantization leads to Fock space. The inner product of Fock space depends on the background metric, hence this quantization will never arise in a background independent formalism. So we do not avoid it because we are stupid, it is simply not an option. The question is then to find an inner product for states which are functionals of a connection mod spatial diffeos. The only known way to do this is to first construct a kinematical Hilbert spaced that carries an exact non-anomalous rep of the spatial diffeos and then use that unitary rep to mod out by the diffeos . The uniqueness theorems tell us the result is unique. If you don't like this please at least acknowledge the argument just described and either accept it or propose an alternative background independent quantization and do the work to show it is consistent.

Anonomous: See my talk at the loops 05 conference, details are in a paper under preparation.

51. **Thomas Larsson**
January 22, 2006

either accept it or propose an alternative background independent quantization and do the work to show it is consistent.

Such a proposal was discussed in the end of this thread, in particular in this post. For details, see e.g. this forthcoming book The manuscript is not available online for copyright reasons, but similar material can be found in hep-th/0411028, hep-th/0501043, and hep-th/0504020.

Today I was rereading gr-qc/9903045, since the more philosophical papers by Rovelli belong to my favorite literature. The key message I got out of it is that one should believe both in QM in GR, or rather in the key ideas of both theories. To me, the key property of QM is encoded in lowest-energy representations. Consequentially, anomaly freedom must be given up, but we knew that from 2D gravity anyway.

52. **boreds**
January 22, 2006

Hi Lee

Lubos has posted a lengthy critique of your comments on his site. There's a lot of blogging there, but I'd be interested in your response to this point (which I think is the key thing in NP):

You: The freedom to specify spin foam amplitudes does not map onto the freedom to specify parameters of a perturbatively non-renormalizable theory.

Lubos: Of course it does. Take all spin foam Feynman rules that lead to long-range physics resembling smooth space and assume that the space is not empty. This may be a codimension infinity set but its dimension will still be infinity. The parameters of higher-derivative terms at low energies will be functions of the parameters defining the spin foam Feynman rules. There is a one-to-one correspondence between them.

53. **Zorq**
January 22, 2006

“Zorq, the distinction between a finite theory and a uv fixed point is the following: a lattice QFT or condensed matter physics model with a fixed lattice spacing is a finite theory.”

No wonder you have trouble making yourself understood, when you use standard terms in nonstandard ways.

A lattice QFT or condensed matter physics model with a fixed lattice spacing is a cutoff theory. All physical quantities are finite (that’s what having a cutoff means), but explicitly cutoff-dependent.

A finite theory is one where physical quantites have no explicit cutoff-dependence. This is much more restrictive than saying that the theory has a cutoff.

At least, that’s what everyone else in the world means by “a finite QFT.”

“The point in LQG is that AFTER carrying out the regularization procedure and defining the diffeo invariant states and operators from the limit of the regulator removed, there remains a theory with a fixed, but spatially diffeo invariant cutoff.”

And I am asking, precisely, about what happens when you vary this latter cutoff. How do you need to change the couplings in the LQG Hamiltonian in order to maintain invariance of physical quantities? That’s the RG, applied to LQG.

Go back and read my previous comments, now that (I hope) we have the definitions straight.

54. **fh**
January 22, 2006

“And I am asking, precisely, about what happens when you vary this latter cutoff.”

You do realize that this “cutoff” does not arise from the regulator, that is, it is not put in by hand. Physics shouldn’t be invariant under it’s variation anymore then under the variation of, say, the speed of light.

55. **Brett**
January 22, 2006

The problem I have observed with the LQG terminology is that it seems to take the point of view that many theorists had in the relatively early days of QED renormalization. That viewpoint was that all the infinities of the theory were somehow “real,” meaning for example, that the bare electron charge was really infinite and the bare mass was, in some real sense, zero. The regularization procedures were simply mathematical necessities that allowed us to parameterize all the fundamentally infinite quantities.

Nowadays, thanks in large measure to the work of Wilson on the RG and the lattice regularization of gauge theories, we tend to have a different view. While it is possible that the infinite constants that arise in renormalization are really infinite, we tend to think of them as simply large but finite (or in some cases, not even large). We expect that new physics at some high scale will change the structure of the theory. This new physics might or might not be a renormalizable QFT, but we still expect that the low-energy effective theory will be renormalizable (although one must be careful about applying this RG rule of thumb too generally).

In the first viewpoint, a theory with a fundamental physical cutoff is “finite,” because, if we know that cutoff, all the amplitudes of the theory are finite numbers. If the operators are defined appropriately, no renormalization is required. However, the modern viewpoint recognizes that whether the cutoff used corresponds to somthing physical at the Planck scale or is merely a mathematical device is pretty much irrelevant. In either case, one can look at the low-energy effective theory, using essentially the same kinds of tools.

One can always deal with the problem of having a nonrenormalizable theory by setting a finite cutoff and describing the theory at that cutoff scale. There are then unambiguous predictions for all processes. This is a valid deductive procedure; however, it is no help in the inductive process of working backward from observation to get the fundamental theory, simple because there are an infinite number of parameters in the original high-energy theory.

January 22, 2006

> While it is possible that the infinite constants that arise in renormalization are really infinite, we tend to think of them as simply large but finite (or in some cases, not even large).

There is no such thing as an “infinite constant”. \infinity + exp(-x^2/2) is just as infinite as \infinity.

Lee wrote:

“Lubos, the finiteness is achieved kinematically, once the procedure just described is done the theory is uv finite WHATEVER the dynanmics, again just as in a lattice QFT with fixed lattice spaceing.”

Dear Lee, the comparison with the lattice QCD is very apt because the finiteness of lattice QCD is obviously completely fake. You can put any bad-behaved theory on a lattice and assume that this makes everything finite. The problems of the original theory, if there are some problems, immediately re-appear if one tries to take the continuum limit as a dependence on all the details of the lattice theory – i.e. the cutoff-dependence – which is a manifestation of the same problem in a regulated description.

Putting a UV-sick theory on a lattice does not solve the problems; it is just either a translation of the problems to different variables, or – if you want to claim that the problems are gone – it is hiding one’s head into the sand because one does not want to *see* the problems. But the same problems are still there. You can’t simply solve such basic physics problems in such cheap ways – like saying that you make a cutoff.

…

I am confused how Prof. Kowalski-Glikman and Prof. Smolin and others may disagree about the basic question whether DSR predicts an energy-dependent speed of light. Is it just a terminological disagreement or a physical one? My understanding is that DSR violates the constancy of speed of light and it simultaneously violates locality in a brutal way, by any distance, because locality requires a linear representation of the energy-momentum vector transforming under the Lorentz group.

(DSR is deformed special relativity whose symmetry group is the contraction of the q-deformation of the (anti) de Sitter group, which introduces nonlinearities to the [J,P] commutators.)

But do you agree that GLAST should detect something that will look like energy-dependent speed of light? DSR is all about the speed of light. It's almost like string theorists disagreeing whether there are any strings in string theory. 😉

Anonymous asked "… how do you expect the matter degrees of freedom to emerge? …".

With respect to exceptional spin foams based on structures like those of N=8 supergravity, here is a quote from Peter G. O. Freund's book "Introduction to Supersymmetry" (Cambridge 1986, at pages 117-119) about N=8 supergravity structure:
"… Einstein … repeatedly emphasized the conceptual imbalance between the two sides of his gravitational equations. On the left-hand side sits the Einstein tensor … a genuinely geometrical construct, whereas on the right-hand side we find the energy-momentum tensor totally unspecified by the theory. …
The situation in N=8 supergravity … is radically different. … All basic forces AND all basic forms of matter now appear in the SAME supermultiplet. … Einstein's 'complaint' is answered. … No previous physical theory haas exhibited anything like this degree of self-containedness and completeness. …".

Maybe this is one of Lee Smolin's "reasons" that he "… always discuss[es] dynamics in the spin foam picture …",
and
maybe it is also a reason that Lee Smolin said in hep-th/0104050 "… Supersymmetry appears to be related to triality of the representations of Spin(8) …".

January 22, 2006

The inner product of Fock space depends on the background metric, hence this quantization will never arise in a background independent formalism. So we do not avoid it because we are stupid, it is simply not an option.

What I don't understand is that I can write down the GR + Standard model Lagrangian, and it looks completely diff-invariant and (other than the need for a spin structure) background independent to me. What you seem to be telling me is that, when I want to quantize this thing, I should picture that R over on the left as completely different from all the other things and quantize it in a completely different manner than everything else. First of all, it's not clear to me that we can do this because everything interacts with gravity. But, I also don't see why shouldn't apply your 'background independent quantization' to the whole shebang and, thus, never see the beta-function in QCD, for example.

I don't see why you focus on Fock space, either. Fock space is a way to quantize freeish theories that have a particle interpretation, but there are plenty of other types of QFTs — certain CFTs, for example.

60. **D R Lunsford**
January 22, 2006

TS – I solved the energy problem without SS. It's not necessary. The sources are derivatives of the gauge field along the (not assumed small) extra dimensions.

61. **Luboš Motl**
January 22, 2006

Dear Brett,

I completely agree with your observation that our LQG friends often happen to speak about the infinities in QFT in the obsolete, pre-RG, pre-1970s way. If they applied their ideals to all disciplines of physics, they would also reject the Standard Model, because it has "infinities", but accept Fermi's four-fermion interaction because they don't recognize renormalizable and non-renormalizable theories as long as they have infinities and they are proud about it. 😉

Of course, we have known for quite some time that this understanding is flawed, despite the fact that this ignorance did not prevent people from calculating QED loops before the 1970s. Infinities that are regulated or parameterized with a cutoff are just a technicality, and one must do a lot of other work afterwards to figure out whether these infinities are lethal, and if they are not, what are the physical predictions. We can make physical predictions for renormalizable theories where the low-energy physics is independent of the details of the short-distance physics.

My understanding is that the LQG friends just feel to throw up when they see a divergent integral and it stops them – much like others who feel anxious when they're told that space and time can mix. Many things in physics however can't be done with such a phobia. There is a lot of thinking required after we see the first infinity.

More generally, I feel that our LQG friends prefer form over content. Formalism over formalism-invariant physical insights and predictions. Technicalities over profound principles. Lee has unfortunately said it too many times for me to think that I just misunderstood something. He likes the idea that all LQG people are using the same formalism(s), the same methods etc. I think it is a bad sign that says something about the intellectual breadth of the community, and this observation of limited technical resources has nothing to do with the physical coherence of the actual theory or theories.

Formalism, much like the Greek alphabet, is not yet physics even though some people may find it difficult enough to believe that it must be. Carlo Rovelli has informed us that he has not yet digested quantum mechanics – well, yes, quantum gravity and renormalization group are slightly more complicated than quantum mechanics and maybe one should first digest quantum mechanics before he or she starts to solve more difficult matters. Of course that my feeling is that people tend to over-emphasize formalism if they learn it and they feel that it is about the maximum they can learn.

In real physics, people work with many formalisms (often subconciously) whose equivalence they often understand well, and they parameterize UV divergences using many methods – dim reg, brute cutoffs, Pauli-Villars, lattice – whose equivalence for the actual physical predictions should be comprehensible for a physicist, and this equivalence is based on the logic of RG. Making an "infinity" finite by one of the methods is not yet a solution of a problem. It's just a translation of the same problems to different variables.

In LQG, one randomly picks one of these regulators – something like a lattice – and promotes is to a principle. That's of course not very deep and it does not solve any problems. Lee has even explicitly said that he solves all UV problems independently of dynamics. If he does so, then we can be sure that his solution is independent of physics 😉 because the nature of UV problems much like 99% of other things in physics DOES depend on dynamics. If an argument does not depend on it at all, then it's surely wrong.

I feel that the focus of LQG is not on the things that can actually be extracted from a theory but on the limitations what we are actually allowed to think, believe, or use, instead of physical predictions. We are not allowed to use integrals involving UV divergences because they're bad. We are not allowed to do perturbative expansions or other expansions because they're bad. Instead, we should like spin networks that have never been connected with anything remotely similar to observable physics because they are a nice formalism that a community uses.

We are not allowed to consider theories where geometry is just an approximate concept arising from a deeper or broader structure because any additions to GR are bad; GR is essentially a holy scripture and the real goal is to show that we don't have to modify it at all because of "unimportant" novelties such as quantum mechanics. All these things that we are "banned" from doing may be bad for our LQG friends, but they are absolutely necessary for doing theoretical physics at a decent level. Sorry, Lee, if I am the first one who says it to you.

All the best
Luboš

62. **Zorq**
January 22, 2006

"You do realize that this "cutoff" does not arise from the regulator … Physics shouldn't be invariant under it's variation …"

To return to the *point*, there are an infinite number of arbitrary coupling constants in the LG Hamiltonian. These are not fixed by diffeomphism invariance or background independence.

Without a principle to fix them, LQG would be utterly unpredictive. I offered and RG fixed point as one mechanism for fixing them.

You don't like that? Fine. What principle *does* fix them?

63. **Luboš Motl**
January 22, 2006

A few examples of the focus of LQG on the form instead of the content:

Preference over the way to regulate infinities – lattice instead of dim. reg. or Pauli-Villars or other regulators.

Preference over the way how calculations are done – dislike for perturbative methods.

Preferences over Hamiltonian vs. Lagrangian descriptions – it is very important for the LQG people which one should one choose.

Needless to say, neither of these questions is an important question in physics these days. They're mere superficial technicalities. College kids may talk which regularization they prefer but when they grow up, they will eventually understand why it does not matter. The same holds for Lagrangians and Hamiltonians – in any working theory with both of these approaches, they're simply equivalent. Of course, LQG is probably inconsistent so it can't even be shown that the two approaches are equivalent, but that's another reason to abandon such a theory, not a reason to start medieval debates which formalism is "better".

Another example of the preference of form over content are the statements about "background independence". Physics of string theory is manifestly background-independent and the third chapters of all major textbooks explain why. A modification of the background we start with is equivalent to a condensation of physical particles in the original background. That's why we know that there is just one theory and not many theories that depend on a background.

But what our LQG friends find very important is how we actually write down the calculations of the physics predictions. The best observables in quantum gravity is the S-matrix – no one, not even our LQG colleagues, has invented better ones. So we evaluate the S-matrix. The S-matrix makes it necessary to choose a background around which we expand, in order to know what the Hilbert space is – so that we can calculate the scattering amplitudes. This is just about a calculational method, a superficial feature of our strategy to approach physical questions. It does not change anything about the fact that dynamics of string theory is background-independent – and that there is just one theory.

But Lee seems to prefer the form so he would tell us that we are not allowed to expand, and just because we expand things in this way, string theory *itself* fails to be background-independent, which is of course nonsense. I subscribe wholeheartedly that we would be happier if we had a language for string theory that "sees" all the backgrounds simultaneously as solutions of some universal rules. But this dream is not a real necessity. It is just about the mathematical methods that Nature and the world of mathematics can offer us. It is not really a physical question. Nevertheless, it seems to be more important for the LQG friends than physics.

In string theory, we have many contexts in which various descriptions are easier and "default". In AdS/CFT, we really find the physical states of the graviton only. For example, we can go to the light-cone gauge in the pp-wave limit. The unphysical components of the metric are not there. Still, we know that the physics is exactly equivalent to physics that we can also write down covariantly, modulo diff invariance. I am afraid that it is fair to say that any technical step or detail of this kind would just distract our LQG friends far too much so that they could not concentrate on physics – which is what is left from the calculations after we divide by all unphysical details associated with individual formalisms.

Physics is non-trivial and it rules while formalisms are superficial and trivial and they suck. Sorry, Lee.

64. **fh**
January 22, 2006

"We expect that new physics at some high scale will change the structure of the theory."

That is precisely the case in LQG style QFT, which is why people who try to attempt to understand LQG in terms of effective field theories like the QFTs that make up the standard modell and their perturbative expansion, or in terms on analogies to lattice QFT which are often misleading and nevermore then analogies, (like Prof Motl) have such a hard time.

LQG introduces a genuinely new class of QFTs (background independent), with genuinely new structures at high energies and so on. Wether these are physical or not is an open question but the observation that they are different from ordinary QFT is, well, obvious. Most of the tools and intuitions from background QFT do not carry over. Freidel showed however that QFTs in the ordinary sense CAN arise in a certain limit from this new class of QFTs. This is of course crucial, if that was not the case then the objections that these new QFTs can't have anything to do with reality since they do not incoporate the old QFTs would be valid and severe (Freidel said in his presentation at Loops05 that he personally thought of this as a clear branching point of LQG, had this failed then he would have given up on LQG), however this is not the case, and it is hence worthwhile and ever more promising to study this new class of QFTs.

I should note that I am just a beginner in this field, either. But the above is basically why I choose to study it.

65. **Lee Smolin**
January 22, 2006

Thanks everyone for the many comments. Ill try to answer as many as I can:

To Boreds: Take the case of 2+1 QG coupled to some matter QFT, with arbitrary couplings, treated as a spin foam model. This was solved in the recent work of Freidel and Livine. The answer is the same matter QFT on a non-commutative geometry which is kappa-Poincare. None of these are in the class of perturbatively non-renormalizable QFT's on smooth Minkowski spacetime. So when you quote Lubos as saying, "Take all spin foam Feynman rules that lead to long-range physics resembling smooth space…" the answer is that there are no theories in this category because all such spin foam theories correspond to QFT's on kappa-Minkowski spacetime which is not smooth.

So there is no correspondence, because the two classes of theories have different low energy symmetry algebras.

To Zorq, Im sorry if I "use standard terms in non-standard ways." Part of the problem is that the properties of LQG with regard to finiteness are different than previous examples and its hard to discuss this with people who have not looked into the actual calculations and proofs. The point is that diffeo invariant QFT's are a new type of QFT and have features not shared by either perturbatively renormalizable QFT's or lattice QFT's. Now,you ask, what is the relationship between the microscopic Planck's length that serves as the cutoff of the diffeo invariant theory and the macroscopic Newton's constant. To answer this you need to refer to a computable macroscopic quantity. One we have control of is the black hole entropy. By using this we see that the ratio of the macroscopic Newton's constant G_{macro} defined by the black hole entropy formula (Area/4 G_{macro} hbar) to the bare L_{Pl}^2 that comes into the microscopic theory is a parameter of order 1, proportional to the Immirzi parameter. This is how we know there is no infinite renormalization. As I said, there are other calculations that lead to the same conclusion.

To Brett: because of what I just said, measuring Newton's constant is, up to a computable dimensionless constant of order unity, a measurement of the microscopic planck scale. If you like, from a RG point of view because the only coefficient of an invariant term that can contribute to microscopic physics-besides the cosmological constant-is an irrelevant operator, and because you can compute the black hole entropy in closed form, a measurement of a macroscopic quantity determines a microscopic cutoff. This is a very different case from that of marginal couplings that we are used to in perturbatively renormalizable theories. The point of view in LQG is then not like the early days of QED, it is nothing but the modern Wilsonian RG point of view applied to a case where there is no marginal coupling so the low energy limit is dominated by an irrelevant coupling.

To Lubos, how is it that there can be disagreement about a prediction of DSR is that there can be different identifications of elements of the kappa-Poincare algebra with the observed energy and momenta. In 2+1 this ambiguity is fixed by the coupling to gravity. Jurek has one expectation as to how this will work in 3+1, I and others have another. Mine comes from a semiclassical calculation that shows directly an energy dependent speed of light (hep-th/0501091).

To Aaron, yes, when the standard model is coupled to gravity, the whole thing must be quantized using LQG technology. You cannot quantize a theory half by background independent methods and half by background dependent methods. This has been developed in detail, for example in Carlo's and Thomas's books and reviews for all the standard model fields. The result is not surprising and the limit in which gravity is turned off can be check and is reasonable. In the Hamiltonian picture, if you fix a gravitational spin network (setting to zero the terms in the Hamiltonian constraint coming from gravity) the result looks like a lattice theory for the matter on that fixed graph.) Or, in the spin foam picture, if you set the gravitational constant to zero, the spin foam for the remaining matter degrees of freedom is nothing but the perturbative expansion of the matter QFT (see Freidel et al again for this.)

Lubos, I am afraid I can't understand your comments, they do not reflect any detailed understanding of how the actual calculations and proofs are done. Let me just start with the first line of one of your lengthy comments: "Preference over the way to regulate infinities – lattice instead of dim. reg. or Pauli-Villars or other regulators."

For the millionth time, LQG does NOT USE LATTICE methods. It is not a matter of "preference", the methods of background dependent theories such as dim reg or Pauli Villars CANNOT BE USED, because if the whole metric is an operator there is no background metric, which is needed to define them. Nor can lattice regularization be used as that also depends on a background metric. We had to invent NEW METHODS for regularization, suitable for gauge theories whose dynamics is defined on a manifold with no metric and we did so (This was why it took some years of careful work to develop LQG). They are roughly like point splitting regularization but somewhat more complicated because one has to ensure that in the limit in which the regulator is removed the resulting states, inner products and operators are spatially diffeo invariant. This is more intricate and constraining than the regularizations defined by background metrics.

I could continue to correct each comment you make line by line, but as almost nothing written there corresponds to what is actually done it would take a book. I would ask you once again to please study the details and understand them. There are valid criticisms and limitations to LQG which are worth discussing, but its hard to argue with someone who is unwilling to understand the actual results and claims.

Zork, What principle does fix the couplings? First, we don't know that there are an infinite number of consistent couplings, either at the Hamiltonian level or the spin foam level. What we know is that there is one ordering of the Hamiltonian constraint that is consistent with diffeo invariance, which has the standard two parameters. It is not known how many others there are. But as I said, none of the regularizations of the Hamiltonian constrains I know lead to the exchange moves, and so none are acceptable.

While there is some uncertainty, I believe this is because in the Hamiltonian approach one regulates by point splitting in space and not time. So to get a good evolution amplitude we regulate with spin foam methods. At the spin foam level we know of one evolution amplitude that has been proved to have uv finite sums over labels, we do not know how large the space of amplitudes with that property is. It would be very worth knowing this, but it just hasn't been done.

Second, I personally did not reject your proposal of using the RG to find one. A theory with a cutoff can still have a non-trivial topology of RG flow, the different universality classes of which define the possible low energy behaviors. After all this is what happens in the standard theory of 2nd order phase transitions in 3d condensed matter systems. I have for years strongly encouraged the development of RG ideas to the problem of selecting the good spin foam theories. It is more complicated, see papers of Markopoulou on the RG for spin foams to understand why (gr-qc/0203036, hep-th/0006199) but some progress was made and I believe much more progress could be made on this.

To fh: sorry to repeat some of your remarks,

Thanks, Lee

66. **Aaron Bergman**
January 22, 2006

The result is not surprising and the limit in which gravity is turned off can be check and is reasonable

Now I'm confused. Let's do the harmonic oscillator coupled to gravity. I thought we had established that quantizing the harmonic oscillator (or QCD or whatever) alone by LQG techniques gives an experimentally incorrect answer. Now are you claiming that, instead, if do the coupling to gravity, quantize the entire system and then take G->0 instead, we get a different result than if we had never turned on gravity in the first place, and that that result is the correct one?

67. **Zorq**
January 22, 2006

"[W]e see that the ratio of the macroscopic Newton's constant G_{macro} defined by the black hole entropy formula (Area/4 G_{macro} hbar) to the bare L_{Pl}^2 that comes into the microscopic theory is a parameter of order 1, proportional to the Immirzi parameter. This is how we know there is no infinite renormalization."

As I explained above, you learn nothing of the kind. Stop using the words “infinite” and “infinities” and start using the language of modern Renormalization theory.

Once you do, you will see that the relation between the low-energy Newton’s constant and the bare coupling in the LQG Hamiltonian is exactly what one expect of any theory with a cutoff at L_p. It is not some deep breakthrough, but a trivial observation.

“Zork, What principle does fix the couplings? First, we don’t know that there are an infinite number of consistent couplings, either at the Hamiltonian level or the spin foam level.”

Yes, we do.

There are an infinite number of polynomials in the Riemann curvature and its covariant derivatives that can be added to the spin-foam action. A similar infinite set of couplings exists, also, in the LQG Hamiltonian.

Neither diffeomorphism invariance, nor background independence fixes those couplings.

What does?

68. **Aaron Bergman**
January 22, 2006

One other thing. You refer to a ‘uniqueness theorem’ a number of times. How does this reconcile with the well-known fact that there are a number of inequivalent quantizations of gravity in 2+1 dimensions?

69. **Anonymous**
January 22, 2006

Lee,

Here’s my attempt to make some progress in this conversation while keeping the discussion civil. It appears to me that you and some of the others in this debate are speaking two different languages. And while I can understand that you want people to look at the details of LQG, I think you would do well to formulate a response in a language others can understand *without* looking at these details. Otherwise, we will naturally tend to be skeptical. I really think that if you want to be taken seriously you have to be able to answer this question at a rough, hand-waving level, without appealing to any theorems. Otherwise your claims seem to run counter to basic intuition.

So let me try to formulate a question in a clear way, and hopefully you can give at least a heuristic response that does not require knowing the technical details.

In ordinary QFT we know that there are numerous irrelevant operators involving gravity that one can add to the Lagrangian. Their infinitely many undetermined coefficients at a given scale account for the nonrenormalizability of gravity. Furthermore, none of them in any way violate basic principles of background independence or diffeo invariance.

So, a field theorist wanting to understand your work naturally will ask, are you saying there is a UV fixed point? If not, what principle relates the various couplings?

As far as I can tell, your answer to the first question is no, there is a cutoff. So the next question becomes important: why are there not infinitely many choices of theory in your cutoff theory?

At this point you seem to appeal to the details, but a good heuristic answer would be a great help to an outsider wondering if it’s worth looking at those details. If some deeper principle fixes the whole set of infinitely many coefficients (or reduces them to a smaller finite-dimensional set), what is that deeper principle like? It can’t just be background independence, because these terms don’t inherently violate background independence.

You stress that these theories reduce not to usual QFTs but to some kappa-deformed theories, but it doesn’t seem that that resolves the problem either. Such a deformation doesn’t make gravity renormalizable.

Whatever happens in your theory, there must be some way to give us at least a rough explanation of how it fits with these facts. Just saying “it’s not an ordinary QFT” is a deeply unsatisfying answer. If it reduces to an ordinary QFT at some point below the Planck scale (up to whatever kappa-deformation you’re claiming there is, which must be a small effect to fit with observed data), then somehow it has to determine the usual coefficients for the Wilsonian RG to take over. And so there has to be something very special going on, *beyond just background independence*. For instance, in string theory the sort of heuristic answer I am looking for is that the infinitely many fields of arbitrarily high spin constrain the interactions.

(I’ve been saying things like “there has to be” a lot, but if you can explain why *that* is wrong, that would be interesting too.)

Thanks!

70. **Anonymous**
January 22, 2006

Oops, I seem to be duplicating Zorq’s question in a much more long-winded way. I guess we were writing at the same time.

71. **Who**
January 22, 2006

fh
(Freidel said in his presentation at Loops05 that he personally thought of this as a clear branching point of LQG, had this failed then he would have given up on LQG),…

http://www.math.columbia.edu/~woit/wordpress/?p=330#comment-7811

I remember that. I have the video (whereas you, I expect, were present).

It was impressive. I have not yet heard people in some other lines of research say, even in retrospect, an empirical or mathematical result that would make them abandon their theory and change fields. The way he said this convinced me he was absolutely serious about it. Then jokingly:

“But the fact that I am here talking to you shows that it worked out…”
or words to that effect.

I believe that Freidel has a new paper (co-authored with Baratin?) in preparation which looks into the 4D case. Again the question is, if i understand correctly, does the does the gravity theory specialize to give matter QFT if you let G go to zero. Do you know anything about this, fh?

72. **Lee Smolin**
January 22, 2006

Hi everyone, thanks, again Ill do my best to answer clearly.

First to Zorq: You assert: “There are an infinite number of polynomials in the Riemann curvature and its covariant derivatives that can be added to the spin-foam action.” No, we don’t know this because the spin foam amplitude is not expressed in terms of polynomials of the Riemann curvature. It is expressed in terms of invariants of quantum groups, such as q-15j symbols. I would not be surprised if there are an infinite number of such possible amplitudes, but I know of no result that shows so.

Further, as I thought I emphasized, there are conditions to be imposed. One, for sure, is the uv finiteness (in the sense that sums and integrals converge) of the sums over labels in a spin foam amplitude. This is quite restrictive. Only a few solutions are known, (see as usual hep-th/0408048 for exact references to the finiteness proofs for spin foams). We just do not know how large is the space of spin foam amplitudes that have this property. So I am making no claim here, either way. But you asked for restrictive conditions and this is an important one. OK?

You also say: “A similar infinite set of couplings exists, also, in the LQG Hamiltonian”-to which similar remarks apply. The LQG quantum Hamiltonian constraint is not expressed in terms of classical quantities and it has to satisfy some quite non-trivial consistency conditions coming from the operator constraint algebra. We do not know how large is the space of solutions to these. As I mentioned we know of only a few.

(Also, I thought I was using the language of the Wilsonian RG, and I agree I was using it to make a trivial point.)

Now, to Anonomous. Thanks for your helpful attitude. You ask, “In ordinary QFT we know that there are numerous irrelevant operators involving gravity that one can add to the Lagrangian….so why are there not infinitely many choices of theory in your cutoff theory?” I hope the above answers you clearly. The point is that the spin foam action is NOT made by writing classical spacetime diffeo invariant expressions in the continuum and then subjecting them to a regularization. Once you are in the spin foam or group field theory language the amplitudes are expressed in a different framework-that of quantum group invariants. This is consistent with the idea that there is no continuum below the Planck scale. And there are conditions imposed. The conditions of finiteness of sums over labels of spin foam amplitudes is pretty restrictive, so there could easily be only a finite space of solutions to it. But this has not been shown so I am not claiming it is true.

Now about 2+1: “You stress that these theories reduce not to usual QFTs but to some kappa-deformed theories, but it doesn’t seem that that resolves the problem either. Such a deformation doesn’t make gravity renormalizable.” First, the point of the argument was to directly show that an argument given by someone was wrong because, again, none of the DSR theories are in the class of perturbative QFT’s on Minkowski spacetime. Second, DSR theories can be uv finite because there are maximum energies in sums over momenta.

You want a heuristic explanation for why a diffeo invariant regularization procedure results in finite operator products. OK, here is one that was very helpful to us originally. (again see 0408048). In the absence of a background metric all operators are distributions and all distributions are densities. So when defining an operator product in the absence of a background metric you have to carefully keep track of density weights.

We regulate by point splitting, which means we introduce an auxiliary background metric q_0 just for the purpose of defining the distance between points. We have to define the product of two operator valued distributions to be one operator valued distribution. In general the result has inverse powers of the distance measured in units of q_0 times determinants of q_0 to soak up the density weights. If the resulting operator is to be diffeo invariant (under actions on the quantum fields) it cannot depend on q_0 because q_0 is not acted on by the operator that generates diffeos. It turns out this means it cannot depend either on the distance measured in units of q_0 (this is seen by an argument where q_0 is scaled.) Thus, a diffeo invariant operator extracted from the limit in which the regulator is removed cannot depend on q_0. Hence because all divergences are measured in units of q_0 there can be no divergences. This is borne out by the detailed calculations. But what kind of operator can appear? Only one that is a natural integral over an operator of density of weight one-as the density weight can in the limit only come from the operators. Since local field operators have density weight one, this can come from an n’th root of the product of n operators, each of density weight one. This is exactly how area and volume operators are defined.

There is another trick which is to represent the inverse of the determinant of the operator metric as a commutator of operators that can be defined in the regulated theory. This allows us to construct further finite operators including the Hamiltonian constraint.

To Aaron, about the limit G to zero in 2+1 see Freidel and Livine for how it works in detail. Remember I am talking here about a spin foam calculation, so the result comes from a path integral and not the Hamiltonian theory. You can ask, could this have been seen in the Hilbert space and how would the limit G to zero look there? I don’t know (I hope that is ok as these are new results.) It seems like a good research problem, perhaps you would like to work on it.

Also, what inequivalent quantizations of 2+1 gravity are you referring to?

73. **Wolfgang**
January 22, 2006

> what inequivalent quantizations of 2+1 gravity are you referring to?

I guess the ones described e.g. by Carlip ?
While there are different ways to quantize 2+1 (and Ponzano-Regge is among them) , they do not give the same results.

74. **Wolfgang**
January 22, 2006

Lee,

let me use this opportunity to ask how the exact solution of Martin Pilati for strong-coupling gravity fits into your picture ?
http://prola.aps.org/abstract/PRD/v26/i10/p2645_1

75. **Aaron Bergman**
January 22, 2006

Also, what inequivalent quantizations of 2+1 gravity are you referring to?

See Carlip, here

You want a heuristic explanation for why a diffeo invariant regularization procedure results in finite operator products.

That was not the question anonymous (or zorq) was asking. “Finiteness” is not the issue here. I think you’re conflating renormalization with the removal of infinities, and they’re not the same thing. I assume we all believe in effective field theories. I can write down a cutoff EFT for gravity, and there are an infinite number of free couplings in the Lagrangian. At a given value for the cutoff, does LQG tell me what the ‘correct’ values for those couplings area?

76. **Luboš Motl**
January 22, 2006

Dear Lee,

please accept my apologies in advance but I often find your comments to be a good reason to wisely smile rather than learn. It does not matter whether you call the spin network a "lattice" or "non-lattice". What's important is that it is a discrete regulator and it shares the same features with the lattice. More concretely, it translates the irrelevant couplings to cutoff dependence and infinitely many undetermined couplings at the cutoff scale – namely the Planck scale.

You argue that the regular methods are bad, and your (…) methods that you (…) had to invent are better ones, exactly confirming my last comment about the focus on form instead of the content. Let me remind you that the standard ways to quantize general relativity have led to actual physical insights of a Nobel prize caliber such as black hole thermodynamics, unlike yours (…). Expanding quantum fields around a classical background is actually what gives a control over physics of quantum gravity, at least to the leading and subleading orders. Denying the partial success of this approach and the relative failure of these discrete approaches seems as far too crazy an attitude for me to discuss about it in length.

You also give this answer to Zorq:

"Zork, What principle does fix the couplings? First, we don't know that there are an infinite number of consistent couplings, either at the Hamiltonian level or the spin foam level…"

Maybe you don't know it, but those of us who have studied and who actually know LQG at the technical level, not just the popular one, DO know that there are infinitely many couplings that are equally consistent as long as any continuum limit is possible and as long as you can write at least a single term in the Hamiltonian, whatever definition of consistency we pick. For example, if you allow us to introduce "moves", we can include diff and gauge invariant terms with multiple (N) moves. (If you don't allow moves, you will likely end up with an ultralocal theory where different points are decoupled forever and where the speed of light is zero.)

These couplings are nothing else than the spin-networkization (this obscure word is to prevent your vacuous criticism for my using the usual word "latticization" – and be sure that it is my terminology and not yours that is standard) of the low-energy effective couplings. The infinite degeneracy of these couplings is an obvious fact and we can write infinite families of these couplings for you in the case that you really don't know them. You will find this answer in all expert papers about the question whether the number of possible LQG Hamiltonian couplings is finite.

If you think that you have found the unique Hamiltonian for LQG, everyone will be happy to read a paper about it.

Your sleight of hand with the "non-smooth" kappa-Minkowski spacetime cannot circumvent the actual theorems showing that what you say is not possible and that our effective field theory arguments apply to LQG much like any other theory of physics. Kappa Minkowski spacetime is moreover smooth – what it lacks is locality, not smoothness (by which I mean the continuous character and unboundedness of momenta).

Any physical theory of the type we look at must be approximated by effective field theories (fine, not necessarily Lorentz invariant, but almost exactly Lorentz invariant) at low energies. There is no way out and trying to generate obscure terms containing Greek letters with a "special status" just in order to avoid conclusions that can be made does not lead anywhere – because you don't actually address our questions, you just avoid them by pompous terminology.

Whenever someone says that XY cannot work because 2+3=5, you invent an explanation why rational thinking and 2+3=5 cannot be used in your context because your context is surely "better" and "above" these dirty theorems that mortal human beings actually use. 😉

The theorems we know have been designed exactly to deal with possible theories like LQG and LQG is in no way a counterexample of these theorems.

Another method that unfortunately resembles fast commercials from cheap TV stations is your format of a sentence "this has been fully solved / answered … in a recent paper by Livine / Rovelli / Dreyer / …". Whenever one actually looks at these papers, one either finds incoherent noise, or wild speculations full of wishful thinking, or a discussion about a simple and different topic that does not imply anything whatsoever for the question that was discussed. This may be a good method to fool the badly informed laymen for five minutes but I am afraid it is not a good starting point for a serious discussion among physicists.

This has been strikingly the case of the statements about the black hole entropy in LQG. As we know, the initial papers about it were just wrong because they incorrectly neglected the higher spin punctures that do contribute, as we know today. This has started a whole industry attempting to show that the prediction of LQG is actually correct and the Immirzi parameter should be proportional to log(3) or log(2) or something like that. That would be great, people thought, because having computed the entropy, LQG could compete with string theory on this important front.

Newer papers have revealed that the entropy predicted by LQG is proportional neither to log(3) nor to log(2). Moreover, it has also been shown that the result from quasinormal modes of a generic black hole is not proportional to log(3) or log(2) either but instead, to yet another number or a function of the BH parameters, more precisely. In summary, all conjectures about the correctness of the LQG BH entropy or even its relations to quasinormal modes – much like the general conjectures about the quasinormal modes themselves – have been shown to be obviously false (note that it was not just one side that was wrong, it was both sides as well as the conjectured link) and everyone who has worked on these things has known this conclusion at least since 2003. The magnitude of black hole entropy is completely obscure from the LQG viewpoint (even if you accept the strange assumption that the black hole interior does not contribute) and all known calculations lead to contradictions.

Still, I've seen a much newer comment of yours claiming that the coefficient of the LQG BH entropy has been verified or something like that which I frankly find rather incredible. It is even hard to decide whether you actually believe what you're saying because it seems really difficult after 100 papers or so that show that the statement is false.

Best
Luboš

77. **Lee Smolin**
January 22, 2006

Hi, I hope the following is useful.

First, with respect to strong coupling limit of quantum gravity in the context of LQG, see THE G (NEWTON) —> INFINITY LIMIT OF QUANTUM GRAVITY, Viqar Husain , Class.Quant.Grav.5:575,1988. This was early days, probably the results Viqar got on the strong coupling limit could be much improved with what we have learned since.

I am very happy to talk about effective field theories, "I assume we all believe in effective field theories…" Yes, BUT we must be careful to remember that the class of effective field theories are labeled by the symmetries and gauge symmetries of the ground state. There are separate classes of effective field theories for Poincare invariant, kappa-Poincare invariant and broken Poincare invariant theories. This is an elementary fact, but it is the key point I have been trying to make. If you have two theories and one describes perturbations around a ground state that has symmetry P and the other has a ground state with symmetry Q and P is not equal to Q then they are not described by the same class of effective field theories. Becauuse each term in the effective action should be separately invariant under either P or Q and they are not the same. Is that clear?

Having said this I don't understand what we are arguing about. I agree there is some set of possible amplitudes of spin foam models. I mention that it is likely that these will be restricted by the condition of finiteness of sums over labels. I mention that we do not know how large the space of such good spin foam models is. Some of you would have bet there were no such theories, so I'm surprised if you are now cavelierly insisting there are infintie numbers of them.

I do not deny it is possible it may be infinite, but I also will not be surprised if the condition of finiteness is restrictive and there are only a few parameters. But the bottom line is we don't know. I also agree that these will map to effective field theories. I only insist that if Poincare invariance is q-deformed, or the geometry is non-commutative as is the case in 2+1 this is NOT the same class of effective field theories that are constructed by perturbation theory around flat Minkowski spacetime. I agree it would be very interesting to know how the parameters of the finite spin foam models map to the parameters of the effective field theory with the appropriate ground state symmetry. I don't say more because as I've said already, we don't know the answer for 3+1. It is only very recently we know the answer for 2+1 with matter. What is not clear about this?

If someone thinks it is known or obvious that the space of spin foam amplitudes which lead to convergent sums or integrals over labels for any spin foam diagram is infinite dimensional, please provide details as this would constitute an important new result. Otherwise, do not presume to know the answer to an open question. By the way, let me stress sincerely it would be very important to characterize the space of finite spin foam amplitudes, and I hope someone will take this on.

As for black hole entropy, the only thing I need for the argument I made is that the ratio of area and entropy is a finite number. So the technical issue of the right way to count the states is irrelevant because all proposals lead to finite ratios.

78. **Zorq**
January 22, 2006

"If you have two theories and one describes perturbations around a ground state that has symmetry P and the other has a ground state with symmetry Q and P is not equal to Q then they are not described by the same class of effective field theories. Becauuse each term in the effective action should be separately invariant under either P or Q and they are not the same."

I'm not at all clear what you mean here. We are talking about pure gravity theories, right? I thought your mantra was that General Relativity (and, the infinite generalization thereof, involving higher powers of the curvature and its covariant derivatives) is background-independent.

So, you claim (or hope) that spin-foam theories will not have an infinite number of independently adjustable couplings. (Why? There are an infinite number of quantum-group invariants that you could, in principle, write down. Why stop at 15j-symbols?)

Let's assume you're correct.

That means that, when passing to the effective continuum field theory, it picks out unique (or nearly unique) values for all the infinite number of couplings.

Computing the coefficients of the R^2 and R^4 terms in the supergravity effective action has been an illuminating activity in String Theory. What are the R^2 corrections to the Einstein-Hilbert action, predicted by spin-foam theories?

79. **Lee Smolin**
January 23, 2006

Zorq asks "There are an infinite number of quantum-group invariants that you could, in principle, write down. Why stop at 15j-symbols?"

Because, to repeat myself, not all of them are likely to have the following property: that the sum over labels on a fixed spin foam converges. This good property implies uv finiteness of a spin foam model. Some models have it (gr-qc/0104057,gr-qc/0508088, gr-qc/0512004) and I hope you agree that it is a reasonable selection principle. We don't, to my knowledge, yet have a classification of which spin foam models have this property.

He asks also: "I thought your mantra was that General Relativity (and, the infinite generalization thereof, involving higher powers of the curvature and its covariant derivatives) is background-independent."

The poiint is that once we are in the quantum theory., there is no metric or manifold. Hence background independence cannot be implemented by choosing a diffeo invariant classical action, for there is no manifold or metric that classical action can be a function of. The classical manifold, metric and curvature themselves can only emerge in the low energy limit.

So the effective field theory analysis will not be background independent, it will only describe excitations of a particular ground state. Hence it must take into acocunt the symmetry of the ground state one is studying excitations of.

Finally, we cannot assume that any term that appears in the effective action of a poincare invariant graviton theory will appear in the effective action of a kappa-poincare invariant theory. We just don't yet know what the combination of diffeo invariance and kappa-Poincare invariance will allow for possible terms in the effective action.

As for whether there are R^2 terms in the effective action and what their coefficients are, this information should I agree be extractable for each particular spin foam model. For the Barrett-Crane model, this may soon by possible by extracting it from the calculation of the propagator done by Rovelli et al. (gr-qc/0508007) in that model. They are working steadily towards this goal.

Thanks, Lee

80. **Zorq**
January 23, 2006

"Because, to repeat myself, not all of them are likely to have the following property: that the sum over labels on a fixed spin foam converges. This good property implies uv finiteness of a spin foam model."

And I will repeat, for the unwary, that this usage of the phrase "uv finiteness" has nothing to do with the notion of uv finiteness found in the textbooks.

"So the effective field theory analysis will not be background independent, it will only describe excitations of a particular ground state."

Will the effective field theory, at least, be writable as a generally-covariant local functional of the metric? (In other words, an Einstein-Hilbert action + higher corrections.)

If so, then all that can happen is that the coefficients of the various terms in the action can change.

So you're claiming that the coefficients one extracts for the (generalized) Einstein-Hilbert action will be different in different backgrounds?

Interesting …

“Finally, we cannot assume that any term that appears in the effective action of a poincare invariant graviton theory will appear in the effective action of a kappa-poincare invariant theory. We just don’t yet know what the combination of diffeo invariance and kappa-Poincare invariance will allow for possible terms in the effective action.”

What do those words mean? What *other* constraints are there on the (generalized) Einstein-Hilbert action above and beyond locality and general coordinate invariance?

81. **L.**
January 23, 2006

Surely mr. motl is joking when he promotes Nicolai et al. to quantum gravity experts, with no offense intended to them.
Sure it is fun to do physics but it doesn’t mean that this is not a serious activity where it takes much more to become an expert in a field than writting an incomplete review on a field as it was a few years ago, writting a research paper that adress and solve a problem is for instance an example of what it at least takes. I hope the next paper of Nicolai will be a resarch paper adressing some of the issues he cares about and i am sure knowing his capability that it will be interesting.

I will try to answer peter’s initial request hoping but not feeling totally sure that it might help the debate at this point.
The latest review of Nicolai et al. is much more satisfactory than the previous one, which essentially was describing the field as it was circa 1998 ignoring most of the work that was done since namely on spin foams exactly with the motivation to adress some of the issues he mentionned their.
He tries in the new review to include some of the more recent material and some of the problem he point out are problems recognised in the community for some time and some of them being already adressed in the litterature. I don’t think that was their intention (Nicolai is a genuine skeptic i think, and we need skepticism in science, its healthy) but sometimes in the presentation it looks like they are dicovering the issues they talk about and edged on making the impression that people working on this are not aware of the issues or concerned. Yes making a deeper relationship between spin foam and LQG is important (see the recent work by perez on this and on ambiguity in LQG, the recent work of Thiemann on the master constraint and some older and important work by Livine and alexandrov who made key progresses in this direction) and Yes adressing the semi classical limit is a necessary and key step (more remark later on that).
There is however a certain number of imprecisions, omitions and misunderstanding in their review. I will talk only about the spin foam section.
For instance when they present the riemannian spin foams they confused what is done in the litterature namely a quantisation of riemmanian quantum gravity with some hypothetical and to be defined hawking-like wick rotated version of Lorentzian gravity.
The purpose of spin foam is to construct the physical scalar product, and this means that we sum over history with exp i S. No direct relation is therefore a priori expected between Lorentzian and Euclidean theories. That’s why both Lorentzian and Euclidean model are studied, lots of the techniques are similar the lorentzian case involving non compact groupsis technically more challenging.
When they discuss the Barrett-Crane weight they confused the 15j symbol prescription (which describes a topological field theory) with the 10j symbol prescription which deals with gravity and present this as an ambiguity.
They also make the wrong statement that the spin foam approach is plagued with the same amount of ambiguity as LQG. This is not correct, the ambiguity in LQG amounts to ambiguities in the choice of the vertex amplitude (like different spin regularisation) whereas there is a large consensus on the form of the 10j symbol (in fact the intertwinners that needs to be chosen are shown to be unique).
There is an ambiguity in the choice of edges amplitude but this amounts into a different choice of normalisation of spin network vertices.
If one chooses the canonical normalisation that comes from LQG this edge amplitude is fixed uniquely. The possibility to have less natural normalisation was introduced later as an exploration of these models especially in order to have finite spin foam models when loop correction (bubbles) are included (gr-qc/0006107). This attracting possibility was later dismissed by showing that if one insists on preserving spacetime diffeomorphism invariance at the fundamental level and it was argued that the spurious divergence that arises in these higher loop amplitudes are signature of residual diffeomorphism (gr-qc/0212001).
They forgot to mention that the Hilbert space on which LQG and Barret-Crane model are isomorphic in the riemannian case, they forgot to mention that there are many different and independent derivations of this weight from the dynamic of GR.
They present as an other ambiguity the restriction to tetrahedral weight. This restriction is perfectly consistent with the fact that 4-valent spin network are enough to construct states with non zero volume and that any LQG dynamics act within this subspace which should be though as a superselection sector of the theory.
So this means that the line of thought that starts from a classical action and construct a quantum gravity weight as singled out one prefered possibility.if one singled out the canonical normalisation.
This doesn’t mean that this model is definitely the right one and having the correct semi-classical dynamic is the key issue, but it shows that
by adressing the problem of the dynamic in a covariant way and focusing on the implementation of space-time diffeo, one proposal stands out from microscopic derivation and adress in a satisfactory way some of the LQG issues, which is by itself an important result.
I don’t want to give the wrong impression and claim that everything is settled down for this model, there are still some study and questionning going on about this proposal which is not totally free of potential problems which are not really the ones presenting in NP (except that we are still lacking a strong physical argument for the canonical choice of edge amplitude), but clearly the presentation NP is very far from fair and accurate.

They mention some problems with 2D regge triangulations having to do with spiky configurations without mentioning and knowing (even if they cite the relevant paper in a footnote) that this problem is now fully understood in the more relevant and interesting three d case (these spiky configuration are just an overcounting due to redundant gauge degrees of freedom, a issue that was overlooked in the first works).

Also they completley miss the point about how we reached triangulation independence and the fact that there is a auxiliary field theory called group field theory which naturally gives the prescription allowing to compute triangulation independent spin foam amplitude. This is one of the main line of developpement of spin foam model it started a while ago now (hep-th/9907154) and not mentionning this line of work which explicitely adress and solve one of the issue they worry about is not a small ommission.
For instance they say `A third proposal is to take a fixed spin foam and sum over all spin’ and cite (hep-th/0505016) which exactly show on the contrary how to consistently sum over spin foam in order to get a finite triangulation independent positive semi definite physical scalar product and allows for the first time computation of dynamical amplitudes. This proposal is uniquely fixed by the microscopical model and if one stick to Barret-Crane with canonical normalisation this gives
a uniquely defined scalar product (so far for riemmanian gravity).
This is very far away from the picture they draw. The best I can do understand how they came up with this false understanding, is that they haven’ read the paper because its pretty clear that what done there is not what they describe.
Concerning the semiclassical issue they don’t mention at all the new line of developpement which consist of coupling quantum gravity to matter and integrate out the quantum gravity field in order to read out what is the effective dynamics of matter in the presence of quantum gravity.
this allowed to solve in a completly unambiguous way this issue in 3D.
They don’t mention all the other work in this directions involving coupling to matter field which were presented at Loop2005 (work of lee starodubtsev, baratin …)
I could continue but i think i can stop here for some detail criticism of their work. If i was referee of this paper i would at least suggest them to go back to their drawing board before submitting it.

82. **boreds**
January 23, 2006

Hi Lee and Zorq

“To Boreds: Take the case of 2+1 QG coupled to some matter QFT, with
arbitrary couplings, treated as a spin foam model. This was solved in
the recent work of Freidel and Livine. The answer is the same matter

QFT on a non-commutative geometry which is kappa-Poincare. None of
these are in the class of perturbatively non-renormalizable QFT?s on
smooth Minkowski spacetime. So when you quote Lubos as saying, ?Take
all spin foam Feynman rules that lead to long-range physics resembling
smooth space?? the answer is that there are no theories in this
category because all such spin foam theories correspond to QFT?s on
kappa-Minkowski spacetime which is not smooth."

I don't know much about QFTs on kappa-Minkowski spacetime. But I
presume that if you try to perturbatively quantize GR around this
background that it will be non-renormalizable, and that there will be
an infinite set of counter-terms. Is Lubos correct in saying that this
infinite number of parameters corresponds to ambiguities in the
spinfoam amplitudes? (Even if he was wrong on saying Minkowski instead of kappa-minkowski?)

I think you are saying that it does, *but* that it is not 1-1 because of
restrictions on the spinfoam side. Is it known what restrictions
`finiteness' in LQG terms places on the low energy couplings?

Zorq, I'm not completely certain what you're referring to when you
talk about corrections to supergravity, but…

the R^4 corrections etc you'd normally talk about in sugra are not the
same beast as the higher order terms in a wilsonian effective
action. they are really giving you equations of motion for the vevs of
the graviton and other fields, so in qft terms are more like a quantum
effective action.

You're right, string theory does (also) constrain the infinite number of
parameters
in the wilsonian action—but my (imperfect) understanding of this is
that the calculation is done in SFT, is hard and is not
equivalent to calculating sigma model beta-functions (or whatever).

83. **Juan R.**
January 23, 2006

Sorry, but i continue being skeptic about LQG capabilities.

The only good thing about LQG i can say is that their believers are often less arrogant and more honest that stringers and we may admire they after of decades of hard work. For example, i newer saw a LQG beggining a talk on quantum gravity with the (in)famous "there is only an approach to quantum gravity" so characteristic of arrogant stringers talks.

I (as others) consider that string theory is pure nonsense in many ways (and expressed several points) but I would say (as others also) that LQG is not consistent. None new paper or talk can convince me, since only way to convince me that LQG is a good approach would be changing LQG by another **NEW** approach.

I am sure there will be quantum gravity research still for a few years…

—

Juan R.

Center for CANONICAL |SCIENCE)

January 23, 2006

Concerning renormalisation group issues i am not sure that all the experts that covered this subject always have in mind that we are talking about quantum gravity and that some of the major results in this fields needs qualification when applied to this subject (the notion of scale, scaling in background independent theory is way more subtle). It doesn't mean that this cannot apply of course and there are beautiful news results and research going along this line recently, namely in the work of Reuter et al. and Percacci et al. Niedermaier et al. etc… they have by the way revived (not proven, there is a difference) the asymptotic scenario which is another way to go around non renormalisability.
This is not free of difficulty either (being sure that the statements made are really diffeo invariant being one of the major one).
An other key and special point about renormalisation group in GR is the fact that G_{N} is at the same time a coupling constant and a wave function normalisation which can be used to fixed your set of unit. The natural unit we work with in quantum gravity is planck unit, in this setting the notion of fixed point is not well defined because the renormalisation group flow vector field (the beta function) depends on the cut-off. If you try to work in cut-off unit (which is the usual scheme but much more delicate concerning diff invariance) a very important subtltety arise that the change of unit is not really invertible, as an introduction see for instance \hept-th0401071.

By the way an interesting concidence is that having asymptotic safety is realised then in Planck unit the cut-off parameter have a finite value and the effective anomalous dimension at the non gaussian fiexed point is two dimensional. These renormalisation facts resonates strickingly with the picture arising from background independent approaches, wether its LQG, dynamical triang or spin foams.
I don't know if this is just accidental or something deeper is going on, one should be careful but it is interesting. I just wanted to make sure that our local experts on the renormalisation are really tune up to apply it to gravity.

Also 2+1 gravity when treated as a perturbation theory around flat space is non renormalisable but however finite and unambiguously defined. Of course i don't want to imply that what happens there apply to the 4D case, but this exemple should be applied to most of the statement made here in order to make sure that it doesn't provide a counterexample
Concerning the very nice work of Carlip and the potential ambiguities in 2+1 (did you know that the world revolved since then?), lets recall that the ambiguities that are described in the work of Carlip refer to the quantisation of pure three d gravity on the torus. A case that we can now do in the back of the envelopp.
This case is far too simple and especially singular (it is a non stable RSurface)to be generic, in order to chose the right quantisation you have to show that it is possible to consistently quantised the theory on all types of background while respecting the symmetry. This means that you have to give the prescription to glue amplitudes and extend the quantisation to higher genus surfaces and include topology changes while respecting the diffeomorphism symmetry of the theory.
The Ponzano-Regge model properly understood does exactly the job and pick one particular candidate available (Maas operator of weight 1/2 if i remenber correctly) in

the torus as being consistent and anomaly free, I don't know of any proof or evidence that an other inequivalent but consistent quantisation scheme exists.
I don't have a proof either that that the other possibility are necessarilly inconsistent an interesting but difficult open problem. The bottom line is that there is only one full quantisation of three d gravity known today where everything can be computed: the spin foam quantisation, which is also shown to reduce to the t'hooft quantisatisation of the theory when the later apply and to the hamiltonian chern-simons quantisation, when the later apply namely if you restrict to cylinder.

85. **Urs**
January 23, 2006

Concerning those kappa-Minkowski spacetimes: The deformed symmetry group is the *global* symmetry group of these spacetimes, right? These gadgets are still manifolds whose tangent spaces carry a Minkowski metric, right?

86. **Zorq**
January 23, 2006

Bords:

No, I *am* asking about the Wilsonian effective action. You are right that, at 1-loop, this differs from the 1PI generating functional. The latter includes loops of light particles, whereas the former includes only loops of heavy particles (the stringy modes we are integrating out).

So, to extract the Wilsonian effective action, one needs to subtract off the contribution of loops of light particles (cut off, as necessary, at the String scale).

At tree-level, the Wilsonian and 1PI effective actions coincide. And, even there, one has nontrivial R^2 and R^4 corrections, due to the exchange of massive string states.

Note that the Wilsonian effective action determines, not just the vacuum, but also the *dynamics* of the light fields.

Lee claims (apparently) that, even in pure-gravity, the higher-order corrections to GR, encoded in the Wilsonian effective action, are different in different LQG vacua. (But not, for some reason, the values of G_N and the cosmological constant? Why don't those differ from vacuum to vacuum, as well?)

"You're right, string theory does (also) constrain the infinite number of
parameters in the wilsonian action …. "

OK, let me address that, so that, at least we can have two paradigms for how the infinite number of a-priori independent couplings get fixed (the first is a UV fixed point).

As just discussed, the low-energy theory has an infinite number of coupling constants (as any effective theory must). They do *not* approach a fixed point as we go to the UV. Instead, at the String scale, the effective field theory breaks down, and is replaced by the full String Theory.

For present purposes, the best way to describe that theory is to use Zwiebach's covariant closed string field theory. That is also a theory with an infinite number of coupling constants. But they are not independently adjustable. In fact, they are fixed by a new principle. The BV Master Equation recursively determines all of the couplings.

Now, before Lee starts complaining, Zwiebach's covariant closed string field theory is not manifestly background-independent. One needs to choose a nilpotent derivation, "Q", of the *-algebra, and a choice of Q singles out a background. Moreover, we only know how to solve the BV Master Equation in perturbation theory, so that, too, cannot be done in a background-independent fashion.

But, since Lee says that the effective action extracted from spin-foam theories isn't background-independent, either, I would say, "people in glass houses …"

87. **Lee Smolin**
January 23, 2006

To Boreds,

You " presume that if you try to perturbatively quantize GR around this
background (kappa-Minkowski that it will be non-renormalizable, and that there will be an infinite set of counter-terms." -To my knowledge its not known if this is true or not, perhaps someone else knows. Otherwise it would make a good research project. The reason it may be false is that some DSR theories incorporate maximum energies and momenta.

To Zorq, "Will the effective field theory, at least, be writable as a generally-covariant local functional of the metric?" Again, not known, but a good research project. One conjecture is it will be writable as a function of an energy dependent metric as in our work on rainbow gravity with Magueijo.

btw by uv finiteness we mean you sum over the labels on intermediate states and, rather then diverging as is the case in perturbaive QFT when the labels are momenta and the sums are unbounded, the sums are convergent. The fact that this doesn't coincide with textbook meanings in perturbative background dependent QFT is obvious, but again, our point is you have to learn a new kind of QFT.

If i can make a remark, the questions being raised are good ones, what is confusing is the adversarial tone. The discovery by Freidel and Livine that in 2+1 quantum gravity with matter there is an effective field theory on kappa-Minkowski is very recent. We don't know that this is the case in 3+1, although we know how to try to show it and it is in progress. We don't know whether there will be any version of effective field theory besides this one, which describes the excitations of a ground state with deformed poincare invariance. Since the fundamental theory is not formulated in spacetime and spacetime geometry is emergent, it is not obvious or known whether there will be a diffeo invariant effective field theory of the kind which is assumed to exist in formal treatments of the path integral. Why isn't it good-and exciting-when research indicates a new way of thinking about things that might succeed in a case where the older approaches have been unproductive?

To Juan, Thanks, indeed many of us see these as models which allow certain ideas and hypotheses to be precisely explored. We are open minded and if you have a new approach that is good and not bad. But at the same time, rather than rejecting a whole research program you might try to take the attitude of learning from its successes. You can even contribute to it while keeping an open mind as to its ultimate success. This is after all science.

Thanks,

Lee

88. **Luboš Motl**
January 23, 2006

No, I am not joking that I consider Nicolai et al. experts, and probably leading experts, in LQG and all aspects that have and have not been achieved by LQG. And if you ask me whether they understand it better than some older colleagues of them in the field, my answer is Probably yes.

89. **boreds**
January 23, 2006

Zorq—yes, it is clear what you mean now.

I just wanted to check you weren't equating the 1PI corrections with the wilsonian action.

90. **boreds**
January 23, 2006

sorry Lee didn't intend for that to sound adversarial. I would be interested if someone can discuss (as you suggest) effective field theories on kappa-minkowski; I don't have much intuition about what the differences would be.

91. **Who**
January 23, 2006

L, congratulations on your results of the past year and best wishes for what is in progress.

I did not expect to see you posting here at Peter's. Thanks for these helpful comments!

Be well.

January 23, 2006

Concerning the very nice work of Carlip and the potential ambiguities in 2+1 (did you know that the world revolved since then?)

You'll have to take that up with Carlip, then — I'm certainly not an expert on the subject. From p. 42 of this from '04:

> More than an "existence theorem," though, the (2+1)-dimensional models also provide a "nonuniqueness theorem": many approaches to the quantum theory are possible, and they are not all equivalent.

93. **Zorq**
January 23, 2006

Lee said:

"The fact that this doesn't coincide with textbook meanings in perturbative background dependent QFT…"

Aside from my last comment to Boreds, *nothing* I have said in any of my comments in this thread have relied on perturbation theory. The Wilsonian Renormalization Group is a nonperturbative concept.

"'Will the effective field theory, at least, be writable as a generally-covariant local functional of the metric?' Again, not known, but a good research project."

I'm surprised at this response. If the answer were "no," then it's clear that one ought to dismiss the whole approach for having violated general coordinate invariance (whatever protestations to the contrary).

"The discovery by Freidel and Livine that in 2+1 quantum gravity with matter there is an effective field theory on kappa-Minkowski is very recent. We don't know that this is the case in 3+1, although we know how to try to show it and it is in progress."

Integrating out gravity, to obtain an "effective theory" of just matter makes sense (barely) in 2+1 dimensions. In 3+1 dimensions, where gravity has local massless degrees of freedom, attempting to integrate out gravity (or any other massless degrees of freedom) is daft. The result will be a nonlocal mess.

Why would you expect anything nearly as "simple" as kappa-Minkowsi?

94. **Wolfgang**
January 23, 2006

Lee and L.,

it is encouraging that quantization of gravitation in 3D seems possible,
but as far as I know there are enough open questions (e.g. on the question if length is quantized) and it is not clear if different approaches give the same result (but the earth keeps revolving).

We also know some results in 4D for the strong-coupling limit and it would be nice to compare e.g. LQG with earlier results to see if different approaches give the same result.

95. **Who**
January 23, 2006

Wolfgang

> Lee and L.,
>
> it is encouraging that quantization of gravitation in 3D seems possible,…
>
> We also know some results in 4D …

Since you speculate about future results, the next development in 4D that I am expecting is reference [17] in hep-th/0512113
where they say

—quote Freidel-Livine—
We have shown how to write the 3d Feynman evaluations as expectation values of certain observables of a topological (abelian) theory. This (abelian) theory was then identified as a particular limit of the quantum gravity theory. This result suggests that **the Feynman evaluations of 4d QFT could be reformulated as expectation**

values of a 4d topological model. This is supported by the fact that 4d gravity becomes topological in the G → 0 limit [16]. This would be interpreted as the zeroth order of the spinfoam model for 4d quantum gravity [17]. …
—endquote—

Reference [17] is listed as “in preparation”. It seems to me that a lot depends on how that work goes. I am hopeful.

96. **Urs**
January 23, 2006

Aaron,

as far as I recall from last time we discussed this on Jacques’ blog, those LQG uniqueness theorems pertain to the kinematical Hilbert space only.

97. **Wolfgang**
January 23, 2006

Who,

I am looking forward to this paper. Just one more time I would like to make myself clear: I agree with Lubos that different formalisms should give the same results for the same physics; 3D gravity and strong-coupling gravity are cases where this can be checked (by the way I would be interested to also see how string theory compares!). So far different formalisms seem to give different results and some basic questions are un-answered.

98. **Chris W.**
January 24, 2006

This is a follow-up to Peter’s update; see the last section of gr-qc/0601095: **1.3.1 The UV problem in the background independent context** (p. 19-21).

99. **Thomas Larsson**
January 24, 2006

Lee Smolin said:
The inner product of Fock space depends on the background metric, hence this quantization will never arise in a background independent formalism.

This is a serious objection, of course. The absense of an invariant inner product was listed as one of the four most important open problems in the conclusion of hep-th/0504020. It now seems that this problem is solved as a by-product of eliminating the overcounting of states in the classical harmonic oscillator, reported in hep-th/0411028. However, this is work in progress and success is not guaranteed.

Note however a that diffeomorphism-invariant inner product can sometimes be defined without reference to a metric; for half-densities and, if the number of spacetime dimensions n is even, for n/2-forms. But this is not very relevant, of course.

Krauss and Susskind versus Horgan

January 22, 2006
Categories: Uncategorized

Lawrence Krauss and Leonard Susskind have a letter to the editor in this week's New York Times Sunday Book Review, complaining about John Horgan's NYT Book Review essay Einstein Has Left the Building of a couple weeks back. For some discussion of an earlier Susskind-Horgan exchange about another NYT piece of Horgan's, see here and here.

Krauss and Susskind write that "Horgan evidently sees the two of us as being on opposite sides of an imagined controversy", but that "the fact is that there is little of substance that we disagree about." They accuse Horgan of thinking "that reconciling quantum mechanics with Einstein's theory of gravity is a frivolous pursuit", whereas "both of us feel that reconciling the conflict between gravity and quantum mechanics is one of the deepest problems in modern physics." They comment about extra dimensions:

As for Horgan's bête noire of physics — higher dimensions, or what he refers to as "hyperspace theories" — he writes: "But pursuers of this 'theory of everything' have wandered into fantasy realms of higher dimensions with little or no empirical connection to our reality." That both of the present writers recognize that additional degrees of freedom of one sort or another are needed to characterize the physics of elementary particles may come as a surprise to Horgan. What the two of us may disagree about is what may be the likely physical and mathematical basis of this fact. But we both recognize that the mathematical spaces that we already deal with in describing the quantum theory of matter are in a certain sense more mathematically exotic than simple possible extra physical dimensions.

It seems to me that Krauss and Susskind are creating a straw man to attack here, not really dealing with Horgan's actual criticisms, the full text of which was:

Especially as represented by best sellers like "A Brief History of Time," by Stephen Hawking, and "The Elegant Universe," by Brian Greene, physics has also become increasingly esoteric, if not downright escapist. Many of physics' best and brightest are obsessed with fulfilling a task that occupied Einstein's latter years: finding a "unified theory" that fuses quantum physics and general relativity, which are as incompatible, conceptually and mathematically, as plaid and polka dots. But pursuers of this "theory of everything" have wandered into fantasy realms of higher dimensions with little or no empirical connection to our reality. In his new book "Hiding in the Mirror: The Mysterious Allure of Extra Dimensions, from Plato to String Theory and Beyond," the physicist Lawrence Krauss frets that his colleagues' belief in hyperspace theories in spite of the lack of evidence will encourage the insidious notion that science "is merely another kind of religion."

I don't see Horgan here criticizing the attempt to quantize gravity as "frivolous". His criticism of physicists as having "wandered into fantasy realms of higher dimensions with little or no empirical connection to our reality", is a justifiable one that deserves to be seriously addressed. Krauss and Susskind's comment that Horgan would be surprised that both of them think that new degrees of freedom will be needed to characterize elementary particle physics doesn't seem to have any basis in fact. Horgan isn't making broad claims that physicists shouldn't look for new degrees of freedom, he is very specifically referring to the use of extra space-time dimensions.

Krauss and Susskind at least implicitly take Horgan to task for referrring to such extra dimensions as "hyperspace". He may well have picked this up from Michio Kaku who wrote a book with this title. By the way, tonight Kaku will be appearing on the Art Bell "Coast to Coast" radio program, a program which is mostly concerned with UFOs and the like. If Krauss and Susskind want an example of the kind of theoretical physics research that Horgan is bothered by, they could check out this radio program.

Comments

1. **Chris W.**
   January 22, 2006

   > Many of physics' best and brightest are obsessed with fulfilling a task that occupied Einstein's latter years: finding a 'unified theory' that fuses quantum physics and general relativity, *which are as incompatible, conceptually and mathematically, as plaid and polka dots*.

   I do see in this a thinly veiled exasperation on Horgan's part with the belief—as expressed in research priorities—that such a unification is possible and worth pursuing. It seems to me that he has made fairly clear in his earlier writings that pursuit of this goal (and others, such as the nature and origin of consciousness) is likely to lead into a swamp of, as he calls it, ironic science.

   In a way he's right. We may become mired in just such a swamp. That risk has always existed when confronting difficult theoretical problems. Successfully facing the risk is what has distinguished great scientists from the much larger number of talented and competent practitioners who shy away from it, are defeated by it, or fall victim to it and lose their bearings.

2. **Lubos Motl**
   January 22, 2006

   Congratulations for having upgraded from Krauss's silly opinions about extra dimensions to Horgan's idiotic opinions about the whole modern science. What's the next step? Defending Dembski against those who argue that more than a "click" by an intelligent creator is needed to create and explain the world? 😉

3. **anon**
   January 22, 2006

   I find the letter by Sootkind and Krauss totally SLEAZY and DISHONEST. My opinion of Sootkind's tactics in debating and politics was already very low, but my opinion of Krauss is now lower.

   "That both of the present writers recognize that additional degrees of freedom of one sort or another are needed to characterize the physics of elementary particles may come as a surprise to Horgan."

   Really! Horgan would be surprised by that? Ever since Newton, physicists have used "additional degrees of freedom of one sort or another". Any person of normal intelligence will have no problem realizing that by "hyperspace", Horgan meant extra space-time dimensions. Only a genius String Theorist could misread that.

4. **mathjunkie**
   January 23, 2006

   Krauss and Susskind write that "Horgan evidently sees the two of us as being on opposite sides of an imagined controversy", but that "the fact is that there is little of substance that we disagree about."

   Does it mean that Krauss wanted to reverse his claim that String theory is a colossal failure?

5. **secret milkshake**

January 23, 2006

maybe somebody has gotten to him.

6. **brst**
January 23, 2006

I am amazed at the straw-man arguments Krauss(it was expected of Susskind) has used to attack Horgan. This is pathetic. The credibility of physicists, not just string theorists, is sinking like a stone. I think Krauss should retract his book since "there is little of substance that they disagree about" .

Who is going to be next? Et tu, Peter?

7. **Juan R.**
January 23, 2006

I do not read anything wrote by Horgan after i read his *End of Science* book.

Reading that Peter Woit has wrote above, it appears that Horgan is just maintaining the RELEVANT and PURELY SCIENTIFIC point that he exposed in his book years ago about the (non)verificability of the exoteric ideas of string theory (such as tiny extradimensions).

In his interview to Witten, Horgan claimed that both extradimensions and Planck scale strings were really non-verifiable and therefore outside of science (physics).

Witten's esxhasperation to lack of empirical evidence is well-reflected in the interview.

I would not use the word 'idiotic' other used in this blog, but i find particularly relevant Witten's belief (exposed in the book) that aliens already discovered GR, supersimmetry, QFT, and string theory but not necesarily in that order 🙂

—

Juan R.

Center for CANONICAL |SCIENCE)

8. **Dumb Biologist**
January 23, 2006

It is odd that one would bother to write an entire book about what "little of substance" there is to disagree about. I wonder what these extra degrees of freedom, if not extra spatial dimensions (compactified or otherwise) are supposed to be.

My understanding of Krauss' thesis was that there's some psychologically-bequiling quality posessed by "extra dimensions" that draws great minds into la-la land.

At any rate, is not testability the most pressing issue? Extra dimensions may be 100% real, but if it takes god-like technology to probe them, it seems throwing the bulk of theorists' efforts into theorizing about them is putting the cart before the horse, and apparently discounting the possibility that the vast gulf of energy scales between what we can currently test and the Planckian realm may hold some big surprises.

For folks whose research must be mathematically consistent, it's surprising to see this level of rhetorical incongruity.

9. **woit**
January 23, 2006

mathjunkie,

Krauss has said that his "colossal failure" quote was taken out of context.

D.B.,

Not sure exactly what "extra degrees of freedom" Krauss and Susskind are talking about. One possibility is supersymmetry which is sometimes thought of as involving "extra (fermionic) dimensions", another is gauge theory itself, which in some sense involves extra "internal" dimensions.

10. **Dumb Biologist**
January 23, 2006

OK. Thanks!

11. **Chris Oakley**
January 23, 2006

It could also be that the "degrees of freedom" refer to the amount of Superstrings in the theory. Krauss is saying that unless this parameter is zero then the theory will be a "colossal failure"; Susskind is saying otherwise. The so-called "disagreement" – massively exaggerated by Horton – is only over this one unimportant parameter.

12. **ksh95**
January 23, 2006

How's this for off topic.

Peter, what ever happened with the trackback issue?

13. **Quantoken**
January 23, 2006

Juan:

Interesting to know that Witten has the belief that aliens have figured it all out: "aliens already discovered GR, supersimmetry, QFT, and string theory" How did Witten know. Did he belong to religious sect that happen to believe so? Or how could he be so certain that aliens study super string theory at all? Maybe the aliens never ever started the super string theory, but worked on something else instead? How could Witten know it is super string theory that the aliens studied, not something else?

I propose to Witten that we utilize some of those giant radio telescope dishes, and send out a telegraph to the space asking about questions in super string theory. Some where in the universe there must be advanced alien civilizations capable of intercepting our messages and they may be kind enough to response with some easy answers.

Or maybe we get no response at all, in which case the anthropic principle answer would be that these aliens, who are so advanced they figured everything out, figured out that those earthlines must be too stupid and too primitive that they are still wasting their time on super string research after two decades, and which we aliens know a long time ago is a deadend.

14. **woit**
January 23, 2006

Quantoken and Juan,

Stop with the nonsense about Witten and aliens. This is just a reference to Witten's speculating about the possibility of various ideas about theoretical physics being discovered in a different order.

ksh95,

Still don't know what's going on about this. Actually I couldn't access trackbacks at all there for the few days, so I thought something was up. But it appears to have been a problem caused by some cookies my browser was using, deleting them returned things to normal.

A member of the arxiv advisory board tells me someone from the arXiv has promised to contact me this week and tell me what is going on. Will let you know what I hear.

15. **Lubos Motl**
January 23, 2006

Horgan's book definitely tried to picture Edward Witten as a person who is confused by ideas about aliens.

If there are two possible explanations – Edward Witten being confused or John Horgan (with all people who endorse him) being a complete idiot, which explanation do you think is more likely?

http://motls.blogspot.com/2006/01/when-krauss-and-susskind-are-right.html

16. **D R Lunsford**
January 23, 2006

I wonder if the aliens have confused ideas about Witten? They seem to think the smart people live in trailer parks.

17. **plato**
January 23, 2006

> General use of hyperspace as a term for such domains dates back at least to the 1940s; it is found in Asimov's epochal Foundation novels and probably predates those.

Does anyone know "for sure" where this term came from?

18. **Joe Zhou**
January 23, 2006

Slightly off topic. In an interesting paper (hep-th/0601162) Delia Schwartz-Perlov and Alexander Vilenkin conclude that the volume distribution for the cosmological constant is nonflat near the observed value, which seems to invalidate previous calculations based on the anthropic principle.

19. **ks**
January 24, 2006

Idiots vs fanatics. I guess I'm a little in favour for idiots. It's simply healthier to be too stupid to not believe in things that don't exist. The same thing with sensitivity and paranormal awareness. It's better to be a little too dumb to feel spooky phenomena.

20. **mathjunkie**
January 24, 2006

Woit said:
Krauss has said that his "colossal failure" quote was taken out of context.

Sorry, Peter, my English is not very good as it is not my mother tongue. So, does it mean that Krauss was referring to something else that is a "colossal failure" but not to string theory?

21. **Chris Oakley**
January 24, 2006

Maybe he decided to order a latte one day at the physics department canteen instead of a capuccino. Not liking it as much, he then decided that this move was a "colossal failure".

22. **Simon**
January 24, 2006

Actually, in string theory there is not such a big difference between degrees of freedom and space-time dimensions. Quantizing in Minkowski space for example, the space-time coordinates appear as fields in the worldsheet theory. In compactifications to 4 dimensions, what is required for consistency is not really to add 6 dimensions, but to add a conformal field theory on the worldsheet with the right central charge. Sometimes these fields can be interpreted as the coordinates of a compact manifold, and other times not.

Two examples of the latter are general Landau-Ginzburg models, and some interesting recent discoveries of nongeonetric flux compactifications: hep-th/0508133. It's also important that in CFT moduli space, one can moove smoothly between geometric and nongeometric backgrounds. So in the context of compactification (as opposed to say intersecting brane models) it really is better to think in terms of degrees of freedom of a conformal field theory than extra dimensions.

This equivalence of degrees of freedom and extra compact dimensions is not unique to string theory. This is the essence of Kaluza–Klein theory – one can study a K-K expansion of any field theory on R^4\times S^1 for example and find a field theory just on R^4, in this case with an infinite number of fields.

Anyhow, we know for sure (from unitarity bounds) that there are new degrees of freedom to be found even at the weak scale – most likely a Higgs boson. The same sorts of arguments, applied to graviton scattering, require that new gravitational degrees of freedom appear at (or before) the Planck scale. I guess Susskind and Krauss are just saying that they disagree about what these might be – but not about whether they exist, and not about whether they will seem exotic (as they probably will) if they are ever discovered.

23. **Steve Myers**
January 24, 2006

Maybe I'm being too general here for a group of theoretical physicists, but on the question of dimensions: I've mentioned before that you can always get a symmetry by adding dimensions. Also, suppose you are writing an algorithm to generate (compute) the world, you might use 100 dimensions (degrees of freedom) but the result, the output should only have 4. In real time targeting of tanks, for example, with the input signals from a sidelooking radar, you begin with 12 dimensions and compact them to 7 so you can do the calculations in real time, but the missile you fire and the tank you hit (?) exist in a world of 4 dimensions. In an even more practical example: the number of degrees of freedom of a diaper making machine are greater than the number of atoms in the universe but the product produced holds 3-D excrement. One last thing: the possible worlds of many dimensions and "the landscape" have the odor of Anselm's ontological proof. Is physics entering another Dark Age?

24. **D R Lunsford**
January 24, 2006

Steve – if you have a specific, physical reason for introducing more dimensions, and a specific, physical ontology for them, then you are inside the boundary of science. When you introduce them to make an already wacky idea somewhat credible, you are close to the edge. When you introduce them in a way that had been discredited 30 years earlier by one of the great physicists, in order to make a wacky idea credible, and then you spend the next 25 years beating an unworkable strawman, you are over the fence into non-science.

-drl

25. **Dumb Biologist**
January 24, 2006

Help for the ignorant, please:

"Degree of freedom" here seems to encompass just about any quantifiable or qualifiable property of a particle; what it both can do and be. Is that correct? I guess I have a primitive understanding of the term, more like "what's the particle's position, momentum, spin" and so forth. Would, say, the ability for a lepton to be a muon or an electron be considered a "degree of freedom" for a lepton? I thought a string theorist would answer that question by saying "because the string can vibrate at a certain frequency, wrap around compactified dimensions of a certain shape, and is so wrapped at a certain tension, it looks like a particular kind of lepton". I.E., the ability to move around in a particular way gives the string its observed properties, and the extra dimensions provide the "degrees of freedom" to so move.

26. **Simon**
January 24, 2006

D.B.

Those are good questions. What is meant by degrees of freedom depends to some extent on the context, i.e. classical mechanics, field theory or string theory. Perhaps the following will help:

Classical particle mechanics:
– Here things are as you say – each component of position or momentum is a degree of freedom, i.e. the number of d.o.f. is how many numbers you have to give to specify the state of the system.

Nonrelativistic quantum (particle) mechanics:
– Here even a single particle is described by a wavefunction, which requires an infinitely many numbers to specify. So we often think of the number of d.o.f. as the number of generators of the Heisenberg algebra (esssentially positions and momenta). But very few discussions in particle physics take place in this context.

Classical field theory:
– There are classical systems with an infinite number of d.o.f. as defined above, e.g. the electric field. Formally, one can understand a field as a harmonic oscillator at each point in space–time. Here we think of a d.o.f. as an component of a field – see the next section for comments.

Quantum Field Theory:
– Here a degree of freedom refers to a component of a field. But there are many subtleties. Some of these are as follows:
– Gauge Theories – here some of the d.o.f. (i.e. some of the ways the field can change) are local symmetries of the action – thus the description of the system in terms of gauge fields is redundant, and there are fewer d.o.f. than there appear.
– On shell/Off shell – The equations of motion of the theory are extra constraints on the fields – further reducing the number of independent components. We call the ones left "on-shell d.o.f". The full set are called the "off-shell d.o.f".
– Propagating? – Sometimes (particularly in supersymmetric theories) it's useful to have fields whose equations of motion are algebraic, i.e. not differential equations. So you don't have to put in initial conditions to solve them. They can be solved and the solution substituted in to the action to eliminate them if we want. These are called "non-propagating d.o.f." A non-supersymmetric example of this is general relativity in 2 dimensions.

String Theory:
One caveat: In an important sense it isn't yet known what the fundamental d.o.f. of string theory really are. If we study perturbation theory about a fixed background, we get a quantum field theory with an infinite number of fields (although a finite number with masses less than the Planck scale) – corresponding as you say, to the different oscillations and winding modes of the string. But we know that the appearance of an infinite number of d.o.f. is misleading from the AdS/CFT correspondence. There, string theory in AdS is seen to be equivalent to a field theory with just a finite number of fields (N=4 SYM). Moreover, prior to the discovery of the AdS/CFT correspondence there were widely held expectations that something like this would happen – going under the general name "holography".

27. **Simon**
January 24, 2006

One last comment: the reason why an extra dimension (a few extra degrees of freedom) can be replaced with an infinite number of fields in a K-K expansion, is that those infinitely many fields also come with infinitely many gauge redundancies. More details are in hep-th/9410046.

28. **Dumb Biologist**
January 24, 2006

Wowza! OK, that will take some digestion, but I sincerely appreciate the effort to answer the question, and I guarantee I will put at least commensurate effort into understanding it (to the limits of my intellect, of course!).

Thanks!

29. **Simon**
January 24, 2006

D.B.
No problem. The posts above do assume some technical knowledge, and leave a lot unsaid, so don't worry if they're confusing – you can always ask more more questions!

30. **Tony Jackson**
January 24, 2006

I absolutely agree with you about Kaku. Here's more from Art Bell:

"Kaku also forecast into the far distant future when our universe will be dying out. At such a time, a Type 3 or 4 civilization (capable of manipulating huge amounts of energy) might construct a massive machine that could make space and time unstable. With an atom smasher the size of a solar system, he hypothesized it might open up a bubble ten light years across, through which our civilization could escape into another universe."

This is just a bad Star Trek episode. The man is an embarrassment to honest physicists. I stopped taking him seriously when he made a fool of himself campaigning against the launch of the magnificent Cassini probe.

31. **J.F. Moore**
January 24, 2006

Very well put post. It makes me wince every time I see someone who should know better make a logically weak argument against Horgan (the worst being ad hominem). It seems to have happened a lot in the last decade.

32. **Dumb Biologist**
January 24, 2006

Awright…just blast this post, Dr. Woit, if you feel I'm being an annoying newb here. I'll understand completely.

To Simon (or whoever cares to answer): This AdS/CFT thing. I read Maldacena's article in SciAm, and while he didn't mention "conformal field theories", it was pretty clear that's what he was describing. Hence, I know probably about as much as my brain can handle about "anti-de Sitter space". Clearly, doing physics in this kind of space has had some exciting consequences.

Now I know some flat maps of the Earth are called "conformal" because, while distorted in some ways, they preserve some important features of an actual globe, and can even be more convenient in some ways (a straight line on a Mercator projection always has a constant heading, for instance, though it's harder to find the shortest distance between two points than it is on a globe). That seems to be roughly analagous to what's going in in modeling physics in one less dimension than usual. Apparently, out of this has come a rigorous demonstration of the idea that all you need to know about a volume can be represented on its surface, and this makes doing quantum gravity easier by turning it into a field theory something like QCD. You can talk about gravity in terms of stringly lines of gluons, or something like that.

Okaaay…So, not surprisingly, I'm at about my limit even attempting to grasp most of this, but here goes: What happens to all the compatified dimensions when all of space looks like a flattened image of negatively-curved hyperbolic solid?

33. **Simon**
January 25, 2006

D.B.
Ok, more good questions. Conformal symmetry is a very interesting subject, but it's obscuring the important issues here. First, there are (at least) two conformal field theories in AdS/CFT. One is the theory on the worldsheet of the string in AdS (with some suitable extra dimensions). The other (eponymous) CFT is the `dual' theory in some sense living on the boundary of AdS. The first is a 2d theory, the second is 4d.

Most importantly: whereas in the 2d theory, conformal symmetry is required for consistency, it is not so required in the 4d theory. What is meant by this is that theories without conformal symmetry are also (in a slightly different way) dual to string theories in AdS. This result which was expected because of a very general argument of 't Hooft in the 70s, has recently been fleshed out in more detail. And it lends hope to the idea that non-conformal field theories like QCD can be reformulated as string theories. It is expected that this duality would relate strongly coupled regions of one theory to weakly coupled regions of the other, so the eventual goal is to access the low energy bound states of QCD (which at present cannot be derived analytically because of the strength of the coupling) through the low energy excitations of string theory.

I haven't said much about what conformal symmetry actually is – you can think of it as a generalization of `scale invariance' – i.e. rescaling all the lengths in the system by a same amount, although it this isn't really quite the same thing. Remembering that shorter lengths are equivalent to higher energies, and vice versa, you can see that a theory like QCD (or for that matter the rest of the standard model) where the strength of the coupling depends on the energy, cannot have conformal symmetry. (In that case it's interesting that the classical QCD does in fact possess scale invariance, but it is broken by quantization).

34. **Urs**
January 25, 2006

> you can think of it as a generalization of `scale invariance' – i.e. rescaling all the lengths in the system by a same amount, although it this isn't really quite the same thing.

It is 'local' scale invariance, meaning invariance under rescalings that differ from point to point. Equivalently. it means that only angles have an invariant meaning, not lengths.

35. **Simon**
January 25, 2006

There are a few things here one might want to have separate terms for. There are local scale transformations that act directly on the metric – these are called Weyl transformations. Changes of coordinates that happen to result in rescalings of the metric are conformal transformations. But surprisingly there are more ways to do this than you might think. You can rescale the coordinates – so called dilatations. But there are also `special conformal' transformations, which roughly, invert the coordinates, translate them, and then invert them again.

The special conformal transformations have some interesting consequences. They can move any point in space-time out to infinity. As a result, in a conformal field theory it is not possible to localize interactions in a conformally invariant way. This is why many people say that it makes no sense to calculate scattering amplitudes in CFTs, and why people should just calculate correlation functions.

36. **D R Lunsford**
January 25, 2006

Simon said

As a result, in a conformal field theory it is not possible to localize interactions in a conformally invariant way. This is why many people say that it makes no sense to calculate scattering amplitudes in CFTs, and why people should just calculate correlation functions.

This doesn't sound right. It's certainly not right in Weyl conformal geometry. In fact the latter comes about precisely from thoroughly localizing metricity. Weyl therefore called it "pure infinitesimal geometry".

Discover Interview Online

January 24, 2006
Categories: Uncategorized

There's an extended version of the interview of me by Susan Kruglinski in the February issue of Discover magazine that is now available, for free, on-line.

Before anybody starts yelling about AdS/CFT or topological strings when they read the headline "No one has a plausible idea about how string theory can explain anything", I'll just point out that, yes, it's certainly plausible that some day string theory will explain something about QCD, and it already has explained some things in mathematics. The headline is a summary of some things I say in the interview, and in context it should have been clear I was talking about the use of string theory to predict anything not already predicted by the standard model.

Update: Harvard string theorist Lubos Motl has posted his commentary on the Discover article. If you read the comment section there, keep in mind that he is deleting comments from anyone who disagrees with him. I encourage anyone new to the current controversy over string theory to read what I have to say, read what Lubos has to say, and carefully look into the scientific issues involved to make your own judgement about what is going on here.

Comments

1. **anonymous**
   January 24, 2006

   'In mathematics there is much more of a culture where people spread out and devote their lives to thinking hard about something that interests them. … when the problems are very hard and no one knows what to do, I think people need to be willing to dig in and spend years thinking about something different than what other people are thinking. And there really isn't the kind of institutional support within the physics community for this kind of behavior, whereas there is in mathematics.'

   There is probably too much indoctrination in favour of strings to allow this. Physicists know it is highly unlikely that they could change the mainstream, so they prefer to stick with it. The fear of being blacklisted for non-standard ideas is quite real at the lower levels in physics. Those who rise to the higher levels usually have more mainstream ideas.

2. **Gravity**
   January 24, 2006

   Peter, i enjoyed the interview. i hope it attracts some new readers. i'm a layman, but like your log anyway. i learned about the landscape through it, and about interesting links between math and physics. certainly it's one of the more exciting sites on the web.

3. **Quantoken**
   January 24, 2006

   Peter says: "I was talking about the use of string theory to predict anything **not already predicted** by the standard model."

   Peter I guess you have to further correct your statement. You sounded as if you think string theory already predicts everything that SM predicts, it just does not go beyong SM. That's far from being correct, not only has string theory not predicted anything beyond SM, it does not predict any thing that SM predict, either. It simply has **not** made any prediction whatsoever. Zero, Nada.

   It's important to point that out because we keep hearing string theorists make claims like "SM can be derived from string theory" or "string theory leads to GR" or so. Those are flat out lies. You can't get SM starting from string theory. You can't derive the Einstein Equation of GR from string theory. You can't calculate any of the coupling constant or anything from string theory. Zero, Nada.

   I also made some comment disputing the notion that just because string theory leads to very rich mathematical structures from a very few assumptions that it necessarily has to have something to do with the nature. My comments can be found on Lubos's blog.

9. **A. nonymous**
January 24, 2006

Peter, have you noticed that Lubos is your greatest ally in your fight to lower people's regard for string theory? I would imagine that a lot of people who read the article will look at your blog, then look at Lubos's review of your interview, and draw the obvious conclusion.

10. **Dumb Biologist**
January 24, 2006

I'm not qualified to draw any conclusion except that level of rancor borders on frightening. I'm glad I've chosen to stay anonymous. Maybe it makes me a coward, but who needs enemies like that.

11. **Christine**
January 24, 2006

> **Even string theorists admit that it is not really a theory. What is it?**
>
> W: The best way to say it is what people have now is really an approximation to a theory. The kinds of equations that they have now are the kinds of equations you would get in an approximation scheme to some underlying theory, but nobody knows what the underlying theory is.

Merriam-Webster Dictionary on "approximation":

> something that is approximate; especially : a mathematical quantity that is close in value to but not the same as a desired quantity

or, on "approximate":

> nearly correct or exact (*"an approximate solution"*)
> *thesaurus*: being such only when compared to something else

These definitions in purely logical terms lead one to conclude that string theory cannot be an approximation scheme because the underlying theory to be compared with (viz., quantum gravity) is *unknown*. So in order to be an approximation scheme [*to something known*], string theory should be compared with a well established theory (or experimental data) in the regime where it applies (e.g., it should unambiguously reproduce — or approximate — the classical limit, SM particles, etc, that is, all fundamental observed phenomena that it is supposed to encompass or describe). But of course, things cannot stop there.

So, one is lead to conclude that such an "approximation scheme" should be somewhat viewed as an euphemism to "prediction" in order that things make sense. String theory must not only reproduce the physical properties of the fundamental constituents of nature to a reasonable precision [*if is is to be seen as truthful approximation scheme to well known facts*], but also *predict* new phenomena or indirect effects related to the Planck scale physics [*if it is to be seen as a truthful quantum gravity theory at some stage*]. Only then string theory can be more clearly evaluated.

16. **robert**

January 25, 2006

Sad to say, the author of Cosmic Variance's 'Best physics paper ever', Isacc Newton, was quite as nasty as Professor Motl in his interactions with his contemporaries – even his 'standing on shoulders of giants' comment was a scarcely veiled insult to the diminutive and deformed Hooke. So Lubos is merely carrying on in a great tradition, albeit one that does not show physics and physicists in a very positive light.

17. **Christine**
January 25, 2006

I have a personal theory on Lubos Motl but I will never discuss it.

Science is obviously made by people, and people have a large spectrum of behaviours.

18. **anonymous**
January 25, 2006

Christine, see film showing Motl's hair growing as he attempts smile: http://www.kolej.mff.cuni.cz/~lmotm275/morf/lhm.gif
May it be best for all that Motl remains angry 😉

19. **Kasper Olsen**
January 25, 2006

Maybe we should try to comment on what Peter was actually saying about string theory – and not so much if we like Lubos or not? 🙂

(I'll have to read the interview with Peter first, then I'll post my comments).

Best, Kasper

20. **mathjunkie**
January 25, 2006

Don't know if Ed Witten will read this comment page and the message below:

Hi Ed Witten,

Please make a verifiable prediction from string theory to prove that the anti-stringy people are wrong. Then, Peter's famous "Not Even Wrong" webpage will have the heading changed to "I was wrong".

mathjunkie

HeHe…

21. **Urs**
January 25, 2006

> Please make a verifiable prediction from string theory

That's easy. Weakly coupled perturbative string theory predicts that there is an energy scale at which the massive excitation modes of the string are visible.

If true, this is verifiable.

What is not so easy is to *falsify* this prediction.
That is because the statement is of the form

"there is at least one x (in the set of energy scales) such that …"

Not observing any stringy modes below any fixed energy scale E therefore does not suffice to falsify this.

Note that even though this prediction is verifiable, it might well be wrong. It could be that strings exist but are not weakly coupled, so that perturbative string theory does not apply. It could also be that there are no strings at all.

But if you see any higher string excitation, then you have verified this prediction of perturbative string theory.

22. **anonymous**
January 25, 2006

Vague non-quantitative 'predictions' are not scientific. Can you predict the exact energy of the massive excitation modes and therefore prove it is within range of experimental measurement?

23. **Nigel**
January 25, 2006

"What is not so easy is to falsify this prediction." – Urs.

Does this place string theory at the level of astrology?

24. **a**
January 25, 2006

In my opinion the situation is:

1) Quantum gravity likely gives undetectably small effects in any relatistic experiment.
2) Despite this, theorists studied quantum gravity hoping that it could lead to a unique theory of everything, able of predicting something.
3) Strings seem to give a unique theory, but in 11dimensions.

4) In string models the complicated physics that we see at low energies mostly comes thanks to a complicated enough higher dimensional set-up, rather than from theory.

I think that 4) is the reason that prevented strings to give so far results relevant for physics. It is often said that to progress we need “a deeper mathematical understanding of string theory”, but the real problem seems harder: we do not know the geography of extra dimensions.

(By the way: I posted a similar comment on Lubos blog, and it was deleted. Even if it is not possible to constructively discuss about physics, it remains my favourite trash show).

25. **Urs**
January 25, 2006

> Does this place string theory at the level of astrology?

No. It is common for scientific theories to make predictions that are verifiable but not falsifiable.

The standard model demands that there is a Higgs field, but does not predict at which energy it will be found.

Not that there are no problems with string theory. But blanket anti-hype like “is not scientific”, “does not predict anything” are, in their crudeness, not any different from the original pro-hype like “will predict particle masses in a couple of months”.

You don’t have to like string theory. But if you reject it, you might want to do so for the correct reason, not just because you read the latest tabloid headlines.

26. **Urs**
January 25, 2006

> It is often said that to progress we need “a deeper mathematical understanding of string theory”, but the real problem seems harder: we do not know the geography of extra dimensions.

But that’s the point. As long as the non-perturbative formulation of the theory is not fully understood it remains inconceivable how vacuum selection should be understood properly.

27. **a**
January 25, 2006

To Urs:
ok, one can try to study if non perturbative effects reduce the possible number of vacua from 10^500 to something more reasonable, or maybe even one. But this looks like hoping in a miracle, while the alernative view looks (at least to me) the true one: many vacua are possible, no vacuum selection mechanism exists, we are in one of them for no special reason.

28. **Urs**
January 25, 2006

a,

right, I agree. I just think that when, while doing research, you run into something that is getting out of control, you might want to pause and try to understand what is really going on at the fundamental level in the hope to get back in control again, instead of starting to wildly speculate and play around with a network of conjectures.

29. **Nigel**
January 25, 2006

“It is common for scientific theories to make predictions that are verifiable but not falsifiable.

“The standard model demands that there is a Higgs field, but does not predict at which energy it will be found.” – Urs

But the Standard Model is only accepted for predicting many confirmed details about measurable nuclear interactions!

Kepler worked as an astrologer to live, because his alternative physics wasn’t popular, and astrology was in his day a highly mathematical enterprise (epicycles, etc.). String theory and astrology are similar in being unscientific uses of mathematics.

“You don’t have to like string theory. But if you reject it, you might want to do so for the correct reason, not just because you read the latest tabloid headlines.” – Urs

If it can’t be falsified, nobody can disprove it. The real problem with string speculation is arrogance. With the mainstream embedded in untestable speculation, the subject is unhealthy. It would be better if there was more effort given to alternatives.

30. **Urs**
January 25, 2006

In the discussions here the target always tends to be moving.

If the statement is that

“People should look at alternative approaches.”

I have no problem with that.

If the statement however is

“String Theory is Astrology.”

then that’s nonsense.

String theory may be better than astrology and still not suit your needs. So go ahead and work on something else.

31. **Haelfix**
January 25, 2006

Incidentally, to outsiders it seems like there are a lot of venemous attacks going on in quantum gravity.

Be assured, the statement holds true in a number of fields in physics. If you go to a lot of astrophysics and phenomonology meetings invariably you end up seeing the same childish name calling and intellectual chest pounding (at least, on occassion).

But many of us have learned that thats a good thing in the end, some people just need that sort of fire and controversy to keep working and motivated to keep an edge. Its also vital to remain skeptical of everything and anything (that includes above all, yourself) so controversy really serves its purpose in physics.

People get used to it, and then its all fun and games thereafter.

32. **Urs**
January 25, 2006

> controversy really serves its purpose in physics

Indeed. I think it is a good thing to have a critical discussion of the topics that are being critically discussed here (which usually is string theory and LQG, whether or not this is intended). I wish sometimes the dicussion would consistently be more fruitful, though. Let's get away from that yellow press attitude towards research.

33. **amused**
January 25, 2006

The following comment is seeking refugee status here after having been deleted on Lubos' blog (like a's above). It's a bit less polite than what I would normally post, but should be seen as an attempt to communicate to Lubos in his native language. Since it was in response to his "review" of Peter's Discover interview, where he once again derided Peter's credentials, hopefully it is semi-on topic here.
……………………..

Lubos, it is disingenius of you to write that someones scientific credentials can be evaluated just by looking up their publications and citations. All of us working in physics know that it takes very little to publish a paper in a supposedly respectable journal these days. It can be easily done by following the general prescription of "monkey see, monkey do", and some people have made careers out of this. Others have made careers out of riding on the coattails of famous senior colleagues, and it is quite amusing to see how some of these young "hotshots" go dead researchwise when put in a position of having to develop their own independent research program after getting a faculty position at an illustrious institution (not looking at anyone in particular, Lubos).
Citation numbers often have limited relevance as well, especially in "hot" subareas such as string theory where people are striving to churn out as many papers as possible and artificially inflating each others citation counts in the process.

To get a meaningful evaluation, the criteria need to be refined. The only physics journal that is non-trivial to publish in is Phys.Rev.Lett., so one possibility is to count the number of single-author publications a person has in there. How would you fare under this criterion, Lubos? Would you do better than Peter Woit, whose credentials you are so fond of disparaging?

(That was of course a rhetorical question. For those who can't be bothered to look it up, Lubos has 0 papers in PRL, while Peter published a paper there on his own as a grad student.)

34. **Fabien Besnard**
January 25, 2006

Urs,

"No. It is common for scientific theories to make predictions that are verifiable but not falsifiable."

True. But the converse is wrong, and that's the problem. Making verifiable but unfalsifiable predictions does not grant scientificity to a theory. You carefully omit to say this, but if Mathjunkie had said :
"Hi Ed Witten,

Please make a falsifiable prediction from string theory to prove that the anti-stringy people are wrong. Then, Peter's famous "Not Even Wrong" webpage will have the heading changed to "I was wrong"."

That would have been a far more interesting challenge.

35. **woit**
January 25, 2006

Urs,

You neglect to mention that, besides massive excitation modes, perturbative string theory predicts a host of things that are clearly wrong (exact supersymmetry, massless fields, etc.) and would falsify the theory if you took these as serious "predictions". On alternate days you argue that string theory really is a predictive science and that its predictions shouldn't be believed (because we don't yet know the full theory).

36. **Quantoken**
January 25, 2006

Urs:

It's an insult to astrologists for you to compare string theory to astrology. Astrology is certainly not science, neither is string theory.

But Astrology is still way much better than string theories. Astrology at least make observations of the natural world and try to make connection with the reality world: They observe lunar phases and other astronomic phenomenas. Actually the ancient science of astronomy was developed on top of astrology. Today's astronomers still have to rely on detailed written recordings left by ancient astrologists to get data on astronomical phenomenas that happen in the past, like supernovae explosions some thousands of years ago. **In that sense, astrologists had made invaluable contribution to science**, by making those detailed observations, and left detailed recordings of what they saw. That's experimental science in its honesty!

What has string theory contributed to science? Nothing. They make no connection to the reality world whatsoever. They do not make predictions. Astrology at least try to make some predictions. The net contribution of super string theory is actually negative, by draining resources away from actually useful scientific researches in other fields, and by polluting the public's perception of what science research is really about.

Lubos is poorly trained in basic physics instinctions and is not qualified to make judgements of science in general. See [this post of his, appraising a stupid research idea](), and my response below.

Quantoken

37. **Urs**
January 25, 2006

Actually, I was trying to be careful with always inserting the right qualifications. There is perturbative ST with some non-perturbative effects included by hand, and it does predict (in the weakly coupled regime) stringy effects. If there should be no viable phenomenological vacuum for this theory, then it is wrong. But I don't know if none such vacuum exists.

We all need to be careful with making these statements. I could turn your accusation around and note that you oscillate between "predicts nothing" and "has been falsified". Somewhere in between there is a truth.

38. **Dombono**
January 25, 2006

But what if we do a perturbation about a flux compactification?

39. **woit**
January 25, 2006

A few remarks about Lubos's posting:

Ever since I've started publicly criticizing string theory, I've learned a lot about how academics behave when the facts are against them. The tactics employed are:

1. The ad hominem attack. Attack your opponent's credibility and right to say anything on the subject. This is Lubos's main tactic today. If you believe him that I shouldn't be listened to, there's not much point in me saying anything to defend my credibility. I'll just point out that by now he and I have both written hundreds of pages about this controversy on our respective weblogs. Read large chunks of both of them and make up your own mind who is more credible.

In Lubos's comment section there is a commenter "Hmm" who is also making ad hominem attacks on me and my credibility. Funny that whoever he/she is, they do this anonymously so that one has no way of knowing who they are, and deciding whether you should trust their judgements on this issue. Whatever you think of Lubos, at least he doesn't engage in the sleazy behavior of making anonymous personal attacks.

2. The straw man attack. Misrepresent or even misquote your opponent's words, then attack them as stupid and ignorant for saying something inaccurate. Lubos doesn't much bother with this one today, but he's normally quite fond of it, as are many other string theorists and string theory partisans that I have debated with.

3. Censorship. When you can get away with it, by any tactic available, keep people who disagree with you from being heard. Lubos is now doing that with his comment section, anonymous string theorist referees stopped Cambridge University Press from publishing my book, someone (presumably Jacques Distler) is using their influence with the arXiv to censor links to my weblog postings there. The internet makes this tactic less effective as it gives people who are censored various means to get their views heard anyway.

4. Intimidation. I've heard from many, many physicists that they agree with many of my criticisms of string theory, but are afraid to be publicly associated with them because of repercussions for their career. The over-the-top personal attacks from Lubos don't help his credibility much, but they do frighten quite a few people into keeping quiet so that they don't get subjected to this kind of thing.

The fact that the string theory community as a whole seems to have no problem with Lubos's behavior adds greatly to this intimidating effect. It makes many physicists feel that if they criticized string theory they would both be the target of vicious personal attacks by Lubos, and, once targeted, behind-the-scenes retribution by his colleagues in terms of things like evaluation of their grant proposals, refereeing of their papers, invitations to conferences, and hiring of their students.

About the only string theorist around that I've noticed having anything critical to say about Lubos's behavior is Aaron Bergman, who often comments here. The fact that no one else is willing to do so seems to me a deeply shameful commentary on the state of this field.

40. **Urs**
January 25, 2006

> But what if we do a perturbation about a flux compactification?

There is no known flux compactification which is phenomenologically viable or well enough understood to check if it is phenomenologically viable, or is there?

41. **woit**
January 25, 2006

Dombono,

Urs kind of refers to this. One problem is that if you try and fully stabilize moduli using a flux compactification, you have to introduce non-perturbative objects like branes, and it is difficult to be sure that your perturbative expansion is reliable. It's also true that even making optimistic assumptions about this, no one has come up with such a thing that is at all realistic or where you can calculate things and compare to the standard model.

Urs,

Yes, at times I both say "predicts nothing" and "has been falsified", but I think I'm being consistent here. The situation is that string theory is not well-understood enough to make any reliable predictions. If you choose to believe in the unreliable predictions of the theory, on the whole they're wrong.

42. **Urs**
January 25, 2006

> on the whole they're wrong.

In that so far every concrete vacuum which has been constructred is phenomenologically wrong. But since there are more vacua than have been constrcuted…

And so on and so on. We can exchange these arguments for ever, it seems.

43. **Tony Smith**

January 25, 2006

Peter Woit said "… anonymous string theorist referees stopped Cambridge University Press from publishing my book …".

Maybe I have just not been reading the web closely enough, but IIRC that is the first time that I heard of a book publisher bowing to censorship pressure from the string theory community.

Given the stature of Cambridge University Press, I am surprised.

Maybe I shouldn't be surprised, given the "blacklist[ing]" mentioned by anonymous, the "invective" and "rancor" mentioned by DB, and some of my own personal experiences,
but
somehow it seems to me that censorship of book publishing takes the plunge of physics into a Dark Age to a whole new level.
The only ray of light that I see is that Peter was able to find a publisher with enough courage to publish the book: the English publisher Jonathan Cape – congratulations to the people at Jonathan Cape.
In fact,
that is yet another similarity between the situation in physics and the Boondocks MLK episode, in which "… CNN named Martin Luther King one of the 10 most unpatriotic Americans … His book was banned … King renamed his book "Dream Deterred" and it was finally released by a small publisher …".

I agree with Peter's statement "… The fact that no one else is willing to …[criticize the situation]… seems … a deeply shameful commentary on the state of this field. …".

I guess that my Huey Freeman – type "dream" that some prominent string theorist might stand up against the descent of physics into a Dark Age will remain an unfulfilled dream.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

44. **woit**
January 25, 2006

About Tony's comment,

I don't want to make much of the censorship issue, since as I said I don't think censorship attempts are very effective, at least not in this case. As for Lubos censoring his comment section, all it achieves is to have people post them here, together with the news that he is censoring them, not exactly adding to his credibility. As for the arXiv trackback issue, it's not of great importance, and who knows, someday the powers that be may even get around to letting me know what is going on there, and the story may be different than the way it now appears.

As for the book, it's being published June 1 by Jonathan Cape in the U.K., here in the U.S. by Basic Books in the fall. String theorist referees at Cambridge were within their rights to write reports saying they felt it would be a terrible thing if Cambridge published the book. I do wish however that they had felt it necessary to seriously come to grips with the book's argument, instead of dismissing it out of hand. It was also not at all unreasonable for Cambridge to be unwilling to publish something over the strong objections of prominent scientist referees.

In the end, the publication of the book ended up being delayed a bit, but it's now a significantly better book than the version Cambridge was looking at. I wasn't ever that worried about it not finding a publisher at all. There's a wide enough variety of publishers out there that sooner or later it would have found a home, although I'm quite grateful to the people at Cape for the encouragement I have had from them.

45. **D R Lunsford**
January 25, 2006

My God, Peter, they rejected your book? That makes me want to smash things. How did it come to this?

Urs – you're a smart guy. Get out of that mess and away from those people.

-drl

46. **andy**
January 25, 2006

Professor Woit,
Your interview in Discover magazine is really great. I enjoyed reading it. Any of Lubos' commentary can be sent directly to /dev/null.
-Andy

47. **woit**
January 25, 2006

drl,

Cambridge not wanting to publish the thing isn't surprising, prestigious academic presses don't often publish stuff that lots of prominent academics in the field would object to. In the end though, it is being published by some excellent publishers in Britain and here, who I think will even do a better job than Cambridge in terms of making sure it gets wide attention. Not a situation I'm at all upset about.

48. **Tony Smith**
January 25, 2006

Peter said "… It was also not at all unreasonable for Cambridge to be unwilling to publish something over the strong objections of prominent scientist referees. …".

Even if I were to agree for the sake of argument that it was OK for Cambridge to be unwilling to publish "over the strong objections of prominent scientist referees",
I am still unhappy that the "prominent scientist referees" made such "strong objections" to the publication of a reasonable criticism of certain aspects of string theory.

If a theory or model cannot stand up against the publication of reasonable criticism, then it does not deserve to be considered scientific.

Peter also decribed the "prominent scientist referees" as "anonymous string theorist referees", indicating that they chose to hide behind a shield of anonymity, which seems to me to be a further clear indicator of serious problems.

(Note that although referees MAY choose to remain anonymous, it is NOT required of them. In fact, back when I did refereeing for a journal, I disclosed my identity to those whose papers I refereed and gave specific reasons for rejections, so that if they so chose they could discuss the matters with me directly.)

Tony Smith
http://www.valdostamuseum.org/hamsmith/

49. **woit**
January 25, 2006

Tony,

In the Cambridge story I'd just like to make clear that I don't have any real problem with the people at Cambridge; their behavior was professional and not unreasonable. As for the string theorist referees, my problem with them was not the anonymity, that's standard in this kind of situation. Actually of the two very positive referees, one I still don't know who it is, one I do know (since he told me himself). There was also a mathematician referee who didn't want to comment on the controversial parts of the manuscript; he was fine with letting me know who he was and we later had an interesting conversation about the mathematics involved.

I do agree with you that there was a problem with the behavior of the string theorist referees. They didn't at all respond to the points made in the book, or find anything inaccurate there, but still chose to recommend strongly against publication. In an ideal world, a referee faced with a book by an author whose point of view they don't like, but who has his facts straight, should not be so strongly objecting to its publication.

50. **Dumb Biologist**
January 25, 2006

Since I've chosen to be cowardly, I'm going to try to limit my contributions to questions and very general commentary of a perhaps critical, but scrupulously non-pejorative nature, out of a sense of fairness. Don't know if I have the self-discipline, but fair's fair, so I should at least make the effort.

51. **Not a Nobel Laureate**
January 25, 2006

In the absence of experimental data, people can and do hold very strong opinions. But until there's experimental data, that's all they will every be – opinions and beliefs.

Reading this blog about these quasi-theological disputes reminds of my "feet don't fail me now" thoughts as I sought to remove myself as far away from HEP as possible post-PhD. Haven't looked back. Can't imagine how people could find such a sterile field interesting.

52. **fh**
January 25, 2006

Regarding Lubos, I have had an extensive (email) debate about LQG with him in the past (as I was choosing what to persue). It seems his style has seriously deteriorated.

On the Interview I have to say that it is certainly fairer, clearer and calmer then most of the anti string stuff one usually sees floating around these days. It's well done.

53. **Hmm**
January 25, 2006

Peter–

Since I advised Lubos not to waste his time debating you, I will take my own advice and interact with you here exactly once. There is nothing in my "attack" on you that is not objectively true, although admittedly without tact. I said you couldn't make it as a research physicist or mathematician–this is true, looking both at your history of research and your current position. I said you have achieved your 15 minutes of fame by finding something you can do which doesn't require creative talent in physics–this is also true. You aren't being interviewed for Discover because of some great new insight or research direction you have opened up. I said you haven't contributed anything positive to physics. Again, looking at your research record, this is simply true (perhaps I could have been nicer and said "very little positive" to physics). I said that I think you are pompous–ok this is a personal opinion, but frankly, if I hadn't made any contributions to a subject, I wouldn't attack it in the popular press of all places, and I would certainly tell my interviewer something like "you should know I haven't really done any work in 15 years", rather than a rather pompus sounding "I have thought about these problems for 20 years". It is very hard to take you seriously, Peter, because as I said on Lubos's blog, its not like you're an iconoclast with your own brilliant ideas that people are ignoring–for heavens sake, you spent the 80's working on lattice gauge theory. In your interview you were perfectly happy to give the impression that you were forced out of the field because of string theory, whereas it is quite clear you were forced out because you were working in not very interesting ways on peripheral problems. You should know that the field has a way of keeping iconclasts and contrarians with talent around. Many people not working in string theory continued on in theoretical physics or mathematical physics and made important contributions. Quite unlike what you and many of your readers think, theorists of all types value independent thinkers *with real talent* above everything else. By "with talent" I mean with the ability to generate non-trivial, surprising insights, in whatever area they work in. It is not nice to say but it is most likely you were forced out because you didn't have "it" for creative research at a high level at the time. There isn't any evidence in the usual currency of science–papers–to show you did. Its true that there have been geniuses who didn't write many papers–Ken Wilson springs to mind–but (A) the few papers they did write before their breakthroughs still showed some real spark, and importantly (B) before making their breakthroughs, they weren't going around giving interviews to popular magazines about their thoughts on subjects they didn't know much about. They were *busy working hard*, on making their breakthroughs. You are no Ken Wilson. The other things I mentioned on Lubos's blog were comments on your publications and citations. As I said their, this doesn't represent everything, there are many cases where great works are ignored for a long while etc. etc., but over twenty years, *some* signal should show here. As I said, having 11 papers with a total of 220 citations does not exhibit any signal. Lubos makes the mistake of comparing this with Witten, but the real point is that this doesn't even compare well with the record of a somewhat above average fresh PhD.

I brought these things up simply because from the piece in Discover, or the Astronomy editorial a while ago, and certainly from your comments on this blog, one would certainly come away with the impression that you speak with some authority. It is quite shamelessly self-promotional of you to mislead people in this way. You are not a serious scientist, Peter–serious scientists write papers and debate in the literature and make real substansive constructive criticisms and propose new directions of research. You don't.

Finally, I am writing this anonymously precisely because otherwise I would spend far too much time discussing these things with other people insteading of doing physics, which I will happily return to doing now. People don't have to know who I am to evaluate my claims–for instance they can just go to SPIRES (http://www.slac.stanford.edu/spires/hep) and check your publication record as I did. Really, I was only trying to encourage Lubos to not waste his time constantly debating you, but its clear he can't be swayed. I myself have wasted enough time on this already. I leave you (and your readers) with the same thought I left with Lubos–spend your time doing physics. Physics is all that matters in this business invariantly, everything else is sociological junk. Don't spend all your time on sociology, write papers! Do research! If you hate theories that don't make predictions, work on ones that do, write up your ideas, post them on the arxiv. You will find (and I suspect you have already found) that this is infinitely harder than ranting every couple of days, even if it strokes your ego to have so many people chime in and agree with you. But making even small contributions to physics is ialso nfinitely more important and rewarding.

54. **andy**

January 25, 2006

The previous post had zero substance. This is probablyconsistent with the content of his or her “scientific papers.”

55. **Arun**
January 25, 2006

Hmm, it doesn’t take genius to identify bullsh*t when one sees it, and it is an abdication of responsibility to say that because one lacks genius, one should keep quiet about bullsh*t. Moreover, a contribution may be valuable even if it is not by a genius, much cited and with brilliant work. In fact, simply raising an alert on the lack of physical content of certain research programs may be a valuable contribution, especially in an age when skepticism is met with personal attacks rather than any reasoned argument.

56. **Arun**
January 25, 2006

Physics is all that matters in this business invariantly, everything else is sociological junk.

I think that is exactly what Peter Woit is saying, where is the physics? string theory is sociological junk. (Actually, he isn’t quite saying that, but Hmm’s hyperbole deserves such a response.)

57. **Tony Smith**
January 25, 2006

Hmm, in an anonymous comment critical of Petet Woit,
listed many reasons that Hmm considers Peter Woit to be “not a serious scientist”
but
failed to address ANY of the following substantive points made by Peter in his Discover interview about string theory:
1 – “… At this point they really don’t even have a plausible idea about how to ever make a prediction out of this, or how to use this in order to really explain anything about the world. …”
2 – “… They are certainly using mathematics, and they are building models and writing down equations for them, but the models they are working with just aren’t connected to the real world. There isn’t even any plausible way you could imagine that they are going to be able to connect that to the real world and to use these models to explain some experiment we are seeing. …”
3 – “… The kinds of equations that they have now are the kinds of equations you would get in an approximation scheme to some underlying theory, but nobody knows what the underlying theory is. …”
4 – “… There are some who have basically decided that whatever this theory is, it has infinitely complex possible solutions [known as the string theory landscape]. As for the dream that there’s going to be one solution of string theory and it’s going to be the real world, I think a lot of them have given up on that. So they’re trying to pursue this idea that string theory really is an infinitely complex thing. I think a lot of other string theorists are well aware that if you go down that road you really can’t predict anything and you’re in danger of leaving what is normal science. …”.

So,
it seems to me that most of Hmm’s comment should be dismissed as a mere non-substantive ad hominem attack.

However,
Hmm did make what might be considered a response to the following statement made by Peter in the Discover interview about string theory:
“… it has driven out other sorts of research. The way in which it has been pursued has made it virtually impossible to work on other things in the field. …”.

What Hmm said was:
“… You should know that the field has a way of keeping iconclasts and contrarians with talent around. … By “with talent” I mean with the ability to generate non-trivial, surprising insights, in whatever area they work in. … If you hate theories that don’t make predictions, work on ones that do, write up your ideas, post them on the arxiv. …”.

Although Peter’s blog is not the place to discuss details of my physics model,
I will offer my own experience of being blacklisted by the Cornell arXiv as a refutation of Hmm’s factual assertions.

Please do not attempt to discuss my physics model on this blog, as I will not respond to any comment making such an attempt, and I hope that any such comment will be deleted by Peter.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

58. **D R Lunsford**
January 25, 2006

DB – I only meant that you should not claim a cowardice that doesn’t exist (you’re in here with the sharks!) nor downplay being smart, which you obviously are.

-drl

59. **Peter**
January 25, 2006

Hmm,

If you want to argue with or discuss anything I have to say in the Discover interview, I’ll be glad to do so. If you want to discuss my research work, I’ll be happy to discuss hep-th/0206135 or more recent things I’ve been working on along the same lines.

On the other hand, if you want to discuss my credentials or my right to criticize what is going on in current particle theory research, before I’ll even consider that you’re going to have to begin by telling us who you are and what credentials you have that justify your behavior. Your argument that you don’t have time to do so doesn’t hold much water. Come on, how much time does typing a few characters take compared to the time you’ve spent today repeatedly attacking me at Lubos’s blog and now here?

I think just about anyone who reads Lubos’s blog soon realizes he’s a fanatic, driven half-mad by his inability to answer honest scientific criticism. Lubos’s bullying behavior is execrable, but yours is far worse. Unlike him, you’re not just a bully, you’re also a coward. You should be deeply ashamed of yourself, and there is something seriously wrong with an academic field that at least tacitly supports the kind of behavior that the two of you are engaged in.

60. **Hmm**
January 26, 2006

Ok, I can't resist making one last comment here. First–I didn't respond to the criticisms of string theory in the Discover interview because that wasn't the point of my original post to Lubos's blog–which was really about trying to convince Lubos not to bother in these pointless debates. Peter, you recycle the same points over and over again, and the totally reasonable responses have also been recycled over and over again. I see no point in continuing this excercise. Suffice it to say that none of your criticisms are news to anyone working in the field, and there are even more besides the ones you mention, but the positive indications that this approach to unification and quantum gravity is on the right track outweigh all these things for the people who keep working on it–it's not just that they have invested their lives in it, as you like to think–people in this field are willing to turn on a dime. Maybe everyone is wrong, but the way to convince them of this is not to repeat the same arguments they know anyway over and over, but instead offer any interesting non-trivial alternatives.

Second–I didn't resort to name-calling; while you and your readers did. I simply pointed out the factual aspects of your career as a research physicist–this is maybe not nice since it is rather undistinguished, but it is important for people to know this about you when evaluating your opinions. While you're not strictly dishonest about it you don't go out of your way to paint an accurate picture either–unlike Lubos I should say, who despite much much more impressive research accomplishments goes out his way to say things like "right now I am not one of the leaders in string theory" and so on. But why does your record as a researcher matter? Shouldn't the fact that your questions are valid be enough to convince us to listen carefully to what you have to say about them? Unfortunately I think not–well you can do whatever you want on your blog, but I feel its very inappropriate for much more public forums. The reason is precisley because the field is in the midst of confusing (and also very interesting) times. Now, people who know, from experience, what its like to invent really new ideas know that the birthing process for these ideas can be difficult. They know from personal experience about the murkiness before the light when things fall into place. They have seen important ideas be jeered, be called unscientific, unfalsifiable, "not even wrong", many times before. Thats why in a new confusing era, their opinions count for something, their wisdom is important. Of course different people with such experiences can have different takes on whether the current directions for the field are the right or wrong ones. For instance two of my heros in physics–David Gross and Steven Weinberg–have divergent opinions on anthropic reasoning and the landscape, and both their opinions certainly matter to me. But the fact that you have not been involved in any significant research means, Peter, that you have no particularly interesting insight to draw on into the direction in which things should break. You just repeat the same trivially obvious points over and over again, pretending that they are being ignored because they are "counter-establishment", when in fact they're ignored because they don't add anything interesting or new to to the debate. Your readers should know that string theorists are perfectly willing to listen to outsider criticism. String theory isn't a cabal trying to stomp out everything else, and string theorists are not afraid to ask themselves all the same questions you obsess about. They aren't sticking their heads in the sand.
As an example, Gerard 't Hooft is at all the major conferences, often telling stringers they're full of it, and they don't just nod politely, they listen to him, they think about what he has to say. Why? They know he is a unique intellect, who has been right before in amazing ways about things that were totally non-obvious. On the other hand, without any credentials of this sort, you repeatedly attack people like e.g. Weinberg and Wilczek for thinking about anthropic reasoning–does it *ever* occur to you that there is a reason these two Nobel Laureates, who invented large parts of the standard model and surely know something about what is science, are working on this? Is it really because they are so dumb as to not see your objections? Or might it be that, from past experience, they know that it sometimes pays to push through and explore strange ideas that other people freak out over? I find your arrogance in condemning these people (never mind Lenny!) absolutely breathtaking, Peter.

Finally, I am not going to apologize for remaining anonymous. It has nothing to do with the time it takes to type out my name, it has to do with the time I would have to waste talking to people about why I posted, what I think about all this etc. My point here is *only* to point people to an objective source with which to judge your credentials. As far as me–I can tell you that I disagree with Lubos about almost everything, except that like him (and you) I very much dislike the anthropic principle and the landscape, though unlike you I don't think the people working on it are morons who have given up on science–it might just turn out to be the way things are, though I think it is premature to abandon the hope that we can predict all couplings. Unlike you I like SUSY, and look forward to its discovery at the LHC. I am a fan of string theory. I acknowledge it may be on the wrong track with the Landscape and may be wrong altogether, though it seems more likely to me that it will figure in some unforseen way in the final story. I think people should explore alternatives, but there is a reason so many of the best people continue to be attracted to string theory–even with all the problems, much more seems to come out than goes in.

This really will be my last interaction with this blog. I apologize for having offended you, Peter, but I re-iterate that your non-expert readers should know something about your scientific standing to help them evaluate your opinions in the future.

61. **Boaz**
January 26, 2006

A rhetorical question for Hmm:
Is the concept of "scientific standing" really objective?
Why not be honest about it and say that you and some people you know don't think Peter's that great.
But then that begs the question of who you are and whether your own opinion on this matter should be taken into account.
It really does seem unfair to attack someone's credibility without putting your own out there for examination.

62. **Thomas Larsson**
January 26, 2006

Hmm,

attacking Peter's scientific credentials completely misses the point. Peter should be viewed as the tip of an iceberg, probably containing the majority of the physics community.

Perhaps it had been better if Discovery instead had interviewed Nobel laureates like Sheldon "string theory has failed in its primary goal" Glashow, Martinus "string theory is a figment of the theoretical mind" Veltman, Phil "string theory a futile exercise as physics"Anderson, or Bob "string theory a 50-year-old woman wearing way too much lipstick" Laughlin. Or perhaps with the founder of the string theory group at Rutgers, Dan "string theory is a complete scientific failure" Friedan.

OTOH, all science journalists out there, it is not too late to make new interviews.

63. **a**
January 26, 2006

I think that everybody agrees with hmm that it would have been better if a honest criticism had come from inside. Unfortunately experts remain(ed) silent and outsiders tend to base their judgment on concrete results: on this aspect strings are very poor, and I doubt that the busy work of hmm will solve the situation. Doing physics is not only filling papers with equations, but also discussing which problems it is worth to address.

64. **ks**
January 26, 2006

I think that everybody agrees with hmm that it would have been better if a honest criticism had come from inside.

Is it so? Why do we accept a critical public when we deal with politics but not with science? Why must critisism be constructive? If an idea/ideology does not work than it does not work. Showing this is an act of enlightenement and a public service. Demanding that Peter has to be an intellectual giant who produces new euphorias to the physics community is like forcing from a religious critic being itself a religious founder (or from a political commentator being a politician). Sometimes it should suffice being simply reasonable and well informed.

65. **secret milkshake**
January 26, 2006

I was born to into a communist country. I remember reading this kind of stuff back then: "Who are these so-called dissidents? They are all flakes and failures. We already have an honest, healthy and constructive discussion and it must be in its proper place. We need to have peaceful conditions for further continuation of our creative work."

When Motl wrote "we can't make progress until we get this kind of human garbage lined up against the wall + shot" (he means his critics) he was yearning for the more direct approach.

66. **JE**
January 26, 2006

Hmm said,

"…my heros in physics–David Gross and Steven Weinberg…"

Any researcher in theoretical physics needs to know as much as possible about Gross and Weinberg's great contributions to physics, but I don't think that he/she needs to worship any "heroes". It sounds puerile as an attitude towards research.

67. **fh**
January 26, 2006

The ad hominem attacks are besides the point of course, but I have heard similar criticism from people whoes standing as absolutely brilliant physicists can not be doubted.

For those who obsessively count citations to judge scientific merit, I'm talking about people whoes number of citations is the same order of magnitude as Wittens, if scaled to the size of the field they work in.

68. **Nigel**
January 26, 2006

'…might it be that, from past experience, they know that it sometimes pays to push through and explore strange ideas that other people freak out over?' – Hmm

The word 'strange' is not useful because all new ideas are initially strange by definition.

The mainstream string theory effort is not coming under criticism because ignorant outsiders object to new ideas being 'strange'.

It's that the new ideas, as Woit says, have reached a critical mass and are a self-propagating excursion from the business of modelling and predicting measurable phenomena.

It is interesting that a recipe based entirely on speculation, which produces untestable predictions, has become mainstream, and defends itself using the arrogance of dismissing critics as ignorant.

String theory uses extra dimensions to vaguely 'predict' unobservable gravitons and superpartners that will unify other forces at an energy far beyond experimental confirmation.

Why should tax-payers fund this?

'… it seems more likely to me that it will figure in some unforseen way in the final story.' – Hmm

Sure it will. The guy who comes up with the right theory will have to include a lengthy analysis of string theory in his paper, just to prove he is not plain ignorant of string theory, to get it read…

69. **Christine**
January 26, 2006

"Science is a way of thinking much more than it is a body of knowledge." — Carl Sagan

Any reasonable person — serious researcher or layman — will promptly recognize the value of Peter Woit´s contribution on how to improve our way of thinking over the (difficult) problem of quantum gravity, even if one does not agree with his opinions.

Personal attacks can only be interpreted as some kind of psychological reaction to primitive fear, and only reveals some kind of immaturity for practicing science or any productive activity.

70. **amused**
January 26, 2006

The fairytales of Hmm above shouldn't be left unchallenged.

1) "As an example, Gerard 't Hooft is at all the major conferences, often telling stringers they're full of it, and they don't just nod politely…"

Indeed they don't. I was at an informal talk by `t Hooft once, with Dijkgraaf also in the audience. `t Hooft was saying something negative about string theory and Dijkgraaf's reaction was to get annoyed and walk out. Generally, string theorists regard `t Hooft, Glashow and co. as dinosaurs who made great contributions in the past but whose present day opinions on string theory are ill-informed and don't matter.

2) "theorists of all types value independent thinkers *with real talent* above everything else. By "with talent" I mean with the ability to generate non-trivial, surprising insights, in whatever area they work in."

Oh sure they do. That's why the shortlists on the rumour mill pages are full of young people who are striving to demonstrate their originality and independence by developing new research directions and publishing their independent work in our top journal.
In reality, there are few things that the powers-that-be despise more than the sight of young people trying to do original independent work. Such fools will quickly discover that their PRL publications count for nothing in competition with the smart youngsters who realised that success in this field requires one to ape one's famous elders and ride their coattails as junior author on their papers. Lip service is paid to the noble ideal of supporting independent research, but in practice the powers that be only support their clones, since a clone of them is of course intrinsically better than a non-clone, irregardless of what the latter might have done. (And it is indeed amusing to see how some of these clones go dead researchwise once they get a faculty position and have to start being independent. Lubos is but one example.)

3) "You aren't being interviewed for Discover because of some great new insight or research direction you have opened up…"

Perhaps Peter was being interviewed because he has done more than anyone else to provoke a critical discussion of the state of affairs in string theory? For many years the stringers have been promoting the notion that they are just so incredibly brilliant and are doing so wonderfully well with their reserach program. No need to put a damper on the exuberant hype of Kaku & co.; it will all turn out to be true in the end anyway, and in any case it is good that the public should know how brilliant these people are and how wonderful their work is. As `a' mentioned above, ideally people from within the string community itself should have been the ones to call for a more balanced assessment. But there was no prospect of that happening, so it had to be someone from the outside, and Peter Woit was pretty much the only applicant for the job. Given that string theorist dismiss greats like `t Hooft and Glashow as ill-informed dinosaurs (come on guys, don't try to deny it), it's a bit ridiculous for them to complain about a lack in Peter Woit's credentials. If there really is a shortcoming in Peter's capacity to criticise string theory it will manifest iself through inaccurate/ill-informed/unreasonable statements that he makes. People who want to question Peter's "right" to criticise string theory are invited to point out the occurances of such statements in the hundreds of pages he has written already.

71. **Thomas Larsson**
January 26, 2006

Indeed they don't. I was at an informal talk by `t Hooft once, with Dijkgraaf also in the audience.

Dijkgraaf, like the Verlinde twins, are former 't Hooft students, right?

72. **mhm**
January 26, 2006

"And it is indeed amusing to see how some of these clones go dead researchwise once they get a faculty position and have to start being independent. Lubos is but one example."

This is not fair. Lubos made many original contributions to the research of climate change. And he has done so without any credentials, because they are only needed when talking about strings.

73. **mhm**
January 26, 2006

"Motl wrote "we can't make progress until we get this kind of human garbage lined up against the wall + shot"

Mr. Milkshake, this comment just shows how intelligent and smart Lubos Motl is. Only he, Jacques, Hmm and the other super string theorists are able to think clearly about superstrings, because they are so smart. Their time is very valuable, because they need to think so much and write their blogs and comments.

The laymen belong to "the stupid people" as Lubos once told us.
They can only solve easy problems (like how to make an honest
living). They should only do two things:
a) buy the books about superstrings and admire the great thinkers.
b) pay the bill

74. **a**
January 26, 2006

Dear mhm: in case your full name is Lubos Motl, it was already said that yours is the best trash show; but don't you think it is a bit out of context in a serious discussion?

75. **anonymous**
January 26, 2006

"… Lubos made many original contributions to the research of climate change. And he has done so without any credentials…" – mhm

But Motl's definition of the word 'hypocrisy' has a special exclusion clause just for string theorists! They are allowed to vent views on climatic change without a single paper or citation in that area! This same principle allows they to ignorantly ridicule LQG, etc…

76. **woit**
January 26, 2006

Hmm,

> I will take my own advice and interact with you here exactly once.

Why did I know this was a lie the moment I read it?

Let's see, your claim is that you have to remain anonymous because otherwise you would have to spend too much valuable time explaining why you are attacking me and what you think about string theory. Well, much of your comments are all about these topics, and you seem to be having no problem finding lots of time to go on about them at ever-increasing length. You evidently have plenty of time on your hands to make up nonsense I never wrote (e.g. that Weinberg and Wilczek are morons) so that you can continue to attack me. I think there are two much more obvious reasons for why you insist on anonymity:

1. You're a bully and a coward.

2. You’re a string theorist wannabe, with no credentials at all in this field beyond having read a few popular books on the subject.

There seems to me to be plenty of evidence in your by now many pages of comments for both of these.

Thanks to many commenters who already did a far better job in writing in here to explain why my views might be worth listening to than I ever could. It’s encouraging to see that what I am trying to do here is widely understood and appreciated.

I’d like to point out that much of what I’m trying to do is to not just go on about my own views or criticize those of others. No, I don’t call Steven Weinberg or Frank Wilczek “morons”, instead I as accurately as possible quote what they say, sometimes make some comments on what I think about it, and provide links to every place I know of where their own words are available. I believe this often provides useful information so people who can decide for themselves what they think. Even quite a few string theorists who are not at all happy with my views tell me that they find this valuable.

One of the main reasons I went into science was that it is a subject not based on blind belief in authority figures. If you’re willing to put in the time to understand what people are saying, you can make up your own mind about what to believe. I hope this blog helps people do that.

77. **fh**
January 26, 2006

I like to think that hmm is actually Lubos talking to himself, if for no other reason than that it amuses me.

78. **woit**
January 26, 2006

fh,

Unfortunately I’m quite sure they’re different people and it’s a sad fact that Lubos’s fanatical views and behavior are not unique to him. For one thing “Hmm” has a native speaker’s command of the English language, unlike Lubos. My guess is that “Hmm” is the same person as “Michael” who every so often posts comments here about how incompetent I am. He seems to live in the Boston area and may have some sort of connection to Brandeis.

79. **J.F. Moore**
January 26, 2006

Pete Woit’s (or more generally, anyone’s) credentials are only relevant to the argument to the extent that the reader does not understand the issue at hand and must take on faith the position of the one making the argument. Anyone who takes the minimal time to grasp what’s going on, even at a very basic level, must admit there are some problems with superstrings, at the very least a huge dichotomy between the advertised power of the theory (esp. 10-20 years ago) and the actual power, if power is meant the way it is for almost all of science, as having the ability to make predictions.

80. **J.F. Moore**
January 26, 2006

Sorry, I didn’t mean to abbreviate your name like that, Peter. I blame my new bluetooth keyboard.

81. **anon**
January 26, 2006

Peter,

I think Lubos is being quite successful in his main objective: intimidation. While it will hardly affect your behaviour, it sends a strong message to others who might be contemplating taking a public stance on various issues you discuss.

Not quite effective as the “line up ’em up and shoot” technique he learnt in his native country, but he’s adapating it well.

82. **amused**
January 26, 2006

Thomas: yes, Dijkgraaf and the Verlinde twins were `t Hooft’s students. Not all of his students became string theorists though (e.g. van Baal), and conversely, not all Dutch string theorists were his students (e.g. de Boer).

mhm: That was hilarious 🙂 It was supposed to be ironic, right? Or are you really LM?

83. **Tony Smith**
January 26, 2006

If Hmm is anonymous, Hmm’s qualifications must be judged based on material in Hmm’s posts, and I have only read Hmm’s two comments on this blog.
However,
it is possible to evaluate Hmm’s mentality to some degree by considering the following excerpt from those posts, in which Hmm said to Peter:

“… I disagree with Lubos about almost everything,
except that like him (and you) I very much dislike the anthropic principle and the landscape
… I like SUSY … I am a fan of string theory. …”.

I wonder if leaders of the conventional superstring community, such as Ed Witten, will ever realize that their community is ill-served by allowing such people as Hmm to act as their advocates,
and
whether those leaders will ever speak out loudly against Hmm and others of that ilk,
or
whether those leaders will continue, by their silence, to endorse them.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

84. **D R Lunsford**
January 26, 2006

The way to beat the Czechs was to outskate them. At this point, LM has been outskated.

-drl

86. **Adrian H.**
January 26, 2006

As ugly and naked as it is, Hmm's view represents one important aspect of the degeneration of modern intellectual life: this incessant placing of everyone and everything into league tables and rankings. It is a sickness, and it is usually pressed very hard by those charlatans who have worked up a good 'reputation' by doing minor incremental work that advances things infinitesimally. It is usually combined with sycophancy towards the 'great and worthy'; and with maintaining one's presence by skillful networking. It is the way to have a great career at the modern University.

In this lattice structure of good and bad reputation it comes to seem natural that some people are entitled to express their opinion while others are not. Secret Milkshake likened this to the Soviet Union. But it is probably far more insidious than that, because it is self-imposed. People like Hmm have entirely internalised this worthless junk.

What Hmm dislikes about you, Peter, is that you are in effect speaking out of turn—not showing due deferrence to the great and the good. So you can be sure that he got where he is by toadying his way up the ladder. If we saw his publication record I'm sure it would look impressive. Until we looked more closely at just what the acheivement really is. Then it would look shallow and trite: merely dotting the i's on the great men's work.

But it shouldn't upset you, Peter. This is all part of what you are criticising in your blog every day. And I for one hope you keep it up.

87. **Peter**
January 26, 2006

Adrian,

I think you're quite right about the mentality of "Hmm" and a few others like him. There's been a lot of this in recent days due to the Discover article, but there was a certain amount of it since the beginning, when I first started publicly criticizing string theory.

At the time I remember thinking that some of this kind of behavior was highly remniscent of the dominance displays of males in a group of baboons when an interloper who doesn't fit into the hierarchy arrives in their midst. Lots of jumping up and down, flashing of teeth, loud screeching, displays of posteriors (or at least the string theorist equivalents….).

88. **anonymous**
January 27, 2006

I should say that this quote of Chomsky nails it on the head:

"In my own professional work I have touched on a variety of different fields. I've done my work in mathematical linguistics, for example, without any professional credentials in mathematics; in this subject I am completely self-taught, and not very well taught. But I've often been invited by universities to speak on mathematical linguistics at mathematics seminars and colloquia. No one has ever asked me whether I have the appropriate credentials to speak on these subjects; the mathematicians couldn't care less. What they want to know is what I have to say. No one has ever objected to my right to speak, asking whether I have a doctor's degree in mathematics, or whether I have taken advanced courses in the subject. That would never have entered their minds. They want to know whether I am right or wrong, whether the subject is interesting or not, whether better approaches are possible – the discussion dealt with the subject, not with my right to discuss it.

But on the other hand, in discussion or debate concerning social issues or American foreign policy, Vietnam or the Middle East, for example, the issue is constantly raised, often with considerable venom. I've repeatedly been challenged on the grounds of credentials, or asked, what special training do you have that entitles you to speak of these matters. The assumption is that people like me, who are outsiders from a professional standpoint, are not entitled to speak on such things.

Compare mathematics and the political sciences — it's quite striking. In mathematics, in physics, people are concerned with what you say, not with your certification. But in order to speak about social reality, you must have the proper credentials, particularly if you depart from the accepted framework of thinking. Generally speaking, it seems fair to say that the richer the intellectual substance of a field, the less there is a concern for credentials, and the greater is concern for content."

Lubos is clearly not doing his field any flavor.

89. **Adrian H.**
January 27, 2006

Yes, the my-publication-list-is-longer-than-your-publication-list does have certain analogies! 🙂

90. **Ignorant Layman**
January 27, 2006

Dr. Lubos Motl's polemical invective which resorts to a scatologically laced ad hominen attack against his straw man of a crackpot who reads this blog, I think reveals much more about the good professor's lack of professionalism than any amount of learned exposition might otherwise afford us wayward ignoramuses. I think he has hoisted himself on his own petard most ignominiously.

91. **D R Lunsford**
January 27, 2006

Adrian H, in other words, "Cites matters."

-drl

92. **anon**

January 27, 2006

Popular voting systems like citations aren't even democratic! Citations occur when people follow the mainstream ideas. So what? The mainstream was wrong on caloric, phlogiston, etc! It doesn't matter how many citations there are, only if the facts are sound. Citation bureaucracy can work against real innovation.

93. **Ignorant Layman**
January 27, 2006

How about those embarassing expert pronunciamentos such as "Nuclear power will never work," etc., etc.

94. **Juan R.**
January 27, 2006

Peter Woit,

About tactics you are cited above

> 1. The ad hominem attack. Attack your opponent's credibility and right to say anything on the subject. This is Lubos's main tactic today.

He used this tactic here in his attack on Horgan. I have explained to him how splitting data from interpretation of data, e.g. via detecting the existence of quotes 🙂 . Lubos Motl in this blog often some of us use blockquotes instead of " ". You can detect them because they are rendered in a different color, and indented by the console. For example this is a comment section on data and this

> This is a quote

is data (quote).

Peter Woit, if he can learn, i personally wait that in future he can openly critize either data used in some discussion or comments on that data but without resorting to the ad hominem attack.

> 2. The straw man attack. Misrepresent or even misquote your opponent's words, then attack them as stupid and ignorant for saying something inaccurate.

Easily inverted thecnique! No problem with it unless that you cannot reply to the attack, but that is already next point.

> 3. Censorship. When you can get away with it, by any tactic available, keep people who disagree with you from being heard.

This is very ancient! Already guys as Newton were censured by their colleagues. A modern example of censure are ArXiv blacklists, or sistematic rejection of hot topics by some leader journals (e.g. some journals do not acept critical papers on relativity). Another examples are blocking of funding of rival schools, rejecting of position for rival scientists, heavy peer-review, etc.

The natural solution to this point is the re-grouping:

– Newton and colleagues re-grouped and published alternatively.

– ArXiv blacklisted scientists launched new preprint servers.

– People critizing some aspects of relativity publish in alternative journals.

– Searching alternative ways for research funding

– Etc.

> 4. Intimidation. I've heard from many, many physicists that they agree with many of my criticisms of string theory, but are afraid to be publicly associated with them because of repercussions for their career.

Very related to point 3. In fact, may serious studies on revolution on science and alternative ways suggest that best position for launch an alternative or revolutionary way on science is from an independent position, e.g. some emeritus position in some university, chair in a new funded institute, etc. This way you can simply neglect intimidation, so usual in archaic universitary schemas.

This is the reason that I can openly publish criticism on string theory. Those physicists could openly critize that nonsense called string theory if they received alternative careers to actual ones.

It is just a question of time and politics, not a problem that string theory was difficult to evaluate. No real problem with this…

—

Juan R.

Center for CANONICAL |SCIENCE)

95. **D R Lunsford**
January 27, 2006

kshe – right, it isn't obvious to me how this applies. Like I said -confused-.

-drl

96. **Boaz**
January 27, 2006

anonymous quotes Chomsky as saying

> Generally speaking, it seems fair to say that the richer the intellectual substance of a field, the less there is a concern for credentials, and the greater is concern for content.

I think that Chomsky is missing an important piece here. I think that the depth of the relationship of a field to society as a whole is equally, if not more important (regarding receptivity to outsiders' ideas and criticism) than wealth of ideas and substance. Math is a traditional field that is almost universally recognised to be valuable. Math departments have the dual role of developing new ideas in addition to preserving existing knowledge through teaching. And the value is shown by its inclusion in curriculum from elementary school through college. I don't know Chomsky's ideas about the connections between mathematics and linguistics in detail, but I would guess that they do not threaten the existing relationships that mathematicians have with society at large. His views on politics, on the other hand, do threaten the relationship that that group of academics has with society. Political scientists and historians to some extent retain clout by the perception that they advise government and society on some major policy issues. If the value of that advice is being attacked, so is their place in society.

So there seem to be two issues: one is whether a given criticism goes to the heart of a field's relationship with society, and the second is whether that relationship is strong enough that it can take the criticism in stride and improve the health of the relationship. Sensitivity to criticism can mean a fear of it all falling apart.

I think that Lubos does indeed see the position of string theory in society being attacked by Peter and he is responding. So I don't think that it necessarily implies a poverty of ideas, but rather an insecurity of a precarious position. If Lubos felt more secure in his own position and in that of string theory, he wouldn't worry so much that a little criticism would cause the whole thing to collapse.

97. **Adrian H.**
January 27, 2006

”Cites matters." Very nice.

98. **mathjunkie**
January 27, 2006

Citation sometimes can't tell the importance of a research paper. I found that some researchers intentionally increased their number of citations by quoting their published papers in their future publications but their peers cited those published works only very few times.

99. **Jimbo**
January 28, 2006

Congrats to Peter for an excellent Discover interview. Basically what he's been saying for several years to the community, is now getting a vastly wider audience, and will ultimately trickle down to the intelligent lay person, who has seen the glitzy NOVA string special, & other stringy hype, & cause that person to slap themselves on the forehead & say "Hey, the superstringers have definitely broken lock with the scientific method & have gone off into their own little world of mathematics, marketing it as reality".
We cannot really blame Susskind, Witten, Green, Schwarz, Maldecena, Polchinski, Greene, et al. for this sad state of affairs. It is Dirac, their godfather, who justified the stringy crusade with his aphorism, "It is more important to have beauty in one's equations, than truth". Gell-Mann, added fuel to the fire with his "Anything not expressly forbidden is compulsory".
As Peter points out, this is all fine for mathematicians. However, as many theorists still stubbornly believe, physics is an empirical science, which for 300 yrs, has set a higher standard of reality than mere aesthetics.
Lastly, without appealing to reality by consensus, I think the blogs should start a head count in the anti-string camp, perhaps with an arxiv `call-to-arms' note, & ram it down PhysicsToday's throat. Just to drop a few names on record for starters: Feynman, Glashow, Veltman, well, you get my drift…

100. **D R Lunsford**
January 28, 2006

Jimbo – you've misinterpreted what Dirac meant. He's undoubtedly spinning like a new pulsar in his grave, over what has happened.

If only he were alive. I feel like we need one of our elders to return from the undiscovered country, and start kicking ass.

-drl

101. **Thomas Larsson**
January 28, 2006

Lastly, without appealing to reality by consensus, I think the blogs should start a head count in the anti-string camp, perhaps with an arxiv `call-to-arms' note, & ram it down PhysicsToday's throat. Just to drop a few names on record for starters: Feynman, Glashow, Veltman, well, you get my drift…

OK.

102. **Chris Oakley**
January 28, 2006

> It is Dirac, their godfather, who justified the stringy crusade with his aphorism, "It is more important to have beauty in one's equations, than truth".

You cannot blame Dirac for a trend that only really got going in the year that he died. Personally, I think that the "anything goes" mentality can be traced back to something that Dirac was most definitely not responsible for, namely the endorsement of mathematical chicanery in physicists' desperation to "explain" the Lamb Shift from about 1947.

103. **woit**
January 28, 2006

Jimbo,

I really don't agree that the problem is that string theorists have left physics for mathematics. The mathematically sophisticated parts of string theory are actually the valuable ones that may someday lead somewhere. What's really useless and dangerous are things like the "Landscape", which are quite "physical", involve very little math, but are completely noxious and threatening to turn particle theory into pseudo-science.

Given the lack of new experimental results, the pursuit of new ideas about physics based on their mathematical beauty actually seems to me as promising a thing to try as any. It is a great shame that the failure of string theory threatens to discredit research in this direction.

104. **mathjunkie**
January 29, 2006

It seems Lubos reacted violently in his webpage.

For balancing the views between stringy people and anti-stringy people, I hope the Discover magazine could have interviewed Lubos as well.

105. **Who**
January 29, 2006

For balancing the views between stringy people and anti-stringy people,

personally I think science benefits more from calm reasoned debate (by people able to understand others' viewpoint) and I think P. does admirably in the calm-reasoned category

so for balance, on a panel, I would match P. with somebody else—-not someone violent, emotional, bigoted. Same if I were publishing back-to-back interviews in a magazine.

I don't know who it would be—-there's David Gross (but being a nobelist he's awfully heavy)—-Robbert Dijkgraaf is a terrific talker and an attractive advocate—-no, too much glamor for what I have in mind. It is not about salesmanship it is about honest reasoning over scientific priorities.

Now I think of it! Imagine matching Peter with Andy Strominger—-back to back interviews! those are two people who would take pains to understand each other viewpoint and to address each other concerns.
both would scrupulously refrain from adhominem attack. Bravo.

BTW if it were a THREE way balanced thing, I would put up Laurent Freidel as a representative of the alternatives to string research.
I would not just pit Andy and Peter. It is really a triangle, as I see it.
Anyway there is a potential for calm reasoned balanced discussion (no vituperation, no acrimonious Motley) and it might be good for the physicis community. Hope this not too much off topic.

106. **woit**
January 29, 2006

mathjunkie,

I also very much hope that Discover will do a profile of Lubos.

107. **Tony Smith**
January 29, 2006

Who suggests that "… a THREE way balanced …" discussion might be good.

An example of a very good "THREE way" discussion is the book "Triangle of Thoughts" (English translation AMS 2001) by Alain Connes, Andre Lichnerowicz, and Marcel Paul Schutzenberger. The flavor of the book might be seen in the following excerpt from A.C.'s part of the trialogue:
"… String theory was supposed to apply to strong interactions … this theory of little strings moving in space-time implkes the existence of particles of spin 2 and zero mass like the graviton. … string theory has so far been tested only on a strictly mathematical level … in physics, we are still far from the mark. … we can hope that string theory will make it possible to understand the arbitrary constants appearing in the Standard Model, that is, in particle physics; but so far the theory offers nothing substantial in this respect.
One of the major problems is that … supersymmetry … must be broken in order not to contradict the experimental results of the Standard Model …
… A true theory would no doubt have to explain the arbitrary parameters of the Standard Model …".

Please read the book to get the full context of those and many other issues discussed therein.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

108. **Who**
January 29, 2006

Hi Tony, I have not seen "Triangle of Thoughts" but there is an interesting trialog about QG available on arxiv, as a sample of this form:

http://arxiv.org/abs/hep-th/0501103

Ted Jacobson, Donald Marolf, Carlo Rovelli

Ted Jacobson has been a critic of Loop Gravity and related QG in recent years, serves as deviladvocate sometimes at conferences, voicing skepticism, and specializes in observational tests that constrain QG.

Don Marolf has done string research mainly I think, but collaborates with Loop people sometimes. So the trialog is people who are on different sides of quite a lot of issues but can still talk amicably.
=================

I wasn't thinking of a trialog actually, but of some magazine publishing three separate interviews back to back.

A. a critic (like Peter or Larry Krauss, actually many people are vocal critics, some representative)

B. a string practitioner—someone who can acknowledge problems but give a reasonable defense

C. a nonstring researcher who doesnt bother criticizing string!

I have never heard Freidel, for instance, say anything about string. he is too busy with his own research and seems just not interested in string.

Often times you have string apologists for whom string is a huge issue and they act like "if you are not for us you are against string (and motherhood :-))" and all these people who do QG are our ENEMIES and they are our detractors and we must discredit them etc.

But actually many intelligent creative researchers just are not interested in string and never seem to talk about it (at least in public) and they just do their work

(the problem is the artificial restriction of career opportunities for these people in the US, I think—-highly qualified people are in effect denied access to the job market if they do something that is perceived as rival to string—but I don't hear these people openly complaining, instead I hear Smolin sometimes in a sense complaining FOR them.)

so I would publish a triangle of interviews partly just to show that the issue is not just PRO and CON string—there is active QG research by people for whom string is basically IRRELEVANT. Having the discussion always focus on pro-and-con string gives a distorted picture because inflates string importance.

well I’m not a magazine editor and no one should hold their breath waiting for a brace of cool interviews about diversifying particle theory research in the US or anything like that.

congratulations to Discover for having the one with Peter that they did, which is some progress at least

Die Physik steckt in der Krise

January 25, 2006
Categories: Uncategorized

The German weekly *Die Zeit* has an article this week by Max Rauner about string theory, the Landscape, and the controversy over whether this is science or not. My German is rather shaky, but as far as I can tell it's an intelligent summary of the controversy, emphasizing Susskind and his new book, and quoting many of the usual suspects. The same issue also has an interview with philosopher of science Martin Carrier about the question of whether or not string theory is a science.

Update: Eli Rabett has put up a translation of the article into English on his blog.

Comments

1. **SomeBody**
   January 25, 2006

   I love how the article manages to quote the number of universes both as 10500 and as 10 with SUBscript 500…

   The philosopher Reiner Hedrich (apparently asked to "bring order" to the physics debate in Germany?!?) has a cool soundbite. Translating freely from the article,

   »The Multiverse theory is reasonable in its logic", says Hedric, "but not reasonable enough to be science." The research program reminds him of the pre-Socratics of ancient Greece: it's "a metaphysical contemplation of nature".

2. **Wolfgang**
   January 25, 2006

   The only thing really new in this article is the comparison of quantum theory and general relativity to an old married couple sleeping in separate beds …

3. **Frisean**
   January 25, 2006

   Martin Carrier says: "Eine strenge Unterscheidung zwischen Wissenschaft und Metaphysik, wie man sie früher verlangte, macht man heute eigentlich nicht mehr."

   translates to sth like "A strict seperation between science and metaphysics, as it was demanded in past, is not made today any more."

   Can this be taken serious? I am a layman, but I doubt all philosophers and scientists will agree on that.

   The German term Wissenschaft means more than empirical science but I consider this statement to be very questionable. Maybe I am a little naive, but a Natural Science should ask for empircal evidence while metaphysics has not and can be entirely speculative or is this not true any more? Elsewise the boundries between metyphysics/religion on the one side, and empircal sciences on the other science become diffuse or even not existent.

4. **D R Lunsford**
   January 25, 2006

   Frisean – certainly it's the most important topic. To me, string theory failed when it trivialized Democritus by introducing strings to begin with. That string theory fails as science is no surprise – what has not been much said is how utterly it fails as metaphysics, by completely failing to provide a sensible ontology. On this level, it's "too ugly to contemplate" rather than being right or wrong.

   -drl

5. **Quantoken**
   January 25, 2006

   Wolfgang said: "The only thing really new in this article is the comparison of quantum theory and general relativity to an old married couple sleeping in separate beds … "

   I thought they were never married to start with.

6. **D R Lunsford**
   January 25, 2006

   Q – actually GR and QM have much in common.

   1) Ultimately both are based on g_mn.
   2) Both are stymied by the volume element (reducibility of metric, electroweak symmetry breaking)
   3) Both are forced to endure unacceptable physical ideas (singularities).
   4) Both have a hard time dealing with sources, and treat them as an external thing
   5) The Lagrangian seems ad-hoc (conformal weight of R, Higgs mechanism)

   There are five obvious ones – I could think of more.

   -drl

7. **Chris W.**
   January 25, 2006

   DRL,

   Aren't you willing to contemplate alternatives in fundamental physics to a Democritean ontology as *starting point*? Obviously the modern conception of the atomic constitution of matter is quite different than that considered by Democritus, although the latter is clearly a historical antecedent.

   Furthermore, the modern notion of physical fields as being fundamental, which evolved from Maxwell's electrodynamics as it was freed from the assumption of an underlying medium (the ether), is something that transcends Democritean atomism. Of course atomism and field theory have been largely fused in the context of quantum field theory. Finally, there is the notion of spacetime itself as dynamical, which the ancients were hardly in a position to anticipate.

That said, the ontological problem with string theory is arguably that strings are themselves merely a starting point, leading into a wilderness of higher dimensional structures and various (partial) formulations of M-theory. The upshot is an ontological shambles.

Some would say that, in view of things like dualities and effective field theory, this is both expected and unavoidable; we should just get used to it. Someday I think this situation will be viewed by as an enormous joke played on us humans. In a sense, we have played the joke on ourselves; we're capable of being too mathematically creative for our own good.

8. **Chris W.**
January 25, 2006

Physics and cosmology have always been, in part, a "metaphysical contemplation of nature". However, that metaphysical contemplation has, at its best, spawned empirically potent, testable ideas. To me, the profound irony of our current predicament is that it evolved out of the most proudly empirical and anti-metaphysical movements in modern physics—the developments of atomic, nuclear, and particle physics (and arguably, condensed matter physics). (A further irony: Ernst Mach, the intellectual godfather of this anti-metaphysical attitude, never accepted atomism as having a proper place in physics, even up to the time of his death in 1916.)

I believe we do need to reconsider the metaphysics and ontological basis of physics, and how it *supports* the subject as a science. The trouble is, that's *hard*; most metaphysics is indeed crap.

9. **Peter**
January 25, 2006

Please, keep the discussion here to the topic of the article I was posting about. Several people have complained to me recently that there's too much rambling and anti-string ranting, unrelated to the topic at hand. I'll be deleting a lot more such comments in the future.

10. **Geon**
January 26, 2006

"The only criticism of what I've been doing over the years that I would actually agree with is that I should have spent less time thinking about string theory and complaining about it and learning about it just to criticize it, instead of devoting time to more positive things that I should be pursuing. "

In my opinion, arguing over whether string theory is science or not or finding endless links on articles on this matter does not serve any good for the statement made by Peter. We all know for sure that philosophy won't get us anywhere, so why not "Think your best thoughts, and devise ways to test them "? quote Feynman.

11. **plato**
January 26, 2006

> **Physics is in the crisis: The dream of the world formula burst, the new theories is hardly more examinable. Does it at all still concern in the cosmology science?**
>
> Free love, LSD, anti-war demo. Leonard Susskind took part in all that "and still more", as he stresses……

Google has a translator

It seems there is to be a connection between "earlier thinking" on Susskind's part, to what has emerged from him, into what is given of science? I think this is right, so far from what is above?

From outide the US, historical information would be gathered and formulated into German thinking conceptual based on language? It sets the tone? Can German concpetualization really get the feel of the man?

If the attack is to come, must it not be on what has been preceded here in earlier idealizations with regards to "degrees of freedom" and "dimensional analysis?"

Here I do not want to detour from article, so that is all I will say. How would charactor assissination support this article?

I hope translator was helpful.

12. **Quantoken**
January 26, 2006

Peter:

I must point out that you have been hypocritical that at one moment you complain about censorship on ARXIV and on Lubos's blog. And the next second you turn around and threatened even more rigorous censorship on your own blog. That does not look good on you. To be fair I see nowadays Lubos is actually much more tolerate on different opinions than you do. What's the point of having a discussion if no alternative opinions are allowed?

Quantoken

13. **AG**
January 26, 2006

quantoken you're boring, go away.

14. **ObsessiveMathsFreak**
January 26, 2006

Here's a full translation of the page, curtesy of google.

15. **ObsessiveMathsFreak**
January 26, 2006

Sorry for the double post.

The article does mention that other theories were also very speculative in the past. It mentions the kinetic theory of heat and the atomic theory of matter and even copernicus gets a look in.

Creationism was brought up in the article, but I think Intelligent Design was not.

The article (translation) mentions:
"It takes every now and then decades, to scientific pagings in the scientific community recognition is often still longer and, until it accepts the public. ….Sometimes revolutions are also broken off, and one returns to old conceptions."

Which I suppose is an accurate decription of how science works. There seem to be epochs, wherein certain theories are in vogue. Sometimes, these theories are verified, sometimes they are superseeded. I suppose time, or rather *data*, will tell if this is the case for String Theory too.

16. **Robert**
January 26, 2006

The article is not so much about string theory but about the 'multiverse', the idea that beyond what we see as our universe, there could be regions that are vastly different from ours since the fundamental constants are different. This might be realised in string theory but could as well be realised in other theories as well.

If one believes in a "theory of everything", that is a theory that does not have numerical parameters (like the electric charge [aka fine structur constant] or the mass of the electron) this theory should have a way to explain the numerical constants of the standard model of particle physics. One popular way to do that is to promote them to fields that happen to have these values.

But this brings with it the possibility that these fields take different values at different places. And voila: the possibility of the multiverse. In this case one rather has to explain why these fields vary so little in the region of the universe that we observe.

17. **Frisean**
January 26, 2006

My point was about the article.(the linked interview in particular)

And I still feel disturbed about the statement that one does not really distuingish between metaphysics and science any more. At first look, this is confusing and dangerous, also regarding the following statement within the interview, that intelligent design is not disputed to be science, instead merely claiming that its credibility is bad reagarding its capability to explain phenomana.

If I stick to this notion, everything is science, als althogh not everything is "good science". What`s the benefit of using the term science then at all?

18. **Mark LaFlamme**
January 26, 2006

The beauty of string theory for somebody in my profession is the very thing that gets criticized. I'm a reporter and columnist in Lewiston, Maine, but I'm also a novelist. Last month, my novel "The Pink Room" was pubished and it's doing very well. I owe it all to the uncertainty of of the various theories and the creative leg room that presents to a person writing a science based work of fiction. The story is of a leading physicist who attempts to use the science of string theory to bring his daughter back from the dead. The idea is that the energy of the human soul seeps into one of the higher dimensions. It's an idea that may be no more or less easy to disprove than the existence of those higher dimensions to begin with.

19. **Thomas Larsson**
January 26, 2006

If one believes in a "theory of everything", that is a theory that does not have numerical parameters (like the electric charge [aka fine structur constant] or the mass of the electron) this theory should have a way to explain the numerical constants of the standard model of particle physics.

Or the spin of the electron (in units of the spin of the photon).

Spin, charge, mass, and anomalous dimensions are really quire similar – eigenvalues of generators of certain symmetry groups. Why shouldn't they be explain similarly?

20. **D R Lunsford**
January 26, 2006

Geon – it's doing a lot of "good". Before his evaluation paper and this blog, the problems of ST were still under the rug where they'd been swept years earlier, and they would have stayed there. What Peter is doing is an absolute "good" IMO.

-drl

21. **D R Lunsford**
January 26, 2006

Frisean – perhaps I was not clear – yes metaphysics and physics must be clearly distinguished! But, the latter cannot proceed until the former is settled. They off each other as progress is made.

-drl

22. **A.J.**
January 26, 2006

Quantoken —

There's a very good reason for Peter to censor his blog: He doesn't want it to degenerate into a forum for crackpots. Deleting advertisements for loony theories is good practice, just like deleting ads for porn sites. It keeps the signal to noise ratio high.

Likewise, deleting anti-string raves and content-free personal attacks on people who don't participate in these discussions (e.g. Ed Witten) is a good idea.

Deleting well-reasoned, on topic comments from people who disagree with him is bad practice, of course. But I haven't seen any evidence that Peter does this.

23. **anon**

January 26, 2006

Mark LaFlamme,

HILARIOUS post. Satire best way to exorcise Motl.

24. **woit**
January 26, 2006

I'm deleting a series of comments from someone who hoped that string theory would help him communicate with his wife after she passed away, and someone making fun of this. This is not funny, but sad. Please no more of this kind of thing here.

25. **Mark LaFlamme**
January 26, 2006

I hope no one feels I was a part of the earlier discussion involving the man who hoped to contact his dead wife. The novel "The Pink Room" is completely genuine and doesn't hold a position one way or the other on the reality of string theory. I have such a tenuous grasp on the science, I could be swayed one way or the other by a well placed argument. I'm enjoying the exchanges in here so far. Read about Mr. Woit's views last night in Discover. An amazing piece, really. And Discover typically seems to love string theory. It's a credit to them that they allowed such a dissenting voice.

26. **D R Lunsford**
January 26, 2006

Chris W – I did answer your question but it got deleted. I wasn't ignoring it. Perhaps you should post the (very intersting) question on SPR.

Or here's an idea – Peter could create sci.not.even.wrong and we could discuss it there. Or on alt.lubos.shutup.shutup.shutup.

-drl

27. **D R Lunsford**
January 26, 2006

Mark LF,

It's a credit to Peter that his clear voice is being heard even by sensationalists.

-drl

28. **xpinor**
January 28, 2006

Isn't the *10500* a remarkable tracer for the competence of science writers? Is it really unreasonable to expect somebody who writes about physics and string theory, in particular, to be able to recognize the origin of this number and recover the original meaning? What kind of judgment of the subject matter can be expected from anybody who isn't?

29. **woit**
January 29, 2006

xpinor,

In general I don't think you can blame the 10500 business on science writers. The problem is that lots of the software that magazines and newspapers use doesn't properly deal with sub/superscripts, thus the problem. Even this blog sometimes has this problem, someone is complaining in another post that their superscript appeared fine in a preview, but then got mangled when the comment appeared.

30. **Dr. Andre Bresges**
January 29, 2006

Dear colleagues,

I've got the printed Issue of the german ZEIT on my tabletop (this happens since I am a german physicist). I want to assure you that the 10500 typo is NOT in the printed issue, just in the online version.
Dr. Max Rauner studied physics in Boulder, Colorado and usually knows well what he talks about.
DIE ZEIT is a recommended weekly journal for "science, politics, culture and business". Its authors are usually domain experts, urged and assisted by the editors to use "plain language". Customers / target Group are decision makers in the fields aforementioned. Editors are e.g. the former german chancellor Helmut Schmidt and the former german minister of culture Michael Naumann. Congratulations, Peter.
Prof. Reiner Hedrich takes part in biochemistry and physics workgroups on a regulary base. His project is designed to "sort" the arguments in cosmology discussion, not to "bring order" to the discussion as SomeBody translates it (sounds different?).
Apparently the German Science Foundation considers the whole controversy "f****d up beyound any recognition" (never found that term so fitting than with cosmology:-) and asked someone to explain the state of the art in plain words before adressing politicians where to throw the research money into.
If you have any further questions concerning the translation or cultural background, feel free to ask. My email adress is found on my website.

André

Northeastern University Researchers Find Signs of Extra Dimensions

January 26, 2006
Categories: This Week's Hype

If you believe the headline of a press release issued today by Northeastern University, its researchers have found evidence of extra dimensions. The actual text of the press release tells a different story, that they haven't found evidence of extra dimensions. One can't blame the headline writer too much though, because the text itself is full of enough hype and nonsense about string theory and extra dimensions to confuse most people.

According to the press release text:

Researchers at Northeastern University and the University of California, Irvine say that scientists might soon have evidence for extra dimensions and other exotic predictions of string theory.

…IceCube, now under construction, could provide the first evidence for string theory and other theories that attempt to build upon our current understanding of the universe…

"To find clues to support string theory and other bold, new theories, we need to study how matter interacts at extreme energies," said Anchordoqui…

In recent decades, new theories have developed – such as string theory, extra dimensions and supersymmetry – to bridge the gap between the two most successful theories of the 20th century, general relativity and quantum mechanics…

Anchordoqui and his colleagues say that extragalactic sources can serve as the ultimate cosmic accelerator, and that neutrinos from these sources smacking into protons can release energies in the realm where the first clues to string theory could be revealed….

"String theory and other possibilities can distort the relative numbers of 'down' and 'up' neutrinos," said Jonathan Feng.

The half a dozen references to string theory in the short press release might lead the gullible to think that we're about to be provided with evidence for the "exotic predictions of string theory", but that has little relationship to the reality here, one aspect of which of course is that there are no "predictions of string theory" about any of this.

The occasion of the press release is the appearance in Physical Review Letters of a paper by Anchordoqui, Feng and Goldberg entitled Particle Physics on Ice: Constraints on Neutrino Interactions Far Above the Weak Scale. The authors discuss the possibility of using the difference between up and down observed rates for collisions of ultra-high energy cosmic ray neutrinos to get information about neutrino cross-sections at around 6 Tev center of mass energy, far above the energy scale for which we now have data about these cross-sections. They conclude that the data from the AMANDA array operating at the South Pole since 2000 already provide some constraints, and that IceCube, the next generation array now being installed there, could at 90% confidence level rule out a 40% enhancement of the neutrino cross-section over the Standard Model values.

What's interesting here is not that extra dimensions have been found, but rather the opposite. AMANDA results show no evidence of the kind of enhanced cross-sections you might expect from some extra-dimensional scenarios, and it seems possible that IceCube will rule out such extra dimensions at energies accessible by the LHC even before the LHC comes on line. For a similar but earlier argument of this kind, see a discussion by Jacques Distler a year and a half ago concerning an earlier paper by these same authors that argues that the Pierre Auger Observatory, another cosmic ray observatory now taking data, may also be able to rule out extra dimensions observable at LHC energies before the LHC is turned on.

There's also some mention of this over at Lubos Motl's blog, with half the posting devoted to scatological attacks on this blog and its readers. I really think he's losing it. Note that following current arXiv policy, a trackback linking to Lubos's posting has appeared at the arXiv listing for the Anchordoqui et. al. paper, but no such trackback will be allowed to appear to the posting you are now reading.

Update: One of the problems with the endless number of absurdly overhyped press releases about string theory is that they get widely distributed.

Update: The Slashdot article does contain a useful extended comment from someone working for AMANDA/IceCube.

Update: The headline on the press release has been changed by the people at Northeastern. It now reads "NU researchers say South Pole detector could yield signs of extra dimensions ".

Comments

1. **SomeGuy**
   January 26, 2006

   "There's also some mention of this over at Lubos Motl's blog, with half the posting devoted to scatological attacks on this blog and its readers. I really think he's losing it."

   Look at his replies to Quantoken…

2. **woit**
   January 26, 2006

   I did. Scary to see Quantoken making a lot more sense than Lubos.

3. **Christine**
   January 26, 2006

   I must say sometimes reading this blog is so amusing.

   One the serious side, concerning these experiments and the search for extra-dimensions, see this interview dated April 2004 with Dr. Feng (sorry if that has been posted before).

   Christine

4. **woit**
   January 26, 2006

   Thanks Christine, that interview does provide some interesting context for this.

5. **A. nonymous**
January 26, 2006

There's something that I don't like about when headlines which say "X has been found" are followed by stories which say "X has not been found". It strikes me as dishonest, in a very precise and obvious sense. Perhaps it was always this way and it's just being brought to my attention more nowadays, but I have the impression that this kind of thing occurs more frequently now than it ever has in the past.

6. **Lubos Motl**
January 26, 2006

Dear Peter,

Quantoken makes much more sense to you than I do because your understanding of physics is much closer to Quantoken than to mine.

Best
Lubos

7. **blank**
January 26, 2006

It's like they hired Ari Fleischer to start writing physics press releases.

8. **Quantoken**
January 26, 2006

Lubos:
Clearly you can't make sense of your "prediction" except by deleting my last comment on your blog. In that comment I pointed that your so called string prediction:

Predictions from TeV-scale excited strings:

http://arxiv.org/abs/hep-ph/0204112

are merely groundless wild guesses. You first have to **fix** the string scale at certain arbitrary value, exactly 1TeV, before you can calculate something. But then no one from your camp is willing to tell us un-ambiguously exactly how much is the string scale, 1 TeV, or more, or less? As such you could **always** wait until you get the data and then tweak your parameters to make it fit, and thus always claim victory regardless of the outcome.

As a matter of fact, you are already hyping a victory of super string theory with champaignes, before the experiment even begins 🙂

That is NOT a prediction. A scientific has got to be falsifiable. You tell me some specific numbers and put them on the table, **with no strings attached**, and then if the experiment does not come up with the number you predicted, you admit you were wrong. And you claim victory if your number is proven correct. You are unable to make even one such definite prediction, so you are not science.

Of course, it will be impossible for super **string** theorists to make a none-ambiguous prediction with **no string attached**.

Quantoken

9. **A. nonymous**
January 26, 2006

It's true – Lubos didn't have a good answer for Quantoken, so he deleted the comment. Surely even Lubos must be ashamed of this kind of sore-loser behavior. Is the shame of losing even a single point in an argument just too much to bear? Must he resort to censorship to prevent it?

10. **X**
January 26, 2006

Just an opinion – discussion of someone's personality on a blog that is mostly about ideas is not good. Surely we can discuss – if it is interesting – Motl's ideas on climate, physics, string theory etc., without discussiong Motl? Or for that matter, anyone else? I think it best that personal opinions about people remain just that – personal and private. Physicists – even when they blog – are not public figures in the nature of politicians and glitterati. The latter depend on getting people talking about them, but not so with physicists. I find comments like "Motl is such-and-such" or for that matter, our host "Peter Woit is such-and-such" rather distressing; I hope I'm not alone in this.

11. **Quantoken**
January 26, 2006

Peter:

You commented that IceCube could produce some results before LHC is turned on. That's incorrect. The experiment hasn't even been built yet by the time LHC is expected to be turned on. So far they have only installed 8 detection strings, out of a total of 80. The completion will be at least a few years away. Even when it's all set up, they expect to run the thing for **15 years** to collect just a few events.

See how the string theorists are already celebrating that extra dimentions have been verified, when in fact the experimental instrument has not even been built! Let's wait until it's all up and running, and an unfortunate matching penguin dropped his egg and tripped on the wires, triggering a false event record, I bet they will not hesitate to open up quite some champaigne bottles. Just look at how they hyped on the so called CSL-1 anormalcy.

Now as I point out on Lubos's blog, the author's estimation of event count, (4 down event and 20 up event), based on 15 years of instrument running, is way too optimistic and completely off the mark. In calculating the event count the author assumed **6×10^38** target nucleons, for example. Even a 3 year child can calculate that one cubic kilometer of ice contains only 9×10^37 nucleons, not 6×10^38.

Why researchers lack such basic skills to even estimate how many atoms are in one cubic kilometer of ice?

Also, when some one do an experiment like that and you know he has a full agenda to obtain a certain outcome that he prefer to see. How would you think about the credibility of such experiment result, before it even started? He is already going every where and give interviews claiming how extra dimention is confirmed! He probably have the experiment report written already, munus filling in the date and time, before the machine is turned on. How could you trust that he will not manipulate the actual data some how to fit his expected outcome, like Eddington did?

Quantoken

12. **Undergrad.**
January 26, 2006

I'm only an undergraduate student (in Europe), so I'll accept the fact that most people on this blog know far more physics than I do.

That said, I stumbled on to this blog some months back, because I wanted the other side of opinions on String Theory.

One thing I wish to say is about Lubos Motl. I am literally shocked after reading his posts that this man is a professor in a major university.
Lubos, you act like a five year old. Your obviously a very intelligent man, but you do yourself a disservice with your highly reactionary writings across the net.

If there is one thing you've shown me it's that adults who revel in "playground politics" make their way into the highest levels of acedemia.

Finally, if you respond to this, at least come up with an insult that supersedes the "U r gay" classification.

Great blog Peter and thanks for directing me to modest theoretical physics and away from exotica.

13. **blank**
January 26, 2006

Given that string theory gives something like 10^500 predictions for any given experiement, Lubos figures the odds are pretty good that one of those predictions will be verified. Predicting which of the 10^500 predictions will be verified is an uninteresting task left for lesser minds.

14. **A. nonymous**
January 26, 2006

Undergrad: It takes a lot less to be a professor in an American university than in a European university. In Europe, you have to hold a specific chair, and that often means waiting for another professor to retire. In America, "professor" is little more than a lob title, more or less equivalent to "researcher" or "lecturer". That said, a job as a professor at Harvard was considered quite prestigious before they gave one to Lubos.

15. **Peter**
January 26, 2006

Quantoken,

You're quite right that it will take longer than I thought for IceCube to be completed, not till 2009-10. However, between now and then I believe AMANDA will still be running, and taking data together with increasingly large parts of IceCube as it is completed in stages. I haven't really looked into whether and when these South Pole experiments will be able to put the kinds of bounds on neutrino cross-sections needed to rule out various extra dimension scenarios at various scales. Maybe someone reading this blog knows the answer to this.

On the other hand, your constant belief that the people designing these experiments don't know what they are doing is kind of out of control. The idea that they're making elementary mistakes and intent on fabricating data or not carefully analyzing it is just ridiculous.

16. **Dumb Biologist**
January 26, 2006

Haven't there been a few rare recorded cosmic rays that were so wildly energetic they were dubbed "Oh My God" particles? Did anyone notice those creating micro-black holes? I imagine if they did, we would have heard about it…though maybe no one was looking for that properly at the time, so it passed undetected. If not, wouldn't they put a pretty high-level constraint on micro-BH production? Like millions of times more energetic than what we can produce in the LHC kind of constraint?

17. **Dumb Biologist**
January 26, 2006

Oh, that was kind of in response to Christine's link…

18. **Quantoken**
January 26, 2006

Peter:

I believe you should be able to calculate the number of atoms in one cubic kilometer of ice. Any one can do that calculation. But they got the number wrong by 7 times. Would you not call that an elementary mistake if one can't even count atoms?

It's unbelieveable, but many researchers are incredibly stupid. Example like this. A researcher tried to figure out how much cloud is covering the earth, but looking at the dim reflection on the dark side of the moon. Some one with average intelligence would know it's much easier just to look at the earth directly from satellites.

And these few days some researchers claimed on the Nature magazine that they discovered an earth like planet 25, 000 light years away, but detecting brief brightening of certain stars due to gravity lensing. And Mark Troden et al appraised it. Some one know a little bit of GR should at least be able to estimate the focal length of the allerged gravity lense, and find out that it could not possibly focus the light on the earth 25,000 light years away, but the focal point where you can see the brightening effect should be much closer. See my comment here, which was by the way censored by certain cosmologists. Some people really just don't know the stuff they are supposed to know in their profession.

To a researcher nowadays, I guess publishing paper and being able to survive in academy, is way much more important than maintaining some decent scientific honesty. Outright fabrication of data may be rare and exceptional, but dirty tricks in data manipulation are widespready. When you have collected a rare data sample which you are not sure whether it is just background noise or legitimate, and you have not collected much data in 15 years, and the data seems to be a "good" one adhering to your expected result, I bet most people will be VERY inclined to simply count it in, instead of discarding it, especially when is no one watching over your shoulder.

The bottom line is scientists are as human as every one and they do pee on the streets, when no one is watching. The important thing is one should always maintain a healthy skepticism against everything and cross-exam things in order to find the scientific truth.

19. **Peter**
January 26, 2006

Good question, Dumb Biologist.

Don't know if this is what you were referring to, but since 1972, there have been some very high energy cosmic ray events reported with anomalous characteristics, called "Centauro events". There was some speculation these were black holes, I haven't heard anything about these recently, and am also curious what is now known about them.

20. **Peter**
January 26, 2006

Quantoken,

Sometimes you write sensible things, other times, like this, you behave like a complete crackpot. I'm so baffled I can't quite bring myself to delete your latest nonsense. But no more, please!

21. **Dumb Biologist**
January 26, 2006

Well, being very unoriginal, I just googled it, and got this:

http://en.wikipedia.org/wiki/Oh-My-God_particle

According to a link from this wiki, the original OMG was a proton with the mass of a bacterium.

There might be more on this stuff of greater technical interest to you via the Hi-Res Fly's Eye, that might answer your questions. They link some talks that I probably can't understand:

http://www.cosmic-ray.org/

22. **anon**
January 26, 2006

undergrad,

"Great blog Peter and thanks for directing me to modest theoretical physics and away from exotica."

Sorry to hear that you are letting this blog affect the direction of your career. It is a sad reminder that this small nuisance that I believe most of us think little of (at least I do aside from the occasional comic relief that it provides) actually has sway over people who don't see it for what it is: a gathering place for individuals who have discovered that it is far easier to obtain a sense of intelligence by attacking the accomplishments of others than to learn a subject thoroughly and make a serious contribution themselves.

The constant attacks on string theory that take place here are based on a very superficial knowledge of the subject and display an amazing level of ignorance. I do not mean to denigrate the intelligence of those who make such attacks, as there is a difference between ignorance and stupidity. Rather, it appears to me that the attackers simply have not taken the time to learn the subject. That is certainly not a crime as I, for instance, have not taken the time to adequately learn LQG despite the fact that it is a subject that one might argue is quite relevant to my career, more so perhaps than string theory is to many of the posters here. On the other hand, I don't spend my time publically attacking LQG based on the superficial knowledge that I do have. I recognize that I lack credibility on the subject and leave the debate of LQG's problems and merits to those whose interest is sufficient that they took the time to thoroughly understand it.

Finally, I should mention that you might take a look at the recent posts of Lubos and Hmm in order to put this blog into context. Both of these individuals are a bit abrasive to say the least (I see that you have noticed this about Lubos already 🙂) but the main points that they convey are actually quite accurate.

23. **A. nonymous**
January 26, 2006

Peter, DB – this is just a rumor, and I'm not saying where it came from, but certain people believe that the impossibly high-energy cosmic ray events seen at AGASA weren't actually as high-energy as it was originally thought, and the energies looked artifically high due to miscalibration of instruments. That leaves only one event at the Fly's Eye detector, and one event alone isn't enough to justify all the excitement. Certain people were asked not to say these things too loudly at a time when it might have jeopardized funding for the Pierre Auger observatory.

Time will tell. If certain people are right, then there will be no more cosmic rays observed with energies beyond 10^20 eV.

24. **Peter**
January 26, 2006

D.B.,

The kind of events seen by Hi-Res are the ones that Auger is designed to study, gathering a lot more events in order to understand what the flux of these things is at the highest energies. There's a controversy here, since above a certain energy, such cosmic rays from extra-galactic sources should lose energy by collison with CMB photons. If they're really there, something interesting in going on, one proposal is that Lorentz invariance gets modified, with a modified dispersion relation at these energies. Within the next few years, data from Auger is supposed to resolve this.

I still don't know though what happened to the Centauros…

25. **D R Lunsford**
January 26, 2006

DB – yes there are cosmic rays that are so energetic that nothing known can account for them. They aren't little black holes, just ordinary matter moving very, very fast.

Now if you look at galaxies, there is all kinds of evidence of extraordinarily energetic processes, fitting into characteristic patterns (rings, jets, ..). Most likely whatever is ripping these galaxies to shreds is also making these ultra-energetic cosmic rays. One doesn't need to impute some new pathological state of matter – just explain why these galaxies are so disturbed, and with such a consistent morphology. Science used to be like this – look, measure, speculate, theorize, calculate, confirm.

(The standard answer is "supermassive black holes". Basically, anything that can't be immediately understood is thrown over into the catchall of black hole dynamics. It's instant gratification for academics.)

-drl

26. **Michael**
January 26, 2006

Peter, you and Quantoken behave like an aging married couple. First, you publicly defend him. Then, in the privacy of your own blog you chastise him.

I think you two are made for each other, so be nice. Emphasize things you have in common rather than disagreements. For example, you could try and figure out if the off-diagonal SU(2) is compatible with the GUITAR. Good luck!

27. **Peter**
January 26, 2006

Hi anon/Hmm,

Funny how yesterday there was one anonymous coward Lubos supporter from the Boston area writing in, but promising not to come back, now there's a new anonymous coward Lubos supporter from the Boston area appearing here with the same personal attacks, made in much the same style. What's your excuse for remaining anonymous? Are you also a very busy man like "Hmm", too busy to explain why you are attacking me?

Whoever you are, your behavior is even more pathetic than that of Lubos.

28. **Dumb Biologist**
January 26, 2006

OK. Well, if the OMGs were really spurious readings, then that's a bummer. Let's just say they're not (which no one is claiming on-the-record, it seems), and that cosmic rays (probably protons) can whip around at these absurd energies. Where they come from is certainly interesting, but what I wonder is *why* people talk about detecting the decay of micro-BH's (and hence evidence of large extra dimensions) in the atmosphere rather frequently, or even in the LHC if we're lucky, when it would appear the most energetic cosmic rays detected rule out such observations.

It would seem, based on the above, the only way they can exist is if relativity needs modification in a rather radical way at high energies, and perhaps they don't believe it yet.

29. **Michael**
January 26, 2006

Not that it matters the least bit, given that anonymous is anonymous, but I'm not "Hmm".

30. **Peter**
January 26, 2006

Well "Michael", who knows if you're "Hmm" or "anon". But, like them I know you're in the Boston area. Maybe Boston is just full of lots of cowardly Lubos supporters who are very busy.

Actually, looking at the IP addresses, it looks to me like "anon" is a Harvard undergraduate, possibly living in Lowell house. Having done my time there, this conjecture seems all too consistent with the pompous tone of the comment.

31. **Michael**
January 26, 2006

Well, Peter, *I* know who I am. 😉 What does my IP-address look like?

32. **Peter**
January 26, 2006

Michael,

You're a lot cruder and stupider than the conjectural Lowell House undergrad. What's your excuse for remaining anonymous? As far as I can tell, you're at home somewhere in the Boston area using a DSL connection.

What's going on up there around Boston? Is it something in the water?

33. **A. nonymous**
January 26, 2006

> what I wonder is why people talk about detecting the decay of micro-BH's (and hence evidence of large extra dimensions) in the atmosphere rather frequently, or even in the LHC if we're lucky, when it would appear the most energetic cosmic rays detected rule out such observations.

There have only been about 20 or so putative events observed so far beyond the cutoff, which is about 5×10^19 eV. You might need to observe millions of incoming highly-energetic cosmic rays before you'd see a black hole being created. Of course, nobody knows how many events you'd need or what energy they'd need to be at; it depends on factors like the size of the extra dimensions. Larger extra dimensions should make black hole formation easier, and so on. You might need energies hundreds of times what has been seen so far, and, unless there's a source of ultra-high energy cosmic rays right beside us, scattering by the CMB should leach energy from the rays so that by the time they reach us, they're below 10^20 eV.

Incidentally, Peter, didn't Lubos accuse you of sock-puppetry not so long ago? I wonder if people are more inclined to suspect others of crimes when they commit those same crimes them themselves.

34. **Peter**
January 26, 2006

A. nonymous,

Thanks for the information about ultra high energy cosmic ray events.

Certainly Michael=Lubos is not impossible. I never did figure out what was up with Lubos and his strange idea that I was "MathPhys", quite possibly you're right that he thought that because of what he is up to.

35. **Michael**
January 26, 2006

Thanks, Peter. Yes, I am at home in Boston using my DSL connection. 😆 I laughed out loud when I saw that you actually answered my question, as if I didn't know… On a second thought, I think it makes you look like a nice guy. Kind of guileless, I guess.

What's my excuse? I don't need an excuse. This whole blog thing of yours isn't really serious in my mind. I don't want to give my good name for this little bit of pastime bickering.

Don't be too bitter about it, please. It's not even my intention to offend you too much — well, I sure enjoy bantering you a bit. You must have known that you can't run this kind of blog without facing some headwind, right? So please save the "all Boston is tainted" comments, will you?

36. **Michael**
January 26, 2006

No sir, I'm not Lubos either. 😆

Good lord, had I known I'd cause such a severe case of paranoia, I might have surfed elsewhere…

37. **Peter**
January 27, 2006

Michael,

No, I didn't think you were Lubos. His style is quite distinctive and anonymity isn't his thing. And no, I'm not the bitter sort, not in general, and certainly not at the moment, when life is quite good for many reasons. I didn't say anything about "all Boston is tainted", you string theory partisans have this mania for putting quotes around words I've never written.

Actually I'm quite fond of Boston. I greatly enjoyed the years I spent living in Cambridge, as a student and later in life. I have old friends there and my brother and his family live just outside Boston, so I visit regularly. Still the fact that a metropolitan area of only 2-3 million people contains more than one person as delusional as Lubos about string theory seems quite remarkable. There must be some sort of explanation….

38. **Michael**
January 27, 2006

Peter, it's not a coincidence, of course. Boston has the largest per capita density of high class academics in the world. This is particularly true for string theory.

Good night now.

39. **anonymous**
January 27, 2006

Peter,

These string theorists REALLY despise criticism, surprising for so-called scientists. You should have seen this "Michael" type anonymous behaviour coming a mile away. When you initially started the blog, I recall that the physicists that were critical were not anonymous (e.g., the fool Mark Srednicki of UCSB made of himself, Distler's moronic rantings, http://www.math.columbia.edu/~woit/wordpress/?p=3#comments, Motl of course, and others)

Once, however, having tried arguing and then realizing that they can't deal with the arguments, the coming of ad hominem and anonymous attacks were as obvious as the coming of men in white coats to escort Lubos to a mental clinic.

I think these type of attacks are a sign of success. You're quite a gadfly!

40. **a**
January 27, 2006

This time the controversy between Quantoken and Motl is about physics, so it can be clarified without insults. They miss that IceCube can also see events orginated below the instrumented region, such that its (energy dependent) effective volume can be bigger than 1 km^3.

As a general comment, I think we should pay more attention to people planning, building and operating experiments, rather than to people writing papers and funny press releases.

41. **woit**
January 27, 2006

> Boston has the largest per capita density of high class academics in the world. This is particularly true for string theory.

Somehow "high class" isn't really the term that comes to mind to describe Lubos and his anonymous fans….

42. **Thomas Larsson**
January 27, 2006

Boston has the largest per capita density of high class academics in the world. This is particularly true for string theory.

Population of Princeton, NJ: 14,203
Population of Boston, MA: 589,141
Population of Cambridge, MA: 101,355

So there are more than 41 times as many prominent string theorists in Boston than in Princeton?

43. **Quantoken**
January 27, 2006

a:

Wrong. First, the instruments detect visible photons. However clean the polar icea may be, lights do not penetrate much more than a hundred of so distance. Second the goal of the instruments is to correlate several detectors to identify the direction the muon is going, therefore inference the direction of the original neutrino. It can determine the direction only when the event is happening within the ice of the IceCube.

44. **Quantoken**
January 27, 2006

Peter says:

"Somehow "**high class**" isn't really the term that comes to mind to describe Lubos and his anonymous fans…. "

I would say **high** is the perfect word describing the status of super string theorists like Lubos et al. They are too high in the thin air they can't make their feet touching the solid ground of reality. Of course you know what the word "high" is often associated with when it comes to certain substance.

I prefer to stand on solid ground. Let some one else high.

Quantoken

45. **a**
January 27, 2006

Quantoken: muons (not photons) can travel for kilometers in ice. And by detecting a part of their path one can reconstruct its direction.

46. **Nick**
January 27, 2006

Quantoken's CosmicVariance Blog spells out his problem with the number of nucleons estimated in the ICE-CUBE paper. It seems the blog asserts that the water molecule has 3 nucleons, instead of eighteen which is the correct number. (You have to count all the protons and neutrons, not just the nuclei.) This accounts (almost) for Quantoken's problem that the estimate given in the paper is 7 times too big.

47. **J.F. Moore**
January 27, 2006

I had to check it for myself since I couldn't believe someone could make such a mistake while boldly chastizing others as apparently being below the toddler level in thinking. But you're right, Nick, it's there. "The water molecule contains three nucleons…." Wow. Just incredible.

48. **woit**
January 28, 2006

Please, no more discussion of Quantoken's mistakes about physics, this is far too large a topic and could easily overwhelm this poor blog.

49. **sunderpeeche**
January 28, 2006

And now for something completely different (as they say on Monty Python) … trackbacks. It seems that indeed the arxiv does not post trackbacks to this blog. But never mind. It seems that this blog has attracted sufficient prominence to garner interviews for Peter etc. I am reminded (perhaps for no good reason) of the blurb for Monty Python and the Holy Grail = "makes Ben Hur look like an epic". Why worry about trackbacks? Make it a subtitle "Not Even Wrong" ~ "Not even trackbacked by the ArXiv" (trackedback?). Trumpet it to the world with pride! It puts the ball in their court.

50. **woit**
January 29, 2006

sunderpeeche,

I kind of agree with you. But what is really weird about this story is that I can't even get anyone at the arXiv to admit to me that they have decided not to allow trackbacks here.

51. **Tony Smith**
January 29, 2006

Peter said "… I can't even get anyone at the arXiv to admit to me that they have decided not to allow trackbacks here …".

My memory is quite fallible, but I seem to recall from an earlier blog entry or comment that someone promised Peter that a representative of the Cornell arXiv would contact him about the trackback situation during this past week. Did that not happen? If it did not happen, was a reason given for the failure to contact and explain?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

52. **sunderpeeche**
January 29, 2006

As I recall, there was a blog entry about trackbacks (or lack thereof), maybe 1 month ago.
a) Peter said he had made (numerous) polite requests to have trackbacks from the arXiv, to no avail.
b) Peter also said someone at Cornell promised someone at arXiv would look into the matter and respond. Evidently there has been no reply.

And so today " … I can't even get anyone at the arXiv to admit to me that they have decided not to allow trackbacks here."

Let's be careful about this.
"Not even trackbacked by the arXiv" is a statement of fact.
It even (potentially) embarrasses the arXiv.
Not the same as "Blacklisted by the arXiv" (choose some other milder word).

What attitude to project here? My 2 cents worth is "I (Woit) have a blog which has attracted considerable attention. It is respected. If the arXiv chooses not to include trackbacks to this blog, it's their loss not mine. My blog can stand on its own merits."

But it's not my decision to make. Just an opinion.

53. **woit**
January 29, 2006

Tony and Sunderpeeche,

The person from the arXiv who was supposed to contact me last week didn't. I'll follow up this week, although this issue is not at the top of my To Do list. Sure, my attitude is pretty much the one Sunderpeeche recommends, but I also would like to see the arXiv management and advisory board take some responsibility for what they are doing. My suspicion is that I'm not hearing from them because at least some of the relevant people are not comfortable backing what I'm assuming is Distler's decision that the arXiv should not allow trackbacks to a blog that is too critical of string theory.

54. **Dumb Biologist**
January 31, 2006

There's a New Scientist blurb on the subject:

http://www.newscientist.com/article.ns?id=dn8654

55. **woit**
January 31, 2006

D.B.,

Just looked at the New Scientist article. I especially like the quote from John Schwarz, who demonstrates the new version of the scientific method now popular among string theorists:

"If something non-standard is established, string theory has a long list of exotica that would provide candidates to explain it"

So, if this experiment does detect an elevated neutrino cross-section at high energies, I guess this will prove string theory…..

56. **Dumb Biologist**
January 31, 2006

I wonder how long the "long list" is. I also wonder how long the list has to be before the meaning of the word "prediction" is strained beyond meaning.

57. **D R Lunsford**
February 1, 2006

DB – In physics "prediction" doesn't just mean that a new type of material event is seen. It really can mean two other things:

1) A workable phenomenological hypothesis is given a sound theoretical basis within a new framework.

2) A hitherto unsuspected phenomenon is unearthed.

3) 1 and 2 are not independent

For example the Dirac theory satisfies all of this (spin, antimatter, statistics). There was a theory of spin which was taken directly from lab phenomenology, but antimatter had never been seen. In fact Dirac thought at first he'd explained the polarity of electron and proton. Antimatter was experimentally discovered some time later.

-drl

3-400 Pages?

January 27, 2006
Categories: Uncategorized

I'd been wondering what's up with Witten and his ongoing work on geometric Langlands. He has been giving talks about this since last summer, and in the past has always quickly produced a paper (often a quite long one) once he has some new result like this that he's publicly talking about. It had surprised me that it was taking him unusually long to get this written up, but now comes news from Anton Kapustin (via Lubos) that Witten is working on a document 3-400 pages long. This length would certainly explain why it is taking longer than usual, and surely the end result will be something quite interesting. The Kapustin rumor also claims that whatever this 300-400 page thing is that Witten is working on, it's not a paper. Mysterious… The obvious guess is that it will actually be a book.

Comments

1. **D R Lunsford**
   January 27, 2006

   Maybe it's the Lagrangian for string theory.

   -drl

2. **secret milkshake**
   January 27, 2006

   Maybe a series of related papers, back to back. It would be helpful if it was; new ideas are needed.

3. **A.J.**
   January 27, 2006

   Wow. That's getting into Grothendieck territory. I wonder if it's something about topological field theories: Cordes, Moore, & Ramgoolam's quote-unquote "lecture notes" are nearly 250 pages and are still sometimes painfully terse. And my advisor's new lecture notes on Geometric Langlands are about 150 pages.

4. **ObsessiveMathsFreak**
   January 27, 2006

   Not quite related to Sting Theory, but on the matter of scientific papers; Some papers are just far too long. A great many writers seem to be caught up in *how* they are doing something rather than *what* they are doing. Appendices are fine, but I for one would rather that papers' main bodies be more succint than they currently are.

   A 300 page paper is clearly going overboard. I'd imagine 90% of the potential audience will be daunted and over 50% of those who begin will turn away after a few brief forays.

   Appendices for dull, but important, stuff, like large data sheets, mathematical derivations, etc, etc. But flashy diagrams go in the main text, naturally. And for heavens sake *put comments on your mathematical equations!!* A series of mathematical equations just thrown down is like a sequence of uncommented computer source code. i.e. impossible to work with. Tell us what, how and most importantly *why* you're doing something.

5. **D R Lunsford**
   January 27, 2006

   Peter, RE this comment

   The idea seems to be to use a TQFT given by a twisted version of N=4 supersymmetric Yang-Mills… Then one does dimensional reduction using as 4-manifold a Riemann surface times the upper-half-plane, and ends up with a sigma model of maps from the upper-half-plane to the Hitchin moduli space of flat connections on the Riemann surface. The boundary degrees of freedom are branes, and the S-duality of the 4-d theory is supposed to give a duality at the level of the sigma model that corresponds to the fundamental duality one is trying to understand in the geometric Langlands program.

   This sounds very impressive but I have no idea what it has to do with physics. By sigma model do you mean Kaehler metric? Or something like the Higgs mechanism? -confused-

   -drl

   -drl

6. **ksh95**
   January 27, 2006

   "By sigma model do you mean ….."

   I presume Peter means the same sigma model that's in every field-theory/critical-phenomena book ever written.

7. **woit**
   January 27, 2006

   drl,

   The sigma model is just a 2d qft involving fields that are maps from the upper half plane (that's your space-time, if you like) to a complicated space, the moduli space of solutions to a 2-d (different 2d!) gauge theory coupled to a Higgs field.

   This subject looks quite interesting, but also quite complicated. I'd kind of decided not to spend more time on it until Witten's paper came out, figuring it was a waste of time to try and figure out the details of this based on fragmentary notes of his talks, when a complete paper would soon be available.

8. **MathPhys**

January 27, 2006

He’s probably wrting a Lecture Notes in Physics, or Asterisque type monograph.

9. **Xerxes**
January 27, 2006

Just wanted to chime in with an opposite opinion from ObsessiveMathsFreak. I love long papers. People spend so much effort in papers trying to make themselves look very clever at the expense of clarity. If it takes you 100 pages to say clearly what you could have said succinctly in 25 pages, am I going to charge you for the extra bandwidth those 75 pages took to download? No, I’m going to shake your hand for explaining things clearly.

Besides, if I already know the material and just want to cut to the chase, I can always skip over to what I want to see using the table of contents. Can a reader who doesn’t know the material already fill in the blanks from a shorter paper? Nope, he’s out of luck.

10. **blank**
January 27, 2006

Actually, he’s working on a new book for the popular audience:
“Warped Personalities: Susskind, Motl, and the Illusion of Intelligence”

11. **xpinor**
January 28, 2006

[tex] 3^{400} [/tex] Pages?

12. **mitchell porter**
January 28, 2006

3400 pages?

So he went overboard on the case-by-case analysis of vacua…

13. **mitchell porter**
January 28, 2006

That’s odd, the preview showed the 400 as a superscript, as I had intended.

14. **secret milkshake**
January 28, 2006

I wonder if there is a technique that could help a bunch of thinking people to avoid commenting on the stuff published by Motl. It is like the ankle itch – it gets worse by frequent scratching it. Unless causing more inflammation is the purpose of this blog, I would suggest more self-discipline

15. **woit**
January 29, 2006

I fear that I just find Lubos too entertaining and his behavior too perfect an example of what is wrong with the way string theory is pursued for me to suggest that people ignore him.

16. **Tommaso Dorigo**
January 29, 2006

Hello,
just a note to say thanks for linking my site… I am doing the same!
Cheers
T.

17. **Kielbasa**
January 29, 2006

Without Lubos, where would Peter find enough materiel for his blogg?

18. **woit**
January 29, 2006

Kielbasa,

This month, all I need is the NYT book review. See my latest posting.

19. **sunderpeeche**
January 29, 2006

“materiel” (as opposed to “material”) is the werewithal an army needs to prosecute a war …. non-native English (which I assume is the case here ~ “kielbasa”) is wonderful.

Macrame

January 29, 2006
Categories: Uncategorized

This month, the New York Times book review has been the place to follow the latest debates about what is going on in particle theory. This started with an essay by John Horgan on January 1, which drew letters to the editor from Lisa Randall on January 15, and Lawrence Krauss and Leonard Susskind on January 22 (this last letter was discussed here).

The January 15 issue also had a not very positive review of Susskind's recent book (discussed here). In today's (January 29) issue, Burton Richter has a letter commenting on and contrasting the recent work of Randall and Susskind. He's positive on Randall, since he sees her as trying to come up with testable predictions, but about Susskind he has the following to say:

Susskind and the Landscape school have given up. To them the reductionist voyage that has taken physics so far has come to an end. Since that is what they believe, I can't understand why they don't take up something else — macramé, for example.

Richter is an emeritus Stanford professor, ex-director of SLAC, and won a Nobel prize in 1976 for his role in the "November Revolution": the discovery at SPEAR in November 1974 of the "Psi" particle, a bound state of a charmed and anti-charmed quark (also found by a group at Brookhaven led by Sam Ting, who called it the "J" particle). Since he is emeritus, presumably Richter doesn't attend Stanford physics department faculty meetings anymore, which is too bad, since I for one would love to see Susskind, Richter and Robert "string theory is like a 50-year old woman trying to camouflage her flaws by wearing way too much lipstick" Laughlin debating department hiring policy.

On the same page as Richter's letter, there's an ad for a book called "Reality Check", by David L. Weiner. I don't know anything about the book but the advertising blurb goes like this:

It turns out that the ape-like mechanisms that remain in our brains not only can create mental turmoil if we don't meet their primitive expectations, but their penchant for pecking order and status can create far-out realities we think are absolutely true. These may cause us to inflict unwarranted harm on others, limit our own potential, or both.

Seems to me this book might explain some of the reaction to the recent interview in Discover magazine.

Comments

1. **CarlB**
   January 29, 2006

   About those Centauros…

   There was little mention of them last year. The most interesting parts of them are the apparent tendency to have extreme transverse momentum and to spread in lines. These two things are exactly what one would get if one had a superluminal cosmic ray. That is, unlike a regular cosmic ray, the debris would not stay with the lead particle but would spread out as the speeds differed.

   There is another aspect of cosmic rays that can be explained by superluminal lead particles, and that is the mystery of why AGASA keeps finding excessive energies for UHECRs as compared to the other experiments.

   It turns out that AGASA measures energy by creating electrical pulses whose height is proportional to the deposited energy. Then the pulse is allowed to decay through an RC time constant. The result is a pulse length proportional to the log of the energy, and so they measure the pulse length. A superluminal cosmic ray will naturally produce longer shower pulses by retriggering (i.e. the lead particle gets there first, and the earlier produced showers show up later). This will spoof the AGASA electronics to measure excessively high energy. There is another cosmic ray experiment (Russian, if I recall correctly) that uses similar RC decay electronics, but has circuitry that prevents retriggering.

   I think the best theoretical explanation for the Centauros, in the context of current physics, is that they are outliers in the statistics of pion production. But that doesn't explain the tendency for them to have extreme transverse momentum. Oh, and they tend to react more strongly than protons, which some say is caused by them being heavier nuclei.

   There is a recent theoretical paper saying that UHECRs are superluminal, but they didn't note the Centauro evidence for this. I should send them a letter.

   Carl

2. **Wolfgang**
   January 29, 2006

   > the New York Times book review has been the place to follow the latest debates about what is going on in particle theory

   Clearly, the best place to follow the latest debates is "The Official String Blog", you can find the link on my blog.

3. **anonymous**
   January 30, 2006

   The last sentence of Richard's review spoils it all:

   "As a scientist and an experimental physicist, I am rooting for Randall."

   This gives a rather strange impression to the public: both are equally valid and reasonable approaches and its just my preference to "root" for the later one.

   It lacks any firm punch whatsoever. Sort of what american fundamentalists would have everyone believe in biology: there is evolution and there is intelligent design, and we're rooting for evolution.

   This way of putting it almost validates the intelligent design side.

4. **anonymous**
   January 30, 2006

   Oops, I meant Richter.

5. **fh**
   January 30, 2006

   The punchline is before, “Macrame”. I think he leaves no doubt whatsoever that Landscape is giving up.

6. **anonymous**
   January 30, 2006

   Though I love the sentence:

   “Susskind also is a believer in extra dimensions.”

7. **Who**
   January 30, 2006

   agree with anonymous about Richter’s phrase
   “a believer in extra dimensions.” factual but a nice ring to it.

   Two months till April, when Peter’s book comes out.
   Lucky timing, with the spotlight these days often on
   displays of string inanity, untestability.

8. **woit**
   January 30, 2006

   Who,

   I see that the book is listed on some sites as coming out in April, but I was told publication date in the UK is June 1. It should be ready to go by April, but I believe that things have been slowed down a couple months to keep the time lag between the UK and US publication shorter.

New String Theory Blog

January 29, 2006
Categories: Uncategorized

Thanks to Wolfgang Beirl for the news that there's an exciting new string theory blog, called The Official String Blog.

Comments

1. **Thomas Larsson**
   January 29, 2006

   Comments by Peter Wrought, Lubos Bottle, and Jacques Distiller.

2. **secret milkshake**
   January 29, 2006

   I am sorry, this is not very subtle but malicious it is. This one is on level of adding a mustache to the picture of princess Di, or writing about Dildo Baggins in "Bored of Rings"

   A good parody takes on a serious tone + unperturbed jargon. Only after few paragraphs it should slowly dawn on uninitiated observer that something isn't quite right. Of course, the best part of a good parody is the confused reaction of people who got taken by it.

   Here is example of a good parody (from a completely different field):

   http://video.google.com/videoplay?docid=-7687402682106917664

3. **clandestine malt**
   January 30, 2006

   jeeez it's just for fun dude… string theorists are really on the defensive these days… (assuming you are a string theorist, that is–I don't know who else would have that virulent a reaction to a little joking web page)

4. **secret milkshake**
   January 30, 2006

   Maybe somebody who does not like borderline-moronic spoofs? (C'mon – you could do better than this, doode).

5. **clandestine malt**
   January 30, 2006

   okay–duly noted that all humor too silly for the milkshake is malicious.

   I wonder what Lubos thinks

6. **Thomas Larsson**
   January 30, 2006

   Milkshake, note that Gates, Rocek, Grisaru and Siegel are close to being string theorists themselves. They are at least closely involved in SUSY.

7. **secret milkshake**
   January 30, 2006

   Lllame is the word you were sarching for, Clarice. Lame and vitriolic.

   A reaction cannot become virulent but bad taste can. There is Webster to help you.

8. **secret milkshake**
   January 30, 2006

   T Larsson: you are right – yours is way better

9. **anon**
   January 30, 2006

   Are u sure it's a spoof? Check out the FAQ's:

   Q. Is string theory related?
   A. Related to what?
   Q. Related to the real world?
   A. What was your question again?

10. **fh**
    January 30, 2006

    Siegels Parodies vary in quality, his anthropic principle one is great for example, http://insti.physics.sunysb.edu/~siegel/parodies/misanthrope.html

    —

    This hidden argument we call the Misanthropic Principle. It goes something like this:

1. I can't solve this problem.
2. Therefore, you can't solve this problem.
3. Hence, this problem can't be solved.
4. So, it's got to be just dumb luck.

11. **D R Lunsford**
January 30, 2006

The Main Sequence of Researchers:

http://insti.physics.sunysb.edu/~siegel/parodies/graph.gif

-drl

12. **Adrian H.**
January 30, 2006

For anyone who grew up with Mad magazines this qualifies as parody, and good parody at that.

But no one seems to have asked the important question, the question that Hmm would undoubtedly want to know the answer to: are Gates et al *allowed* to run a blog? Have they published enough? And what are their citations like?

I just hope they're not nobodies who have not received permission to speak.

Concerned from Tunbridge-Wells

13. **Luboš Motl**
January 30, 2006

Dear Peter,

your comments about the "landscape problem" have really no relevance for the calculation of the Yukawa couplings in the heterotic model of Ovrut et al.

The topic of your blog is to transform everything to the "landscape problem" – much like a student who has learned the birth of date of William Shakespeare and wants to transform every exam question about history and literature to the number 1564.

But one can't discuss any concrete physics questions in this way. Sorry.

Best
Bottle

14. **woit**
January 30, 2006

This is off-topic for the posting about a parody blog, but then again, maybe not, because Lubos and his blog increasingly seem to be a parody.

The scientific point at issue is about a very recent paper claiming to calculate Yukawa couplings in a specific heterotic string background. When Lubos wrote a post hyping this result, I wrote in a comment pointing that that the authors were ignoring the main problems with doing this: how do deal with the moduli and supersymmetry breaking. These problems are what lead to the landscape, since the only known way of fixing the moduli leads to exponentially large numbers of possibilities.

There was an exchange of comments, with Lubos displaying the usual string theory partisan mixture of insult, ad hominem attack and straw man argument. Faced with having this pointed out to him, he moved on to the next tactic: censorship. Here's the comment that he evidently had no answer for, so dealt with by deleting it:

"Lubos,

Your tactic is always the same: ignore the point I'm making (one that you know well is quite serious), then make up things I never said in order to use those to criticize me as ignorant. This behavior is stupid, dishonest, and highly scientifically unethical. You should be ashamed of yourself.

Let's look at how your dishonesty works explicitly:

1.
In this case, you are ignoring the problem posed by the moduli, and you are well aware that it is a deadly one. The paper in question notes
explicitly that fermion masses will depend on the moduli.

2.
You claim to show that I'm wrong and don't know what I'm talking about by writing:

"Nope. We are not choosing fluxes "in order to stabilize the moduli"."

I never wrote that "We are choosing fluxes in order to stabilize the moduli", I just said that the numbers like 10^500 that one hears for the size of the Landscape come from the number of choices of the fluxes, and these correspond to ways to stabilize the moduli. Do you know of a way of stabilizing all the moduli that doesn't involve this? If so, lets hear it. If not, acknowledge that you were dishonest to bring this up.

As for supersymmetry breaking, your claim that:

"marginal operators can't be classically affected by supersymmetry breaking"

is irrelevant. We're not doing classical physics here.

If you have any honest points to make, I'll respond to them, but I'm not going to waste any more time dealing with your dishonesty, interspersed with stupid, nasty, personal attacks. When you were a young graduate student, this kind of behavior was a bit amusing. At your age and stage of your career, it's just pathetic."

15. **Alejandro RIvero**

Poll:

What is the more interesting comment to the conference on the future of string theory for you?

I am doubing between this

Bottle says:
9:20 AM
String theory is just as well proven as evolution. In fact, DNA is an open twistor superstring.

and this

Bottle says:
9:32 AM
Hey, can we stay on topic? Which is, “Global warming is caused by the cosmological constant.”

The deepd inside of bottle in global warming and related issues is fascinating but the open ‘twistor’ comment is really great!!!

17. **Christine**
January 30, 2006

Concerning the parody blog in question: funny and frivolous. (Now I am waiting for “The Official Loop Quantum Gravity Blog”…)

There is one thing that I would like to have. Peter Woit writes down his top 5 criticisms to string theory. Lubos Motl *objectively and concisely* addresses these 5 topics. After that, Peter and then Lubos may offer one final statement on their points of view. No personal attacks allowed.

I would like to have this framework fixed at the sidebar of my blog page. No, it is not supposed to be a joke. I really would like that.

Thank you,
Christine

18. **Dumb Biologist**
January 30, 2006

The blog is kind of funny, but, as mentioned above, it’s also blindingly obvious that this a joke. The best examples of parody dance gingerly about the “fine line between stupid and clever”, and never stray too far into either territory.

The Bogdanovs might help them concoct something more subtly ironic. It would be amusing to see who could be fooled.

19. **John Gonsowski**
January 30, 2006

Actually the interesting part technically is where Peter and Lubos agree (landscape is bad, things like AdS/CFT are not the real world, Witten is brilliant). Their disagreement is not so much where string theory is now but where it will be later and what needs to be done now to make things as good as possible later. Even if Peter was wrong about some particular string theory detail, who cares, smart people correct each other all the time, it’s the way science is supposed to work. Even if string theory is extremely close to finding the right answers they could spend hundreds of years not finding it cause of the way they get fixated on particular ideas. The parody has some truth about the way people can cluster around an idea not yet worthy of such clustering.

20. **MathPhys**
January 30, 2006

I heard that, more than 20 years ago, Warren Siegel used to say “If Ed became crazy, would anybody notice?”.

21. **Dumb Biologist**
January 30, 2006

Awright, after a bit more reading, some of this is damn funny.

22. **a**
January 30, 2006

What Siegel presented as parodies are real difficulties of strings and high energy physics. E.g. the “lobotomy” parody, which is older than the landscape, contains the main criticism to string theory:

“In 11 dimensions, you can predict things uniquely; in 10 dimensions, you can predict up to a factor 5 of uncertainty; but by the time you get to 4 dimensions you can predict any value you want for a result.”

One can find similar examples of masked criticisms in old published papers. The big merit of Peter is saying in public what many physicists think, but prefer to discuss only privately.

23. **blank**
January 30, 2006

Thank goodness nobody had ever told me that a "good" parody has to be so subtle that is doesn't even make me laugh.

Actually Siegel's parodies seem to be the very opposite of a "good" parody: they seem an obvious trivial farce at first, but the more you think about them, the more they seem to accurately capture certain realities of string theory culture.

24. **Dumb Biologist**
January 30, 2006

Yeah, I must admit, after giving it more than a cursory look, there's a good amount of wry cleverness beyond the blatant silliness, so I should withdraw my earlier comment.

The recommendation letter thing was laugh-out-loud funny…and not at all isolated to physics.

25. **D R Lunsford**
January 30, 2006

DB – the parody is also of the magisterial tone that runs through many papers – this makes it doubly funny for someone used to reading papers.

-drl

26. **Levi**
January 30, 2006

No way is this a parody.

The advice in the appendix on The Art of Giving Seminars in "How I Spent My Summer Vacation" is pure gold. Or consider this, from the Dictionary of Common Phrases in "The Nonabelian Names of God":

"We'll have to save further questions for the end of the talk." —– "You've found the crucial flaw in the theory, so give everyone a chance to run away before it hits the fan."

27. **Quantoken**
January 30, 2006

That was a funny web site. Thanks for the laugh. I always thought Jacques's last name as "Distiller" until I read it more carefully 🙂 But you got Lubos's last name wrong! It's not "Bottle", but **Mottle**, or, **Multi-Bottle**. M like the M in Multiverse, or M-theory. For string therists, it's not Universe, but rather **Multiverse**, so of course Lubos's correct last name should be **Mottle**, not Bottle.

28. **Dumb Biologist**
January 30, 2006

He is the best student we have had in as long as I have been here…He is not quite good enough for us to hire here, but he is certainly better than anybody you have there…He hasn't written any landmark papers yet, but then, neither have you.

Indeed, gold…and about as accurate a reflection of the subtext of such letters as has ever been offered. It's as if my advisor's mind were an open book to be read. 😉

29. **Dumb Biologist**
January 30, 2006

Randomly, I'm reminded of the more overt (albeit probably benign) contempt expressed in another recommendation letter…

Dear Einstein,
This student is good, but he does not clearly grasp the difference between mathematics and physics. On the other hand, you, dear Master, have long lost this distinction.

30. **Omni**
January 30, 2006

GUFFAW!! That site was a riot!!

I find it vaguely disturbing, though, to find highly educated people categorizing themselves as ANTI something; if you have what you believe to be a valid theory that's backed up by proof, why not call yourself an adherent of that theory, rather than being anti someone else's theory… and if you DON'T have your own theory, why not go quietly about your research until you DO have one, rather than making an issue of being anti?

I idolize theoretical physicists, but I have to say; this is childish and unworthy of you. The truth is out there; please stop nay-saying and finger-pointing and FIND it.

31. **Dumb Biologist**
January 30, 2006

I rather doubt everyone around here is being contrarian just for the sake of it. I personally think the ANTI-science forces running amuck out there have rather elevated the stakes in the age-old debate over what is science and what isn't. I've said here before, it's bad enough when science is attacked from without, but it's excruciating when it's corrupted from within. One needn't have a "better" alternative to an idea that is unscientific to have something positive to say. It might be enough to reassert the essential need for a scientific theory to be, at least in principle, experimentally testable. It's also essential that a scientific theory be falsifiable, so that, if and when it is falsified, one can even know when to abandon a faulty approach and do the very thing you suggest, which is find a better idea.

If a theory fails both qualifications, it's hard not to feel concerned. I'm not sure about all of Superstring theory, but it seems almost certain this Landscape business (and probably all anthropic arguments) are about as anti-scientific as it gets. Even if it's 100% true, we'll never know anyway, so why, as a scientist, would anyone bother with it? And if someone is promoting such ideas, in the capacity of a scientist, to an interested and admiring public, is it inappropriate for others to decry the harm being done?

32. **John Gonsowski**
January 31, 2006

There are people here with their own theories. Unfortuneately string theory acts like a monopoly does in the business world and makes it quite difficult for new ideas to take hold (even new string theory ideas). The string theory powers that be even seem to be actively keeping some of the ideas here out of the arXiv archive.

33. **D R Lunsford**
January 31, 2006

John – even Penrose is ignored. He gives the simplest conceivable argument showing that inflation, to take an example, not only doesn't fix what it's supposed to fix, it actually makes it worse*. The alternative for it is to resort to anthropism. Since no one seems to be willing to abandon inflation, we can only assume that anthropism has already taken a seat.

Penrose's argument can be understood by an undergraduate. So why doesn't it have a prominent place?

-drl

* http://www.princeton.edu/WebMedia/lectures/

Look for Penrose lecture "Fantasy"

34. **science**
January 31, 2006

String theory has 'queered the pitch' for physics ideas. Few people have the time or inclination to study the details of the maths of stringy M-theory. String theory hype says they can 'predict' gravity, the Standard Model, and unify everything.

This is equivalent to saying: 'all alternatives are unnecessary' or, more clearly, 'all "alternatives" are crackpot junk that is not science.'

Notice that the first line of defence ignorant people have against criticism of mainstream is to claim there is no alternative. When you point out that you are critical BECAUSE alternatives are being suppressed, they then sneer at the alternatives because they haven't had the level of funding of mainstream string theory for 2 months, let alone 20 years…

35. **Juan R.**
January 31, 2006

Lunsford,

And what about the Nobel Gell-Mann and his five brains?

He carefully claims that string theory even if finally correct will be not a TOE, and emphasizes that antrophic principles are either nonsense or trivial and still there is people stating in talks that string theory may explain everything or that anthropism is a revolution in science.

—

Juan R.

Center for CANONICAL |SCIENCE)

36. **Ignorant Layman**
January 31, 2006

I wonder what all you critics think of Johnathan Swift's fey Island of Laputa in Gulliver? Was it an unserious error in parody or a classic skewering?

37. **science**
January 31, 2006

Swift's parody on crackpot mainstream scientists went wrong. He portrayed the truth of what scientists of the Royal Society were up to, but it was so crazy people thought it was mad or exaggerated.

Attempts to chemically revert sewage into food, to store energy in cucumbers, and to train blind people to paint pictures, were really made. This is innocent compared to the claims made for strings.

38. **Ignorant Layman**
January 31, 2006

Faw! It all sounds like Alchemy to me.

39. **Christine**
January 31, 2006

Is it possible that the general public is starting to think that String Theory is silly?

Silly String Theory For Dummies.

Silly String Theory In Computer Science.

Silly String Theory In Artwork.

Silly String Theory, a Cabaret Performance.

[I do not mean that I think String Theory as a whole is silly, this is just meant a joke considering this parody thread].

BTW, I would like to know whether there are any papers with a lucid evaluation on the merits and demerits of string theory, published in a peer review journal?

40. **matt d**
January 31, 2006

String theorists remind me a lot of the Intelligent Design crowd.

That was a funny site, thanks Peter.

41. **John Gonsowski**
January 31, 2006

Danny, at least Penrose (and Peter) can get themselves into Discover Magazine so maybe there's some hope. Surprised Penrose didn't mention Paola Zizzi in relation to the ORish alternatives.

http://www.valdostamuseum.org/hamsmith/cosm.html

42. **woit**
January 31, 2006

Christine,

I don't know of anything quite like what you are looking for, perhaps the closest is Lee Smolin's hep-th/0303185. Not sure if it was ever published or peer reviewed, if so the comments from string theorists would have been interesting to see.

43. **D R Lunsford**
February 1, 2006

John,

Penrose's lecture was fascinating. His bizarre visualization of phase space was sort of unnerving (like all fractals). Although you couldn't call him a dynamic speaker, his argument was so clear that it held my attention. Well worth attending.

-drl

The Future of High Energy Accelerators

January 31, 2006
Categories: Uncategorized

One of Fermilab's recent colloquia was by James Rozensweig of UCLA on the topic of Reinventing the Accelerator for the High-Energy Frontier. Video and Powerpoint slides of the talk are now available.

Current accelerator technologies are up against very fundamental physical limits. In the case of circular proton colliders like the LHC, the fundamental limiting factor is the strength of the magnets and the size of the ring. The LHC uses a 27km ring and 8.36 Tesla superconducting magnets, and the energy scales linearly with the magnet strength and ring size. So one could get beams an order of magnitude more energetic than those in the LHC by using a 270km ring, but the cost of such a thing is likely to be prohibitive. One could also try and design higher field magnets, but the current record for this kind of magnet is only about 16 Tesla.

For circular electron colliders, the limiting factor is the energy loss to synchrotron radiation and these energy losses scale as the fourth power of the energy. LEP was probably the highest energy collider of this kind anyone is ever likely to build, since it already was using an amount of power a sizable fraction of that of the city of Geneva. One could try and use muons, which are much heavier so synchrotron radiation is not a problem, but they decay quickly so there are lots of problems with storing them in a collider.

These considerations mean that there is only one viable route to much higher energies, a linear collider, and this is the path that the ILC project is pursuing. What limits the energy in a linear collider like the ILC is the combination of the energy gradient one can achieve and the length of the machine. The superconducting RF cavities being studied for use in the ILC are inherently limited to gradients of less than 40-50 MV/m, with something like 35 MV/m a likely realistic number. With this gradient, to get up to a TeV in energy would require a length of about 33 km, about at the outer limits of what is possibly affordable. Realistically, to get to higher energies than this, one needs to find some way to get much higher energy gradients.

Rozensweig's talk covers this material, but goes on to discuss various exotic new technologies that in principle can provide these much higher gradients. He describes progress on a long list of these, the most advanced of which is the CLIC project at CERN which uses the wake-field from a drive beam (a second accelerator). Much more exotic are various proposals involving lasers and plasma waves, some of which have been used to achieve gradients of 40 GV/m over short distances in the laboratory.

So, now all one has to do is to achieve a stable, high luminosity beam and make this work over kilometers not centimeters…. Not going to happen any time soon, but the distant future of high energy physics may depend on this kind of technology.

Update: I should also have mentioned here an article on this topic in the current (February) Scientific American entitled Plasma Accelerators.

Comments

1. **Tony Smith**
   February 1, 2006

   Peter says "… One could try and use muons, which are much heavier so synchrotron radiation is not a problem, but they decay quickly so there are lots of problems with storing them in a collider.These considerations mean that there is only one viable route to much higher energies, a linear collider, and this is the path that the ILC project is pursuing. …".

   As an advocate of muon colliders (see my comments on Peter's blog entry at http://www.math.columbia.edu/~woit/wordpress/?p=328) I have some biases here, but it seems to me that Fermilab is putting all its eggs in the ILC basket at least in part because of possible radiation hazard to Chicago of a muon collider at the Fermilab site.

   Unfortunately for Fermilab, there are a lot of uncertainties about building the ILC in the first place, and about its site if it is ever built.

   For example, a Charles Seife article in Science 308 (1 April 2005) 38-40 (and no, it does not seem to be an April Fool joke, although some physicists probably wish it were):
   "… Fermilab's Tevatron, due to shut down around 2010, could be the last large particle accelerator in the United States. …
   … Fermilab's Butler says, "a large number of U.S. physicists at the Tevatron are already planning to work at the LHC; they have exit strategies."
   But Butler isn't happy about the new venue. "This field is being outsourced," he says.
   The one big hope for U.S. accelerator physics is the ILC. "We're going to go for
   the linear collider," says Orbach. …
   For Butler and other physicists, the projected completion date for the ILC in the middle of the next decade is another huge obstacle. … a timetable that puts the ILC at the end of the next decade or beyond would leave an entire generation of physics students without access to an accelerator in the United States. …
   But the leader of the majority party in the U.S. House of Representatives isn't ready to make a firm commitment. "If [the ILC] fits within certain parameters, we'd like to keep it in the U.S.," Hastert says. The biggest of those parameters is the cost, estimated by DOE at $12 billion, of which the host country would presumably pick up half. …".

   Even if the ILC is built, if it is part of an international collaboration involving countries like Japan and China (which hold ots of dollars due to the inability of the USA to compete in trade of manufactured goods), then it may be that the money people in Japan and China will insist on an Asian site. As a Physics Today article at http://www.physicstoday.org/pt/vol-54/iss-9/p22.html about Snowmass 2001 said:
   "… But one cannot see the Pacific Ocean from the Illinois prairie. This geographic truth was pointed out rather bluntly at Snowmass by KEK director Hirotaka Sugawara. He reminded his audience that the joint work on the copper linac design in the US and Japan was undertaken with the understanding that the machine would be sited somewhere on the Pacific Rim … Sotoru Yamashita of Tokyo University was more specific: Europe already has the LHC … it was now Japan's turn to build an energy-frontier machine. …".

   In short, the future of high energy experimental physics in the USA looks to me to be highly uncertain at best, which is doubly sad because the USA theoretical high-energy physics community seems to be insistent on following a program that is Not Even Wrong.

   Tony Smith
   http://www.valdostamuseum.org/hamsmith/

2. **a**
   February 1, 2006

   The main problem of a TeV-scale muon collider is it would emit neutirnos, giving unacceptable radiation hazards, see e.g. hep-ex/0005006.

3. **woit**
   February 1, 2006

Tony,

I think it's true that high energy physicists are putting all their eggs in one basket, the ILC. The problem is that, for reasons outlined in the posting, there isn't really any alternative. Things like a muon collider or exotic acceleration technologies are a long ways away from the point where one could come up with a viable design and try and get someone to fund it. The ILC is really the only possibility for at least the next ten years or so, and probably longer.

4. **anon**
February 1, 2006

"Much more exotic are various proposals involving lasers and plasma waves, some of which have been used to achieve gradients of 40 GV/m over short distances in the laboratory."

It seems to me that accelerator physics is frozen in time; it hasn't changed much for the last 25 years. Aren't these "exotic" proposals at least that old? Am I being fair in accusing HEP of a shameful, inexcusable failure to innovate in accelerator physics? Isn't this failure a mayor cause for the failure of HEP theorist to produce predictive theories?

5. **sunderpeeche**
February 1, 2006

I was going to write a reply to Quantoken about electric v magnetic fields, but the post got deleted. Oh well … probably for the best I think. I was also going to say essentially the same thing as Woit in previous post …. the scale of machines for TeV energies is such that there can really be only one in the world. The ILC is about the only scheme which is buildable with today's technology (muon colliders are far future). Even then it will take many years. Exotic acceleration technologies are probably the only hope in the long term, but the key word is "long".

6. **Tony Smith**
February 1, 2006

Peter said "… The ILC is really the only possibility for at least the next ten years or so, and probably longer. …".

If so, then:

1 – What odds do USA high-energy physicists give that it might get built ?

2 – If it were to be built, what odds do they give that it would get built in the USA ?

3 – If it were to be built outside the USA, what do they think would be the consequences for USA high-energy experimental physics ?

If they aren't willing to give reasonable odds for the sake of discussion, does that mean that the pattern of wishful thinking that has corrupted the superstring community has entered the experimental community ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

7. **sunderpeeche**
February 1, 2006

I read anon's post just after submitting the previous.
If I may reply to anon ….. yes, acceleration techniques haven't changed much in 25 years (though superconducting rf was an innovation). The exotic ideas (use of plasmas) have indeed been around for that long, if not more. Shameful failure to innovate? The plasma wakefields etc are difficult ideas, not easy to make practical, even after all these years. But there has not been a lack of trying.

8. **Quantoken**
February 1, 2006

Tony:

Good question. But I guess no one is willing to discuss the odds that things they wish for will be built. It's painfully clear, if one is honest to himself in admitting, the odds are pretty low at this moment.

Frankly I think it is now a good time to mossball things up for a few decades, and let the public money be spend on something more useful in short terms, like alternative energy research. Later, when you guys figure out a better way of doing experiments, then we can fund you again.

Quantoken

9. **AR**
February 1, 2006

There has been tons of discussion about the challenges of building the ILC. See for example Turner's talk below.

http://www.linearcollider.org/cms/?pid=1000069.

The odds of the ILC depend very much on what happens in the next few years: it is likely that if the LHC does not find anything but a Higgs, then the ILC will not be built. If there are lots of surprises, then the chances are a lot better.

Site selection is usually put off as much as possible, so nobody knows the odds that will be built in the US.

If it isn't built in the US, then US experimentalists will rack up a lot of frequent flyer miles. But they'll cope.

10. **woit**
February 1, 2006

Tony and Quantoken,

I don't think anyone has a good estimate what the odds are that the ILC will be funded and built in the US. It certainly is true that if it is not built in the US, that will be very bad news for US high energy physics, and specifically for Fermilab if it is not built there.

My guess is that the decision whether to build the ILC won't be made until 2009-2010, at which point initial results should be coming in from the LHC. A lot depends on what the LHC finds. If it finds something interesting that would require the ILC to fully understand, that will help a lot. If it finds nothing at all and it then looks as if there is nothing new for the ILC to study up to its highest energy of 1 Tev, that will be a big problem. No one knows which of these is more likely, that's the biggest question in HEP right now.

On top of this, everything depends on the US budget situation several years down the road. I don't think anyone can predict that either, except that the US will still be struggling with what to do about budget deficits. Bush's announcement last night that he wants to double the budget for fundamental physics research may or may not lead to anything and may or may not go to HEP. We should know soon when his administration submits their FY2007 request. But the bottom line is that the budget situation is unclear for later this year, much less for 2009-2010.

And, no, even if the idea made any sense, you can't "mossball" an entire scientific field. Much of the budget pays scientists and technicians. If you throw all of them out of their jobs and have them move into other careers, they're not going to be coming back.

11. **David**
February 1, 2006

anon:

You've got to be kidding me by implicating accelerator physics as the major cause for HEP theorists not producing predictive theories. "Oh so sorry Mr./Miss String Theorist, we can't provide the gazillions of TeV you need to verify your theory, so it's our fault your theories don't predict anything."

And as for innovation, do you have any idea of how incredibly hard it is, for example, to build an experiment to test plasma wakefield acceleration, using an electron beam with the right properties? Sure these ideas existed on paper for a long time, but the technology needed is incredible.

The real problem is money. We could build a linear TeV collider now if we want, but we would need a LOT of real estate and a LOT of power and a LOT of money. This is obviously why accelerator physicists are investigating high-gradient alternatives, but these alternatives are technologically challenging. Even building a "warm" linear collider at X-band (11.424 GHz) to achieve higher-gradients as compared to the SLC at S-band (2.856 GHz) is quite challenging. The high fields alone lead to RF breakdown and pulsed heating that prevent high gradients from being achieved. These phenomena opened up a lot of study involving material science and surface physics. There are just so many impediments to technologically achieve high gradients that it requires years of experiments, analyses and simulations. But more importantly, it requires a lot of money which is hard to obtain. The accelerator field is making a lot of progress, but this progress is not really seen by an outside observer because they usually only see the big machines that finally get built.

12. **J.F. Moore**
February 1, 2006

Agreeing with sunderpeeche, there has been a lot of progress in acclerator research over the last two decades. Part of the apparent slowdown compared to the blinding progress of the preceding four or five decades is that all the low-hanging fruit is gone. The new developments are harder to realize, just like in any field of technology.

Regarding the 'eggs in one basket' criticism, I don't think there is much choice politically. If they don't get the ILC, they can push for something more exotic perhaps, but they need to get everyone on board now, with no apparent alternative and present a unified front to have any hope of landing the ILC.

As for the odds, you make the best proposal you can as a team and move on with it. The numbers I've seen don't seem unreasonable (e.g. not terribly out of scale with currently funded large science projects), the biggest problem is to make all of the politicians agree. THere's not much point in doing statistics and hand-wringing when you have no real alternative in any case, is there?

13. **Tony Smith**
February 1, 2006

Peter said "… Bush's announcement last night that he wants to double the budget for fundamental physics research may or may not lead to anything and may or may not go to HEP. We should know soon when his administration submits their FY2007 request. …".

Deb Riechmann wrote an AP article dated 1 Feb 2006 and carried on a Forbes web page at http://www.forbes.com/entrepreneurs/feeds/ap/2006/02/01/ap2492673.html that said in part:
"… In addition to the money for the tax credit, Bush wants to double over 10 years the investment in agencies that support basic research in the physical sciences and engineering, a $50 billion commitment.
The research money – $910 million in fiscal 2007 – would fund research programs at the National Science Foundation, pay for 500 new researchers at the Commerce Department's National Institute of Standards and Technology and 2,600 new researchers at facilities operated or assisted by the Energy Department. …".

If the ILC costs $12 billion (a DOE estimate according to a Charles Seife article in Science 308 (1 April 2005) 38-40), then
it might fit comfortably within a $50 billion increase over the next ten years
and
if the USA is the major funding government, then the USA should be able to dictate the site location, and it is possible that Fermilab might get the ILC and give high-energy experimental physicists a home in the USA.

Of course, that presupposes that the Bush budget idea would be supported by the next administration. Since Bush cannot run again, Fermilab will have to hope that the new president will not do to the ILC what Clinton did to the SSC (i.e., campaign promises to support it, followed by pulling the rug from under it).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

14. **J.F. Moore**
February 1, 2006

The implication that the SSC was viable in 1993 is not too credible. Many members of both parties in congress had the long knives out for that project for years before they finally succeeding in shutting it down – it was the prior Bush administration that kept it alive by lobbying so hard.

As for whether the SOTU numbers for DOE, NIST and NSF will ever materialize, I would suggest looking at past promises and comparing them to realities to develop one's own prediction.

15. **Quantoken**
February 1, 2006

Peter:

It's wishful thinking that if LHC finds something interesting then ILC may be founded. Just look at Hubble Telescope, it's finding something interesting every day but yet it's let to retire early. The bottom line is you need to look at priorities. And high energy particle physics research is clearly NOT the priority right now.

Don't you guys listen to the Bush address carefully? The predominant theme is "energy", "alternative energy research", "Get rid of America's oil addiction". That certainly has something to do with department of energy. But high energy physics is now just a step son of department of energy. Bush emphasised nanotechnology (material science), super computing, and alternative energy research.

Predictably, money will be shifted away from un-important fields, to areas that are now considered priority. The priority is alternative energy research, not dark energy research. The important things is replacing black gold, not researching black holes. For high energy physics research, the party will soon be over.

Quantoken

16. **Tony Smith**
February 1, 2006

J. F. Moore said "… As for whether the SOTU numbers for DOE, NIST and NSF will ever materialize, I would suggest looking at past promises and comparing them to realities …".

For two examples:
during the 2000 campaign, Bush promised tax cuts for big business, and he delivered; and
during the 2003 SOTU, Bush promised to remove a threat of Iraq under Saddam Hussein, and he did indeed remove Saddam Hussein as ruler of Iraq.

Therefore, it seems to me that if Bush feels strongly about a big idea, he will move to support it. That leaves the question as to whether or not Bush feels strongly about high-energy physics as a big idea.
Quantoken says "… high energy physics is now just a step son of department of energy. Bush emphasised nanotechnology (material science), super computing, and alternative energy research. …".
However,
as J. F. Moore said, "… it was the prior Bush administration that kept … the SSC … alive by lobbying so hard …", and it seems to me that with respect to high-energy physics it might be like-father-like-son.

Even though I agree with some things said by J. F. Moore, his statement about my comment:
"The implication that the SSC was viable in 1993 is not too credible"
is inaccurate and easily refuted as follows:

I did NOT state, and did NOT imply, that "the SSC was viable in 1993".

In fact, I said "… what Clinton did to the SSC ..[was]… campaign promises to support it, followed by pulling the rug from under it …".

Clinton was elected in 1992, and when he took office in 1993 he pulled the rug from under the SSC and it was terminated. According to an article by David Ritson in Nature 366 (16 December 1993) 607-610:
"… even with Bush's personal support, the SSC had a narrow escape in 1992.
… in the summer [of 1993] … Clinton publicly supported the SSC. But how far this support extended in private is questionable .
… The [USA] house [of representatives] instructed its representatives in the conference committee to terminate the SSC. This action ended the SSC early in October [1993] …".

There are lessons that the ILC supporters should learn from the SSC.

First, unless regional rivalries about sites within the USA (such as Illinois v. Texas) are fully reconciled, Clintoneque backstabbing can be fatal.

Second, the ILC management must avoid undisciplined cost controls and arrogant behaviour, both of which were severe problems with the SSC.

All things considered, it seems to me that maybe Bush might feel strongly enough about high-energy physics to support the ILC, but since Bush cannot run in 2008, it will be necessary for his successor also to support it.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Just so that nobody will have grounds to accuse me of being a pro-Bush propagandist, I will state for the record that in 1992, 1996, 2000, and 2002 I voted for Perot, Perot, Libertarian, and Libertarian for USA President.

17. **J.F. Moore**
February 1, 2006

My point was simply that congress was ready to kill SSC for years. Whatever motives you want to ascribe to Clinton notwithstanding, the vultures were circling well before he was elected, which is supported by your pull quote from Nature. If a line item desperately needs vigorous presidential support to save it, it doesn't require "backstabbing" to end it, it requires folding your arms and doing nothing.

More importantly, I think you are fooling yourself if you think the Bush administration has any commitment to physics, or even science at any level. Most of the things in these speeches are pure fluff. How about evaluating the hundreds of promises all presidents have made in SOTU addresses, including the promise of _every_ president since Nixon, some of them multiple times, to reduce our dependence on foreign oil, when over the same period the fraction has gone from under 30% to about 60%?

By the way, a quick calculation shows that this bold doubling initiative, even if it happens, will result in a 7% annual increase. Between payroll, insurance, and facilities charges, most places have a hard time keeping status quo with only a 5% increase. I am being kind and not counting overhead, which always rises faster.

18. **ObsessiveMathsFreak**
February 2, 2006

I had a feeling that particle accellerators were in for a redesign. I knew that circular accellerators did not scale very well, but to the fourth power! Gad-zooks!

I wonder has anyone tried some genetic algorithms to "evolve" a better energy gradient process, rather like an evolved antenna.

19. **sunderpeeche**

February 2, 2006

It is a consequence of basic (classical) electrodynamics that the radiated power goes like P ~ E^2B^2 where E= energy and B = magnetic field. Solve the Lorentz eqn for ultrarelativistic motion in a circle of radius R and you get B ~ E/R, so P ~ E^4/R^2. Nobody has found a way around this. So to reduce the power output one needs big rings (large R). The circumference of LEP was 27 km. FWIW LEP dissipated 18 MW at its top energy of sqrt(s) = 209 GeV. Also FWIW the SSC (20 TeV protons) would also have dissipated synchrotron radiation (I think several kW), the heat load of which would go into the superconducting magnets … another problem for the machine/magnet design.

20. **Tony Smith**
February 2, 2006

An AP article said "… Bush wants to double over 10 years the investment in agencies that support basic research in the physical sciences and engineering, a $50 billion commitment. …".

J. F. Moore said "… a quick calculation shows that this bold doubling initiative, even if it happens, will result in a 7% annual increase.
Between payroll, insurance, and facilities charges, most places have a hard time keeping status quo with only a 5% increase.
I am being kind and not counting overhead, which always rises faster. …".

Although I am not sure exactly how the AP article's "bold doubling" deals with inflation etc,
if I use for the sake of argument J. F. Moore's method, it seems to me that, based on a present $50 billion budget "in agencies that support basic research in the physical sciences and engineering":

$50 b x (1.07)^10 = $98 b, giving roughly a "new" $48 b over the initial $50 b, or doubling as described by J. F. Moore;
and
$50 b x (1.05)^10 = $81 b for J. F. Moore's "status quo",
so
that the "bold doubling" from $50 b to $50 b plus $ 50 b = $100 b would give $19 b over and above a 5% "status quo" amount,
and
$19 b is still more than the $12 b cost of the ILC,
so
even under J. F. Moore's own reasoning, "basic research in physical sciences and engineering" could:
maintain its "status quo";
build the ILC with USA money at a USA site; and
spend $7 b on new and different stuff.

I should also mention that if ILC were sited at Fermilab, funds that now go to the Tevatron (within the present $50 b) could be assigned to the ILC, thus reducing the ILC's demand for new money.

Of course, J. F. Moore could move the goal posts by pleading about " overhead, which always rises faster".
However,
maybe faster-rising-overhead is a symptom of poor cost control management, which is one of the factors that killed the SSC,
and
maybe refusal to restrain overhead is a symptom of management arrogance, which is another of the factors that killed the SSC.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – If one is asking a President for support for ILC, and a President makes public statements about a budget that could support ILC, it seems to me to be impolitic to say things like "… you are fooling yourself if you think the Bush administration has any commitment to physics, or even science at any level …", particularly in view of the strong support for the SSC by the first Bush administration. Why bite the hand from which you are asking to be fed?

21. **woit**
February 2, 2006

Tony and J.F. Moore,

I'd suggest postponing further detailed speculation about exactly what the Bush administration is going to do for a few days, until they release their 2007 budget figures. In any case, discussing what this means for 10 years from now is pointless: Bush will be long gone, things will be very different, and the history of promises like this is that they are forgotten after a few years. But soon we'll know something solid that means something, whether and how Bush's rhetoric will be reflected in next year's budget request.

22. **J.F. Moore**
February 2, 2006

Very good points, Peter. I totally agree about trying to predict the politics of this a decade out.

I will simply clarify at this stage that in general, budget increases are not pre-normalized to inflation, let alone expected rising costs. I agree that even so there is room for ILC. We will have to see what happens.

23. **Steve Myers**
February 3, 2006

As I recall it wasn't only politicians who were anti-SSC. Phil Anderson had a long letter in NY Times attacking it. And it's very hard to justify spending billions on research that is so removed from people's everyday lives. There's the problem.

24. **sunderpeeche**
February 3, 2006

Phil Anderson persistently attacked the SSC. (What is hypocritical is that after the SSC was cancelled solid-state physicists expected some of the $8B to go to their field. It didn't. It's not as if there was an $8B pot and "how shall we spend this on physics"?) It is also true that the initial cost estimate was approx 1.5B, this increased to about 4.5B when the Central Design Group (which leased space at LBL) developed their design. When SSC took over from CDG (and relocated to Texas) the revised cost estimate was 8B, with a possibility of 11B. This was simply too much for anyone and the thing was cancelled. Also the SSC was advertised (at least initially) to "regain the lead in HEP for the USA", and for the USA to have the "world's highest energy accelerator". It was hard to get other countries to contribute so that the USA could wave the flag.

25. **Jack Sarfatti**
February 11, 2006

It's called due process. The paper was endorsed by a several people independently. I have a PhD in theoretical physics from the University of California and unlike some of you who are being outsourced I will not have to be driving cabs or working at Burger King. 🙂

26. **Alejandro RIvero**
February 12, 2006

Well, *J. Sarfatt* did some publications on physics during the years 1963-1973, and I guess he had a theoretical phycsics PhD 🙂

Categories: Uncategorized

David Goss wrote to tell me that Physics Web has an article about physics weblogs. The theorists quoted are Sean Carroll, Paul Cook and Dave Bacon.

There's an article by Michael Green in the latest Nature Physics reporting on the recent 23rd Solvay conference (mentioned here and here). Green notes that "Much of the discussion focused on string theory" but that "the structure of string theory is still so badly understood that it does not yet deserve to be described as a 'theory' at all — it is more a 'work in progress'." He describes the discussion at Solvay about anthropic explanations of the CC as "lively", but that Polchinski et. al. have yet to carry the day: "there is a strong body of opinion that holds that it may be premature to decide which parameters are environmental within string theory, as the structure of the theory is still poorly understood and will surely hold further surprises."

The same issue of Nature has an essay by Lawrence Krauss entitled Anthropic Fever where he starts by explaining the standard Landscape story that fundamental physics is really an "environmental science", but then goes on to write:

But I have been wondering whether things might actually be much worse. It could be that many different combinations of laws could allow life to form, and that it is a pure accident, not favoured by any particular probabilistic explanation, that the constants of nature result in the combinations we experience in our Universe. Or, it could be that the mathematical formalism is so complex that the ground states of the theory might not be mathematically determinable, even in principle.

Whether or not nature is ultimately 'undecidable' in this strong sense, these ideas point to a possible future for particle physics that is very different from the past. Fundamental physics might not be restricted by any underlying grand mathematical structure that would 'explain' why the Universe is the way it is. It's a possibility that I hope will be wrong, but it's a possibility nonetheless.

This kind of worry seems to me completely misplaced. There's not a shred of evidence for it, and the only reason people have been engaging in this kind of speculation is that string theory led them down this sorry path. Finding a trackless swampland at the end of the path doesn't mean that physics is destined to spend the rest of eternity mucking about in a swamp, it is far more likely that a wrong turn was taken quite a ways back.

Last night a write-up by Nati Seiberg of his rapporteur talk at Solvay appeared at the arXiv, entitled Emergent Spacetime. It does a very good job of laying out the reasons that people often say that string theory suggests that our standard concept of "space" needs to be revised, that perhaps space is an "emergent" concept. Personally I don't think the different reasons that Seiberg lays out add up to a very convincing case. For one thing, string theorists have been trying to come up with a new "stringy" version of space for twenty years now, without much success at all. They are still far from anything like a consistent proposal of what this new idea about space will be, and the various evidence given by Seiberg is rather incoherent, leading to different kinds of generalizations of space, not pointing to any one of them in particular.

The past two days there was a conference at Harvard on Black holes, topological strings, and invariants of holomorphic submanifolds, which also included some lectures in memory of Raoul Bott by Sir Michael Atiyah, S. T. Yau, and Dan Freed. Lubos has reports on two talks there, one by Robbert Dijkgraaf about a hoped for "Universal Wave Function", a Hartle-Hawking kind of wave-function that would give the amplitude for the universe to be in various parts of the Landscape. The second was by Frederik Denef who spoke on "D-brane ground states, multicentered black holes, DT/GW correspondence, and the OSV conjecture ." Lubos reports on a conversation with Frederik about his two forthcoming papers with Michael Douglas on computational complexity and the Landscape. It seems that what Denef-Douglas show is that, even if everything one would like to calculate is in principle calculable, the problem of identifying a specific string theory background realizing anthropically small values of the CC is NP-hard. This means that in practice you'll never be able to do what landscapeologists would like to do: use the observed values of the CC and maybe some other standard model parameters to identify a tolerably small number of backgrounds, then use the properties of these backgrounds to make predictions. I believe it is this possibility that Krauss is alluding to in his quote above about how the "ground states of the theory might not be mathematically determinable, even in principle."

Update: The last paragraph has been modified to better reflect reality. In its initial version I had assumed from Lubos's blog entry that these computational complexity issues had been what Frederik's talk was about.

Update: Polyakov also has a new preprint based on remarks at the Solvay conference, entitled Beyond Space-time. It's a mixed bag, mostly about various ideas related to AdS/CFT, as well as the cosmological constant. He begins with critical but not completely dismissive comments about anthropic arguments:

Another danger is to get distracted by non-dynamical anthropic arguments, which recently acquired some popularity. I find the anthropic principle irrelevant. It is unlikely to uncover fundamental ideas and equations governing the universe. But, in spite of these misanthropic remarks, I believe that in special cases anthropic arguments may be appropriate.

At the end of the paper, he characterizes the various topics he has discussed as follows:

As it is clear from the list of the references below, these ideas (except for the gauge/strings correspondence) did not attract any attention. Perhaps they don't deserve it. My best hope, however, is that some of them may serve as small building blocks of the future theory, the vague contours of which we can discern at the horizon.

Comments

1. **Kea**
   February 1, 2006

   I read Seiberg's article in disgust: statements like "general covariance is a gauge symmetry" as if that were a complete argument for anything. He also claims to have some radical things to say, but I didn't spot them. What were they?

2. **woit**
   February 1, 2006

   Kea,

   I found Seiberg's argument that "some gauge theories have duals without gauge symmetry, so gauge symmetry is not fundamental. Since general covariance is a gauge symmetry it is not fundamental also" very unconvincing. But in any case, if you are going to abandon space, you don't even know what you mean by "general covariance" anymore, so you are abandoning that too.

   Not sure which he thought were the radical claims. Perhaps his two points at the end:

   1. Maybe every quantum mechanical system is dual to some string theory, so you shouldn't ask "what is string theory", but ask "Which string theories have macroscopic

dimensions" (where, presumably, the answer is "all sorts of them"…l)

2. If you can't think about what it means to be smaller than the Planck length, you have to give up the idea of reductionism as involving more and more fundamental laws that operate at smaller and smaller distances.

3. **Frederik Denef**
February 1, 2006

Hi Peter,

Small correction: my talk was not about the computational complexity or any other feature of the landscape, but titled "D-brane ground states, multicentered black holes, DT/GW correspondence, and the OSV
conjecture [or: why OSV is probably right]". After all, it was a conference about black holes, topological strings and invariants of holomorphic submanifolds, and indeed, I do have a life outside the landscape 🙂

As far as the computational complexity paper is concerned, stay tuned, it will appear soon…

4. **woit**
February 1, 2006

Hi Frederik,

Sorry about that, will correct. I was relying on Lubos's blog, didn't realize he was reporting on a conversation with you, not your talk.

5. **Chris W.**
February 1, 2006

From Peter:

> But in any case, if you are going to abandon space, you don't even know what you mean by "general covariance" anymore, so you are abandoning that too.

I wouldn't be so quick to assume this. See Joe Henson's new review **The causal set approach to quantum gravity** (gr-qc/0601121). Also see John Stachel's recent paper, Structure, Individuality and Quantum Gravity (gr-qc/0507078).

It is quite an admission for Michael Green to assert that "the structure of string theory is still so badly understood that it does not yet deserve to be described as a 'theory' at all — it is more a 'work in progress'", given that he and John Schwarz have been working on string theory for over 30 years.

6. **D R Lunsford**
February 1, 2006

Kea – agreed. I just stop reading when such a statement is made completely out of context.

7. **Arun**
February 2, 2006

I predict that none of the spacetime destroying features of string theory that are described in Seiberg's talk will be met with the derision that LQG's doubly special relativity, etc., receive.

8. **Dumb Biologist**
February 3, 2006

Speaking of LQG…someone is proposing what I guess is a concrete test of quantum gravity within that framework:

http://physicsweb.org/articles/news/10/2/2/1

I don't know how reliable this news is, or if I'm misinterpreting, but it seems to suggest that some LQG folks are proposing looking for a humanly-observable feature of BH formation that could possibly falsify their theory…meaning it's bona fide physics, at least potentially.

9. **Christine**
February 3, 2006

There are also some initial (negative) results for chaotic quantum foam models using quasar halos.

10. **anon**
February 3, 2006

DB, if that article is right, all they have to do is observe a brief dimming during the final flash of a dying star. Since there are 10^12 stars in our galaxy, with an average lifetime of 10,000 million years, about 100 must die each year in the Milky Way alone. Automatic CCD observation programs (of the kind used by Perlmutter to observe the spectrum of very distant supernovae) could be adapted to observe these flashes. This is very interesting.

It's excellent news that at last LQG is being taken seriously by some people. (Sorry Peter if this is off topic…)

11. **Brett**
February 3, 2006

The number of visible massive star collapses in our galaxy is less than one per hundred years, not one hundred per year.

12. **Dumb Biologist**
February 3, 2006

Thanks for the link and some of your exposition on your blog, Christine. Perhaps it's best to continue discussion over there so as to not get too far off topic.

Finding a trackless swampland at the end of the path doesn't mean that physics is destined to spend the rest of eternity mucking about in a swamp, it is far more likely that a wrong turn was taken quite a ways back.

His statement is also false, because we do have a good idea that *'many different combinations of laws'* WILL NOT *'allow life to form'*… so *'the value of the constants'* ARE *'favoured by any particular probabilistic explanation*.

So there is no evidence for anything that was quoted, and fundamental physics is therefore, more-likely to be restricted by an *'underlying grand mathematical structure that would 'explain' why the Universe is the way it is*.

And don't even tell me that my points aren't relevant.

14. **woit**
February 4, 2006

Please take discussion about conditions under which life forms to some other more appropriate forum. Virtually all the discussion along these lines that people keep posting here has little to do with the topics I'm posting about, and is just adding to the noise level.

15. **dan**
February 5, 2006

" (Sorry Peter if this is off topic…)"

Dear Peter or Lubos or Urs,

Given we have some prediction for LQG of a dying star, what would string theories' prediction be? Would it be similar to what LQG predicts or would it be different, and if different, how different? (see below)

We have LQG's prediction. Does string theory predict a naked singularity as classical GR does, or does it predict something different? Even if string theory has problems with SUSY and landscape, could it offer a prediction regarding singularities as LQG has done?

Speaking of LQG…someone is proposing what I guess is a concrete test of quantum gravity within that framework:
http://physicsweb.org/articles/news/10/2/2/1

"However, in the final stages of a star's collapse, the curvature of space-time becomes so large that classical general relativity theory no longer holds and quantum-gravity effects should take over. By applying the techniques of loop quantum gravity — a leading candidate for a quantum theory of gravity — Joshi and co-workers calculated that a dying star does not form a naked singularity but has all its mass thrown away in a flash instead. This burst has a characteristic signature: the star dims briefly before it rapidly radiates away to produce extreme energy gamma rays, cosmic rays and neutrinos. If this fingerprint were observed by astronomers, it might provide the first true observational test for quantum gravity."

16. **woit**
February 5, 2006

dan,

For the 1000th time: string theory predicts nothing at all about this, or about anything else.

As for the idea that LQG makes real predictions in this context, I think this is very unlikely.

17. **dan**
February 5, 2006

The paper in question required a subscription, which I do not have.

http://scitation.aip.org/getabs/servlet/GetabsServlet?prog=normal&id=PRLTAO000096000003031302000001&idtype=cvips&gifs=Yes

Perhaps prediction is too stringent, but perhaps "qualitive expectations consistent with known string theory" is a more specific term in the scenario described in the paper, would it differ or be similar to what LQG predicts, or would it match what GR predicts (a naked singularity)

Lubos actually responded to this post on his weblog

"string theory predicts extra dimensions in the form of Kaluza-Klein modes of known particles; excited strings at very large energies; specific patterns of black hole evaporation; Lorentz-invariant physics; topology changing transitions near the Planck scale; forces different from gravity, and possibly particles associated with supersymmetry and grand unification."

— not that i'm trying to start a flamewar or anything.

18. **Christine**
February 7, 2006

There is a new paper by Craig J. Hogan posted in the arXiv: Nuclear Astrophysics of Worlds in the String Landscape. The readers of astro-ph are mainly astrophysicists. I would say that a good fraction of them do not have any idea on the current debate on this landscape issue! I did not read the paper so I do not know whether the author includes a balanced comment on the fact that the landscape issue is quite an open problem. (Or, to some, a kind of dead end for string theory).

19. **Who**
February 7, 2006

Christine just posted a pretty good reading list for Quantum Gravity.

Since the topic is "Various Somewhat Related Links", and she didn't mention it, I will

20. **Who**
February 7, 2006

Re the two forthcoming papers by Denef and Douglas mentioned in Peter's log entry, this evening Douglas posted
http://arxiv.org/abs/hep-th/0602072
Computational complexity of the landscape I
Frederik Denef (KU Leuven), Michael R. Douglas (Rutgers and IHES)
53 pp, 2 figures
"We study the computational complexity of the physical problem of finding vacua of string theory which agree with data, such as the cosmological constant, and show that such problems are typically NP hard. In particular, we prove that in the Bousso-Polchinski model, the problem is NP complete. We discuss the issues this raises and the possibility that, even if we were to find compelling evidence that some vacuum of string theory describes our universe, we might never be able to find that vacuum explicitly. …"

European Strategy for Particle Physics

February 3, 2006
Categories: Uncategorized

The CERN Council Strategy Group is putting together a document proposing a European stategy for particle physics, in a process to be completed this July. As part of this process, earlier this week the group held an Open Symposium at Orsay, and the presentations are now available on-line.

I've often written here about possible future plans for particle physics in the US, but these presentations give an excellent overview of what is going on in Europe, where the situation is quite a bit better than here. Several of the presentations discuss possible upgrades to the LHC: the SLHC (increased luminosity), the DLHC (doubled beam energy using more powerful magnets), and the LHeC (colliding electrons or positrons with protons, like HERA at DESY, but with 1.4 TeV center of mass energy). Pretty much all the presentations are worth taking a look at, several of them involve an impressive amount of work in putting together a lot of information into a very professional PowerPoint format.

The one presentation about particle theory is by Nigel Glover and compares the performance of European and American theorists by looking at citation counts. There's a lot of interesting data, much of it showing American dominance, but keep in mind that there is a strong "Witten effect" in the data, since he is by far the most influential theorist around, especially in terms of number of citations.

Back here in the U.S., on Monday the Bush administration is releasing its FY2007 budget proposals. An outline of the DOE budget lists an 8% increase in HEP spending to $775.1 million, as well as full funding for RHIC. The NSF should also see a sizable increase as part of the so-called American Competitiveness Initiative. The folks over at Cosmic Variance are experiencing some cognitive dissonance.

Comments

1. **sunderpeeche**
   February 3, 2006

   That's very good news that RHIC will be fully funded in FY2007 (if all goes well thru Congress). BNL has also considered plans for eRHIC (collide electrons against protons/ions). One hopes that such ideas get funded.

2. **Ponderer of Things**
   February 4, 2006

   Playing devil's advocate (to some degree) – why should US be competitive in high energy physics? What possible practical return of investment can be expected from putting money in RHIC, Fermilab, LHC, ILC etc? To taxpayers scientists are thiefs who take their hard-earned money. How do you explain to taxpayers why it's important to continue investing into giant colliders where we seem to be reaching area of diminishing returns? Wouldn't that money be better spent for condensed matter/materials physics research, including nanotechnology, optics, spintronics etc? Never mind chemistry, biology and medicine – areas which produced plenty of bang for the buck already and will be expected to deliver in the near future.

   So – cure cancer and Alzheimers, or find out if string theory is a theory or just a theory about what a theory could be – which would you choose?

   8% increase is quite generous, considering there's no big high-energy project in US past 2009…

3. **woit**
   February 4, 2006

   Ponderer,

   First thing to keep in mind is that US HEP funding is under $1 billion per year, which is less than .01% of US GDP. At this scale, HEP funding is not crowding out funding for anything else worthwhile. The amount of money already being spent on cancer research is at least an order of magnitude higher. You're not going to cure cancer and Alzeimers with the marginal increase in funding for that kind of research you would get by reallocating HEP funding to those uses.

   Besides the small amount of HEP money going to string theory research (which I'll agree should be redirected elsewhere), most of it is going to experimental projects, none of which actually have anything to do with testing string theory. They do have to do with understanding some very fundamental things like where mass comes from, and you can justify funding research on this in several legitimate ways:

   1. Technological spin-offs: for instance, improvements in accelerator technology could have all sorts of applications. If you look at the talk about new accelerating technologies that I recently posted about, you'll see a comment that one beam instability being studied could at least conceivably provide a new route to fusion. A long shot, but for the relatively small sums being spent here, a small chance of a huge payoff is worth the money spent.

   2. Applications of whatever we learn: once we understand electroweak symmetry breaking and where mass comes from, chances are it won't have any particularly useful application. But we don't know, there is a chance of something truly dramatic coming out of this. If we discover a new stable particle (something supersymmetry advocates think exists), there are a lot of things you can imagine doing with it.

   3. Impractical things are important too: personally I don't think all human activity should be devoted to trying to make us live longer and more comfortably. Like art, literature and many other human activities, scientific research designed to better understand the world is of value in and of itself. Much of this kind of thing doesn't need to be publicly financed (arguments about public arts financing rage on and on), but unless we find a lot more hedge fund managers like Jim Simons who want to spend a lot more of their wealth on this, the only possible viable financing for HEP is public financing.

4. **anon**
   February 4, 2006

   1. Hot fusion would create a lot of radiation, the reactor would be irradiated with neutrons continuously. It's not just a 50 year old pipe dream, it's a dirty pipe dream. Any magnetic compression of a plasma is like squeezing an orange, the juice squirts out. You can just about get it to work with a massive amount of energy, meaning technical instabilities could cause it to blow up. It is just so expensive, dangerous and impractical when we have the sun pouring out fusion energy, I can't believe anyone seriously is an enthusiast of fusion power stations anymore. Even Quantoken realises solar cell technology is the way to get fusion power – from the sun.

   2. Understanding where mass comes from is vital, but surely that is a case for more money for new ideas and theory that models reality? Without a proper set of alternative theories (not just stringy fantasy), nobody will know what experiments to do, or how to interpret results. If there is no money put into alternatives to stringy stuff, it will look as if any result must be (or can only be) evidence for one of the 10^500 possibilities covered by stringy stuff.

3. '… impractical things are important too'. You'd make a devilish string theory proponent. I think the excitement has gone from high energy physics, the last really big event was 1983. It's like trying to promote going to the moon. It's a thing of the past, out of fashion.

5. **John Gonsowski**
February 4, 2006

HEP is very related to the ultimate human quest for the meaning of life. There's a reason Pauli and Jung sought out each other. Yes a pure conservative would like no government reaching into his pocket and a pure liberal would like us all to live munk-like and give lots of money to help the poor especially in third world countries. There needs to be a balance of course (for one thing both extremes would collapse the economy and there'd be no money for the pocket or the third world) and I think HEP deserves to be highly favored in the balance given its relation to the meaning of life.

Peter and people like John Baez are certainly right that we need to go back and look at things that seem to have gotten skipped over as things got more and more complex and unrelated to the real world. It's kind of embarassing not to have a well understood idea of where mass comes from. Peter's comment that a GUT needs to have this built-in rather than being ad hoc sounds good. My first comment related to mass (given my many hours spent at Tony Smith's website) would be "What is a leptoquark supposed to do anyways?".

http://home.comcast.net/~jcgonsowski/polytopes.html

6. **woit**
February 4, 2006

anon,

1. Anyone who wants to discuss fusion should do this somewhere more appropriate.

2. If your current theoretical ideas aren't any good, that's when you most need experimental results.

3. If you think particle theory is out of fashion, so not worth thinking about, you're spending your time reading the wrong blog.

John,

Please, discuss Tony Smith's ideas about leptoquarks with him, or with other people somewhere else. That's far off topic, and this is not sci.physics, it's not a forum for people to try and start discussions of their favorite alternative ideas about particle physics. Allowing that quickly leads to a high level of noise drowning out any sensible discussion.

7. **SomeBody**
February 4, 2006

Peter, you say "under $1 billion" and make it sound like nothing to quibble about. That's an easy trap to fall into; a billion bucks is an abstraction which nobody has a real feel for. So let's try to develop one by comparing with median US household income. Asking Google, we find e.g.

http://www.epi.org/content.cfm/webfeatures_econindicators_income20050831

where we learn that the number in 2004 was $44,389 (and falling). Total taxation is roughly 30%, so we do

1E9/(0.3*44,389) = 75093

to find the number of households equivalent to 1 billion of tax dollars. Mind you, a household will generally mean a couple of adult workers + their offspring, so we are really talking the equivalent of O(1E5) people here going to work every day and then giving their every last tax dollar to HEP, leaving nothing for school, social security and so on.

The ILC is expected to cost $12 billion or so. In other words, that project alone will require the equivalent of one million workers – from stock brokers to cleaning ladies – giving their every last tax dollar to HEP, leaving nothing for school, social security and so on.

Money well spent? Maybe, maybe not. But the real question is: do you really think those who earned it would choose to spend it this way, if they were given a choice?

8. **J.F. Moore**
February 4, 2006

Ponderer – The following question of yours in particular is fallacious: "So – cure cancer and Alzheimers, or find out if string theory is a theory or just a theory about what a theory could be – which would you choose?"

It's not a genuine choice. Cancer research has been funded with large amounts of money for many years. This has resulted in great advances in understanding and treating cancer, but certainly no blanket 'cure'. In fact, it is likely that the total cancer mortality rate has dropped more from people not smoking than from all treatment combined.

It is not at all clear that even the extreme of ending all HEP work and diverting the money to cancer would have a significant effect on the existing effort, as it may already be well into the realm of dimenishing returns. Maintaining a healthy, diverse academia by supporting the field and attracting researchers from around the world is probably more important.

9. **anon**
February 4, 2006

Sorry Peter for my style. A definite prediction should be made before experiments, and this requires some revolutionary theory first, that can make the sort of predictions that can be tested.

10. **J.F. Moore**
February 4, 2006

SomeBody – that's a fairly unreasonable way to look at it, since the burden is spread across the whole country, and since the top rate is fixed those with higher income pay disproportionately more. It then depends on what you choose to be a representative household, but I think the total bill for ILC would be under $50 for most of us.

For another perspective, it would also be fair to compare this to other tangible things like the space shuttles, an aircraft carrier group, hurricane Katrina, etc. Yes, a billion dollars is a staggering amount of money, but it must be kept in perspective. The US is paying $350 billion a year annually in interest on our debt alone.

11. **woit**
February 4, 2006

Somebody,

I have several problems with your computations, including the fact that you use a price-tag for the ILC probably so high that there is zero chance it will be funded if that is what the US will have to pay for it, and you assign its total cost to one year, even though it will probably take a decade to build the thing. Another problem is that you use median household income when the bulk of tax receipts are coming from people significantly above the median (because they have more money), and there are other sources of tax receipts (eg. taxes on corporations).

If you assign the marginal cost of any particular thing the government does to struggling families who have just barely enough money to get by, but enough to be paying taxes, that's a good debating trick for the libertarian point of view against government spending, but it makes no more sense than the favorite leftist debating trick to compare whatever one wants to fund to the profits of the Mobil corporation and announce that there's plenty there and they'll hardly miss it. The relevant fact here is that $1 billion is a lot of money, but the total federal budget is over $2,000 billion, so we're talking about less than .05% of the budget.

I confess I have a really low tolerance level for this sort of discussion of politics and economics, especially in this kind of more specialized internet forum. There are 10,000 blogs out there where one can argue generic issues of government spending, please don't do it here. I don't want to participate in that kind of political discussion and I don't want people who enjoy spending their time on that sort of thing to be doing it here.

If you have a point specific to the HEP budget, please feel free to discuss it here, but if it's a generic point about government spending, please take it elsewhere.

12. **SomeBody**
February 4, 2006

Woit: the DOE's $12 billion price estimate for the ILC was posted here a couple of days ago:

http://www.math.columbia.edu/~woit/wordpress/?p=339#comment-8266

Sure, it's not $12 in one year; that's not what I said. What I do say is that those 12 billions represent the total tax take from 1+ million people over one year. As I said, it's a way to get a feel for the reality behind those abstract numbers.

Sure it's a very small part of the total US budget. The same can be and is said for just about any single item in it. That's how the thing keeps exploding. Nobody feels their "tiny" little part is a problem. It's somebody's else's problem and somebody else's money. Result: death by a thousand cuts.

Do I have something specific to say about the HEP budget? Yes: the vast majority of people contributing to it, from the cleaning lady to the stock broker, will never benefit from it in any way, and wouldn't feel any loss were it to go to zero. And I personally find the thought of the cleaning lady supporting people with tax-financed salaries several times higher than hers, to do something which they love and which is generally perceived as fairly high status, but which will never be of any use to her, profoundly disturbing.

As for taxes on corporations, please remember that they are ultimately paid by their clients, i.e. individuals.

13. **Quantoken**
February 4, 2006

Peter:

Don't read too much into the 8% budget increase, taking away roughly 4-5% annual inflation it's only 4%. Not to meantion the value of US dollar is set for a major collapse soon. The extra money is barely enough to pay for the electricity bill for RHIC. At 100 megawatts power consumption and if left running year around, that's 0.8766 billion kilowatt*hour. At 12 cents cost per kilowatt*hour the electricity bill alone runs into $100 million.

We all know that further development of accelerators of ever higher energy level is quickly running into **prohibitive physical limits**. If you increase the energy 10 times, the accelerator ring will increase diameter another 10 times, the technical complexity and cost of the machine goes up 10 times, and the electricity consumption goes up a 10 times as well. There is really NO physical room for such growth as accelerators are already consuming electricity of whole cities, and occupying sites of whole city big, and takes monetary contributions of many countries just to built and run. Do you think you can get the next generation accelerator built on 8% budget increase? Not a chance even if you get a quadrippling of budget.

And if the new physics is not at TeV scale, but at a scale a few orders of magnitude yet higher (which is much more likely than not), or even close to Planck scale, then you are wasting all the money without discovering any new physics. If that happens that is the end of high energy physics research.

Quantoken

14. **sunderpeeche**
February 4, 2006

I'll refrain from any political comments (even w/o the post from Woit). Mainly I am motivated to write because of Ponderer ~ redirect HEP funding to condensed matter physics, spintronics etc.
("Wouldn't that money be better spent for condensed matter/materials physics research, including nanotechnology, optics, spintronics etc?")

Does it occur to anyone that the electron was discovered by JJ Thomson who was trying to understand the nature of cathode rays? Who among the general population in 1897 cared about corpuscles flying around in evacuated glass tubes? Was the electron really relevant to anyone's lives? Have you ever seen an electron? Does it matter to you?

Mankind has moved forward because of the persistent desire to know the unknown.

15. **SomeBody**
February 4, 2006

But sunderpeeche, all that was done with tabletop experiments, so that was also the scale to be expected of any (then) hypothetical applications coming out of that activity (which, besides, cost very little even by the standards of those days).

Earlier in this thread, Woit says that "If we discover a new stable particle […] there are a lot of things you can imagine doing with it". Really? If it takes an LHC to produce, what will be the scale of its (hypothetical) applications?

16. **sunderpeeche**

February 4, 2006

Ugh.

I guess this blog is for other people. I have to move on with my own life, a bumbling random walk though it may be. I am a fool.

17. **Chris Oakley**
February 4, 2006

I think that there is definitely a problem here. Being able to bring WW2 to an abrupt end boosted the stock of physicists enormously; Oppenheimer, Fermi and Feynman became like rock stars overnight. The public did not seem to have a problem with paying for the expensive toys they then wanted. As long as the brightest and best were driving the process taxpayers were able to some extent to share the excitement for the whole "ultimate question" project. The problem is that it is old hat now. Nothing really dramatic has come out of it. Bigger accelerators and more kinds of "fundamental" particle just counts as more of the same as far as Joe Public is concerned. If the project had led to wholly new things – wormholes, time travel, extra dimensions, etc. – the kind of thing that Superstring theorists like to fantasize about – then I am sure that particle physicists would not have to fight for their share of the science budget.

18. **Marty Tysanner**
February 4, 2006

Peter wrote,

First thing to keep in mind is that US HEP funding is under $1 billion per year, which is less than .01% of US GDP. At this scale, HEP funding is not crowding out funding for anything else worthwhile.

Later Somebody wrote,

the vast majority of people contributing to it [HEP], from the cleaning lady to the stock broker, will never benefit from it in any way, and wouldn't feel any loss were it to go to zero.

It is really unfortunate that Somebody's point of view holds as much sway as it does among people with a "practical" world view. It both assumes a narrow notion of "benefit" (often measured in monetary terms or direct impact on safety or lifestyle) and ignores the ennobling aspects of pursuits of knowledge or beauty for their own sake. It also ignores the fact that a large fraction of discretionary spending by individuals goes toward entertainment in its many forms (travel, camping, tobacco and alcohol, nice cars, sports, music, movies, and so on). That is, people as a whole *choose* to spend their money on things that often have no long term practical value to themselves, but they nonetheless feel it adds to the quality of their life.

Governments at all levels respond to this by allocating large amounts of tax money to subsidize and promote these activities, for example through regulatory agencies, purchase and subsidies of facilities, and law enforcement specific to those activities. Without this public investment much of this simply would not happen or would be available only to the wealthier segment of society. After all, governments became involved in the first place due to a perceived need.

One can look at HEP research spending in this light. It has little direct benefit to the general public, but it serves the many people who are curious about the inner workings of the world around them by giving them something to learn and be curious about. By uncovering new and surprising things in their wider evironment, discoveries make life more interesting to those people, and stimulate their imagination. And yes, even cleaning ladies and stockbrokers can have an imagination and be curious about the world around them, and thus can indirectly benefit from HEP research. Furthermore, many of us think that stimulating the imagination and sense of wonder in others is more ennobling than, say, indirectly promoting or subsidizing alcohol consumption.

Beyond the ennobling and "entertainment" aspects of HEP research, there are practical benefits to society (even cleaning service people and stockbrokers) as well, but again they are indirect. Peter mentioned technological spin-offs, but I think there is an even more important form of spin-off, one that relates to the future well-being of society as a whole. New discoveries stimulate the interest and curiosity of many intelligent students and can have a significant effect on later career choice. Probably everyone reading this blog has at least heard of a smart young person who was excited by scientific discovery and the prospect of exploring the unknown, and their imagination and desire were sufficiently stoked to encourage them to pursue a scientific or engineering career. Encouraging people to enter science and engineering is very important to the future competitiveness of a country, and thus to the standard of living of future cleaning people and stockbrokers, since people in science and engineering tend to earn more and thus disproportionately increase economic activity through purchases, investment and taxes. Further, if there are not enough people advancing technology and creating high technology products, that work will be done in other countries. It is not hard to see that a country that falls significantly behind scientifically and technologically will not offer its citizens as high a standard of living (and government tax receipts will drop too, leading to more debt burden).

Thus, HEP research, like basic scientific research in general, has an important role to play that goes well beyond direct practical benefit to the "vast majority of people contributing to it." Here, as is often the case, benefits cannot be measured in strictly practical terms, or the practical benefits that do result from it come long after the payment has been made.

19. **secret milkshake**
February 4, 2006

Chris, I disagree about 2 things: 1) Oppenheimer indeed was like a rock star and there was the whole sensational mystery of the bomb that grabbed the imagination of the public. It was exciting, great adventure to become a physicist. There was GI bill that greatly boosted uni admissions and physics benefited greatly. Atomic energy was a bright future, not the nightmare. And most of the funding for big accelerators came from DOE, with hope that happy physicists will again find something that is good for bombing the enemy.
2) Feynman was known to all the top guys from Los Alamos because of his success as a leader of the electromechanical machine computational group (that solved the questions about the implosion design) – but relatively speaking he was just teenager-looking bright man with a fresh degree from Wheeler who has not published anything. After war when he joined Bethe at Cornell, he was pretty depressed and occupied with writing the lectures and he was not producing any research for maybe 2 years. Once he put together his the path integral version of QED, his ideas were rather slow to catch on.

20. **John Gonsowski**
February 4, 2006

Peter, yea I was trying a little too hard to make my first comment with my new home page actually relate to my new home page.

21. **Not a Nobel Laureate**
February 4, 2006

Robert Rathbun Wilson, a Wyoming cowboy who built the world's highest-energy particle accelerator laboratory with the eye of an artist, the shrewdness of a banker and the conscience of a human rights activist

…

Wilson was not only a pioneering scientist, but a powerful spokesman for science. He reached a height of eloquence in his testimony before the Congressional Joint Committee on Atomic Energy in 1969. He was asked by Rhode Island Senator John Pastore about the value of high-energy physics research in the support of national defense.

"It has nothing to do directly with defending our country, except to make it worth defending," Wilson said.

http://www.fnal.gov/pub/ferminews/ferminews00-01-28/p1.html

There's no School like Old School.

22. **SomeBody**
February 5, 2006

Marty Tysanner, two points:

1) I have no problem whatsoever with people choosing to spend their hard-earned money however they please. They earned it; it's theirs to do what they want with. If the cleaning lady and stock broker really feel like you say about HEP, nothing's keeping them from donating money to it. (At this point there is usually some smart Alec who retorts "But we will never get 12 billion for HEP by voluntary donations!", apparently not realizing the implied condemnation of using tax revenue for HEP; remember how democracy is supposed to be by the people, for the people?)

2) There have never been so many things to spend on in science and technology which have both the potential to excite and enthuse those footing the bill, the general public, AND to produce real benefits for them. You need only pick up a few popular science mags to read all about them. How many articles about HEP do you see in those mags? In any given month, chances are that it's not even one. So this part of the argument is a red herring. Questioning the legitimacy of spending huge sums on HEP is not synonymous with questioning spending on science and technology at large.

23. **Haelfix**
February 5, 2006

I very much doubt there is anyone who can seriously point a finger at American research in high energy physics. As a fraction of population we so dominate the field its not even worth arguing about. Frankly its to the point where questions like this are more or less nonsensical. Everyone who is serious in science goes to conferences in the US, interacts with physicists working in American universities and so forth. At this stage, race/nationality/gender/whatever is a nonissue anymore, its more or less a global search, and ra ra ra patriotrism doesn't make much sense any more (eg is this particular scientist working at Berkley or at the university of Tokyo).

As far as I see it, we won that closed minded national race years ago, and had the foresight and intellectual integrity to make it a nonissue. Everything is now 'open source', and silly bickering about who is better than the other at this stage is ridiculous.

If you go to CERN, and other leading areas of particle physics, I very much doubt you'll find people who even think like that. That community isn't just European, its quite distinctly global in character.

24. **Quantoken**
February 5, 2006

Any one interested can check out the latest status of RHIC on this link. Curiously they just had some sort of **BTA power supply problem**, at 1:00 am Feb 5th, 2006. Any one knows what exactly does that mean? Is BTA the main power?

The RHIC accelerates completely ionized gold nuclear. I am wondering how they cheated on the energy. For example when you accelerate the nuclear to 1TeV, let say, since the nuclear is composed of many protons and neutrons, and when collision happens it's just invidual protons and neutrons hitting each other. So the effective energy of collision is actually much lower that the beam energy, since the energy of individual protons and neutrons is much lower than the collective energy of the whole nuclear. Any explanation?

Quantoken

25. **nuclearPancakes**
February 5, 2006

To answer Quantoken's question:

The meaningful parameter for energy in heavy ion collisions is \sqrt{s_{NN}} not \sqrt{s}. All results from the RHIC projects are reported as such, no "cheating" neccesary…

-nuclearPancakes

26. **J.F. Moore**
February 5, 2006

Q: BtA is the Booster-to-AGS transfer line. AGS is the older Alternating Gradient Synchrotron which is now incorporated in the RHIC complex. In short, it is a very small part of the system, but like most accelerators every small part has to work to do an experiment.

27. **Ponderer of Things**
February 5, 2006

just to point out – if it was up to me, I would half the military R&D budget and put the gained money into fundamental and applied sciences, including HEP.
But from the point of view of taxpayer I don't see a very compelling argument to continue supporting huge accelerators like ILC. I agree that there has been some "trickle-down" benefits, like synchrotron sources, but overall I am hard-pressed to point to some direct practical benefits of high energy physics from the past 30-40 years or so. I can see the type of arguments other areas of experimental physics will be making to improve their own funding situation, but not so much for HEP. Cancellation of SuperCollider project was the beginning of the trend, and if I had to guess, ILC is doomed as well – and the rest of the world will probably not support it if US bails out.

28. **woit**
February 5, 2006

Somebody:

You didn't quote the full text of the estimate for the ILC cost, it mentioned that the assumption was that only half would come from the host country. As far as I know, the ILC design effort still is not at the point of coming up with a final number for the total cost. One of the main goals of the design effort is to figure out how to do this as cheaply as possible. The people involved are well aware of the SSC fiasco. My guess is that $12 billion is an upper bound. The final cost estimate may be significantly below that, and if it is much above that the project will not be taken seriously. Half of that ($6 billion) I think is a good estimate of the upper limits of what the federal government might consider funding. If spread over ten years, that is $600 million/year, a large fraction of the current spending of over $800 million/year. So the ILC cost can't be accomodated within the current budget unless one shuts down almost all HEP labs and research for the duration. However, it could be accomodated within a not inconceivably large budget increase (there was this guy on TV recently going on about doubling the budget for physics research…)

As for arguments about how the average person wouldn't want their tax dollars used for this kind of thing, how about letting them speak for themselves? This is a democracy, which (if it were functional, but that's way off-topic…) works by letting people choose representatives who reflect their views to make this kind of choice for them. The HEP budget is debated by Congress each year, any ILC proposal will be exhaustively examined and debated, including all these issues of whether there will be any practical benefits, how people feel about spending these sums on what may be pure knowledge, and whether the money would be better spent on other forms of scientific research. Opinions held by people on these issues are all over the map, and don't divide nicely according to the standard partisan divisions.

29. **SomeBody**
February 5, 2006

Woit:

What difference does it make if half the taxpayers contributing to the thing are not in the US? We are still talking the equivalent of 1+ million people working for a year to finance it (actually more the less of the funding is from the US, since median income is lower in almost all other countries).

I agree completely with you that those footing the bill should be allowed to speak for themselves. We all know how that is done: by letting them spend their own money as they see fit (e.g. by donating it to a church, a charity, cancer research, the NSF or whatever they see fit) instead of handing it over to politicians.

You are an intelligent man, so you know perfectly well that the electorate's opinions about the value of HEP will never be properly represented by Congress or other elected body. It's just too small an issue to even be brought up in a campaign, other than possibly in special-interest constituencies which may hope to get a site (which, as usual, means that there are special interests lobbying FOR spending on this or that project, while nobody has a comparable interest in lobbying against it).

Letting elected politicians make the decisions in such a matter is therefore not an example of representative democracy; it's an example of chance & special interests at work.

30. **woit**
February 5, 2006

Somebody,

Sorry, from your rhetoric I think we fundamentally disagree about the proper role of government and how representative democracy should work Further discussion though would just lead to the kind of pointless back and forth about this that I think is a complete waste of time and that I don't want on this site.

So, I'll invoke my undemocratic, totalitarian powers here and announce I'm deleting any further discussion along these lines.

31. **plank**
February 6, 2006

"Feynman was known to all the top guys from Los Alamos because of his success as a leader of the electromechanical machine computational group (that solved the questions about the implosion design)"

I don't think this is correct. To my knowledge Feyman's group did solve a problem related to the implosion design but it turned out the problem was "unphysical" and thus the solution irrelevant.

Am I wrong?

32. **anon**
February 7, 2006

plank, Feynman says in one of his books that he was transferred to the IBM punched card sorters, becauses the guy in charge of that department was fired by Oppenheimer for wasting time. http://www.lanl.gov/history/atomicbomb/computers.shtml says: 'Feynman worked out a technique to run several calculations in parallel on the punched-card machines that reduced the time required.'

33. **Tommaso Dorigo**
February 7, 2006

Dear Woit,

I am spending some percentage of my time working at an improvement of the Level 1 trigger for the CMS experiment. My problem is that
1. I don't believe SLHC has any reason to exist, and
2. I don't believe it will, either.

Your job as theorists is to keep us motivated. I don't feel much so. Please help me: convince me that
1. LHC will find some hints that there is anything more than SM+higgs out there (ok, it will see the Higgs, so what ?)
2) LHC findings will prove that one needs to run at a x10 luminosity for a few more years, with the same projectiles and CM energy.
Would you ?

Cheers
T.

34. **Chris Oakley**
February 7, 2006

Hi Tommaso,

I apologise for the unsolicited reply, but personally I do not think that LHC or any other experiment will see the Higgs, because they probably do not exist – I say this on the basis that scientific explanations invoked out of desperation tend not to be the correct ones.
Keeping you motivated is not part of my responsibility as my presence was not required in the theoretical physics community 20-odd years ago, but, look on the bright side: what you are doing may have an application outside of physics. Who knows – you may even end up with an industrial process named after you.

35. **sunderpeeche**
February 7, 2006

Motivated?
Many accelerators which have become famous did so for reasons totally unconnected with the motivation for building them. The Bevatron at Berkeley was built to produce the antiproton (which did garner a Nobel Prize), but it really became famous for Alvarez's work with the 72″ bubble chamber (discovery of several resonances). SPEAR at SLAC was built as an e+e- collider (the linac could only do fixed target expts) but nobody realized SPEAR would produce the psi (charmomium) and the tau lepton. The AGS at BNL was built to demonstrate strong-focussing (and push proton synchrotrons to higher energy). But nobody guessed it would produce 3 NP-winning expts (i) muon neutrino was not same as electron neutrino, (ii) CP violation (iii) J particle (J/psi with SPEAR).

Machines that were built to find the top quark (PEP, PETRA, TRISTAN) did not find it (though PETRA demonstrated gluons via 3-jet events).

Nobody knows for sure what LHC will find.

36. **woit**
February 7, 2006

Hi Tommaso,

Probably the best advice is to not pay much attention to theorists, but, given that, here's the opinion of one theorist:

1. Supersymmetry, in the commonly studied form, is quite unlikely to exist. I doubt that there is such a thing as a superpartner for each particle with opposite statistics. I've always worried that LHC experimentalists will focus too much of their effort on this possibility, especially in designing the triggers. I'm curious to hear how much specific models like supersymmetry influence the trigger design.

2. I'm also rather dubious about any of the well-known extra dimensional models. They're not mathematically elegant, don't convincingly solve any problems of the standard model, and even if they are the way the world works, there's no good reason for their effects to be visible at the LHC, but not the Tevatron (i.e., no reason for the relevant energy scale to be in that range).

1. and 2. are pretty negative, but there is a strong positive case that something new and exciting will show up at the LHC which isn't visible at the Tevatron. You'll finally be getting to the energy scale where direct study of electroweak symmetry breaking begins to be possible. The fact of the matter is that there is no good theory of electroweak symmetry breaking, so in a sense this is the best possible situation for an experimentalist: you know you'll be in an unexplored energy regime where something new and important has to happen, but the theorists don't really have a good idea about it. For thirty years, experimentalists have been behind the theorists because the standard model at energies below the electroweak breaking scale is just too ridiculously good. Going from the Tevatron to the LHC, there is a serious chance that this situation will completely reverse itself.

More cautiously, there is a danger that at LHC energies all that will be visible will be a scalar standard model Higgs, with the interesting dynamics of electroweak symmetry breaking only visible at higher energies. That's the possible downside, and it's real, but I actually think the chances of seeing something unexpected are less than the chances of this.

My own best guess is that electroweak symmetry breaking is due to something theorists don't understand at all yet, maybe physics coming from a gauge anomaly, or even a new kind of mixing of space-time and internal degrees of freedom different than ones studied so far. If so, LHC experimentalists may be in for a very exciting and very confusing time.

As for follow-ons to the LHC, it seems like you'll have to wait until the LHC has run for a few years before being able to make a sensible decision. I don't know at all what the relative costs are, but if an energy doubling is possible, that seems more likely to turn up something new. The LHC energy may be just around all sorts of interesting thresholds, and getting above them might be much more important than more luminosity.

37. **Quantoken**
February 7, 2006

Peter:

Doubling beam energy would require either doubling the strength of the magnetic fields of the powerful superconductive magnets from 8.33 Tesla to 16.66 Tesla, or dig a new tunnel of double the diameter of the current LHC, and therefore also double the number of the magnet used along the circumference. The first is technically un-achieveable currently and the second one is also prohibitive in cost.

On the other hand, increasing luminosity involves just trying to squeeze the cross-section of the beam to smaller size at point of collision. But it's easily said than done. It takes years of patient fine tuning of numerious instrument parts to just get it right to achieve the luminosity at design level.

Quantoken

38. **Tommaso Dorigo**
February 8, 2006

Thanks for your answers here to the various contributors… A few points:
1) I am quite happy to agree with most if not all of what you (woit) say about the new physics the LHC will probably be able to explore.
2) the SLHC needs to be funded and a strong physics case be made well beforehand, which means possibly now or in the next couple of years – thus dramatically without any real knowledge of whether the LHC will work at all.
3) going to more energy is unfeasible – I agree – but going to 10^35 is most probably just a matter of time and patience, no huge upgrades being necessary. That a x10 lumi does not buy as much as a x2 energy I totally concur.

Cheers,
T.

Down the Rabbit Hole

February 5, 2006
Categories: Film Reviews

About a year and a half ago I wrote here about going to see the movie What the Bleep Do We Know?, a rather spectacularly stupid and lunatic film which extensively misuses quantum mechanics. This weekend, a sequel called What the BLEEP – Down the Rabbit Hole opened here in New York, and I figured I owed it to my readers to check out the this new movie.

There were two good things about it. First of all it was advertised as being 2 hours and 34 minutes long, but ended about 15 minutes earlier than I expected (I kept checking my watch…). Secondly, I don't have to write a lot about it and can just refer you to the posting about the first film since a large part of it is exactly the same.

The whole plot involving Marlee Matlin appears to be exactly the same footage. It was pretty painful to have to watch this again, although I am kind of fond of the wedding party/orgy scene. The "scientists" involved were essentially the same group of crackpots as in the first film. It looked like the interviews in this version were mostly outtakes from the first version, with some additions. Among the physicists, about the only non-crackpot was Columbia philosopher of science David Albert. He was said to have objected to the editing of the first version, which made it appear that he agreed with the nutty ideas about quantum mechanics of the filmmakers. In this version, he is saying perfectly sensible technical things about quantum mechanics, but they're embedded in the middle of the nuttiness about QM promoted by the filmmakers (the usual: entanglement=we are all connected, superposition=anything you want to be true is true).

The new material includes interviews with a crackpot parapsychologist (Dean Radin, from the "Institute of Noetic Sciences"), and a crackpot journalist (Lynne McTaggart). It also includes some new animations featuring a cartoon character (Captain Quantum or some such). The first of these starts off with a not-bad depiction of the two-slit experiment before getting silly. The second is tacked on near the end and brings in a new exciting idea that wasn't in the first film: Extra Dimensions! Captain Quantum liberates some poor fellow cartoon character who is trapped in 2d due to her fearfulness, bringing her to enlightenment by showing her that there is a third dimension. There's mercifully little about string theory, mostly John Hagelin going on about how the superstring field is the field of consciousness.

If you feel the need to know more about this for some odd reason, there's a web-site, and a bunch of reviews of the film: a credulous one from Seattle, and more sensible ones from Portland ("feels like a lame, double-dipping cash-grab"), and Arizona ("They should market What the Bleep!?: Down the Rabbit Hole like a breakfast cereal – '50 percent more nuts.'").

Update: Since the Sunday New York Times Book Review now every week has something about string theory, I guess I better mention today's edition, maybe just by quoting from one review, by Dick Teresi about The Fated Sky: Astrology in History, a history of astrology by Benson Bobrick.

Shortly into my marriage (about six hours) my wife purchased a white-noise generator to counteract my night terrors… Recently, it has begun dispensing orders: "Kill, kill your publisher."

The mathematician Michael Sutherland diagnosed my condition. "It's called apophenia," he said. In statistics, apophenia is a "Type 1 error," a false alarm, the experience of seeing patterns in meaningless data. I must have caught it from the theorists I interview.

In the early 20th century, experimenters demonstrated that randomness rules… Yet today superstring theorists insist they will reconcile the lumpy, acausal quantum world with the smooth determinism of relativity…

So when the playful and innovative historian Benson Bobrick writes in "The Fated Sky" that 30-40 percent of the American public believes in astrology, I am shocked. Why so few, given the raging apophenia among our scientific elite? Astrology, the belief that human lives are ruled by the stars and planets, is no nuttier than current cosmological models, which feature an "anthropic principle," giving our puny, three-pound brains a central role in the universe…

Traditional astrologers, like string theorists and cosmologists today, were often wonderful mathematicians…

Modern man can choose from a veritable smorgasbord of Type 1 errors: string theory, neo-Darwinism, cosmology, economics, God. Astrology is as good as any, and Bobrick demonstrates that it has a rich, colorful past to draw upon. As for me, I answer to a higher authority. Now, if you'll excuse me, I must go kill, kill my publisher.

Teresi's take on modern physics is much sillier than John Horgan's. Maybe the next few weeks letters columns will have letters pointing this out.

Comments

   February 5, 2006

   Oh great. When the first one came out I had to deal with the bubbling of various acquaintences who thought it was compelling stuff. Generally I was labeled as 'closed minded' for dismissing the quackery too quickly. I couldn't claim a single 'conversion' to critical thinking or skepticism on any of the topics. My depressing conclusion was that this kind of thing really speaks to something in a large part of the populace, probably the same people who listen to Noory's show on AM – the one Kaku makes guest appearances on.

2. **Sean**
   February 5, 2006

   It's not really a sequel, just an expanded version of the original. For what it's worth.

3. **D R Lunsford**
   February 6, 2006

   Astrology and alchemy are actually early forms of psychology, hence not subject to comparison with what we know as hard science.

   Also, there are bodies of knowledge not arranged around causality.

   February 6, 2006

   Just thought I'd contribute a trackback to my What the Bleep!? post. Excerpt:

I suppose I'll eventually have to don a fake mustache, clothespin my nose, and go endure this movie, since people often bring it up when I tell them what I do for a living:

ME: …so, at least in the black-box model that we can analyze, my result implies that the quantum speedup for breaking cryptographic hash functions is only a polynomial one, as opposed to the exponential speedup of Shor's factoring algorithm.

PERSON AT COCKTAIL PARTY: How interesting! It's just like they were saying in the movie: reality is merely a construct of our minds.

5. **Don Smith**
   February 6, 2006

   When I heard about the first movie, I thouht it was a film of the imagination. Then I heard it advertised on Art Bell's raido show and then I learned that this was suppose to be a work of fact. It came close to another very bad movie: "UFOs Destination Earth".

6. **Lucifer**
   February 6, 2006

   It must have indeed been torture to watch that movie again! I could barely get through it myself, only by fast forwarding through certain parts including the wedding party/orgy scene, was I able to subject myself to such excruciating mental distress. Which makes me wonder how such a terrible movie has become so popular? I know Dr Fred Alan Wolf was touring Australian universities down here late last year, charging $150 for a 3 hour seminar called "The Spiritual Universe", and I'm sure that's just a small part of a much larger world tour to promote his books and the movie.

   It gives me such peace of mind to know, that Dr Quantum as he is also known, is seen as such an authority in this field.

7. **Juan R.**
   February 6, 2006

   D R Lunsford Said,

   > Astrology and alchemy are actually early forms of psychology, hence not subject to comparison with what we know as hard science.

   Hum! CHEM 308 may disagree 🙂

   There were several "alchemies" and your generic comparison with psychology completely wrong. There are a lot of misconceptions about alchemy by outsiders of chemical science.

   Preparative (not philosophical) alchemy was "so hard" as current science. In fact, several early alchemical processes, methods, and instrumental are still used in any current chemistry laboratory (see CHEM 308 in http://www.humboldt.edu/~catalog/courses/chem_crs.html).

   E.g. any modern chemist has used in some time one of the discovered alchemical processes: Maria's bath.

   Fractional Distillation

8. **Kent Bye**
   February 6, 2006

   I understand the message of the original What the Bleep, but I disagree with the strategy and tactics of the filmmakers.

   From a scientific and journalistic perspective, the filmmakers only interviewed people who agreed with their perspectives. I would have liked to have seen more dissenting viewpoints incorporated within the film — especially in this latest expanded version of the film.

   The argument that they're trying to make is that is that Biology & Psychology are trapped within a Philosophy of Science of Reductionism and that moving towards a "Quantum Ontology" would help incorporate the subjective aspects of our consciousness within healing modalities.

   > * Mainstream Medicine = Objective = Reductionistic = Classical Netownian Physics
   > * Complementary & Alternative Medicine = Subjective = Interconnected & Holistic = Quantum Ontology

   In other words, our beliefs, perspectives and worldviews are the first filter of our experiences and can actually have biological correlations. So instead of taking pharmaceutical drugs to feel better, there are less invasive methods of Complementary and Alternative Medicine that could relieve symptoms and cure the underlying disease. People are turning to these methods because they seem to work even though mainstream science hasn't validated them yet.

   There was a recent front-page New York Times article called "When Trust in Doctors Erodes, Other Treatments Fill the Void" that helps explain why What The Bleep has struck such a nerve:

   > Haggles with insurance providers, conflicting findings from medical studies and news reports of drug makers' covering up product side effects all feed their disaffection, to the point where many people begin to question not only the health care system but also the science behind it.

   Americans are spending around $27 billion per year on CAM therapies because of an "increasing distrust of mainstream medicine and the psychological appeal of nontraditional approaches as with the therapeutic properties of herbs or other supplements."

   The NIH set up the National Center for Complementary & Alternative Medicine to help research and vet some of these Mind-Body treatments, and so there has been some science-based research done in this area.

What the Bleep is obviously not trying to build any bridges with mainstream science, but is trying to reach the audience that is already actively engaged in these types of Mind-Body practices like meditation and yoga. It's entertainment, and not science or even good journalism. But it is good enough entertainment for those who are sympathetic to the larger critique of the quick-fix mentality of modern medicine.

The film started out in one theater, and was able to build up enough word of mouth to spread to other theaters, and it was eventually picked up by a distributor to get a wider release. I've written about the grassroots marketing implications of the film from a independent film perspective that cites a NYT article on the viral spread of the film.

I've also actually interviewed a number of people from this community for my collaborative documentary on the state of American journalism.

In my case, I was trying to draw parallels between:

* Mainstream Medicine = Objective = Mainstream Journalism
* Complementary & Alternative Medicine = Subjective = Blogging

There are obviously a lot of problems with how journalism covers science issues that can be traced to a reductionistic "He Said / She Said" mindset that takes whatever the political institutions have to say about issues as gospel — even if there is a critical mass of dissent from the academic community.

I found some interesting insights into this problem from the interviews, and I'd love to hear more feedback on it.

I'm going to release the audio soon, and would to have some of your critical perspectives to help peer review some of the material that I've conducted. That way I don't end up including information in my final film that hasn't been fully vetted. Thanks

9. **Eric Dennis**
February 6, 2006

Kent,

That's really great, and I feel your energy, man. But the problem is that your pet ideas on psychology and pharmacology have no connection whatsoever to quantum mechanics. That you seem to know this and it doesn't give you pause betrays a basic intellectual dishonesty which is not going to be particurarly effective when who you're trying to snow is a group of professional scientists. I mean aren't there any tarot card blogs or bulk granola sales sites that may be a little more on your wavelength?

10. **woit**
February 6, 2006

Please, stop it with the personal hostility.

And alternative medicine should be discussed elsewhere. I personally have no problem with the idea that the mind-body interaction is trickier than modern medicine sometimes thinks, but have never seen any evidence that this has anything to do with quantum mechanics. This is a blog about physics, not about biology or medicine.

11. **Kent Bye**
February 6, 2006

The problem with What the Bleep is that the filmmakers try to make it seem like Quantum Physics has already bridged these gaps.

I realize that the gaps haven't been bridged yet, but I believe that they may be on a converging path that could be bridged within the scientific community within the next 5, 10, 20 years.

But I believe that there are underlying grains of truth within What the Bleep that are undermined by the heavyhanded tactics of the filmmakers. You check out NIH's NCCAM for scientifically-validated research in this field.

But I'm **more interested** in the parallels between the split between Mainstream Medicine and Complementary & Alternative Medicine and Mainstream Journalism and New Media (i.e. blogs, podcasts, videoblogs)

Mainstream medicine views CAM treatments as too subjective and invalid just as mainstream journalists view blogs as too subjective and invalid.

There are grains of truth in both approaches, and I'm particularly interested in how to bridge these into a more inclusive journalistic paradigm — specifically through collaborative media.

And it is in that spirit that I want to add more scientific peer review principles to the process of journalism and filmmaking.

12. **Dumb Biologist**
February 6, 2006

I'm reminded of a statement I read someplace, to the effect that the philosophical vacuum left by the retreat of organized religion can be as bad or worse than what came before it. At least before there was a measure of cohesion and discipline. The New Agey flapdoodle that springs up in every crack left in the old, decaying edifices of the major Western religions often aggressively misappropriates a laundry list of the more "out-there" philosophical ramblings of various scientific luminaries on the nature of existence and epistemology. The result is a superstitious Frankenstein's monster of the most horrifically ecumenical sort, where Christ occupies the captain's chair next to extraterrestrial aliens telepathically linked with Gaia and the few New Age cognoscenti who are gifted enough to "grok" the significance of modern revelation.

Oh, and of course, anyone who holds sentiments of the above sort is terribly uncritical, unskeptical, and close-minded, a slave to a dogmatic materialist religion that stifles true understanding, or so we'll be told. I tend to think, in the face of it all, that no matter how much knowledge we acquire, and no matter how successful the methods of skeptical inquiry in producing concrete results, we will *never* be free of superstitious nonsense. It's an in-built trait, and the price of admission to sentience, in all probability. Perhaps it's more amazing that some percentage of the population appears to be more free of it than others.

13. **Kent Bye**
February 6, 2006

"And alternative medicine should be discussed elsewhere."
I apologize for the previous post, I had already hit the submit button.

"never seen any evidence that this has anything to do with quantum mechanics."
I agree that there hasn't been anything convincing published making a direct connection. From the interviews I've done, my observation is that this community uses metaphors from quantum mechanics to intuitively understand certain healing concepts.

I also believe that What the Bleep dishonestly blurs this line, and as a result undermines aspects of alternative medicine.

14. **matt d**
February 6, 2006

We sure do have a lot of "functional" nutjobs in America anymore. I mean, not only are wackos like Teresi able to vomit up their baseless and pointless views without any formal counter-arguments, but they're able to get jobs that allow them to do it.

I'm sure it pays well too.

You're doing a great job keeping the herd in line, Woit.

15. **Not a Nobel Laureate**
February 6, 2006

As a profitable and low risk business venture, there are few areas of endeavour that can beat out Religion of either the Established or New Age Nutjob variety.

16. **secret milkshake**
February 6, 2006

people making crazy claims about their remedies/beliefs usualy do not not irk me much – you can try to prove or disprove such claims if you care enough about the particular subject. But things need to be spelled out. What really gets me are the charlatans that are throwing fog; obfuscation is such a common and profitable form of dishonesty.

17. **Chris W.**
February 6, 2006

Kent Bye: *From the interviews I've done, my observation is that this community uses metaphors from quantum mechanics to intuitively understand certain healing concepts.*

Few abuses of scientific ideas are as widespread as the abuse of them as a source of "metaphors," without any serious effort to critically examine their applicability to the domain in question. Some aspects of Newtonian mechanics used to get this treatment, but they're now considered old hat.

18. **Boaz**
February 7, 2006

Regarding "abusing" science for metaphor…
I used to really fight against this. My sister would ask me about my research (accelerator physics theory) and I would say a few words and she'd quickly find that the words could be used metaphorically to say something she thought was interesting about something entirely different. For example, instabilities are sometimes described as a "resonance" and perhaps just the linking of these two words could seem (or be!) insightful. My response used to be to immediately shut this down by saying "no! resonance has a very precise technical meaning and has nothing to do with human relationships or sociology". But I've become more tolerant and now I don't really see a reason to stop this thinking as long as nothing false is said about the technical subject. I know that this can be insidious in a public debate when the authority of science is borrowed to support something false or some bad logic as is done in "What the bleep". But the scientist's job is only to correct false statements about the world, not to prevent concepts from being used metaphorically. Do you really know enough about these "alternative healing practices" to know that quantum mechanics doesn't provide some useful metaphors?

19. **Adrian H.**
February 7, 2006

Well here is some good news. Many of my students saw 'What the Bleep' when it came out, and mentioned it in class, but all of them seemed to realise it was crackpot nonsense. No one defended it; no one thought it was anything other than a bunch of people tossing about loose ideas.

The person who puzzles me is this John Hagelin guy. Did he really go to Harvard?? I saw a videod talk by him once and swear it was the sort of stuff that a freshman would have laughed at. Ridiculous statistics, ignorant basic physics. It wasn't even a good con. Surely he could pull the wool over our eyes in a more respectful way?

20. **robert**
February 7, 2006

Theoretical physicists are not wholly innocent when it comes to invading alien subject areas (for example economics, sociology, epidemiology) convinced that they have something immediately useful to add. Sometimes this is fruitful (Simons' money making machine), sometimes it is not (LTCM, catastrophe theory applied to prison riots). Sensible interdisciplinary dialogue is essential, especially in troubled times like these when all rational thought seems to be, at best, undervalued and, more likely, under concerted attack. Too often, however, things descend to the level of 'Science Wars' and what the bleep; one wonders, as Tom Tom Club put it, 'What are Wordsworth?'

21. **Kent Bye**
February 7, 2006

Constantino Tsallis talks about the importance of metaphor to the advancement of science in an Physica A article called "Some Thoughts on Theoretical Physics"

> "The greatest thing by far is to be a master of metaphor. It is the one thing that cannot be learned from others; it is also a sign of genius, since a good metaphor implies an eye for resemblance." wrote Aristotle in his *Ars Poetica* [322 AC]. And many — perhaps virtually all — scientists, conscious or unconsciously, take as granted that without metaphors, no scientific progress would exist. One may go even further: without metaphors *that have some form of beauty*, no efficient progress in science would exist, no new ideas would emerge!

After reading this article, I do believe that there is a lot of value of turning to quantum physics for metaphors that can add layers of complexity and predictability to other knowledge domains.

Yet at the same time, I think that it is important to disclose the degree of connection to the original domain as well as to make clear that you're using mathematical models in a metaphoric way of understanding how systems might operate. By this standard, "What the Bleep" fails on both accounts and too often blurs the line between the fringe frontier research and mainstream scientific enquiry.

22. **Juan R.**
February 7, 2006

> Constantino Tsallis talks about the importance of metaphor to the advancement of science in an Physica A article called "Some Thoughts on Theoretical

Physics”

It would be good if one day he talk about

the importance of science to the advancement of metaphors

Then, maybe he would discover like metaphoric is his proposed entropy and the little science around those lot of papers and talks published by the Brazilian group.

I are reading lot of appeals to quantum mechanics and supposed links with other stuff. I wonder if they know they are really talking…

In my talks with many people i see that word quantum is used as a sinonym of fantastic, unusual, etc. instead of in his original sense of quantum. Quantum mechanics is a “mechanics of the quantum”.

Adrian H. said:
“The person who puzzles me is this John Hagelin guy. Did he really go to Harvard?? I saw a videod talk by him once and swear it was the sort of stuff that a freshman would have laughed at. Ridiculous statistics, ignorant basic physics.”

I am much less surprised by Hagelin’s behaviour than you are. I don’t find him that different from the not so uncommon academics that drum up funding support by generating university press releases and grant proposals that exaggerate/lie about the importance of their work. Or the not so uncommon academics that deliberately omit to mention important references from their papers. Personally, I think Hagelin got taught this behaviour you find so objectionable by a broken academic research system. The question is, how to fix it.

Using metaphors to get ideas should be acceptable. After all, the use of differential calculus in areas far removed from what Newton wrote about can be seen as a form of metaphor.

The problem begins when you start thinking that the meatphor proves something in itself as opposed to using it to generate ideas that are tested in the ordinary way.

27. **Michael**
February 7, 2006

I’m not a physicist. I have not seen the film. I do not wish to. I do care very much about this subject, however. I’m sure it is of no surprise to anyone that the film was suggested to me by a post-modern poet. I must remind everyone that such anti-philosophies often arise in the absence of a logical foothold within a society. Paying attention to meaningless information is the fastest way to lose your grip on reality (and a population losing its grip on reality is the quickest way for someone to gain corrupt control of power). Getting a [descriptive] grip on reality is the goal of science at large and the only way to maximize our ability obtain resources and to control our surroundings. Humans cannot surive in the absence of progressive external manipulation. We would be an easy meal without our reasoning faculties. It is hence, undeniably in our best interest to understand an undisputed framework of concrete reality, if only from a survival stance. Survival of our species matter to everyone, so everyone should care about these matters. Those who do not are either lying or of no concern to those who do. Objective science is the only solution to life on this planet. Everything else is a baby blanket.

That being said, the beauty of science is that it not only demands, but patiently awaits proof. This is important and cannot be ignored. No one is up in arms about string theory because we all assume it will see its day in court. Looney ‘Field of Consciousness’ are, however, cause for concern. Proper description of reality demands proof. I am not demoting mathematicians. They are quite adept at proving the reality of the number models they have generated. In the temple of science, the mathematicians’ product, symmetrically sucinct theory, is the shrine. It is the most elegant representation of a given phenomenon. It is, alas, but a representation. Nature, as experiment continues to insist, is not elegant. It is a thick mesh of bruised patterns. The bruises are obvious from the data. Mathematics shows the patterns. Ultimately, mathematics can be no more accurate in modeling reality than the claim that a basketball is a sphere. This does not, in any way, detract from invaluable potential modeling offeres to human kind. It is, in fact, our only strength as a species. We abstract solutions and conquer situations. For questions concerning issues beyond contemporary technolgical capabilities, math must suggest direction. Possibilities, not realities. By its own definition, math is not a complete description-it is self referencing (remember Godel?). But it is the next best thing, it is consistant. This is a quality crackpot “Reality is Whatever the mind wants it to be” theories could stand to be evaluated (and obliterated from existence) by. Remember when the heliocentric universe went out the window? It didn’t stand up to the data. If string theory goes the same way, it would not surprise or sadden me…it would mean data had been generated on the subject, period. Wouldn’t it be fun to turn the theoreticians loose on even two shards of data? For now (until somebody builds better probes), poor guys like Hoit will go on serving up maps to blind physicists on where to dig for that buried treasure.

28. **Chris W.**

Peter Woit said:*I personally have no problem with the idea that the mind-body interaction is trickier than modern medicine sometimes thinks, but have never seen any evidence that this has anything to do with quantum mechanics*.
You may want to check out the **dissipative quantum model of the brain**: http://arxiv.org/abs/quant-ph/0002014

31. **Subhash**
February 8, 2006

I have neither seen the Bleep nor its sequel, and I am perfectly willing to accept that its treatment of quantum mechanics is unsatisfactory. But I did see the much touted Elegant Universe on the PBS, and its treatment of quantum mechanics was also extremely unsatisfactory.

Given that there are diverse interpretations of qm, ranging from positivist to hidden variable, to many-worlds held by serious scholars, not to mention the invoking of consciousness by qm theorists like Wigner and Stapp and neurophilosophers like Pribram, perhaps all one should hope for is a narrative that leaves the viewer with more questions than what he started with before the movie.

If the Bleeps do that successfully, then they might not be all that bad.

32. **Alejandro RIvero**
February 9, 2006

I also disagree with Lunsford statement "*Astrology and alchemy are actually early forms of psychology, hence not subject to comparison with what we know as hard science*." but I think it is useful to consider how a science becomes to be used in psychology (or even self-healing books) because theoretical physics is always in the risk of providing concepts for this psychological focus. We have all seen Energy, Chaos, and even Symmetry, to be used with this goal. Nor to speak of Relativity and Quantum. And even semiconductors ("crystal healing"). But it is even worse in other sciences. Botany, for an instance, as part of the pharmacy sciences. I think the only defense is to get everyone involved on science. And to be honest: if we know that Mercury theroretically transmutes to Gold with exotermic production of Energy, just tell it, but explain it.

33. **Alejandro RIvero**
February 9, 2006

hmm, actually Lunsford statement could be almost correct if telling "Astrology and alchemy are nowadays rudimentary forms of…"
I say "almost" because I know of some living non-psychology oriented alchemists. In fact you can see that Alchemy books are not a best-seller in the "self-healing" sections of libraries, when compared to astrology. This is because of the experimental bias.

Xpinor said,

Peter Woit said:I personally have no problem with the idea that the mind-body interaction is trickier than modern medicine sometimes thinks, but have never seen any evidence that this has anything to do with quantum mechanics.
You may want to check out the dissipative quantum model of the brain: http://arxiv.org/abs/quant-ph/0002014

Peter Woit continues being right: there is not evidence!

The preprint you cited is not a scientific model. "That" is a rather speculative work, with "few" rigorous correlation with real-world data. The development of the model is not rigorous. There are lots of " ". In fact, even the treatment of pure dissipation regimes is non-rigorous and full of half-proofs, asumptions, and several "ifs".

It is also interesting the use of term "quantum" when some of limits worked are precisely classical limits. In the past there was a lot of speculation about quantum behavior of the brain, precisely lot of scientific rigorous **working** models and experimental data suggests that main brain regime is classical one. For example fluctuation currents in ion tansport on two state biological chanels involved in certain basic brain "metabolism" is in perfect correlation with computer simulation of classical models, etc.

From Max Tegmark [quant-ph/9907009]

Based on a calculation of neural decoherence rates, we argue that that the degrees of freedom of the human brain that relate to cognitive processes should be thought of as a classical
rather than quantum system, i.e., that there is nothing fundamentally wrong with the current classical approach to neural
network simulations.

Tegmark also critizes some quantum models of brain elaborated employing string theory methods.

Many people appears to misunderstand long-range correlations doing the brain work as a whole and the so-called non-markovian dynamics (introducing memory effects) with quantum nonlocality or any other exotic quantum effect.

Subhash,

I would prefer "*Given that there are diverse* ***philosophical*** *interpretations of qm*".

35. **Tony Smith**

February 9, 2006

Peter Woit said that he has "… never seen any evidence that … the mind-body interaction … has anything to do with quantum mechanics …".

spinor mentioned "… the dissipative quantum model of the brain: http://arxiv.org/abs/quant-ph/0002014 …".

Juan R said "… The preprint …[quant-ph/0002014]… is not a scientific model. "That" is a rather speculative work, with "few" rigorous correlation with real-world data. … From Max Tegmark [quant-ph/9907009] "Based on a calculation of neural decoherence rates, we argue that that the degrees of freedom of the human brain that relate to cognitive processes should be thought of as a classical rather than quantum system" …".

There have been several quantum models of consciousness in the literature, including work by Hameroff and Penrose (coherent states of microtubule tubulins) and Nanopoulos et al (based on string theory).

None of those models (AFAIK) has been either fully confirmed by exerimental evidence or fully refuted by experimental evidence,
but
at least the Hameroff-Penrose model was motivated by Hameroff's experimental observation that tubulin activity ceased when people were unconscious (under anesthesia) and resumed when they regained consciousness (Hameroff is an anesthesiologist).

As to experimental testability of such models, experiments are difficult, but one necessary aspect of such models (coherent tubulin states) can at least approached, as Tegmark did in his work cited by Juan R.
However,
Tegmark's assessment of decoherence has been challenged by, for example:

Hagan, Hameroff, and Tuszynski, in Physical Review E, Volume 65, 061901, published 10 June 2002, where they say: "… recalculation after correcting for differences between the model on which Tegmark bases his calculations and the orch. OR model (superposition separation, charge vs dipole, dielectric constant) lengthens the decoherence time to 10^(-5) – 10^(-4) s …"
and
Mershin, Nanopoulos, and Skoulakis, in quant-ph/0007088, where they say: "… the particular geometrical arrangement (packing) of the tubulin protofilaments obeys an error-correcting mathematical code known as the K2(13, 2^6, 5) code … We conjecture that the K-code apparent in the packing of the tubulin dimers and protofilaments is partially responsible for keeping coherence among the tubulin dimers. …".

In short,
the question of whether or not consciousness is a quantum phenomenon is still an open one,
and (in my opinion) theoretical model-building and experimental testing of such model components is a good thing that might lead to useful insights.

As an example of such a possibly very useful insight that should be further investigated, see Hameroff's paper in Biosystems, Volume 77, Issues 1-3 , November 2004, Pages 119-136. Its title is
"A new theory of the origin of cancer: quantum coherent entanglement, centrioles, mitosis, and differentiation"
and its abstract (on the web at http://dx.doi.org/10.1016/j.biosystems.2004.04.006) says in part:
"… It is proposed here that normal mirror-like mitosis is organized by quantum coherence and quantum entanglement among microtubule-based centrioles and mitotic spindles … Impairment of [such] quantum coherence and/or entanglement … can result in abnormal distribution of chromosomes, abnormal differentiation and uncontrolled growth … New approaches to cancer therapy and stem cell production are suggested …".

To make my position on such matters clear, I am NOT defending statements like the one presented by Peter with respect to What the BLEEP – Down the Rabbit Hole:
"superposition = anything you want to be true is true".
Actually, the "anything you want to be true is true" part sounds to me a lot like Susskind's Landscape.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

36. **J.F. Moore**
February 9, 2006

The Hameroff-Penrose theory may have been interesting 15 years ago after it was introduced, but it hasn't stood up to scrutiny and is at this point hopelessly riddled with unexplained problems, not the least of which is how coherence can be maintained on such scales (time, space, temperature). I put it in the category of "strains credulity, theory almost certainly wrong, but maybe something interesting in there somewhere", right next to cold fusion.

37. **John Gonsowski**
February 10, 2006

Hameroff is actually in the movie. The movie seems like something Sarfatti would have been good at (in an entertainment sense). Sarfatti is into consciousness models also. I'd hardly say the models are hopelessly riddled, things like single electron transistors and brain wave frequencies seem related to the models.

38. **Juan R.**
February 10, 2006

Therefore, i may conclude that my previous

> Peter Woit continues being right: there is not evidence [that the idea that the mind-body interaction has anything to do with quantum mechanics]!
>
> (you are not cited in above reply Tony Smith) may be still true.
>
> I do not ignore the possibility for some adittional now unknown quantum effect in brain, in fact, the electronic structure of molecules into brain is just modelled via quantum mechanics and, hidrogen bonding and others are just quantum effects.
>
> I clearly disagree is that the whole brain may be considered a quantum body or that consciousness was quantum in essence. This kind of speculation began after of incorrect understanding of quantum measurement processes just after QM was formulated.
>
> I agree with J. F. Moore in that some ideas about microtubules and abnormal coherent states are considered near crakcpotism in biophysics.
>
> I do not know the details of last Hameroff paper you cite and therefore cannot be precise but reading the abstract
>
> The elegant yet poorly understood ballet-like movements and geometric organization occurring in mitosis have suggested guidance by some type of organizing field, however neither electromagnetic nor chemical gradient fields have been demonstrated or shown to be sufficient.

it appears that my previous comment on that many people appears to misunderstand long-range correlations doing the brain to work as a whole with quantum nonlocality or any other exotic quantum effect gains support.

Apparently from the abstract (of course, i can be completely wrong), the philosophy of Hameroff in the article is “it is nonlocal and cannot be explained by a local classical field then is a quantum exotic effect”.

SLAC Physicists Develop Test For String Theory*

February 8, 2006
Categories: Uncategorized

The SLAC web-site today has a feature article entitled SLAC Physicists Develop Test For String Theory*. The "*" refers to a footnote to the title saying "Under Certain Conditions". This is about the 10^{500}th news story making this kind of announcement that has appeared over the past twenty years (like this recent one), and the title is just as incorrect and misleading as all the others.

The story starts with

String theory solves many of the questions wracking the minds of physicists, but until recently it had one major flaw — it could not be tested. SLAC scientists have found a way to test this revolutionary theory, which posits that there are 10 or 11 dimensions in our universe.

and is about a paper by JoAnne Hewett, Ben Lillie and Thomas Rizzo entitled Black holes in many dimensions at the LHC: testing critical string theory. This paper is perfectly reasonable, discussing a proposal for getting information about the number of extra dimensions, assuming Tev-scale gravity (a huge assumption most people think unlikely) and thus production of black holes at the LHC. If the number of extra dimensions is bigger than 6, then 10d superstring theory is ruled out (one can make similar comments about 11d M-theory, whatever that is).

Like all news articles of this kind, this one is misleading in the extreme, since "SLAC Physicists Develop Test For String Theory" is likely to make the unwary think that string theory is now testable. In addition, it's flat out wrong, since the writer made the critical decision to replace "critical string theory" by "string theory". Granting the unlikely assumption that the LHC sees extra dimensions and measures their number. if this turns out to be more than 6 or 7, string theorists will likely just point out that it is only "critical" string theory which lives in 10 dimensions. In recent years there has been much talk about string theories outside the critical dimension. For some discussion of this, see the comment thread of a recent Cosmic Variance posting, where string theorists Eva Silverstein and Clifford Johnson maintain that they see reasons to believe in the existence of string theories in dimensions other than 10. For some flavor of the discussion, here's what Clifford has to say:

…the "person on the street" all too often hears (or implicitly gathers from posts like this) the phrase "string theory requires D=10/11", and it is simply not true and in some years we may well have to be spending a lot of time undoing yet another uncautious claim when/if after doing phenomenology better we find that we don't need to start in higher D and then "compactify". We'll have to go around telling everyone (on the tv shows and radio shows and magazines) "oh…that thing we said about extra dimensions? We were just kidding"…. Just like we're doing now with the whole "unique vacuum" and "theory of everything" phrases…

Clifford seems fond of the idea of sub-critical strings, perhaps even strings in four dimensions (another enthusiast of this idea is Warren Siegel), while Stanford string theorist Silverstein advocates the study of super-critical strings, exactly the ones that would get around the "test" promoted today by her colleagues at SLAC.

Update: SLAC has replaced this article on their website with a new, much more accurate version, entitled "SLAC Physicists Develop Framework-Dependant Test For Critical String Theory". The original version got wide distribution, even appearing on Slashdot.

Comments

1. **D R Lunsford**
   February 8, 2006

   Heh, thanks to you, Peter, they can't get away with this kind of thing now!

   -drl

2. **Lubos Motl**
   February 8, 2006

   The experiments are exactly designed to distinguish between the different scenarios how many dimensions there are and how large they can be, and so on. We won't get the full information from the very beginning, but we will of course learn something.

   As a conservative who believes a big desert after SUSY followed by a GUT scale near the Planck scale, I of course guess that no one will see mini black holes etc., but many of these scenarios are perfectly plausible and we will see how the experiments decide.

   Of course that only anti-scientific activists think that string theory is permanently untestable. String theory is, using an extremely modest language, the framework that parameterizes the space of reasonable possibilities for new physics potentially connected with quantum gravity, and although we can't say with certainty which of these scenarios are correct, we can definitely eliminate many other scenarios that would be possible if we did not know the things arising from string theory.

   And on the contrary, we know scenarios that we would never invent if string theory did not guide us.

   Well, I completely understand that you are scared of the experiments more than the radical Muslims are scared of pictures of Mohammed – because you have spent years if not decades by spreading crap about the end of physics. Well, maybe you will survive, Peter.

3. **blank**
   February 8, 2006

   Peter, why must you be so fact-obsessed?

   Good thing there was a good apparatchuk on hand to put things in proper context.

4. **The Anti-Lubos**
   February 8, 2006

   We won't get the full information from the very beginning, but we will of course learn something.

   This was Peter's entire point. The headline makes it sound like we will get the full information from the very beginning. Surely, a smart boy like you can understand this.

   many of these scenarios are perfectly plausible and we will see how the experiments decide.

Again, no one said that they're not; the contention was merely that this does not constitute "a test for string theory."

Well, I completely understand that you are scared of the experiments more than the radical Muslims are scared of pictures of Mohammed – because you have spent years if not decades by spreading crap about the end of physics. Well, maybe you will survive, Peter.

Mmmm, delicious, nutritious *ad hominem* argumentation! Allow me to participate: Lubos is a jerk.

5. **woit**
February 8, 2006

"radical Muslims are scared of pictures of Mohammed"

"Maybe I will survive"?

Is that some kind of bizarre threat? Lubos, you really are getting mad as a hatter and need to seek professional help.

6. **JoAnne**
February 8, 2006

Anybody who has ever spoken to reporters understands that what generally comes out in print basically does not resemble, in any way, your conversation with the reporter. Tom Rizzo and I spent about an hour with the reporter, explaining all the and's, if's, and but's of our analysis. None of which were included in the first draft of the story. We tried hard to clarify the description of our work in the story, and ended up with the simple asterisk "under certain conditions." And, to be fair, we were told that this story was intended for the general audience at SLAC, including admins, technicians, cafeteria workers, etc, and thus all of the details simply could not be explained. As for the headline that is blazened on the SLAC home page – I saw it for the first time when someone drew my attention to it. I knew it was going to cause headaches….

7. **Chris Oakley**
February 8, 2006

Lubos,

I am happy to listen to reasoned scientific argument from you. Even your polemics are sometimes amusing. But threatening me with the US Marine Corps or Peter with some unspecified hit man is just pathetic.

I cannot believe that you can be a researcher of any great calibre. Anyone with talent will be used to receiving and, for that matter, dishing out strong criticisms of ideas without taking it personally. This is all part of the process of doing research. If you cannot handle criticism you should not be doing research.

8. **woit**
February 8, 2006

Joanne,

I figured that's what had happened. Unfortunately there's an irresistible urge present among journalists who don't know much about this field to turn everything into this "scientists figure out how to test string theory" story. If only they all read my blog….

9. **Chris W.**
February 8, 2006

I think one can safely regard LM's behavior as an example of an occasional and fading Central European penchant for abusive pedagogy: "I'll beat the truth [as defined by me] into you even if it kills us both, you worthless insect!"

(Peter: I don't think this is any worse than "mad as a hatter".)

10. **secret milkshake**
February 8, 2006

to the question of a "fading Central-European pedagogy penchant":

You won't find too many people like this in Prague; we export them

11. **Boaz**
February 8, 2006

Not to say that Lubos statement wasn't abusive, but I wouldn't say it was a threat. He was suggesting that Peter is so afraid of experimental results that may support string theory, that they may kill him, but he might survive. As usual he takes a very extreme interpretation. PW says that headlines about interpretations of experiments are overhyped, LM responds by saying that PW must be deathly afraid of said experiments. One does wonder to what extent it is really posturing and trying to win a propaganda battle, and to what extent he really holds these views. I suppose Chris W.'s interpretation as an abusive form of pedagogy may be right.

12. **woit**
February 8, 2006

Boaz,

Thanks for the interpretation of the Lubos rant. I was honestly having trouble figuring out what is was that might kill me, and what the radical Muslims had to do with it (not that I spent much time trying to puzzle this out, I admit). Now I see, it's those experimental results on black holes at the LHC that Lubos doesn't believe we'll get. Makes perfect sense now.

13. **Quantoken**
February 9, 2006

Peter:

Oh you are so nice! But please do **NOT** believe a word Joanne said above. Come on, Joanne, don't insult people's intelligence by blamning it all on journalists. If it's just one occasional super string theory hype news story, you can have an excuse on journalists not doing their homework. But when there are "10^500" of such types news stories (in Peter's word) out there, **all those are jouranlists fault and nothing of you string theorists doing?** Come on! What about Kakuism we see daily? What about

your own words quoted in quotation marks in the news story? Are they not misleading the people? Are they not your own words?

Journalists LOVE controversial stories. Had you bee a little bit more honest, you could have meantioned to the Journalists that there is a different opinion about string theory, for example from a guy called Peter Woit. The journalist would then love to track Peter down and write up a much more balanced news story.

And NO, you do NOT need to go to any technical details in order to decribe to the public the honest truth of the current situation in the field of super string theory. It can be said in plain English: it's a failure so far and there is little hope any meaningful progress can be made in the next few decades. It's a matter of honesty whether any string theorist is willing to tell that evident truth in plain English.

All the string theory hype stories are the makes of the string theorists themselves. Journalists simply report what you guys told them and you can't blamn journalist for telling an untrue story if you don't tell them the true story in the first place!

Quantoken

14. **Juan R.**
February 9, 2006

I find really interesting that now string theorists as Eva Silverstein and Clifford Johnson maintain in public they see reasons to believe in the existence of string theories in dimensions other than 10 specially the case 4D.

In my Oct 21 post "String theory is not a TOE" in moderated newsgroup sci.physics.strings i did a joke about the infinite malleaibilty of string theory and how even with a "blanck check" -i.e. you can fix anything in the "theory" (even there are versions of string theory without strings!)- they were not advancing science. In page 2 of my April non-technical work, i cited the history of dimensions on string "theory":

4D,… 26D, 10D, 11D, 12D?,…4D again,…

It looks like researching in circles 🙂

15. **A.J.**
February 9, 2006

Quantoken–

Joanne is an experimental particle physicist. Get a clue.

16. **woit**
February 9, 2006

A.J.,

No, Joanne isn't an experimentalist, she a theorist, but of a phenomenological sort, definitely not a string theorist.

Over the last twenty years it has been interesting to watch the relationship between phenomenologists and string theorists, the two dominant groups within the particle theory community. It began with a certain amount of active hostility (think Glashow, who has stuck to his guns), but with the advent of extra dimensional models, there was a definite rapprochement and cessation of hostilities. The phenomenologists could study models with extra dimensions visible at the TeV scale, and thus at least in principle their work might have something to say about string theory (e.g. Joanne's work), and the string theorists could announce that string theory had potentially testable experimental applications.

My personal opinion is that, in this relationship, the phenomenologists have quite often found themselves used as tools in string theory hype. To some extent this story is just one more of a long line of similar examples.

17. **JoAnne**
February 9, 2006

First, as Peter says above I am indeed a phenomenologist – the type of theorist who connects formal theory to experiment. I tend to get irritated when people call me a string theorist. Particle theorists are not *all* string theorists.

Second, this news story is now all over the web. The research in this paper is honest and credible and now it is being blown out of proportion and misrepresented all over the web. Nothing could make me more upset.

I am not having a good day.

18. **A.J.**
February 9, 2006

Whoops. Looks like I need a clue, too. I'm sorry for misidentifying your profession, JoAnne.

Of course, my mistake does not excuse Quantoken's misdirected personal attack. It would be unacceptable in person, and it's unacceptable on the internet.

19. **Tony Smith**
February 9, 2006

As JoAnne says, "this news story is now all over the web", including slashdot, where you can see:

a link to Peter's blog (this entry);

that JoAnne was at Iowa State in the 1980s;

that Ben Lillie says that he has "… replaced the arxive version with the published version: http://arxiv.org/abs/hep-ph/0503178 …" so that anyone can read the serious physics without the PR hype; and

that Ben Lillie also says "… The main point is that there are many "ifs", "ands", and "buts" in the paper that did not make it into the news release. … It certainly can not rule out string theory. We think it's an important and interesting piece of work, but it isn't a definitive "test" of string theory, as the headline suggests. …".

Tony Smith

PS – JoAnne also said "… I am not having a good day. …".
The situation reminds me of Dilbert cartoons, with JoAnne/Ben/Tom as Dilbert the Engineer and the SLAC PR creatures as Marketing-Sales-Weasels.
Don't let Marketing-Sales-Weasel idiocy get you down. Most people in the real world understand that Dilbert is not the bad guy.

A Survey of Elliptic Cohomology

February 8, 2006
Categories: Uncategorized

There's a beautiful survey paper about elliptic cohomology that Jacob Lurie, an AIM 5-year fellow in the math department at Harvard, has recently put on his home page. This paper has been discussed a bit already by David Corfield and by Urs Schrieber.

I don't have time right now to try and write up something comprehensible about those parts of the elliptic cohomology story that I kind of understand, and in any case I want to spend more time reading Lurie's paper. It brings into the elliptic cohomology story several of my favorite pieces of mathematics (Atiyah-Segal completion, Freed-Hopkins-Teleman), in a way that I don't yet understand. But in any case there's a lot of very beautiful and very new mathematics in this paper, mathematics that has tantalizing relations to quantum field theory.

Comments

   February 8, 2006

   "…mathematics that has tantalizing relations to quantum field theory."

   Curious comment: do you refer to section 5.2 or something else? Amazing set of ideas this guy has, I'll agree. I've had the Adams book, for example, on my shelf for years and years, but I don't imagine I shall ever be able to refer to it casually.

2. **Kea**
   February 8, 2006

   The only issue I have after browsing Lurie's papers is that he seems to have solely a homotopy theorist's take on higher categories, rather than a more open point of view which one would expect from someone discussing issues with such a broad scope. Admittedly, I am biased.

3. **woit**
   February 8, 2006

   Kea,

   You're right that this is a homotopy theorist's take on the subject, heavily influenced by the work of Mike Hopkins. But, for a homotopy theorist, Lurie is taking a quite broad point of view.

   The relations to QFT include not just the Freed-Hopkins-Teleman stuff that I'm fascinated by, but other things as well. The whole subject was heavily influenced by Witten's writing down of a 2d QFT that gives the elliptic genus, and more recently Stolz and Teichner and others have been investigating the relation of 2d conformal field theory to elliptic cohomology. There's more about this if you follow the link to Urs's posting.

4. **Michael**
   February 9, 2006

   seems like there is an href missing from the HTML on Urs link. thanks.

5. **A.J.**
   February 9, 2006

   Hi Peter,

   You mentioned a while back (in a post about Freed-Hopkins-Teleman that you hadn't quite been sold on stacks. I think that the Atiyah-Segal theorem might be one good reason to like them.

   In algebraic geometry, the classifying stack of G is the quotient stack pt/G. The nicest way to define this is to start with the action groupoid of G on a point; this is just the category with one object and one morphism for every element of G. If you take its nerve, you obtain the simplicial scheme with G^n in the n-th degree. Taking the geometric realization of this simplicial object gives you Milnor's construction of BG. But this isn't really the best thing to do; you're throwing away information. What you should do instead is think of the functor of points of this simplicial scheme as a Category Fibered in Groupoids. This CFiG isn't a stack however; it's just a pre-stack, doesn't satisfy effective descent. It assigns to a test scheme S, the groupoid Hom(S,pt), with morphisms given by the obvious G-action. To get a nice CFiG, we need to stackify, to study instead objects which are locally maps to the point, but might differ globally by the action of G. This "differing globally by the action of G" really means that we have a G-valued function on every non-empty intersection of local patches. This is exactly the data of a principal G-bundle.

   So what's my point? Well, it's that stacks are good magic. The natural definition of the quotient stack pt/G tells you precisely that maps into pt/G classify principal G-bundles. This magic happens because you made certain to keep track of *how* G acts on th e point. Which results in a nice thing: K(pt/G) is the Grothendieck group of the vector bundles on pt/G. But these are the same thing as G-equivariant vector bundles on the pt, i.e. G-modules. So the K-theory of the stacky pt/G is, in fact, canonically isomorphic to Rep(G). If I understand things right, the Atiyah-Segal theorem is basically an identification of the information you lose by passing to the geometric realization.

6. **Urs Schreiber**
   February 9, 2006

   The entry on elliptic cohomology that Peter is referring to is this one:

   http://golem.ph.utexas.edu/string/archives/000737.html

   Stay tuned for more on Stolz&Teichner in a couple of weeks when I report from this winter school:

   http://golem.ph.utexas.edu/string/archives/000712.html

7. **Urs Schreiber**

February 9, 2006

Hi AJ,

I understand what you are saying, except for this last sentence

> So the K-theory of the stacky pt/G is, in fact, canonically isomorphic to Rep(G).

I guess you mean that this K-theory is isomorphic to the Grothendieck group completion of the decategorification of Rep(G), no?

BTW, if anyone is wondering what AJ is talking about: a chatty discussion of those quotient stacks is given here.

A review of how to think of these quotients as groupoids is given here and here.

8. **A.J.**
February 9, 2006

Hi Urs,

Yes, by Rep(G) I mean the representation ring, not the whole category. (I was using the same notation that Lurie used in his survey.)

Nice expositions, by the way. Now if I could just find a chatty discussion of Quillen's model categories…

9. **Urs Schreiber**
February 9, 2006

> Now if I could just find a chatty discussion of Quillen's model categories…

If you find out anything at all, let me know. Thanks.

10. **D R Lunsford**
February 9, 2006

I wish I could get excited about this. Someone should explain this stuff in a way that is palatable to intuitive thinkers. This sort of exposition is almost unreadable to me.

-drl

11. **Kea**
February 9, 2006

drl

Unfortunately, whereas us poor physicists are just trying to understand, say, M-theory, this Lurie guy is on a fast rocket to trying to prove the Riemann Hypothesis (why else would he be working on higher toposes?) … it ain't going to be easy for us sods to keep up.

12. **kielbasa**
February 9, 2006

"I wish I could get excited about this. Someone should explain this stuff in a way that is palatable to intuitive thinkers."

As opposed to "non-intuitive thinkers."

13. **woit**
February 9, 2006

A.J.,

Thanks a lot for your comment. That's more or less exactly why I've gotten interested in stacks again recently (that K(pt/G)=R(G), rather than the completion). Chris Woodward had given me a more concrete explanation of this (that on the geometric realization you get K-theory classes that don't quite come from representations, and thus need the completion), but your explanation is very helpful. Thanks again!!

14. **D R Lunsford**
February 9, 2006

kielbasa,

Yes non-intuitive thinkers. It should be obvious who they are 🙂

-drl

Lots More Landscape

February 8, 2006
Categories: Uncategorized

Various things from the past couple days related to Susskind, the Landscape, and his book The Cosmic Landscape:

The paper Computational Complexity of the Landscape I by Frederik Denef and Michael Douglas is out. They show that even in simplified models of string theory vacua the problem of finding a model with CC in the anthropically determined range is NP-hard. This strongly indicates that in practice you can't ever do what landscapeologists have optimistically hoped might be possible: pick out those vacua with anthropically acceptable values of the CC, and somehow use them to make predictions. Denef and Douglas end by bringing up a peculiar possibility: what if direct evidence for string theory is found (they're kind of vague on how this going to happen…), but the problem of actually identifying our vacuum state remains intractable?

This raises the possibility that we might someday convince ourselves that string theory contains candidate vacua which could describe our universe, but that we will never be able to explicitly characterize them.

Lubos has a posting about this, including an exchange of comments with Frederik. On the whole I tend to see eye to eye with Lubos about the Landscape, although not here, where he's frantically trying to dismiss the Denef-Douglas results, which look pretty solid to me.

The Philadelphia Enquirer has an editorial entitled A scientific leap, but without the faith, by Amanda Gefter, who did the recent interview with Susskind in New Scientist. Gefter tries to argue that string theory, unlike intelligent design, is science despite not being falsifiable. I don't have the time or energy here to do justice to her argument or the problems I have with it (for one thing, she thinks string theory is breathtakingly beautiful). Science and Theology News has an article about the Gefter editorial called Intelligent design versus string theory which kind of misses the point, claiming that string theory can be falsified.

This month's American Scientist has a review of Susskind's book by cosmologist John Peacock entitled A Universe Tuned for Life . The review is pretty much uncritical, and mainly happy that Susskind is anti-religion:

These obligatory small criticisms should in no way detract from Susskind's tremendous achievement. This book is a fine piece of popular science writing, but it is particularly significant for the timeliness of its message. Susskind emphasizes that the whole structure of the universe requires an active Creator no more than does the human eye or the temperature of the Earth. At a time when more and more people seem happy with a creation that took place 6,009 years ago, this lesson needs repeating.

Peacock actually feels that Susskind doesn't go far enough in trashing the 20th century idea that there is some simple, compelling physical theory that explains the way the world works:

But if life on Earth is a random accident in a universe where only chance yielded laws of physics suitable for life, why stop there? Perhaps string theory itself is nothing special and only part of a wider spectrum of possible prescriptions for reality. If the search for a unique and inevitable explanation of Nature has proved illusory at every step, is it really plausible that suddenly string theory can make everything right at the last? Reading Susskind's book should make you doubt that possibility, in which case we may have reached the end of the search for underlying simplicity that has driven physics since the beginning.

Finally, last night's new papers on the arXiv included the surprising inclusion of one on Emergent Gravity by Jack Sarfatti. Famously, supposedly Sarfatti had been banned from publishing on the arXiv, but now I guess the arXiv has changed it standards. I still haven't heard from them about why they're banning trackbacks to this site, but perhaps there's an explanation as to why they have finally found a paper by Sarfatti acceptable. It includes exactly two references, one to a 1976 paper about defects in condensed matter physics, the second to, you guessed it, Susskind's The Cosmic Landscape.

Update: Chris W. correctly points out that I mistakenly had Gefter referring to string theory as "strikingly beautiful", when it was general relativity she was referring to in this context.

Update: As a commenter pointed out, there's a long, uninformed discussion of string theory and intelligent design over at The Panda's Thumb. Many of the people commenting over there seem to believe that string theory is testable, and even invoke the latest SLAC story. Please don't bring that particular discussion over here now. If you're in the mood, contribute over there. Unfortunately I don't have the time or energy at the moment…

Comments

1. **Chris W.**
   February 9, 2006

   Gefter was referring to general relativity when she used the phrase "breathtakingly beautiful". Regarding string theory, she says:

   …, string theory is lacking in testable predictions, but more important, it is lacking some underlying principle to give it deep explanatory power. Still, scientists pursue it because they see paths of unification, shards of beauty, glimmers of ultimate reality.

2. **Michael**
   February 9, 2006

   http://en.wikipedia.org/wiki/Jack_Sarfatti

   interesting bit on wikipedia about Dr. Sarfatti. he seems like a cool guy.

3. **Christine**
   February 9, 2006

   There is also this paper by Craig J. Hogan I have commented here recently.

4. **Alejandro**
   February 9, 2006

   There is a nice discussion on the "ID vs String Theory" debate going on at The Panda's Thumb.

5. **JP**
   February 9, 2006

When was Sarfatti banned from ArXiv.org? What was the reason?

6. **Alejandro RIvero**
February 9, 2006

The "convince ourselves" parragraph is strinkingl similar to arguments about continuum hipothesis.

7. **woit**
February 9, 2006

I don't know the whole history of Sarfatti's interactions with the arXiv, and I'd rather not have a thread here about the conflicts he and others have had with them in the past. The interesting question of the moment is why they seem to have changed their policy, exactly when he starts writing about the landscape and referring to Susskind.

Privately I have heard through another party that Sarfatti sent out many requests for endorsements, and that he himself doesn't know how many of them led to endorsements, or why the arXiv has changed its policy towards him. I've certainly noticed in recent months some rather, let us to be polite say "non-mainstream" articles being posted, even in hep-th, of a sort that I believe in the past were not allowed. What they had in common was that they somehow claimed to be about string theory. This has raised the question in my mind of whether the landscape pseudo-science gaining ground in the mainstream particle theory community is starting to infect the arXiv in general, leading to a breakdown in long-held understandings of what is legitimate theoretical physics worthy of inclusion in the arXiv, and what isn't.

If anyone actually knows what is going on at the arXiv on this issue, I'd be interested in hearing about it.

8. **Amanda**
February 9, 2006

I've certainly noticed in recent months some rather, let us to be polite say "non-mainstream" articles being posted, even in hep-th, of a sort that I believe in the past were not allowed.

Really? Can you give some examples? Of topics, if you prefer not to be too specific.

9. **woit**
February 9, 2006

I didn't keep specific track of these as I saw them, but here's one example:

hep-th/0601104

This seems to me very much the sort of thing that traditionally would not be allowed on hep-th, with the fact that "string theory" is mentioned the only reason it got on there.

10. **Hal**
February 9, 2006

I know that anthropic and multiverse theories are not well thought of around here, for understandable reasons. Nevertheless there are philosophical arguments that can provide guidance through even the thicket of an infinite multiverse. The basic principle is this: that the universe should be as complex as necessary to create intelligent life, but no more so. Justifying and defending this principle obviously takes more room than is available here in the margin 🙂 so I will just point to the works of Max Tegmark and Jurgen Schmidhuber.

11. **John Gonsowski**
February 9, 2006

One can have a David Deutsch-like multiverse without a Susskind-like anthropic landscape and that's a good thing.

12. **Luboš Motl**
February 10, 2006

I am happy that you consider the newest paper about the anthropic principle and the meta-statistical analysis of the vacua solid, Peter. Why is it good news that Peter Woit goes anthropic? It's because we have finally some kind of diversity in the blogosphere, and I don't have to worry that Michael's and Frederik's attitudes to the vacuum selection issues are underrepresented. 😉

13. **Alejandro Rivero**
February 10, 2006

Well, my own papers had got a good historical record of "unappropiateness" in the ArXiV, and recently I have found they are passing more smoothly. So either my writting is going better, or the arxiv has revamped some criteria after the appointment of new supervisors last year.

14. **Chris W.**
February 10, 2006

From Peter:

> I've certainly noticed in recent months some rather, let us to be polite say "non-mainstream" articles being posted, even in hep-th, of a sort that I believe in the past were not allowed. What they had in common was that they somehow claimed to be about string theory. This has raised the question in my mind of whether the landscape pseudo-science gaining ground in the mainstream particle theory community is starting to infect the arXiv in general, leading to a breakdown in long-held understandings of what is legitimate theoretical physics worthy of inclusion in the arXiv, and what isn't.

How about these: Papers by the author of **A Solution to the Fermi Paradox: The Solar System, part of a Galactic Hypercivilization?**:

> Besides these simple solutions there are many more exotic proposals. For example, a rather drastic expansionist solution is given by the theoretical physicist Cumrun Vafa, at Harvard University, who thinks that the fact that we do not see aliens around could be the first proof of the existence of brane worlds: all advanced aliens would have emigrated to better parallel universes [7].

15. **woit**

February 10, 2006

Chris W.

That is one of the best arguments for brane worlds I know of. Note that this author's papers in recent years have been on in the unmoderated "physics" sections rather than one of the moderated sections like hep-th. What I'm interested in is whether their moderation policy has changed or is changing.

16. **woit**
February 10, 2006

Correction: the "physics" section is also moderated, although presumably in a somewhat different way than the other sections.

17. **Alejandro RIvero**
February 12, 2006

Well I am happy that at least it has been changing or changed during the last year, because it let me to arxive some things I can need to check in the future -lot of susy and/or topcondensation going on-, and it is important to have them handy and public even if not in "publishable" form. I hope it will remain at the current moderation level and no go back to the old ages.

PS: Alejandro, could you please to use at least the initial of your surname, to avoid confusion?
PS2: It seems that a Sarfatti has answered to this thread in a different one.

18. **Christine**
February 21, 2006

P.C.W. Davies submitted this paper recently to astro-ph:

The problem of what exists. The abstract is:

> Popular multiverse models such as the one based on the string theory landscape require an underlying set of unexplained laws containing many specific features and highly restrictive prerequisites. I explore the consequences of relaxing some of these prerequisites with a view to discovering whether any of them might be justified anthropically. Examples considered include integer space dimensionality, the immutable, Platonic nature of the laws of physics and the no-go theorem for strong emergence. The problem of why some physical laws exist, but others which are seemingly possible do not, takes on a new complexion following this analysis, although it remains an unsolved problem in the absence of an additional criterion.

19. **woit**
February 21, 2006

Christine,

Thanks a lot for pointing out the Davies multiverse paper, I hadn't noticed it.!

Swampiness on Long Island

February 9, 2006
Categories: Swampland

At first I thought this must be an April Fool's day joke, but I just checked the calendar, and it's not April 1 yet. For the last few years Stony Brook has been running a workshop on math and physics during the summer, funded by Jim Simons of Renaissance Technologies. The topic for this summer has just been announced, it's "The String Landscape and the Swampland". A poster for the workshop is now on-line, featuring a large picture of a swamp. You really couldn't make this kind of thing up.

Comments

1. **Sakura-chan**
   February 9, 2006

   Susskind can be the Swamp Thing.

2. **Michael**
   February 9, 2006

   Peter, the swampland program aims at boiling down the landscape as much as possible — hopefully killing it eventually. It is a residual part of physics and reason in the whole landscape business and has recently lead to interesting progress (the "gravity is weak paper" by Vafa, Motl et. al.). Why would you mock such a thing? Oh, right! I forgot about your ignorance and agenda — for just one second…

3. **D R Lunsford**
   February 10, 2006

   SWAMP THING
   YOU MAKE MY HEART SING
   YOU MAKE EVERYTHING – GROOVY!
   SWAMP THING!

   -drl

4. **sunderpeeche**
   February 10, 2006

   From the poster (2nd para)

   "These workshops focus on the intersection between physics and mathematics, particularly in the context of string theory. One of the themes of the fourth workshop will be the String Landscape and the Swampland — what are the general constraints on low energy physics that follow from string theory?"

   So it's a picture of a swamp. Why not? At least there is an officially stated attempt to obtain general constraints on low energy physics. The workshop may not succeed (no falsifiable predictions after 20 years after all….) but it's a reasonable poster and a reasonable agenda.

5. **Chris Oakley**
   February 10, 2006

   Michael,

   I cannot speak for Peter, but I can certainly tell you why I think that a conference on the Stringy Swampland chaired by Cumrun "the aliens have left us for a more happening universe" Vafa is a worthy subject of derision.

   This is supposed to be PHYSICS. Remember physics? Experiments that did not work at school … lots of mathematics. Names like Maxwell, Rayleigh, Rutherford and Thomson (after which the forms at my school were named – I was in Rayleigh, but I digress). It is an EXPERIMENTAL science. In the case of the Stringy Swampland possible experimental tests are so far away that one can hardly imagine them. It is a more a case of "I had a dream. It never became a reality, but I refuse to give up on it."

   I did not go into particle physics for the chicks and the fast cars. Sorry, I should rephrase that: IF there had been chicks and fast cars on offer in going into particle physics, THEN it would not have been the reason for my choosing it. I went into it because I wanted answers.

   As an undergraduate, once I got over my initial difficulties with quantum mechanics, I came to appreciate what an outstanding framework it is. Atomic physics can just as easily be called "the application of quantum mechanics to single atoms" and solid state physics can just be called "the application of quantum mechanics to regular arrays of atoms". Nuclear physics suffers from the problem that we do not know the equations of motion, but to the extent that we can apply quantum mechanics to it, we do.

   At the end of my undergraduate course a number of important questions were left unanswered. I was expecting graduate courses on quantum field theory to answer them. I also expected the QFT I learned to have ordinary quantum mechanics contained within it. It does not. QFT as currently practised only applies to scattering processes and so does not have *anything* to say about bound states. Those who laud the Lamb Shift calculation as one of the triumphs of modern science should remember this fact. You can get the phenomenally accurate theoretical value only if you step around a few truly nasty inconsistencies and use a different framework, supposedly more elementary, to provide the basis in which you operate.
   Of course, I did not like any of this, so as soon as I was reasonably able to do so, I set about trying to find something better.

   As this work progressed, I realised that nobody much wanted me to succeed. Whereas I could understand this coming from those whose claim to have already solved the problems I disputed, I could not understand it coming from the particle physics mainstream.

   My approach to problem solving is really quite simple: identify the biggest problem and just go and solve it in the most direct way possible. Listen to others, but ultimately trust only your own judgement.

   This philosophy, I felt, worked in re-doing the bathroom in my mother's house in 1992. It also worked in building systems for derivatives trading at UBS and Nomura, but for theoretical physics, it was a disaster. Even now, if I were to ask to give a talk on my work on theoretical physics, I would just be fobbed off with excuses.

   Yet my philosophy is no different from that of the huge numbers of scientists and technicians trying to do their best at whatever they do throughout the world. These are the people who were *not* child prodigies, and about whom articles do *not* regularly appear in the New York Times. But it is through the efforts of these unsung heroes that the boundaries of knowledge are slowly pushed back, or the quality of life slowly improves. They know that most people will not be interested in their views on extra dimensions or aliens, but, through trial and a lot of error, they become good at one specific thing, something that would be totally boring to anyone other than themselves.

String theorists will probably regard these people as inferior, but as far as I am concerned, it is the String theorists who need to learn.

As far as I can see, theoretical particle physicists behave more like excitable teenagers than scientists. “Right” and “wrong” is irrelevant – “cool” and “uncool” is far more important. In 1982 it was “cool” to do Supersymmetry. So everyone had to do Supersymmetry. Everyone was watching each other, and regulating what they say, either in talks or papers, not on the basis of whether it was true of not, but on the basis of whether it corresponded to the consensual view. I refused to play this game after the first few months. If something was true, I said it was true. If it was false, I said it was false. Result? Soon nobody wanted to hear what I had to say at all. And then, of course, there is the guru factor. Not such a big deal in 1982, but now … if Ed Witten said that the universe was sneezed out of a being called the Great White Arkleseizure it would only be a matter of days before papers started to appear on the flow equations of the sneezing and the reasons why the Arkleseizure had to be white (the latter probably coming from some string theorist in the deep south).

The reason why fundamental physics is where it is today, is simply because *that is where it wants to be*. There is no contact with experiment because they are not interested in experiments. They follow where the group mentality leads them, and if that is into a swamp, then so be it.

“Gadarene swine” was the phrase I heard to describe this phenomenon. Not my words, but those of a highly-respected theoretical particle physicist, but now running the UK’s fusion project.

6. **Chris Oakley**
   February 10, 2006

   Anticipating objections from Lattice gauge theorists: I know that Lattice gauge theories are in reasonable shape for hadronic bound states, but this obviously does not include the Hydrogen atom.

7. **Dombono**
   February 10, 2006

   I don’t know where or how you learned quantum field theory but I guess you took a really bad course on it taught by a perturbative S-matrix guy :). Of course quantum field theory covers bound states and of course computations involving hydrogen atoms are much much simpler and easier and more accurate than computations involving hadrons, both because QED is weakly coupled and also because the hydrogen atom only involves two valence particles. People don’t work on lattice QED (as much) because they don’t need to but there’s nothing stopping anyone from working on it.

   If Witten were to write a paper on the Great White Arkleseizure, he will immediately lose all credibility within a day and will be dismissed as a formerly great physicist-turned-crackpot. Physicists take him seriously because his work has been consistently profound and CORRECT.

8. **woit**
   February 10, 2006

   I realize that this posting was kind of a rant of my own, so encourages ranting, but I’d rather keep that kind of thing to a minimum. Please, stop with the rants, or with responses to them. Except for Lubos of course, whose ranting is kind of entertaining….

   I’ve written about this swampland stuff elsewhere several times, but I guess I should again explain exactly what the problems with it are, since some people seem to not know what it’s about, thinking it is about “boiling down the landscape” or trying to understand whether the standard model can be the low energy limit of a string theory, something obviously of interest.

   Vafa et. al.’s swampland program isn’t about getting rid of the landscape at all, it accepts that all the possible string vacua coming from KKLT and other similar constructions all exist. The “swampland” consists of effective field theories that no one has yet come up with a proposed way of getting as low energy limits of string theory. It explicitly does not include the standard model, for which there are many proposed constructions as string vacua (whether any of them actually do give exactly the standard model, and if so, whether there are so many that the theory is unpredictive, is an open question). This whole subject explicitly is not about understanding the real world, it is about understanding aspects of low energy limits of string theories that have nothing to do with the real world.

   The most recent “swampland” work that has gotten a lot of attention argues that in effective field theories coming from string theory gauge forces cannot be much weaker than gravitational forces. Whether or not you believe this, it’s completely irrelevant to the real world, where gravitational forces are much, much weaker than gauge forces.

   Besides the fact that this subject explicitly has nothing to do with the real world, there’s another problem. Historically there have been lots of claims that “you can’t get X from string theory”, just about all of which have turned out to be true once someone seriously tried to get X from string theory. For one example of this phenomenon, take a look at

   http://golem.ph.utexas.edu/~distler/blog/archives/000651.html

   which is a posting by Jacques Distler about Vafa’s original swampland note. In the posting Jacques gives as an example the supposed fact that you can’t get an effective field theory with only one or two generations of fermions out of string theory. More or less immediately, Volker Braun wrote in to tell him how to do it.

   Besides the above scientific problems, there are other reasons I find the whole thing completely bizarre. One uses the metaphor of a swamp to indicate somewhere extremely unpleasant that you are in danger of getting lost in, stuck in the mud, and unable to ever get out of (e.g. “Iraq is a swamp for the US military, just like Vietnam”). Why would anyone want to describe their proposed research program as going into a swamp, and make up posters with swamp pictures? This really amazes me no end…..

9. **sunderpeeche**
   February 10, 2006

   Swamps are often associated with disease (tropical swamps and malaria). But swamps are also rich ecological systems. They teem with life. Many tropical swamps have large deposits of crude oil under them. Things like peat bogs (not a swamp?) eventually become coal deposits, after millions of years. These things have to start off somehow, and perhaps don’t look pretty at the beginning (if ever). I guess the word swamp doesn’t bother me. But it’s just a personal opinion.

10. **J.F. Moore**
    February 10, 2006

    Perhaps there is an element of psychology at play: taking ownership of a perceived weakness to preempt its use in a derisive way. A common example of this is the outrageous dress used in gay rights marches, or people who poke fun at themselves to offset a deeper narcissism. Just a guess.

    Anyway, it’s not even a very nice graphic that they use.

11. **Who**

    February 10, 2006

    Thanks, I'm glad you think so. That is probably the closest I will come to saying something profound here.

Hawking Goes Anthropic

February 10, 2006
Categories: Uncategorized

Stephen Hawking and Thomas Hertog have a new paper out, called [Populating the Landscape: A Top Down Approach](). It contains his version of the anthropic landscape idea, based on his "no-boundary" idea of quantum cosmology (sometimes also referred to as the "Hartle-Hawking wavefunction"), and he refers to it as "top-down cosmology".

Here's part of the summary:

In a top down approach one computes amplitudes for alternative histories of the universe with final boundary conditions only. The boundary conditions act as late time constraints on the alternatives and select the subclass of histories that contribute to the amplitude of interest. This enables one to test the proposal, by searching among the conditional probabilities for predictions of future observations with probabilities near one. In top down cosmology the histories of the universe thus depend on the precise question asked, i.e. on the set of constraints that one imposes…

The top down approach we have described leads to a profoundly different view of cosmology, and the relation between cause and effect. Top down cosmology is a framework in which one essentially traces the histories backwards, from a spacelike surface at the present time. The no boundary histories of the universe thus depend on what is being observed, contrary to the usual idea that the universe has a unique, observer independent history. In some sense no boundary initial conditions represent a sum over all possible initial states. This is in sharp contrast with the bottom-up approach, where one assumes there is a single history with a well defined starting point and evolution.

and

We have also discussed the anthropic principle. This can be implemented in top down cosmology, through the specification of final boundary conditions that select histories where life emerges. Anthropic reasoning within the top down approach is reasonably well-defined, and useful to the extent that it provides a qualitative understanding for the origin of certain late time conditions that one finds are needed in top down cosmology.

I haven't completely understood this yet, especially the author's claims that they can use these ideas to say something about the shape of primordial fluctuation spectra, but the whole thing doesn't sound obviously any more promising than other approaches to the anthropic landscape. Here, as usual, I agree with [Lubos's comments on this](). But despite this, he seems to have removed me from his blogroll. My feelings are hurt.

Comments

   February 10, 2006

   Re: Lubos Delinking.

   Maybe it's because you've been agreeing with him so much lately. It's probably getting on his nerves.

3. **mathjunkie**
   February 10, 2006

   andy.s has the point.

4. **Dave Bacon**
   February 10, 2006

   Hasn't Hawking always used the anthropic principle? I can remember reading his Brief History back in high school and getting very upset with it for using said argument. And I'm pretty certain that during at least one talk I attended while and undergrad at Caltech (93-97) he gave a talk which basically was in support of the anthropic principle.

5. **A. nonymous**
   February 10, 2006

   I would guess that Lubos does not consider this blog to be 'led by science'.

   Regarding Hawking's paper….

   It would appear that all the anthropic stuff amount to no more than fitting data to observed values. There are three (large) spatial dimensions; use that as a constraint on the present state of the universe and say the word "anthropic" while doing so.

   When he makes contact with string theory, he suggests using the geometry of the internal space as part of the boundary conditions which describe the current state of the universe. Then he suggests that only a few metastable landscape vacua will emerge from his procedure. But the problem is that we aren't able to determine what the present geometry of the internal space is (by any conceivable experiment, as Peter likes to point out). If we were able to determine that, we would know which part of the landscape we were in already. I may be missing Hawking's point here, though.

   He says that the largest contribution to the history of the universe comes from configurations in which the universe popped into existence by quantum means – is this a result which has been proved in Euclidean quantum gravity, or not proved at all, or proved more generally? It sounds a little suspicious when somebody says that the present state of the universe is independent of an initial state because the universe with the prescribed initial state will undergo quantum disappearance and be quantumly replaced by a new one.

   Any predictions which will come from his proposal would seem to need to incorporate more constraints than merely the constraints that come from observed values, anthropic or not. It sounds superficially like his "no boundary" proposal provides the additional information that could lead to predictions, but then for any application of it, he puts his favorite instanton at the beginning of the universe and draws conclusions from that. How do we know that there isn't an uncountable number of possible instantons that can match up expanding Lorentzian space with no boundary?

6. **Kea**
February 10, 2006

A.

Yes. The anthropic discussion isn't too alarming here, because the authors point out that such reasoning is simply one kind of constraint.

"Top down cosmology is also more general than anthropic reasoning, because there is a wider range of selection effects that can be quantitatively taken into account."

7. **Haelfix**
February 10, 2006

Hawking has always been a strong anthropic principle advocate, long before he even was interested in String theory. He used to talk about the unsolvability of the fine tuning problems in Inflation theory during astrophysics conferences. I always thought his point of view was needlessly dark and depressing and premature to the extreme.

Anyway, im not a big fan of the no boundary proposal either (a rare topic in QG I know a little about). Wave functions of the universe and things like that are so plagued by conceptual difficulties (like even trying to define what hilbert space you are talking about), that they are rarely taken to be more than gimmicks by people in the field. Its an old story really, and goes back to the eternal problems of defining time in quantum gravity (eg the WDW eqn), and when to take euclidean path integrals seriously (in the HH approach, the integral is not bounded from below) . Not to mention its kinda problematic to leave so many gravitational degrees of freedom un quantisized.

But in the ill understood field of qg cosmology, I guess crude treatments like this are as good as you're likely to get at this stage of the game, at least until we get a better microscopic treatment from somewhere else (eg perhaps string theory).

8. **John Gonsowski**
February 10, 2006

OK if the present is determining a history does that mean the past's present lives through a history via the future? I may need to rephrase this my head hurts.

9. **R.R. Tucci**
February 11, 2006

I think I finally understand what string theorists mean by the Anthropic Principle. What Hawking et al are doing is a pretty standard Bayesian calculation. I'm not sure that this Bayesian technique will be fruitful in the case of String Theory. I don't even know if it makes sense philosophically and logically to apply this technique to String Theory, but the technique itself is firm and solid, and well known outside of String Theory. This technique can be used within the realm of classical probability to select those classical histories that are more promising, or it can used within quantum theory to select quantum histories.
The "final boundary conditions" correspond to the final nodes of a Bayesian Network, and what they are trying to do is to update the probabilities of the non-final nodes of the network based on their observation of the final nodes. As often happens in Physics, these people are reinventing the wheel. It would help if they were less proud and used the language and techniques that have already been developed by statisticians to do this, instead of pretending that there are no precedents. (For those of you who are not familiar with Bayesian Networks, there are a zillion reviews on the web. A Google search for "Bayesian Networks" yields about half a million hits.)

10. **Steve**
February 11, 2006

I strongly agree with the above comments about rediscovering the Bayesian approach.

Another place to look for background information is the comment that I added to Lubos' posting, where I summarised what I *think* are the relevant parts of the Bayesian approach.

11. **Kea**
February 11, 2006

February 13, 2006

Yes, the link of Peter's weblog appears on Lubos weblog again. They become friends again.

16. **Chris Oakley**
February 13, 2006

mathjunkie,

It could just be that the former StB operative that Lubos hired to rub Peter out has been detained by US immigration. Or he went to the wrong place. Check the newspapers to see if a maths professor called New York at Woit University in Columbia has recently been wasted.

17. **ObsessiveMathsFreak**
February 13, 2006

Slightly offtopic, but I am pleasantly surprised that such a well known and also “venerable” physicist such as Hawking would publish first on arXiv.org instead on a journal. It’s surprising how much times have changed.

18. **Steve Myers**
February 13, 2006

After quick run through of paper — yes, Bayesian. But don’t see much in it. A personal note: back, about 20 years ago, when I wasted my time thinking about cosmology, I wrote Hawking asking about an idea I had that involved infinite neg. E at big bang, plus other dumb stuff. He replied that yes, there at that singularity was the problem & that’s what he was working on. It was a pleasant note & he thanked me for the book I’d sent.

19. **mathjunkie**
February 14, 2006

Chris,

I’ll check the newspapers!

20. **Aaron Bergman**
February 14, 2006

I strongly agree with the above comments about rediscovering the Bayesian approach.

Nobody I know who thinks about this sort of thing is unaware of Bayesian statistics.

Susskind Letter to NYT Book Review

February 11, 2006
Categories: Uncategorized

This is about the sixth week in a row that the Sunday New York Times Book Review has had something about string theory or the Landscape controversy. It has become the main place in the popular press to follow this. Tomorrow's issue contains a letter from Susskind responding to the recent review of his book by Corey Powell.

Susskind has two complaints about the review:

1. That he was not engaging in "braggadocio" by writing "as much as I would very much like to balance things by explaining the opposing side, I simply can't find that other side" since "The comment merely reflects a fact that all parties, on both sides of the controversy, agree upon: as things stand now, there is no explanation of the fine tunings of nature other than the one discussed in my book."

This isn't really accurate. For fine tunings other than the CC, there are other widely accepted explanations (e.g. supersymmetry). For the CC, many people don't believe that the anthropic string theory landscape is really an explanation, at least not a scientific one.

2. He justifiably complains that Powell accuses him of believing that we are about to discover a "final answer" to the problems of fundamental physics. He is quite right that he doesn't actually make any such claim, and that his point of view and Powell's don't differ here.

Update: The Moonie-owned right-wing newspaper The Washington Times has a review of Susskind's book. It describes the argument of the book and ends:
To religious believers, the idea that the universe is designed by a Creator to allow the existence of human life is fundamental. To Mr. Susskind and those who think like him, that idea is so unacceptable that they are willing to abandon the idea that nature follows one set of laws, the principle upon which modern science was founded.

The reviewer at least has noticed that Susskind is giving up on modern science, although he attributes this to Susskind's unwillingness to face up to evidence for intelligent design, instead of unwillingness to face up to the failure of his pet theory.

Comments

1. **Who**
   February 11, 2006

   "… I simply can't find that other side" since "The comment merely reflects a fact that all parties, on both sides of the controversy, agree upon: as things stand now, there is no explanation of the fine tunings of nature other than the one discussed in my book."

   This looks like a remarkable case of forgetfulness (or glossing over the facts). In 2004 Susskind registered the existence of a testable explanation (CNS) by posting attempted rebuttals on the arxiv. One of these was subsequently deleted. He entered into an inconclusive exchange over CNS, which included one or more letters published at Not Even Wrong, if I remember correctly, after Smolin posted hep-th/0407213. Susskind was sufficiently exercised about CNS within the past two years that he ought to be cognizant of it, and acknowledge that he knows of a proposed "explanation of the fine tunings of nature" which is empirically testable.

   The CNS explanation may be wrong, but it makes testable predictions and has not yet been shown to be so. This is normal for scientific theories, which stand until falsified since final confirmation is impossible.

   It is obvious that "all parties, on both sides of the controversy" do NOT agree that no explanation has been proposed and thus that there is no "other side" to be mentioned. Susskind suppresses the fact that he has engaged in heated debate with one of the parties on the other side.

2. **Who**
   February 12, 2006

   BTW the topic of the thread is not Susskind in general so much as the two points he made in his letter to the NYT. We can ignore his complaint #2 which Peter says is justified—it was probably included only for completeness. His complaint #1, however, can be challenged.

   "… I simply can't find that other side" since "The comment merely reflects a fact that **all parties, on both sides of the controversy, agree upon: as things stand now, there is no explanation of the fine tunings of nature other than the one discussed in my book."**

   This assertion was challenged by Peter.

   It can also be refuted by reference to an article by Susskind himself posted on the arxiv

   http://arxiv.org/abs/hep-th/0407266
   Cosmic Natural Selection
   Leonard Susskind

   This article by Susskind deals with a proposed (and so-far not eliminated) "explanation of the fine tunings of nature" other than the one discussed in Susskind's book. The fact that he wrote the article shows that he is aware of the existence of this alternative explanation. So when he says that he "can't find" an alternative explanation, or that one does not exist, he is not being forthcoming, and is spreading a misconception.

3. **arnold**
   February 12, 2006

   was my comment censored? why?

   I am very disappointed…..

4. **woit**
   February 12, 2006

   arnold,

   I was away from this for over a day, when I came back there were a large number of comments, many of them irrelevant to the topic, so I deleted quite a few, but then realized that I shouldn't have deleted so many. Unfortunately, once deleted, I have way of retrieving them.

In particular, someone pointed out that it is not true that “all parties” agree that the Landscape is the only explanation of fine-tuning, that “God said so” is an explanation that has many adherents. This is true, and it’s true that this kind of explanation is just as scientific as Susskind’s.

5. **arnold**
February 12, 2006

Hi Peter,
thanks for clarifying.

I was worried that you were adopting the same policy as Lubos: just ban whoever thinks differently!

In particular I completely agree with you: I wanted to point out again that these two explanations are at the same level. No proof, you have to believe them.

6. **D R Lunsford**
February 12, 2006

arnold – Peter only deletes comments that need to be deleted. As the author of many deleted comments, I can attest to Peter’s editorial skill.

-drl

7. **woit**
February 12, 2006

Can’t decide, should I delete that last one or not… These editorial decisions are sometimes difficult.

8. **Chris Oakley**
February 13, 2006

Those who complain about deleted comments should remember that this is Peter’s party and he can invite who he likes.

Personally, I am just grateful that there is *anyone* at a respectable university prepared to give higher priority to truthfulness than acceptance by the academic community. A lot more of this needs to happen.

9. **ObsessiveMathsFreak**
February 13, 2006

> To religious believers, the idea that the universe is designed by a Creator to allow the existence of human life is fundamental. To Mr. Susskind and those who think like him, that idea is so unacceptable that they are willing to abandon the idea that nature follows one set of laws, the principle upon which modern science was founded.

OK, now I’m lost. This is like an Agatha Christie novel. Can anyone me exactly who believes what now? Is this going to turn out that science was in fact murdered by every other passenger on the train!?

10. **anon**
February 13, 2006

OMF:

Nearly everyone is out to destroy science for their own ends, so Susskind isn’t alone. Newton had to overcome all kinds of bigotry.

Newton is the founder of laws of nature. He discovered an inverse square law proof (for circular orbits only) in 1666, but only published his book in 1687. The major delay was doing extra work and finding a framework to avoid three kinds of objectors:

(1) Religious objections (hence religious style laws of ‘nature’/God)
(2) Petty colleagues who would ridicule any errors/omissions
(3) ‘Little smatterers’ (Newton’s term) against innovation (=> Latin)

It would have been delayed longer if Halley had not funded the printing from his own pocket when he did.

11. **Who**
February 13, 2006

the case for resorting to anthropics always seems to have a step where the speaker throws up hands and says “we have no alternative, it’s forced on us!” (as in the Sussking NYT letter where he pretends he could find no alternative explanation of fine tuning)

This step in argument involves suppressing or conveniently forgetting about CNS. I hope this will be come progressively more awkward. One thing that may help is a new article to appear in ELSEVIER HANDBOOK IN PHILOSOPHY OF PHYSICS, by G. F.R. Ellis of the University of Cape Town. This was posted on arxiv today.

see pages 41 and 46 of
http://arxiv.org/abs/astro-ph/0602280
Issues in the Philosophy of Cosmology
George F. R. Ellis
To appear in the Handbook in Philosophy of Physics, Ed J Butterfield and J Earman (Elsevier, 2006)

quote from page 41
***Option 5: Cosmological Natural Selection. If a process of re-expansion after collapse to a black hole were properly established, it opens the way to the concept not merely of evolution of the Universe in the sense that its structure and contents develop in time, but in the sense that the Darwinian selection of expanding universe regions could take place, as proposed by Smolin [205]. The idea is that there could be collapse to black holes followed by re-expansion, but with an alteration of the constants of physics through each transition, so that each time there is an expansion phase, the action of physics is a bit different. The crucial point then is that some values of the constants will lead to production of more black holes, while some will result in less. This allows for evolutionary selection favouring the expanding universe regions that produce more black holes (because of the favourable values of physical constants operative in those regions), for they will have more “daughter” expanding universe regions. Thus one can envisage natural selection favouring those physical constants that produce the maximum number of black holes. The problem here is twofold. First, the supposed ‘bounce’ mechanism has never been fully explicated. Second, it is not clear — assuming this proposed process can be explicated in detail – that the physics which maximizes black hole production is necessarily also the physics that favours the existence of life. **If this argument could be made water-tight, this would**

become probably the most powerful of the multiverse proposals. ***

quote from page 46
***9.2.8 Physical or biological paradigms—Adaptive Evolution?

Given that the multiverse idea must in the end be justified philosophically rather than by scientific testing, is there a philosophically preferable version of the idea? One can suggest there is: greater explanatory power is potentially available by introducing the major constructive principle of biology into cosmology, namely adaptive evolution, which is the most powerful process known that can produce ordered structure where none pre-existed. This is realized in principle in Lee Smolin's idea (Sec.9.1.6) of Darwinian adaptation when collapse to black holes is followed by re-expansion, but with an alteration of the constants of physics each time, so as to allow for evolutionary selection towards those regions that produce the maximum number of black holes. The idea needs development, but is very intriguing:

Thesis H4: The underlying physics paradigm of cosmology could be extended to include biological insights. *The dominant paradigm in cosmology is that of theoretical physics. It may be that it will attain deeper explanatory power by embracing biological insights, and specifically that of Darwinian evolution. The Smolin proposal for evolution of populations of expanding universe domains [205] is an example of this kind of thinking.*

The result is different in important ways from standard cosmological theory precisely because it embodies in one theory three of the major ideas of this century, namely (i) Darwinian evolution of populations through competitive selection, (ii) the evolution of the universe in the sense of major changes in its structure associated with its expansion, and (iii) quantum theory, underlying the only partly explicated mechanism supposed to cause reexpansion out of collapse into a black hole. There is a great contrast with the theoretical physics paradigm of dynamics governed simply by variational principles shaped by symmetry considerations. It seems worth pursuing as a very different route to the understanding of the creation of structure. 37 **

Footnote 37 is cf Susskind's book, Chapter 13. I have not seen it. Perhaps someone could say what is in Susskind Chapter 13 that Ellis might be referencing?

In any case it is only a small gain but having something in an Elsevier handbook will, I guess, make it a tiny bit more difficult for advocates of anthropics to gloss over the existence of this alternative.

12. **woit**
February 13, 2006

Who,

Thanks for the reference to the Ellis article. I hadn't seen it since I don't normally look at astro-ph. But please, that's the third comment here about Susskind not properly considering CNS. Enough is enough

CNS is just one of several alternatives to the anthropic explanation of the CC that people have proposed, but that don't have very wide acceptance. Maybe it's right, maybe not, but it's a sociological fact in the physics community that this is not an idea that has a lot of adherents. Susskind is correct in claiming that there are no other ideas about the CC that have wide support among theorists. The problem is that, while his own anthropic ideas do now have fairly wide support, there is an even larger group of theorists that would argue that what he is proposing isn't actually a testable scientific proposal. Until he comes up with some kind of test of the idea, the "anthropic explanation" of the CC is something that I think most physicists don't consider an actual explanation.

13. **Aaron Bergman**
February 13, 2006

CNS is just as bad as any other stuff. It's just a different choice of a measure. You still have to include some sort of anthropic prior if you feel that computing statistical probabilities is a useful or interesting thing to do.

14. **Who**
February 14, 2006

Peter, I'd be interested in hearing discussion of ANY falsifiable hypothesis that addresses the values of fundamental dimensionless constants.

Susskind calls this "explains fine tuning"—-which puts a kind of anthropic slant on it right at the start.

I'm not talking about the (narcissistic) question of why the parameters of the standard model are suitable to our kind of life. I mean set the issue of life aside and propose a falsifiable hypothesis that has something to do with why the constants are what they are.

I think you may agree that one cannot effectively counter Susskind's "change the rules to save my baby" initiative just by disapproving of it. Or reporting that the majority of physicists disapprove. One has to make the alternatives visible, and discuss them. You mentioned there are several alternative explanations. Does each make some falsifiable assertion?

Aaron: I believe you are mistaken when you say CNS is "just an different choice of measure". The basic testable assertion CNS makes is that you Aaron cannot show us a continuous deformation of the parameters—a path in parameter space starting at the observed values—with a monotone increase in BH abundance along that path. If you CAN find a small continuous change in the parameters which steadily increases BH abundance then congratulations, show it to us and I will say you have refuted CNS. It's that simple.

To talk Bayesian priors and conditional probability is to unnecessarily force the CNS conjecture into a Bayesian framework, at considerable risk of obfuscation. I have been familiar with Bayesian methods for several decades—a good (statistician, decision theorist, etc.) friend of ours has been a Bayesian at least since the 1960s. The current buzz among physicists does not enthuse me. I think I understand some of the appeal to string theorists in their present plight, and why Bayesian methods look especially good. But I think it is unnecessary complication to put everything into that framework. The initial choice of prior and calculating conditional probabilities are often a bit dubious.

Your comment about "just a different measure" was so brief, Aaron, that I could not be sure whether you were referring to the current Bayes buzz or something else. If it was something else, please clarify.

15. **Aaron Bergman**
February 14, 2006

The basic testable assertion CNS makes is that you Aaron cannot show us a continuous deformation of the parameters—a path in parameter space starting at the observed values—with a monotone increase in BH abundance along that path

No, it doesn't. CNS is just a mechanism saying that there are more universes with black holes than universes without black holes. In other words, the measure is highly peaked around those universes that tend to produce lots of black holes. If you believe in that sort of statistics, then the best you can say is that it is *likely* that we live near the peak of this distribution. This is exactly the same as people putting other measures on the space of possible vacua/theories. It just so happens that this measure has a peak (assumedly.) One would think that eternal inflation, for example, might produce a similar phenomenon. More so, if you do want to do that sort of statistics, you have to look at the conditional probability based on the fact that we exist. Now, as I understand Smolin's argument, this probably isn't a big effect for his assumed distribution, but the principles involved are precisely the same.

16. **Who**
February 14, 2006

The basic testable assertion CNS makes is that you Aaron cannot show us a continuous deformation of the parameters—a path in parameter space starting at the observed values—with a monotone increase in BH abundance along that path

here I am paraphrasing what Smolin gave as the basic testable assertion of CNS in his most recent paper about it. Please see the italicized statement at the bottom of page 29 of his paper
http://arxiv.org/hep-th/0407213
Scientific Alternatives to the Antropic Principle.
this is the bulleted statement of the CNS hypothesis in section labeled "5.2 Natural Selection"

If you will pardon me for saying so, Aaron, you seem confused about what is the basic testable assertion of CNS. I would urge you to carefully read section 5.2 of that paper. Don't rely on what you may have HEARD people say that CNS asserts—read a firsthand source.

I must be brief, not wanting to overemphasize CNS. Perhaps we could discuss this at Physicsforums where we would not be abusing Peter's hospitality if we spoke at length.
———————————-

Peter, I stress that ANY directly falsifiable hypothesis bearing on why the dimensionless parameters of the standard model and cosmology are what they are is of interest. What I want is something like "Statement S" in section 5.2 of Smolin's paper in that it is brief and clearly falsifiable, but it doesn't have to be CNS. It would be great to have several alternative testable explanations.

Even though I am good friends with a reputable Bayesian probabilist, I must say that the current Bayes buzz in physics strikes me as a sign of sickness. Smokescreen and distraction while they get anthropics and the Landscape in through the back door. Just my opinion.

17. **Aaron Bergman**
February 14, 2006

If you will pardon me for saying so, Aaron, you seem confused about what is the basic testable assertion of CNS

No, I'm really not. Smolin is precisely saying that the distribution (ie, measure) on the 'multiverse' is strongly peaked. That's all. Look on page 29. It is no more or less testable than any other peaked measure on the space of vacua (or non-peaked — frankly, I find the whole idea of any measure at all being testable rather distasteful.)

18. **Who**
February 14, 2006

thanks for your reply Aaron. I will not say more about our difference of opinion in this thread, out of consideration for Peter.

19. **Aaron Bergman**
February 14, 2006

It might be worthwhile to elaborate how CNS does not obviate anthropic considerations. Imagine a situation, for the sake of arguments, where the number of black holes — or whatever universe creation mechanism you prefer — does not lead to universes particular suited for life. This does not preclude the existence of life, however; even in a fitness landscape such as Smolin imagines, there is percolation away from the peaks. Eventually, there will exist universes in which life is possible. So, in this situation how would one 'predict' the probability distribution of various parameters? You would condition your distribution on the existence of life. This is exactly what the anthropic types do. That Smolin has chosen a mechanism to get a highly peaked prior distribution isn't particularly relevant towards this point in principle, although the particular distribution Smolin argues for may render the anthropic correction minor.

20. **woit**
February 14, 2006

Aaron,

Please, Who is right, enough about CNS unless there really is something new to be said on the subject. This has been discussed at great length already in other postings as well as in this one.

21. **Aaron Bergman**
February 14, 2006

Actually, given that "Who" posts this stuff on CNS every single time anyone mentions the anthropic principle, I don't think anyone has said this in his presence. I finally got annoyed enough to post it.

But I'll stop now.

22. **Who**
February 14, 2006

on an off topic thing: an essay by Halvorson on Algebraic QFT was just posted
http://arxiv.org/abs/math-ph/0602036
Algebraic Quantum Field Theory
Hans Halvorson, Michael Mueger
202 pages; to appear in Handbook of the Philosophy of Physics (North Holland)

"Algebraic quantum field theory provides a general, mathematically precise description of the structure of quantum field theories, and then draws out consequences of this structure by means of various mathematical tools — the theory of operator algebras, category theory, etc.. Given the rigor and generality of AQFT, it is a particularly apt tool for studying the foundations of QFT. This paper is a survey of AQFT, with an orientation towards foundational topics. In addition to covering the basics of the theory, we discuss issues related to nonlocality, the particle concept, the field concept, and inequivalent representations. We also provide a detailed account of the analysis of superselection rules by S. Doplicher, R. Haag, and J. E. Roberts (DHR); and we give an alternative proof of Doplicher and Roberts' reconstruction of fields and gauge group from the category of physical representations of the observable algebra. The latter is based on unpublished ideas due to Roberts and the abstract duality theorem for symmetric tensor *-categories, a self-contained proof of which is given in the appendix."

I expect Peter would in any case find and report this at his convenience, but it seems like happy news so I take the liberty of noting it.
Halvorson's essay is a contribution to the same Butterfield and Earman Handbook that Ellis essay is in!

23. **urs**
February 15, 2006

> Given the rigor and generality of AQFT

No doubt about its rigor, but on the generality side something seems to be missing in AQFT. There is as yet not a single *physically* interesting QFT which would be describeable by AQFT.

While it is to be expected that sometime in the future QFT will be cast in a mathematical form of the sort envisioned in AQFT, it seems that something crucial is missing.

(For instance the locality condition in AQFT seems to be too strict, precluding field commutators as they appear in gauge theory.)

In our math seminars we have AQFT people sitting together with those working on the FRS description of 2D QFT. This is also rigorous, but it does describe physically interesting interacting theories. But amusingly, nobody knows how these two approaches are related.

> and we give an alternative proof of Doplicher and Roberts' reconstruction

In case anyone is interested, I had mentioned Michael Müger's talk on his new proof of Doplicher-Roberts here.

New Frontiers in Scientific Communication

February 14, 2006
Categories: Uncategorized

The last couple days have seen a new phenomenon, which may or may not be some sort of sign of the times. Two different papers appearing on the arXiv contain references to blog postings:

1. In last night's Cosmological Constant Seesaw in Quantum Cosmology by Michael McGuigan, the first two references are to blog postings by Lubos Motl and Sean Carroll.

2. A revised version of a paper by Alicki et. al. appeared over the weekend. The comment section of the arXiv posting notes that the paper has been revised and expanded in response to comments about it made here and here at Dave Bacon's blog The Quantum Pontiff (where he has a posting about this entitled Arxiv Links to Pontiff, Science at an End?).

Not clear to me what this means. Will it mean the end of science? Will SPIRES add blog entries that are referenced in papers to its database? Will they start counting blog references as well as standard citations, allowing you to search for not just "Topcite" papers, but "Topblog" ones too? Will authors of new papers start regularly getting testy e-mails from blog authors complaining that they haven't referenced their blog postings?

Comments

1. **Aaron Bergman**
   February 14, 2006

   In last night's Cosmological Constant Seesaw in Quantum Cosmology by Michael McGuigan, the first two references are to blog postings by Lubos Motl and Sean Carroll.

   Of course, the idea of a seesaw for the cosmological constant goes back well beyond Lubos's post and that comment thread. I'm not sure exactly what the origin is, but I'm sure someone's informed the author in e-mail by now.

2. **ObsessiveMathsFreak**
   February 14, 2006

   Web references of any kind are a bad idea in any paper, simply because of the volitile nature of the web. How can libraries possibly index and record web references for future study? No web page is going to be around forever, and I'd rather not rely on the WaybackMachine while I'm reading papers.

   A web reference is dodgy at best. Think of those poor future generations.

3. **sunderpeeche**
   February 14, 2006

   The first thought that sprang to mind was essentially the same as that pointed out by ObsessiveMathFreak. There is (perhaps) some degree of permanence to the arXiv, and papers are now regularly published with citations to arXiv papers as well as refereed journal papers. But a citation to a blog posting? What if a post is deleted, either deliberately or accidentally? Both type of events have happened on this blog. Journals strongly dislike references to papers "to be published". The paper in question may be rejected (or not submitted, or revised to say something entirely different, etc.).

4. **Jean-Paul**
   February 14, 2006

   What's the big deal? Published papers always contained references to "private communications". Instead of a link, the authors should simply refer to the name of the commenter, so if you want to get credit, use your real name when posting critical comments.

5. **Alejandro RIvero**
   February 14, 2006

   Hmm yep probably they are closer to private communications (even if public) that to academic papers. Historians of Science can track private communications when perusing private archives, and here there are the additional possibility of caches and waybacks machines (archive.org). It is a sort of "private communication, scratched at Exotic Cafe pub" footnote.Now, if one is interested not in credit but in the argument, one can always email to the author and to the quoted author, as it happens in the case of private comm footnotes.

   I met with a similar problem when I found a citation to a wiki page done in Phys. Rev. D 73, 013009 (2006), and just the same week it appeared I was planning to erase such page!!. Of course it was my fault, because I first quoted it myself in an Arxiv preprint. Worse, what if the whole domain is discontinued when my two years lease expires?

6. **Mark Trodden**
   February 14, 2006

   An author who sees an idea discussed on a blog should do some research to find out the history of the idea and trace it back to a paper if possible. As Aaron points out, this is certainly possible in this case.

7. **Dumb Biologist**
   February 14, 2006

   I'm with Aaron, and I'd say further it's just a damn lazy practice, in my opinion. I don't cite "private conversations" or anything not already subjected to peer review (which I acknowledge to be flawed, but still…). I detest that sort of thing the same way I detest "data not shown". If a private conversation is so critical it deserves mention, then subject the contents of that thought process to peer review itself, in the form of a rapid communication (or equivalent) so that it can itself be cited by other investigators.

8. **sunderpeeche**
   February 14, 2006

   Re: Jean-Paul. For private communications, the permission of the source of the communication is required. There has been personal contact between the author and source (possibly via email, not face-to-face). One cannot, for example, simply cite a hearsay conversation that one has overheard. With a blog entry one can cite any post without contacting the author of that post. There is no implicit assurance of quality control.

9. **Sean**
February 14, 2006

The idea had certainly been talked about long before those blog entries. Still, it's possible that something said on a blog could start you thinking about some idea. Might be more appropriate for the acknowledgments than for the references.

10. **Quantoken**
February 14, 2006

A communication is a communication of ideas and information regardless of what form it takes: Is it by means of print on dead trees, or by exchange of electrons.

And credibility of a piece does NOT attribute to the physical communication channel, but rather attribute to its source: the person from which the piece was originated. When you catch an idea from a person, whether from a paper you read, or from a private conversation in the hallway, you pay the same amount of attention and the idea is equally credible if you think the person is credible.

The only trouble is private conversations and blog posts are not consistently and systematically **archieved** for **easy retrival**. But so troubled are many academic publications. They are archived fine, but retrival is not easy: You need to spend a considerable amount of time making a trip to the school or city library search for it, and then spend money to make photocopies. And then after a while the photocopies got lost. If you are in an institution they do provide "free" instant online access to all the publications. But it's not actually free at all: you institution pays a pretty hefty sum of money for the priviledge. And for outsider, you have to pay $30 each time just for a one week online access to one article of no more than 4 pages.

That's exactly why ARXIV is becoming so popular because it serves both proper archiving and free and easy retrival. But blogs are becoming even more popular because it provides more freedom with less censorship. I am sure proper web tools are being developed so web postings are properly archived for easy retrival when they are being referenced. The only short coming is that academies do not get proper credit for their web postings when it comes time for tenureship consideration. But that can change, too. I am just not sure whether that will actually help or hurt Lubos.

Quantoken

11. **ksh95**
February 14, 2006

Dumb Biologist says:
…it's just a damn lazy practice, in my opinion. I don't cite "private conversations" or anything not already subjected to peer review…

In physics, private communications are a critical part of research. Many an hour is spent at the tail end of a talk or in a collegue's office discussing fine points of a certain idea.

When some one provides a critical insight to some problem it's only fair to somehow acknowledge that person. It's also rude to demand that the insight-providing person spend their valuable time writting a rapic communication.

Now, the appropriate place for an acknowledgement is an exercise left to the reader.

12. **sunderpeeche**
February 14, 2006

"That's exactly why ARXIV is becoming so popular because it serves both proper archiving and free and easy retrival." Indeed yes.

"But blogs are becoming even more popular because it provides more freedom with less censorship." This gets into the murky area of what constitutes quality control and censorship. I submit a paper to a peer-review journal, and it is rejected. Am I being censored? I can (a) rebut the referee arguments (b) submit to another journal (c) post it online (arxiv, blog) or even (d) start my own blog (if other managers delete my posts). I am no longer censored. Is my work of any scientific value? Who can say?

Do not be upset then if string theorists post zillions of papers many (all?) of which may lack scientific value.

13. **Dumb Biologist**
February 14, 2006

Well, benchmonkey biology is certainly a lot different than theoretical physics, I'm sure, but it's not like we don't talk. Sort of along the lines of what Sean said above, I might choose to acknowledge a person whose guidance I felt merited special mention. I might just make the person an author if the contribution was big enough. In either case, everything important about that communication would be contained within the body of the manuscript, where it is readily accessible to the referees and the readers, and attains a level of acceptable review and permance for future citation. I would *not* refer to that content in a citation to, as those above have pointed out, a personal exchange in a highly volatile medium (unrecorded sound waves, blogosphere, I don't care). Nor would I, again, as Aaron points out, let the contents of a conversation stand alone without first making some critical citation of the referencible origins of those thoughts, which, again, can be perused by the reader and referees. It's certainly rude to add, as a citiation, something essentially along the lines of "Joe Blow, PhD sez X, Y, and Z in an email" when J.B. might have cribbed the idea (even inadvertantly) from someone else who took the trouble to submit it to a journal.

14. **anon**
February 14, 2006

"someone else who took the trouble to submit it to a journal."

That person may have cribbed it from an outsider who was suppressed by the journal

15. **Hal**
February 14, 2006

Everyone who publishes on the web should be familiar with Tim Berners-Lee's (the "father of the web") article, "Cool URIs Don't Change", http://www.w3.org/Provider/Style/URI .

Berners-Lee argues forcefully that authors and publishers should leave URIs alone, because the public may be referring to them. Rearranging your web site is not like rearranging your furniture. It's more like changing the road layout in a city. People are dependent on those old addresses still working. There are serious negative externalities to changing URLs. It's as bad in its own way as dumping pollutants in a river – easy and convenient for you, but harmful to the general public.

As for domain names, with costs of ten bucks per year, everyone who publishes should be able to afford one. Let's suppose Peter Woit moves to another institution than Columbia. Suddenly http://www.math.columbia.edu/~woit/wordpress/ won't even be wrong, it'll be dead. This could be avoided if he spent the cost of two Starbucks lattes on http://www.notevenwrong.com and redirected it to his academic URL. Then when he moves, he could change the redirection and everything will still work, all the old links will still be OK.

People think of blogs as just personal hobbies, for their own entertainment. But blogs like this benefit from public feedback and public interest. In exchange for those benefits, blog authors and other web publishers should understand and accept the obligation to become good citizens of the web. A major part of that is insuring that their links will still work in the future.

16. **woit**
February 14, 2006

I've thought a bit about the question of how to keep the content of this blog readily available for as long as possible in the future, including whether I should move to a commercial hosting service and/or get my own domain name (I do own and operate a private webserver and domain name for use by my mother, who is an artist). One problem with a private domain name is that it would soon disappear if I get run over by a bus or am otherwise no longer around. On the other hand, Columbia has been around for about 250 years, should definitely outlast me, and has as part of its mission the preservation and transmission of knowledge. Not clear how long http://www.math.columbia.edu will continue to point somewhere useful, but as long as it does, if I haven't been run over by the bus I believe that I should be able to get someone to configure http://www.math.columbia.edu so that ~woit/wordpress points to wherever the blog material is. If I'm not around, and people think this material is worth preserving, this address is as likely as any to be one that is up and could be configured to point to the right place.

But in general it is certainly a good idea to keep in mind that blog content may be ephemeral. Things of lasting importance should be written up and archived in a form more likely to survive.

17. **anon**
February 14, 2006

'As for domain names, with costs of ten bucks per year, everyone who publishes should be able to afford one.'

Then it gets deleted when the person dies. Some ideas have to stick around longer than 75 years for anybody to pay attention. Aristarchus' solar system of 250 BC was ignored until 1500 AD. What if the internet had been around in 250 BC and Aristarchus bought a domain name instead of writing on parchment?

18. **Quantoken**
February 14, 2006

Hal:

Funny you meantioned that Peter should put his stuff on http://www.notevenwrong.com. It says "this domain is for sale" and I guess it probably cost Peter more than two Starbucks lattes to buy it

There is URL re-direct and I just don't know how it works. Preferably it should be the responsibility of the author of a paper to always maintain a valid URL link or an archived copy of all the references he/she made. If your paper references something, the readers of your paper expect to be about to find the material that you referenced to, and verify by themselves that you have not mis-represented the original material. What's the point of referencing something that no one else can see? (e.g., references like this kind: "For details please look for an un-published and none-exist paper by such and such.") References are much more than mere acknowledgement of credits of other people's work.

Doing so is actually much easier than you thought! Technology already exist and in wide use for things like that. For example various file swapping networks that account for more than 90% of all internet traffic today. How do people get what they want from the web, without even knowing a URL where it is available? Easy, everying is referenced by a MD5 checksum. You just tell the computer the MD5 checksum of the thing you are looking for, and the internet takes care of the rest.

Same thing can be done with online publishing of academic papers. You reference a paper and attach a hidden MD5 checksum of that paper, and make sure a copy of that paper is already available online. And people can instantly gain access and obtain a copy of the exact paper, without you even need to provide a URL. I envision a tool to do all these automatically so adding a paper reference for the author or access a reference for the reader is as easy as one mouse click. That would be real nice. The only problem would be copyright. But then if all authors are willing to copyleft their papers so more users can access them (who doesn't want that), then that's not a problem.

Quantoken

19. **woit**
February 14, 2006

Quantoken,

Your capability of spreading misinformation and nonsense on a wide variety of topics is truly impressive, please stop. And please, other people, don't encourage him.

20. **Dumb Biologist**
February 14, 2006

I agree unjust suppression and other forms of blacklisting can be a problem, but "anything goes" sounds a lot worse to me. Peer review can fail in a number of troubling ways, no question (the whole fictional-cloned-human-ESC catastrophe being exhibit A, in my mind), but the alternatives are probably too chaotic to be workable. Better to make minor corrective adjustments than abandon a largely working system, IMHO.

21. **Quantoken**
February 14, 2006

Peter:

Please enlighten me (and others) **exactly** which part of what I said is mis-information and nonsense. I am all ears to enjoy. Otherwise you are making un-founded and un-supported accusations. Especially it now looks like whatever you can't agree with or whatever you simply don't know about, you automatically call it nonsense. I happen to be an industry expert on online content delivery, mind you.

Quantoken

22. **woit**
February 14, 2006

Quantoken,

I'm extremely busy these days, and the last thing I in the world I have time to do is to discuss with you why your proposals are unrealistic, especially since these are about a topic different than the one I was posting about. I have had a lot of complaints from readers of this blog that allowing comments by you and several other people that shed no light at all on the topics under discussion causes people who do have something relevant to say not to want to participate here. I'll delete any further comments from you or from anyone else about distributing web content. Take them elsewhere.

23. **lurker**
February 14, 2006

don't censor quantoken! his posts are the funniest on the web. I love it when he puts stuff in **bold**.

24. **D R Lunsford**
February 14, 2006

I wrote a paper showing that CC was zero, and why.

No one is interested in results.

February 15, 2006

"An author who sees an idea discussed on a blog should do some research to find out the history of the idea and trace it back to a paper if possible. As Aaron points out, this is certainly possible in this case. "

Really? How? I tried both hep-th and spires and only got this paper!

26. **Juan R.**
February 15, 2006

No, it will not mean the end of science.

In general, Blog entries that are referenced in papers will be not added to scientific databases. I see difficult "they start counting blog references as well as standard citations"

The blogger phenomenom is very related to usual referencial structure of communities as physics or even mathematics. There is not blooger similar phenomenon in chemistry, for example.

It is more, whereas the fragility and open nature of ArXiV and similar repositories are very adequate for physics science, it is very inadequate for the requirements of chemical science, for example.

This is reason that ACS has not launched a chemical ArXiV still. And it is the reason that project for a chemical "ArXiV" (the CPS) was abandoned some years ago.

Howerver, we will see changes in current publication policies in most of disciplines in next few years.

—

Juan R.

Center for CANONICAL |SCIENCE)

allowing you to search for not just "Topcite" papers, but "Topblog" ones too? Will authors of new papers start regularly getting testy e-mails from blog authors complaining that they haven't referenced their blog postings?

27. **ksh95**
February 15, 2006

Really? How? I tried both hep-th and spires and only got this paper!

Wow, is this what we've come to??? You do realize that your local university library has 10^500 distinct ways to perform literature searches.

28. **anon**
February 15, 2006

"The comment section of the arXiv posting notes that the paper has been revised and expanded in responsed to comments about…"

You need to delete the "d" from the end of the new word "responsed" in this post, Peter, it looks careless.

But don't worry, a technical journal I write for published an opinion piece spread over several pages, each headed "Personnel View". When people wrote in to say it should be "Personal View", the editor replied that word check didn't find a fault, so that was to blame…

29. **Carl Brannen**
February 15, 2006

As an example of a website whose author died unexpectedly, but which remains as a source on the web, there is the expert on Clifford Algebra, Pertti Lounesto. His website is still maintained some 4 years later:

http://users.tkk.fi/~ppuska/mirror/Lounesto/

30. **Eli Rabett**
February 16, 2006

I have thought about the issue a bit. It seems to me that the answer is to require authors to submit images of the pages they reference as suplemental materials. For paper journals this could be done on CD (or uploaded to a CD archive) which would be available to interested users although perhaps not on line (e.g. you would have to contact the journal and they would send you the files by Email)

31. **Bill Tozier**
    February 16, 2006

    I recently started a "transmissible questionnaire" that asked folks to look themselves up on Google Book Search.

    One of the things I note is Cosma Shalizi's references in books. Several of which are references to his blog, or to his ur-blog, the *Bactra Review*, or to his Notebooks. Including footnotes, and other references.

    In books.

32. **Thomas Larsson**
    February 16, 2006

    (e.g. you would have to contact the journal and they would send you the files by Email)

    What if the publisher has gone out of business?

33. **anon**
    February 17, 2006

    Bertrand Russell once had a nightmare about the future, where he saw librarians burning old books (including his own) to make shelf space for new ones. Civilisation may collapse, so it is pointless to go to too much trouble if it all ends up destroyed.

34. **Alejandro Rivero**
    February 17, 2006

    The ArXiV is mirrored in all the continents, about a dozen copies. Same of the printed copies of main journals. On the pessimistic side, the extant content of the Alexandrian Library can be compressed into one CD. Of course this is a motivation for "reason-in-march", any physicst should be able to rebuilt the whole theory up to QFT from scratch 🙂

    As for webpages, well a suggestion is to quote the date when the page was consulted. Sort of telling the date of a letter when quoting a letter.

35. **anon**
    February 18, 2006

    'I wrote a paper showing that CC was zero, and why. No one is interested in results.' – drl

    Have you seen Penrose's new cosmological theory? See http://news.bbc.co.uk/1/hi/programmes/hardtalk/4631138.stm

    He argues for an endless sequence of big bangs, but without gravitational collapse. As far as I can make out, if he is right, as soon as the last proton decays the universe will lose all measure of time, and hence spacetime will end, so the universe will become a new singularity leading to a fresh big bang. He says it does have testable predictions, and he didn't mention CC.

36. **Chris Oakley**
    February 18, 2006

    Re: Roger Penrose – The interview reminds me of the following, (from Douglas Adams):

    "There is a theory which states that if ever anyone discovers exactly what the Universe is for and why it is here, it will instantly disappear and be replaced by something even more bizarre and inexplicable."

    [and on the following page]

    "There is another theory which states that this has already happened."

    Penrose seems to be saying that this happens in a continuous cycle.

    I suppose that Susskind, Hawking, Weinberg, et al would regard him as a stick-in-the-mud traditionalist as he also proposes ways in which his idea can be tested.

Fields Medal for Terence Tao?

February 15, 2006
Categories: Uncategorized

Lubos Motl has a posting announcing that Terence Tao will be one of the 2006 Fields Medalists. The announcement of the Fields medals is officially made at the time of the International Congress of Mathematicians, which this year will be in Madrid in August. A few months before the Congress generally there are solid rumors circulating in the math community about who the winners will be. If Lubos is right (and while I don't know his source, this agrees with earlier speculation), the blogosphere will be responsible for a much earlier spread of rumors about this than usual.

Update: Lubos's posting just disappeared. So, maybe this rumor is not right, or maybe it is, but whoever he got it from didn't want it spread so publicly. His posting has been replaced with the comment "I removed information about a certain medal that was far too preliminary."

Comments

1. **Quantoken**
   February 15, 2006

   Not surprising. I guess Yau would definitely be the first one to know who wins, if he is not one of those who decides. And Lubos would learn that quickly due to proximity to Yau's office.

   His Fields winning proof can be found here. I can only understand the first few pages. What interests me is conjecture 2.2, which is awesomely simple and is a much more general statement that can automatically lead to what he is trying to prove. He did not attempt to prove that conjecture. Has any one attempted at that conjecture?

   It's simply stated as that as long as an infinite sequence of integers {ai} satisfy sum(1/ai) = infinity, then it follows that within {ai} you can always find infinite collections of progressive sequences of any arbitrary length, i.e., sequences where all elements bi can be found within {ai}, and bi = p + q*i, 0

2. **anon**
   February 15, 2006

   I followed Quantoken's link above to the Field's medal paper on arxiv.org, and it is 56 pages of beautifully written text and maths. I like the historical introduction, and the way that the various components are described in detail first, instead of referring the reader somewhere else. It's the kind of helpful paper that encourages people who find pure maths a real headache (like me).

   Congratulations to Terence Tao, whether he has won or not! To me what is even more interesting than his childhood story is where he discusses his way of working in an understandable way. See

   http://www.college.ucla.edu/news/05/terencetaomath.html –

   How does Tao describe his success?

   "I don't have any magical ability," he said. "I look at a problem, and it looks something like one I've already done; I think maybe the idea that worked before will work here. When nothing's working out; then I think of a small trick that makes it a little better, but still is not quite right. I play with the problem, and after a while, I figure out what's going on.

   "Most mathematicians faced with a problem, will try to solve the problem directly. Even if they get it, they might not understand exactly what they did. Before I work out any details, I work on the strategy. Once I have a strategy, a very complicated problem can split up into a lot of mini-problems. I've never really been satisfied with just solving the problem; I want to see what happens if I make some changes.

   "If I experiment enough, I get a deeper understanding," said Tao, whose work is supported by the David and Lucille Packard Foundation. "After a while, when something similar comes along, I get an idea of what works and what doesn't work.

   "It's not about being smart or even fast," Tao added. "It's like climbing a cliff; if you're very strong and quick and have a lot of rope, it helps, but you need to devise a good route to get up there. Doing calculations quickly and knowing a lot of facts are like a rock climber with strength, quickness and good tools; you still need a plan – that's the hard part – and you have to see the bigger picture."

   His views about mathematics have changed over the years.

   "When I was a kid, I had a romanticized notion of mathematics — that hard problems were solved in Eureka moments of inspiration," he said. "With me, it's always, 'let's try this that gets me part of the way. Or, that doesn't work, so now let's try this. Oh, there's a little shortcut here.'

   "You work on it long enough and you happen to make progress towards a hard problem by a back door at some point. At the end, it's usually, 'oh, I've solved the problem.'"

   Tao concentrates on one math problem at a time, but keeps a couple of dozen others in the back of his mind, "hoping one day I'll figure out a way to solve them. If there's a problem that looks like I should be able to solve it but I can't, that gnaws at me."

3. **mathjunkie**
   February 16, 2006

   Glad to know that Tao, a Chinese mathematician (correct me if I am wrong), has got a very good chance to win the Fields medal. He will be the second Chinese winning the Fields medal after Yau if he will make it. Tao is modest about his math ability in his speaking. But why are his works important? Somtimes, I don't know why mathematicians like to solve mathematical problems that seem to have little relevance/applications to our daily life.

4. **MathPhys**
   February 16, 2006

   Tao is Australian, probably of Chinese descent, but Australian. I doubt if he finds all this talk about his future Fields medal entertaining.

5. **David MacIver**

February 16, 2006

mathjunkie, I'd suggest that relevance or applications to our lives isn't really a good metric to use for mathematical problems. Or indeed most problems in academia. I mean, suppose tomorrow some bright spark has an 'ah ha!' moment and formulates a complete and consistent theory of everything. Will this help me build a better mousetrap?

Sure, in twenty, thirty year's time the theory might lead to the invention of the quantum frambotzulator, revolutionising the frambotz industry and profoundly changing all our lives. But is that really why we want a theory of everything? Wouldn't it be just as interesting without the frambotzulator?

Of course it would. We don't want a theory of everything because of the technology it might lead to, we want a theory of everything because it's cool and interesting.

You can justify physics by applications to engineering, and mathematics by applications to physics, other practical subjects, etc. but frankly doing so is missing the point. Tao's work will probably never see a useful application, but this doesn't make it any less cool and important.

There's a great quote which is attributed to Feynmann: "Physics is like sex. Sure it has a useful purpose, but that's not why we do it." The same is true of mathematics.

6. **ObsessiveMathsFreak**
February 16, 2006

> It's simply stated as that as long as an infinite sequence of integers {ai} satisfy sum(1/ai) = infinity, then it follows that within {ai} you can always find infinite collections of progressive sequences of any arbitrary length, i.e., sequences where all elements bi can be found within {ai}, and bi = p + q*i, 0

I know of at least one sequence that satisfies this relationship, namely the integers. The harmonic sequence of 1/1 + 1/2 + 1/3….. has no upper bound. And of course in the integers, you can find an infiite amount of progressive sequences if you play with the p's and q's.

7. **sunderpeeche**
February 16, 2006

Lubos had a post reporting a rumor. Later the post was deleted. The post here is a reference to a (now deleted) post of a rumor.

"So, maybe this rumor is not right, or maybe it is, …"
Ugh. The post here should be deleted in its entirety.

If there are "reliable sources" (~ earlier speculations), then cite the credible sources.

8. **Dick Thompson**
February 16, 2006

sunderpeeche, I don't agree, for this reason. The comments on the post have occasioneed some very interesting mathematical discussions. This is quite diffferent from just retailing rumors that "Enquiring Minds Want to Know". 🙂

9. **woit**
February 16, 2006

I wasn't sure whether to leave this post up or not, but don't see a good reason not to. It's true that Terry Tao might not be amused by all this, but if so, I fear that's the price of fame. If and when he does get a Fields medal, he'll have to learn to contend with the massive media attention and the women throwing themselves at him. The Fields medal committee may not be happy if this is a genuine leak, but then it's their own fault for having members who blab to Lubos.

In general I feel that rumor-mongering (when done with scrupulous accuracy), is a fine thing to do on a blog like this. Unfortunately I normally feel constrained not to repeat interesting rumors here, because it almost always would be too obvious to many people who my source was, and said source would not be pleased (and would stop repeating juicy rumors to me). This case is kind of different, Lubos did make a public announcement….

10. **Zelah**
February 16, 2006

11. **Ark**
February 16, 2006

In reference to David MacIver's comment that "Tao's work will probably never see a useful application, but this doesn't make it any less cool and important." I would like to say that this prediction is entirely incorrect. Indeed, please look at Notices of AMS (February 2001) pages 175-186 where you will find a paper by Tao and Knutson for which they both got a mathematics prize already. But, in addition what they are saying this this paper is immediately useful in theory of quantum computation, e.g. see Ann. Phys. 315 (2005) 80-122, and soon will find its rightful place in string theory…

12. **anon**
February 16, 2006

> Ark said:
> ", and will find its rightful place in string theory"
>
> Ark, you should write for John Stewart, or The Onion

13. **Ark**
February 16, 2006

Annon, can you be a bit more specific: who are these people and why do you think that I have to write to them…? especially in connection with string theory?

14. **John Gonsowski**
February 16, 2006

TV Comedian Jon Stewart and spoof website The Onion though I've never seen Stewart's show and only saw The Onion during a web design course. Apparently anon is not a string theory fan though even in that context one has to keep in mind that parts of string theory could stay around and be useful even if string theory is ultimately changed to look a lot like say LQG.

15. **ano nymous**
February 16, 2006

I sort of had the impression that Tao's work has a lot of ingenuity, but doesn't have depth at a level comparable that ingenuity (not counting his work with Knutson).

I tend to think similar things about Mozart's music, too, so the comparison doesn't bother me :). Calling him the Beethoven of math would, though.

(I am willing to be corrected, as I am no authority here.)

16. **ark**
February 16, 2006

John,
thank you for clarifications…I am not fan of the existing string theory formulations as well…Nevertheless, I happen to know how Tao's results can be used in string theory. Normally, good mathematics always find its place in physics.. In fact, I can also see some bioinformatics-type applications of Tao's results as well in near future… Just read the references I've provided…!

17. **David R. MacIver**
February 17, 2006

I knew I should have qualified that statement. 🙂

Ark, I didn't mean Tao's work in general. While I wasn't aware of any specific applications, given what I know about what he does it would seem very unlikely that none of it was applicable (after all, he does harmonic analysis and this is a very useful subject in general). I was referring specifically to the result about arithmetic progressions in the primes, and similar stuff he's done.

18. **zerocold**
February 17, 2006

Ok, the best thing in the world to discriminate the question is to ask Professor Tao. It was what I do with my gmail account my mail was

Dear professor Tao,

Today the blog Not even wrong (http://www.math.columbia.edu/~woit/wordpress/?p=350) has rumored that you won the Fields Medal 2006,

I don't know if you can reply me sincerly but is this notice true?

Thanks for you attention

—
Dr. Piero Giacomelli

His answer arrived this morning:

It's certainly news to me. I actually have no clue who is going to win
the Fields this year.

Terence

—
Terence Tao, Department of Mathematics, UCLA
http://www.math.ucla.edu/~tao
Email: teorth@gmail.com / tao@math.ucla.edu

I belive this closes the question.

zerocold

19. **Troublemaker**
February 17, 2006

zerocold: *I belive this closes the question*.

Not really. He could be, you know, lying.

20. **Anonymous**
February 17, 2006

Well, let's not forget that sometimes the committee awarding the fields medal makes some "political" choices as well; Deligne did his award-winning work in the early seventies, but didn't recieve the fields medal until 1978. The 1974 fields medal went to Bombieri, who would have been over 40 in 1978.

I don't know how old Terence Tao is, but Ben Green is probably not even 30, so he might last another ICM or two…

21. **Anonymous**

February 17, 2006

In the last post, substitute “Bombieri” by “Mumford”.

22. **Adrian H.**
February 17, 2006

Terence Tao grew up in my home town of Adelaide, Australia. He was a famous child prodigy, but is equally famous for being rather shy and retiring. I’m sure there are many in Australia who wish that he had stayed in the country to enhance the country’s mathematics. But he left and we are all rather proud of him. (BTW the level of maths education seems to be slightly higher in Adelaide than in Sydney or Melbourne, and perhaps that contributed to his success in some small way.)

23. **zerocold**
February 17, 2006

Yes he could lying but I cannot see the eventual reason

24. **Zelah**
February 17, 2006

“I sort of had the impression that Tao’s work has a lot of ingenuity, but doesn’t have depth at a level comparable that ingenuity (not counting his work with Knutson”.

An amazing thing for someone who is anonymous to post!
The only mathematician of the twenty century who work was truly abstract and yet got results was Grothendieck! Everyone else, had to ‘localize’ as it were!

An amateur mathematician

25. **Helger Lipmaa**
February 18, 2006

Some of his work has found applications in theoretical computer science. The paper “Gowers Uniformity, Influence of Variables, and PCPs” (Samorodnitsky, Trevisan, http://www.cs.huji.ac.il/~salex/papers/gowers.pdf) at least partially builds up on two papers of Green and Tao. The question of course is whether thereotical computer science itself is an application. 🙂

26. **Luca**
February 19, 2006

Somebody asked about the ICM 2002 proceedings. All the papers are available on the arxiv. One way to find them is to search for “ICM” in the “Journal-ref” entry, or follow the link
http://front.math.ucdavis.edu/search/jr:icm-beijing

At least ten ICM 2006 papers (including Tao’s) have also been posted on the arxiv by the authors.

27. **Zelah**

Yau Survey of Geometric Analysis

February 17, 2006
Categories: Uncategorized

There's a remarkable new paper out from Shing-Tung Yau, entitled Perspectives on Geometric Analysis. Yau is probably the dominant figure in the field of Geometric Analysis in recent years, and in this paper he gives his personal perspective on the field, including many comments on its recent history, where it is now, and where he thinks it is going.

The paper begins with a dedication to Chern, and some personal history of Yau's interactions with him. It includes an outline of the distant and recent history of geometric analysis, mainly by giving names of the mathematicians involved. There are 755 references in the reference section, listing pretty much all the papers that Yau sees as important for one reason or another. This has to be some kind of record for number of references in a paper, especially a paper whose main text is only about 50 pages long.

Yau covers an immense amount of ground, commenting on a very wide variety of topics. This is a paper aimed at those who already know quite a bit about the subject, or who are beginning to learn it and would appreciate recommendations of what they should be reading. It includes very little in the way of expository material aimed at the beginner. There is a long section on "Ricci flow" techniques, which are the topic of a lot of current research and that Yau considers to be "the most spectacular development in the last thirty years." He also has quite a bit to say about "Calabi-Yau" manifolds and their use in physics, commenting that they provide "a good testing ground for analysis, geometry, physics, algebraic geometry, automorphic forms and number theory."

Another expository paper also appeared on the arXiv last night, but one of a very different nature. It's by Ravi Vakil, a young algebraic geometer at Stanford, and it is aimed at explaining how Gromov-Witten theory has been used in recent years to study the moduli space of curves. It includes a lot of expository material about the moduli space of curves, and is designed to be understandable by the non-expert.

Comments

1. **Quantoken**
   February 17, 2006

   Wow, I did not know that **Yau** was actually a fan of **Chiung Yau**'s romantic novels. The poetry he quoted on page 3 was from one of the most popular romantic novels written by **Chiung Yau**, which was also made into movie.
   Curiously it was supposed to be a "she" in the middle of water but Yau made it a "he". Clearly he is dedicating this poetry to his teacher, Chern. Very touching. I would also say that this paper is very readable.

   Quantoken

2. **Joe Zhou**
   February 18, 2006

   Quantoken is a truly confused person. He's spreading misinformation again. Every sentence above is misinformed.

   The poem Yau quoted is ~3000 years old, appearing in the Book of Poem edited by Confucius under the chapter of Winds of Tang.

   The person being sought in this poem is referred to with a gender-neutral third-person pronoun, impossible to translate into English without destroying the poem.

   It's Chiung Yao, not Chiung Yau; no relation here — it's a pen name. In fact the Yao in Chiung Yao is not even a last name. I'll lose quite a bit of esteem for Yau if he quotes from Chiung Yao (eck!)in his paper.

3. **D R Lunsford**
   February 18, 2006

   That is really a wonderful paper! If not for the missing equations of any kind, I might be reading Pauli's encyclopedia article on relativity. However this is exactly what is most needed, a verbal outpouring of mathematical ideas like Klein used to make.

   Readers who may not be familiar should consult "Vorlesung uber die Entwicklung der Mathematik im 19'ten Jahrhundert" for a similar example of mathematical perspective-taking on this advanced level.

   -drl

4. **MathPhys**
   February 18, 2006

   "Vorlesung uber die Entwicklung der Mathematik im 19′ten Jahrhundert"

   is available in English as

   Development of Mathematics in the Nineteenth Century, and published as volume 9 of Robert Hermann's Lie Groups Series.

   It's a great book.

5. **mathjunkie**
   February 18, 2006

   Joe Zhou,

   Hi, just curious about what the Book of Poem edited by Confucius under the chapter of Winds of Tang is in Chinese. (Hope that Peter's weblog can properly display Chinese characters) Thanks.

6. **Quantoken**
   February 18, 2006

   Joe:
   Get real!

There are different ways of translating Chinese names into English. For example Yau himself, it could have been called "Qiu" or "Chiu" using standard mandarin pronunciation. But he prefered his native Cantonese "Yaou", or "Yau". I deliberately used the translation "Chiung **Yau**" for a little bit humor. Too bad you have no sense of humor. It's true it's a 3000 year old poetry, but if it were not for that romantic novel making it widely known, few Chinese even know it, lest along quote it.

7. **Alice**
February 18, 2006

actually, Miss Chiung Yau ever wrote a lyric by adapting that poem from the Book of Poem.. You might feel interested in it. LINK to speical blog (in hinese)–> http://william.cswiz.org/blog/archives/2005-04-10/poem-and-song-part1/

8. **Quantoken**
February 18, 2006

蒹葭蒼蒼，白露為霜。
所謂伊人，在水一方。
遡洄從之，道阻且長；
遡游從之，宛在水中央。

蒹葭凄凄，白露未晞。
所謂伊人，在水之湄。
遡洄從之，道阻且躋；
遡游從之，宛在水中坻。

蒹葭采采，白露未已。
所謂伊人，在水之涘。
遡洄從之，道阻且右；
遡游從之，宛在水中沚。

Yau destroyed the beauty of this ancient Chinese poetry. He should at least give it a taste of ancient-ness, using Shakespear's language style.

9. **mathjunkie**
February 19, 2006

Quantoken,

Thanks for posting the whole poem. I didn't know that you even knew the Chinese language. The Chinese poem is very difficult for me. I can't understand it though I am Chinese.

10. **Lubos Motl**
February 19, 2006

It is actually a Czech poem from 3500 B.C. originally. Let me tell you the original poem in the simplified combined Czech Chinese:

游蒹葭伊蒼，白露為蒹霜。Cestující v tramvaji
水所謂伊人，在水一方伊。mají úsměv na líci,
遡洄遡從之，道阻方且長；když známou znělku zahrají
遡游之從之，宛在水中央。v Hellichově ulici.

蒹葭凄洄凄，白之露未晞。Jemná ruka umělcova
所謂伊游人，之在水之湄。v duši kreslí ideál
遡洄躋從之，道阻人且躋；krásnější než všechna slova,
遡游洄從之，宛在水中坻。a tak je nechám opodál.

蒹葭采阻采，白露水未已。Kde bys hledal v zemi české
所謂中伊人，在中水之涘。krásku ve snu zjevenou?
遡洄從阻之，道游阻且右；Na matfyzu dívky hezké
遡游從阻之，宛在水中沚。nedostaly zelenou.

11. **robert**
February 19, 2006

In less enlightened times it was a commonplace to categorise the Chinese as inscrutable. Is Quantoken having a laugh? Is mathjunkie being facetious? Does ???????; ?? or whatever appear differently on other people's screens? (??>;'?) Is the quantity in brackets a reasonable representation of Charlie Chan? This sequence of posts started out among the more sensible and informative; somehow it was subverted along the way.

12. **Luboš Motl**
February 19, 2006

Dear Robert, you seem to be the only person here who can't read Chinese. Go to your Control Panel / Regional Settings / Languages, and click Install files for East Asian languages. If you don't have Windows, then uninstall your other OS and buy a CD with XP. Otherwise your future is not too bright because the future belongs to China.

13. **Quantoken**
February 19, 2006

Ho ho ho, Lubos:-) You thought no one else here but you knows Czech language? You actually plagiarized your romantic poetry from this Czech web site 🙂

Quantoken

14. **Qui-Quien Hu**
February 19, 2006

and anyway the first line of that Czech poem contains the word
"tramvaji" which means streetcar.
So how can it be from 3500 BC?

15. **worldspace**
February 19, 2006

It's a romantic poem from between 500 BC and 1100 BC in ancient China.

16. **worldspace**
February 19, 2006

Yau wrote a wonderful paper! It's very useful for those who have begun their career in Geometric Analysis.

17. **Luboš Motl**
February 19, 2006

Dear Quantoken, as an internet searcher, you're a superstar. 🙂

Qui-Quien Hu: the electric streetcars were operating in Bohemia long before the Slavs came to the territory. See the history at

http://www.skoda.cz/holding/produkty?catid=11110

2000 years later, Marco Polo actually made his journeys to Asia in order to sell some of these streetcars.

18. **Adrian H.**
February 20, 2006

Back to the Yau paper.

On the first page Yau says that he set Chinese students the problem of a `Jordan curve bounding two surfaces…' He then says that this resulted in an ugly fight at the 60th Anniversary meeting of the Chinese mathematical Society and Professor Wang was forced to resign!

Can anyone throw some light on this extraordinary fracas? What is it about Jordan curves that would cause a professor to resign? What on earth were they fighting about?

(Ah! Academia — such a bucolic environment for seeking the Truth!)

19. **Juan R.**
February 20, 2006

Otherwise your future is not too bright because the future belongs to China.

I thought that future belongs to anyone in China or not.

—

Juan R.

Center for CANONICAL |SCIENCE)

20. **worldspace**
February 20, 2006

Let's focus on "Geometric Analysis". It's really a long one and there are a lot of useful materials. Has anyone read the whole article of Yau's??

21. **Passby**
February 23, 2006

quite funny…

A Variety of Links

February 23, 2006
Categories: Uncategorized

The new Center for the Topology and Quantization of Moduli Spaces (CTQM) at Aarhus University wins my award for the most specialized pure mathematics institute. It will be hosting an opening symposium in a couple weeks featuring several talks that look interesting. If one is going to choose a specialized subject, this is an excellent one. Over the last couple decades the study of the moduli space of curves and of the moduli space of flat connections on a bundle over a surface has led to the discovery of many previously unsuspected relations between different parts of mathematics and between mathematics and physics. The fact that this subject is so fruitful remains somewhat of a mystery, and there is undoubtedly much more to be learned.

The National Academy of Sciences EPP 2010 committee should soon be producing a report with a 15 year plan for the future of high energy physics in the U.S. At the last meeting of the group last month Fermilab director Pier Oddone gave a presentation, focusing on opportunities in neutrino physics, strategy concerning the ILC, and the future of Fermilab.

Last week there was a conference on Particle Physics at the Verge of Discovery at Aspen. Lot of interesting talks on experimental particle physics. For an overview, see the summary talk by Paul Grannis.

The Templeton funded Foundational Questions Institute (FQXi) has announced that it will be publishing its inaugural request for proposals on Monday. This organization is led by Max Tegmark, who will be here at Columbia that day giving a physics department colloquium on From Derision Cosmology to Precision Cosmology. Unfortunately I have to be away that day and will miss the talk although I would have liked to attend it.

Steve Hsu, a physicist with a serious interest in economics, writes:

*You might think science is a weighing machine, with experiments determining which theories survive and which ones perish. Healthy sciences certainly are weighing machines, and the imminence of weighing forces honesty in the voting. However, in particle physics the timescale over which voting is superseded by weighing has become decades — the length of a person's entire scientific career. We will very likely (barring something amazing at the LHC, like the discovery of mini-black holes) have the first generation of string theorists retiring soon with absolutely no experimental tests of their *lifetime* of work. Nevertheless, some have been lavishly rewarded by the academic market for their contributions.*

Scott Aaronson describes his field of computational complexity theory as "quantitative theology", and goes on to note:

Incidentally, it's ironic that some people derisively refer to string theory as "recreational mathematical theology." String theory has to earn the status of mathematical theology — right now it's merely physics! A good place for string theorists to start their theological training is this recent paper by Denef and Douglas.

Lee Smolin is giving a course on background independent quantum theories of gravity at the Perimeter Institute, with the lectures available online.

David Corfield has an interesting posting on research programs in mathematics. It includes links to various things from Ronald Brown including a new paper on Ehresmann's work on groupoids, and his web-page on "Higher Dimensional Group Theory". Among other things worth reading at Brown's site is his account of the origins of Grothendieck's "Pursuing Stacks".

Corfield also points to an excellent list of problems in homotopy theory from Mark Hovey. Hovey starts off with the comment

The biggest problem, in my opinion, is to come up with a specific vision of where homotopy theory should go, analogous to the Weil conjectures in algebraic geometry or the Ravenel conjectures in our field in the late 70s. You can't win the Fields Medal without a Fields Medal-winning problem; Deligne would not be DELIGNE without the Weil conjectures and Mike Hopkins would not be MIKE HOPKINS without the Ravenel conjectures.

I first met Mike Hopkins at a conference in Guanajuato around 1990, and he made a big impression on me. One thing that most impressed me (besides his joking comment that he went into topology because it was a field full of hard-drinking and living guys who got into gun-fights (this last part was a reference to Dennis Sullivan)), was the mathematical ambition he demonstrated. He said that he had up till then made his reputation proving other people's conjectures, but now wanted to start making his own. Mike definitely followed through on this, since a sizable number of Hovey's problems are inspired by him. His talk on elliptic cohomology in Guanajuato was a revelation, and he has over the years continued to work in that area, coming up with dramatic new ways of thinking about the subject.

Update: There is an extensive discussion of the Smolin lectures at Christine Dantas's website.

Comments

1. **Kea**
   February 23, 2006

   Oh, Peter, thank you for the link to Brown's account of *Pursuing Stacks*. I have never before come across this part of the story.

2. **A.J.**
   February 23, 2006

   Hmm… I'm not sure that Hovey needs to worry that outsiders don't care about algebraic topology. It seems pretty clear right now that a lot of future work in algebraic geometry is going to use techniques from algebraic topology. Especially in the theory of moduli spaces. Just look at the way Madsen, Weiss (& Tillman) proved Mumford's conjecture. Or at Teleman & Woodward's proof of the Newstead-Ramanan conjectures. Or have a look at Lurie's thesis: He (and Toen & Vezzosi) are constructing an algebraic geometry where intersection theory always works; to do this, one must mix algebraic topology into the foundations of algebraic geometry.

   Anyways, I don't think the problem is that no one's interested. The problem is that modern algebraic topology (model categories, spectra, etc,..) is difficult to learn. I personally found scheme theory
   easier. The field is still waiting for a Hartshorne to come along and make everything accessible. (Peter May's book is a nice start, but it's doesn't go nearly far enough.)

3. **woit**
   February 24, 2006

   A.J.,

   I think there is a real problem with the perception of homotopy theory (I just spent part of dinner arguing with a colleague about this), and Hovey undoubtedly has encountered it in is career. Mike Hopkins has done a great deal to broaden the scope of homotopy theory and to bring it back into contact with some of the deepest parts of the rest of mathematics. But many mathematicians are not really aware of this work, and one of the main reasons is the one you point out. It's very difficult stuff to learn. A good expository text on the subject could do wonders.

4. **Christine Dantas**
   February 24, 2006

   Dear Peter Woit,

   I have set a space in my blog to discuss Smolin´s lectures in detail, "The Hand of a Master Series". Parts 1 and 2 of the lectures are already being discussed.

   http://christinedantas.blogspot.com/2006/02/hand-of-master-parts-1-and-2.html

   As I have put it, "*Feel free to send your questions, answers, comments, doubts, criticisms, ideas, disscussions and feelings on these lectures*". Students and experts are all invited to
   contribute.

   Thank you very much,
   Christine

5. **Adrian H.**
   February 24, 2006

   "…field full of hard-drinking and living guys who got into gun-fights (this last part was a reference to Dennis Sullivan)),…"

   I've said it before and I'll say it again, there are an awful lot of interesting tid-bits that are being alluded to but where the details are being witheld from us. Will someone fill in this gaping gap?

6. **Christine Dantas**
   February 24, 2006

   Mark Hovey writes in his page:

   > (…) to work on problems that arise externally to algebraic topology but for which the methods of algebraic topology may be helpful.

   Concurrency theory. See the GETCO workshops. E.g.,

   > Recently, ideas and notions from mainstream "geometric" topology and algebraic topology have entered the scene in Concurrency Theory and Distributed Systems Theory (some of them based on older ideas). They have been applied in particular to problems dealing with coordination of multi-processor and distributed systems. Among those are techniques borrowed from algebraic and geometric topology: Simplicial techniques have led to new theoretical bounds for coordination problems. Higher dimensional automata have been modeled as cubical complexes with a partial order reflecting the time flows, and their homotopy properties allow to reason about a system's global behaviour.

7. **woit**
   February 24, 2006

   Adrian,

   For the "hard-drinking and hard-living" details you'll have to ask someone else, but the reference to Sullivan is to the fact that he was shot in the shoulder by gunmen trying to steal his car in Brazil (he had pulled over to the side of the road to take a nap). OK, I don't think he was armed, so "gun-fight" is a bit of an exaggeration….

   Christine,

   Thanks for mentioning the material about the Smolin lectures on your web-site, I'll put in a link on the main page.

8. **Ronnie Brown**
   February 24, 2006

   I see a great motivation for homotopy is that it is related to classification. So I have been led to be interested in the abstract structures underlying homotopy, in order to understand and calculate.

   Also the aesthetic motive leads me to look for arguments which are easy and clear, because they follow a structure, and in order to make sure that I understand them. Not being as clever as many in the field, I need props and guidance, to explain to me, and I hope others also, why something is true, and also where it is going.

   I can't resist advertising here the new revised edition of my old topology book, to be available as `Topology and groupoids', in print and e-version, in a few weeks – see my web site. This is the first step towards a full exposition of `Nonabelian algebraic topology', a bigger job than expected!

   It is amazing that even just double groupoids seem very complicated! They reflect I presume transitions of transitions. This should be useful in ………??

9. **Christine Dantas**
   February 24, 2006

   Dear Peter Woit,

   I appreciate it, thank you!

   Best wishes,
   Christine

10. **Jeff**
    February 24, 2006

    Sir, I'm just an average guy with an infant-like understanding of all of these theories. I found your blog by searching wikipedia for String Theory after hearing someone mention it offhand. Wikipedia had a link to your blog as a critic of string theory. I read your article in American Scientist and I think I understand your criticism. Long

story short, almost everything on your website is over my head, but I was wondering if you could provide me with some resources… book names or articles that might help me to begin to understand what you and your colleagues are discussing.
I am a scholar by no means and will understand if this is below you or a waste of your time. Thank you for any help.

11. **woit**
    February 24, 2006

    Jeff,

    I’ve written a book, coming out this fall, which is intended to be something like what you are looking for. There are lots of books out there, many of which are pretty good, you just have to realize that most of the discussion of string theory is way over-hyped. About the best book about particle physics that I know and that I recommend to people is “The Second Creation” by Crease and Mann. There was a discussion over at Cosmic Variance about popular books, see

    http://cosmicvariance.com/2005/08/24/greatest-popular-science-book

    The two books by Abraham Pais that Clifford Johnson recommends are quite good also.

12. **Kea**
    February 24, 2006

    “It is amazing that even just double groupoids seem very complicated! They reflect I presume transitions of transitions. This should be useful in ………??”

    Some form of relational quantum mechanics! You said it!

13. **Adrian H.**
    February 24, 2006

    Thanks Peter

    The story sounds a bit similar to that of Gareth Evens, the Oxford philosopher of Language. He was shot in Brazil by a street kid, and then, tragically, died of the wound. Evans was quite young at the time.

    Pity —Brazil has a good tradition of serious science and maths, I guess, most notably, Nachbin.

14. **Jeff**
    February 25, 2006

    Thank you for your recommendation, I will have to see if I can find it at the library. I will look for your book when it comes out. Maybe after I read this book, I will stop by here and see if I can better understand what everyone is talking about. Thanks again.

Letter to ArXiv Advisory Board

February 23, 2006
Categories: Uncategorized

After more than three months of effort to try and get an answer about this, I've finally heard officially from the arXiv that trackbacks to my weblog are currently not being allowed by the moderators. I'm sending the following message protesting this to members of the arXiv advisory board.

To the arXiv advisory board:

I was informed two days ago by Jean Poland of the Cornell library that the arXiv moderators will not allow posting of any of the trackbacks to entries in my weblog that I requested more than three months ago. I would like to protest this decision and ask that it be overturned by the arXiv advisory board.

For background on the history of my weblog, my dealings with the arXiv moderators and the arXiv in general over this issue, you can consult the following web-page:

http://www.math.columbia.edu/~woit/arxiv-trackbacks.html

This is a complicated story, and involves a question not of the greatest importance, so you may quite reasonably not want to take the time to get involved in this, but I urge you to consider the two following issues:

1. It has taken me three months of effort to get a simple yes or no answer to the question of whether placement of these links on the arXiv will be allowed. This has wasted a great deal of my time, as well as that of those people who have been kind enough to try and help me get an answer. This is not a professional way of doing business and I urge you to ensure that it not continue to be the way that the arXiv operates.

2. The rejection of all trackback requests by me, requests that refer to postings of very different natures about both mathematics and physics make it clear that the moderators' policy is to not allow any trackbacks to my weblog. I have not been given any reasons for this policy, and can only guess what these reasons are. Given the history outlined in the web-page mentioned above, it seems clear to me that this censorship is primarily driven by the moderators' desire to paint as intellectually illegitimate and suppress commentary that is critical of string/M-theory research. This kind of suppression of dissent, accomplished using arguments that I have not been allowed to see or answer, is scientifically unethical and deserves to be condemned. The arXiv is an exceptionally important resource for the physics and mathematics community, and it is important that it operate according to high standards of scientific ethics.

Best wishes,

Peter Woit
Department of Mathematics
Columbia University
212-854-2642

Update: Sean Carroll's posting about this has finally shaken loose some indication of what argument was used to disallow links to my blog at the arXiv. For details, see the comment section of his posting.

Update: Lubos Motl has really outdone himself with his latest lunatic ranting about this blog. Note that, besides the blogs run by arXiv moderator Jacques Distler, Lubos's is one of only a couple particle theory related blogs that the arXiv moderators allow trackbacks to. That trackbacks to this blog are censored, but allowed to Lubos's (and almost no others not belonging to an arXiv moderator) should be more evidence than anyone needs that there is a serious problem with the arXiv moderation system, and it is due to the string fanaticism of the moderators.

Comments

1. **DSM**
   February 23, 2006

   First: I think the behaviour of the arXiv has been entirely unprofessional throughout this entire process, and I hope that things get quickly resolved in your favour. However, despite the bad blood between you and Lubos, which given what each of you has said about the other by this point is entirely understandable, I think that the following description is unfair:

   This last one [the Reference Frame] is a stew of right-wing, racist and sexist commentary, together with completely fanatical ranting against anyone skeptical about string theory.

   It is unquestionably right-wing, but unless we're to judge trackbacks by the politics of the authors, this is no more relevant than saying that his blog background is blue. I also don't believe his commentary is either racist or sexist, both of which — the former especially — are serious accusations to throw around (I suppose if we define sexism as believing that there are no differences between men and women relevant to their observed behaviours, he's certainly sexist.) One could with equal (in)justice describe you as an antireligious bigot through aggressive and determined misreading.

   He certainly does rant quasi-fanatically against those sceptical of string theory, and I think his over-the-top approach turns a lot of people off, even those who may substantively agree with him on most issues. This may actually be relevant: certainly your tone is usually far more civil than anything Lubos says, so clearly the arXiv can't argue that it's anything but the content of your posts that bothers them.

   I'd stick to the high ground here, which but for such comments I believe is unquestionably yours, and avoid needless detours.

2. **woit**
   February 23, 2006

   DSM,

   You're right, especially about the racism and sexism part, which has nothing to do with what is at issue here. I've edited that page to remove those references.

   You're also right that the fact that Lubos's politics are right-wing is not relevant, however the sort of mindless fanaticism evident in his politics seems to me all of a piece with the mindless fanaticism about string theory. That his political fanaticism is right rather than left wing isn't relevant, that he's a fanatic is.

3. **Michael**

February 24, 2006

Peter, I'm not sure if you're looking for an answer or just trying to pick a fight. If you want an answer, I can help you out: We don't need anyone commenting on string theory papers who hasn't done any research in the area, has been academically dead since the 80s, and invents things such as the off-diagonal SU(2). It simply isn't useful to anyone. Of course, you're free to comment anyway, but it shouldn't come as a surprise that the links to your comments won't be posted on the arxiv. Look, if you want trackbacks, cut a deal with Quantoken.

If you're just picking a fight, well, you have noticed it already: this is going to be one slow and agonizing fight. Certainly for you. Either way, there's no point to your complaining. None. At all.

4. **D R Lunsford**
February 24, 2006

Michael, you are such an ass.

Peter, good luck.

-drl

5. **robert**
February 24, 2006

Not so much ass as asshole; Michael's bitching is so predictable and unproductive, and quite like the reported behavior of ArXiv. There are serious issues at stake here, that have nothing to do with the sniping and sneering that now seems characteristic of forums in which stringy stuff is discussed.

6. **a**
February 24, 2006

It seems that arXiv needs to improve the management of trackbacks. If somebody tried some censorship, at this stage he/she will have realized that it was a stupid idea. People like Michael are doing another similar error: this blog gained a wide audience because Peter has a good point, not thanks to Peter's academical history. Attacking his career will not solve the problem that Peter had the courage to point out.

7. **Chris Oakley**
February 24, 2006

With the attention that this web log gets it seems to me that the ArXiv should be grateful for links from here to there rather than anyone worrying about links going the other way. They should at least take account of the fact that the attacks here are against the ideas and not the people. Not directly, anyway. The same cannot be said of certain physics-politics-ecology-eugenics web logs.

BTW, while we are on the subject of ArXiv – here is a note for Nigel Cook, who I know reads this and whose e-mail does not seem to work:
I have never sent a paper to ArXiv, and so I have no idea whether I am on their blacklist. I have not been attached to a university since 1987. This would be a problem if I did want to submit something. Also problematic is the fact that I think it very, very unlikely that universe (multiverse?) consists of tiny vibrating strings in 10 or 11 dimensions. Not to mention the fact that all the QFT work I have done is in 4 dimensions (3 space, 1 time). Or the fact that I can calculate cross sections which agree with experiment.

8. **nigel**
February 24, 2006

http://arxiv.org/help/endorsement –

'We don't expect you to read the paper in detail, or verify that the work is correct, but you should check that the paper is appropriate for the subject area. You should not endorse the author … if the work is entirely disconnected with current [string theory] work in the area.'

They don't want any really strong evidence of dissent. This filtering means that the arxiv reflects pro-mainstream bias. It sends out a powerful warning message that if you want to be a scientist, don't heckle the mainstream or your work will be deleted.

In 2002 I failed to get a single brief paper about a crazy-looking yet predictive model on to arxiv via my university affiliation (there was no other endorsement needed at that time). In emailed correspondence they told me to go get my own internet site if I wasn't contributing to mainstream [stringy] ideas.

9. **Christine Dantas**
February 24, 2006

Trackbacks open a gate to disputed ideas. The final censorship is always on the hands of the blog´s owner of course. Moderating trackbacks sounds funny. It seems more logic for the arxiv to create their own blog and remove trackbacks from the site.

Good luck.

Christine

10. **axolotl**
February 24, 2006

Well, the whole trackback thing has been a bit of a flop. If they allowed trackbacks from here, then this blog and LM's would dominate! And the administrators probably think that LM is doing enough damage already!

11. **Alejandro RIvero**
February 24, 2006

What is a pity is that this politic of silence is creating a class of "Kremlinnologists" similar to the cold war politic analysts, trying to guess the ArXiv intentions.

I only payed a small visit to the USA the last century, to New York and Austin. My overall impresion was that payed staff (in generic shops, buses &c.) was not motivated to innovate but to follow orders, very impressive for a country where compulsory military service does not exist.

Recently we have noticed an increasing of acceptation in preprint submissions; lets hope that the same will happen with trackbacks. After all, there are a lot less invasive

(they are even listed in a separate window, not in the main abstract presentation)

12. **MRA**
February 24, 2006

    Peter,
    Could you post Jean Poland's entire message?

13. **woit**
February 24, 2006

    MRA,

    I specifically asked Poland whether it was all right to post her e-mail to me, and she asked me not to, so I'll respect her wishes. To summarize her e-mail, it included apologies for how long it had taken to get a response to me, a description of the trackback system as experimental and with policies still under development, and the phrase I quoted about the decision of the moderators.

14. **Sean**
February 24, 2006

    I'm sorry to hear this, Peter. There's obviously no good reason to prevent you from leaving trackbacks, no matter what your opinions about string theory may be. It's disappointing.

15. **Dumb Biologist**
February 24, 2006

    My understanding is the existence of the arXiv system is predicated to some degree on the notion that this method of communicating physics research and other related discourse has supplanted, and is in any rate superior to, the conventional methods of peer review and print media, which presently exist only to siphon grant money away from science to publishers.

    That may be true, and there is no question that, in other fields, even paragons like Science have been deeply wounded by the creakiness of the conventional peer review system. Meanwhile, there's no consensus that it should be completely abandoned, as some standards of authority are highly desireable, if they can be had practically. To that end, greater openness and scrutiny of the review process itself has been suggested, and it appears some journals are moving in that direction.

    Even without any alteration, and with the complete anonymity most referees currently enjoy, they are obliged under the standards of peer review to cogently communicate their reasons for acceptance or rejection of scientific communication. To do otherwise would indeed be completely unethical, and would never stand. I do not think that anyone, in the wake of several recent scandals involving scientific misconduct, is suggesting the system become more closed and inscrutible.

    So, from the perspective of an outsider to physics (but an insider to publishing and reviewing scientific communications), it does seem disturbing that the *de facto* referees of what is apparently the most relevant and prevalent means of communication of physics discourse feel no need whatsoever to explain their actions. I don't want to rush to judgement, as they may have very legitimate practical reasons. They may be swamped with a bombardment of crackpottery, and to explictly reject even the most outlandish communication as such might open a legal can of worms, on top of being a full-time burden.

    It does not appear to my non-expert self, however, that Dr. Woit is a crank. At worst, he's no more of a crank than a fair number of his colleagues, it seems. One need only read the bitter disputes recorded on weblogs between some Stringy and Loopy investigators to see the contempt some professional physicists openly display for one another, and it does not appear that those communications are being supressed by trackback blacklisting. What are the standards being applied here? How is the appearance of impropriety (albeit even to the ignorant) to be avoided? It's not at all clear to me, in this instance, why some justification should not be provided. I'm a taxpayer. Just as the increasingly obvious problems with the standard system of peer review of publically funded science concern me deeply, so also, if the arXiv is a publically-funded resource, does its standards concern me. I think such public curiosity is reason enough to simply provide an explanation.

16. **Chris Oakley**
February 24, 2006

    Dumb (?) Biologist,

    I don't know the answers to all your questions, but I feel I should point out that ArXiv is not a replacement for print journals, it's a replacement for the preprint system. With the latter one would send copies of one's paper to 200+ institutions worldwide at the same time as one submitted it to a journal. It meant that people did not have to wait months to see what you were up to. SLAC keep scans of every preprint they received, a large number of which never ended up in any journal. A side effect of this system was that after the initial mailing one would get a swathe of preprint requests from universities not on the mailing list (I seem to remember getting many from Eastern Europe and Russia).

17. **Dumb Biologist**
February 24, 2006

    OK. My line of questioning was based, to considerable degree, on information provided here:

    http://people.ccmr.cornell.edu/~ginsparg/blurb/

    Especially:

    "It is ordinarily claimed that journals play two intellectual roles: a) to communicate research information, and b) to validate this information for the purpose of job and grant allocation.

    As I've explained, the role of journals as communicators of information has long since been supplanted in certain fields of physics, so let's consider their other role. Having queried a number of colleagues concerning the criteria they use in evaluating job applicants and grant proposals, it turns out that the otherwise unqualified number of published papers is too coarse a criterion and plays essentially no role. Researchers are typically familiar with the research in their own field, and must in any event independently evaluate it together with letters of recommendation from trusted sources. Recent activity levels of candidates were mentioned as a criterion, but that too is independent of publication per se: "hot preprints" on a CV can be as important as any publication.

    So many of us have long been aware that certain physics journals currently play NO role whatsoever for physicists. Their primary role seems to be to provide a revenue stream to publishers, a revenue stream invisibly siphoned from overhead on research contracts through library systems."

    (I hope I'm not violating any fair use standards by quoting the above from this source: http://people.ccmr.cornell.edu/~ginsparg/blurb/pg96unesco.html)

The explicit suggestion is that resources like the arXiv are not just expeditious and inexpensive vehicles for distributing preprints, but that they have rendered at least some physics journals obsolete. Of course my reading may overstate the arXiv's importance, but it does appear that it has indeed assumed a preeminent and independent role as a means of communicating original physics and mathematics literature. Again, I may be reading too much into this, and I don't want to be mistaken in my understanding.

18. **woit**
February 24, 2006

Sean (and others),

Thanks for your supportive comments.

DB,

There are lots of interesting issues about the role of the arXiv as it increasingly replaces the historical role of peer-reviewed journal. But one overriding fact is that it has become extremely important for the math and physics communities, and the people managing it have an increasingly important responsibility.

The arXiv does need to protect itself against crackpots, and I can see justification for a certain amount of lack of transparency at times because of this. I gather that they haven't yet figured out a permanent policy for dealing with trackbacks, but I don't see that an elaborate peer-review process makes a lot of sense here. They just need a moderation mechanism to thwart crackpots, and the problem here seems to be that their moderator(s) is convinced that anyone critical of string theory is a crackpot. The kind of string fanaticism exemplified by people like Motl, Distler and Kuperberg is a minority behavior even among string theorists. My experience has been that most string theorists and I can have a perfectly reasonable discussion of these issues, even though we may strongly disagree about some of them. But those in the string theory community who are fanatics shouldn't be in the position of making moderation decisions at a crucial institution like the arXiv.

19. **Dumb Biologist**
February 24, 2006

I wish I understood it all better, so that I had more to add now than my hopes for a fair hearing of your grievances. Best of luck!

20. **MathPhys**
February 25, 2006

Michael,

Why do you (and Motl) connect and write to this blog? Just to tell Peter Woit how much you despise him? It is clear that he hit a very raw nerve.

I find your behaviour disgraceful. Are you people really scientists?

21. **Quantoken**
February 25, 2006

Peter:

What's the point writting a letter to ARXIV? They already said they are not interested in your opinion. Predictable it will take another 3 months before you see any response and the only response you will get is that they ignore you.

And it is ridiculous for you to defend ARXIV for having to protect themselves against crackpots. They welcome the biggest crackpot of all, the super string theory. I know that till this day you are not willing to consider super string theory as a crackpot, and you still want to consider it as a science. The point is any theory that fails to make a useful prediction is considered crackpot. It doesn't matter that string theorists are honestly making the effort to try to come up with a prediction. That is simply not good enough to differentiate their theory from crackpot. All crackpot theorists DO honestly hope for a useful prediction.

Until string theorists can show that they can make meaningful predictions, and that their prediction can be verified by experiments, I think it is fair and square that super string theory be classified as a crackpot theory. ARXIV therefore is a major crackpot depository.

You might as well instead write to New York Times, or any of the public media.

Quantoken

22. **Haelfix**
February 25, 2006

There is absolutely no good reason Arxiv should ban blogs that are run by faculty at major research institutions. I might disagree with comments here on occassion, but there have been several very enlightening discussions here in the past.

I do however see how it can get a little annoying responding to the same trackback subjects (eg how bad the landscape is for physics) over and over again. It gets a little tiring at times when its the same criticism at every new paper. I think pretty much the entire physics community, as well as even the general public is now aware of these objections, it has been the point of many coffee table talks and its thoroughly known.

I am otoh perfectly open to reading healthy and hopefully new objections, and indeed they do show up on occassion.

23. **Juan R.**
February 25, 2006

There is a broad dilated experience of ArXiv administrators to eliminate any dissident from being heard by the rest of comunity.

It is possible that Quantoken have full reason in that

"What's the point writting a letter to ARXIV? They already said they are not interested in your opinion. Predictable it will take another 3 months before you see any response and the only response you will get is that they ignore you."

In fact, ArXiv administrators are ignoring to blacklisted scientists since many years. They even do not response to blacklisted Nobel laureates, even when they write a formal letter to Nature journal. Here an excerpt:

"The cases documented by myself and others show that there is more to the story."

"The exclusion of particular individuals and particular ideas from arXiv appears to me to be deliberate."

"For example, having stated that a very distinguished physicist's strong support of a submission carried no weight because this physicist "was not intimately familiar with the work in question", the moderators simply ignored subsequent support from an endorser with publications on the same subject.

"The moderators' attitude to any challenge to conventional thinking is likely to result in the loss to science of important innovative ideas."

Has Robertson letter changed ArXiv "moderation" process?

—

Juan R.

Center for CANONICAL |SCIENCE)

24. **Chris Oakley**
February 25, 2006

One possible solution to the "standards" problem in the ArXiv would be to have an area containing papers submitted but not endorsed by the advisory board, preferably with comments explaining why. If anyone finds any of this "crackpottery" offensive, then they could just avoid visiting this part of the site.

25. **Juan R.**
February 25, 2006

Peter Woit

I recomend you the preparation of an open letter was signed by respected scientists for a better (at least open to external check) administration of the ArXiv.

This is the only way i can see you can obtain some success. Best desires!

—

Juan R.

Center for CANONICAL |SCIENCE)

26. **Benjamin**
February 25, 2006

Peter,

I'm neither a physicist nor a mathematician, so I doubt my comments will be worth much to you, but please let me say this. Of course, you deserve the trackbacks from arXiv, but I object to you calling Lubos Motl's blog a 'stew' of 'fanatical' politics. I am a political moderate who can be liberal on some issues and conservative on others. I have no axe to grind. Motl's conservative political views are based on his experience of Communism, and they are not without a great deal of merit. Furthermore, he expresses himself colorfully, which may go over the top sometimes, but is entertaining and thought-provoking. There's nothing 'fanatical' about his views. I think this bit of excess on your part in your otherwise cogent background article that you linked to here does your own worthwhile cause a disservice. However, it is only a slight misstep. As for the validity of superstrings, I too have my doubts, but my opinion is worthless, so I can only say: 'Let time reveal the truth!'

27. **woit**
February 25, 2006

Benjamin,

I don't want to get into a discussion of Lubos Motl's politics, but there is a reason I needed to bring up the issue of his fanaticism and how it is expressed on his weblog. The arXiv will not inform me of the reason it is censoring links to my weblog, so all I can do is try and guess what the reason might be and see if it fits with the evidence given by looking at the other weblogs they do allow links to. Although I would challenge this, I can see how someone might accuse me of at times being insufficiently polite to certain people, or holding fanatically one-sided views. The fact that links to Lubos's site are allowed indicates that this can't possibly be the reason.

While my own political views aren't those of Lubos, my father and his family were Eastern European refugees from Soviet communism and I grew up understanding well their point of view and respecting it. None of them ever behaved in the slightest like Lubos; they were civilized people and capable of treating views they disagreed with with respect. Lubos is a fanatic and an extremist, both in his political and scientific views: you always know exactly what he is going to say about any issue, he goes on and on about how anyone who disagrees with him about politics or string theory is an incompetent fool, and does whatever he can to suppress any such disagreement.

One could argue that fanaticism of this kind is harmless, but the problem is that the moderators of the arXiv, while lacking Lubos's political fanaticism share his scientific fanaticism. This form of fanaticism has done a huge amount of damage by now to theoretical physics, and promises to do much more in coming years unless people take a stand against it.

28. **Benni**
February 25, 2006

Dear Peter,
I think you are banned, because you do not scientific work. You only criticise stringtheorie in a rather "public" manner.
When you have real arguments against stringtheorie(for example if it fails to reproduce an observed physical effect, nonlocal quantum effects could be such cases) then write it in mathematical form to a paper and publish it.
I think you had to wait for an answer because there were discussions on the moderator board.
And they might have decided, that someone, who only wants the general public to inform with short comments that stringhtheorie is not as goog as it is, has nothing to do with a scientific discussion, but only with a person producing himself.
It seems that the Arxiv wants to be a board for scientists, and not for discussions addressed for the general public.
Everyone in stringhteory knows about the landscape, and there is no need, to tell a scientist on this problems. So Arxiv blacklisted you.
Even if I have nothing to do with the moderator board, I think if you write a number of serious papers (maybe 10-20) with your own Ideas, publish them in journals and post them to the arxiv, and make your blog more of scientifically interest (stop stupid mentioning of the same problems everybody knows, post original ideas, come up with new! criticisms on strings which no one thought before), your situation would be much better.
At this time for now, you can only be seen as a man who doesn't produce own ideas, but only himself for the general public with repeated criticism of a theory which is in a crisis (what everyonein stringtheorie knows).

It might be that what you do is very good for students and newbies, who want to start their carrier in theoretical physics. And I think you know, you do it exactly for them. But for science it is nothing, perpetually mentioning that a speculative theory that has 10^500 solutions instead of one. And Arxiv is for science, not for students or newbies.

29. **Patrick**
February 25, 2006

I've been lurking here for a while but never posted before. This is slightly off topic, but I'm in the same boat with Dumb Biologist in that, in my own field (biophysics), we don't have anything comparable to ArXiv. I'm a bit curious about the role it seems to be assuming in the physics community. My question is: to those of you who have been involved in hiring/promotion decisions, do papers on ArXiv carry any weight or are they completely discounted as not "real" until they appear in a peer reviewed journal?

Just wondering.

PLW

30. **woit**
February 25, 2006

Benni,

Well, I actually have published 9 papers, one in a conference proceedings, the other 8 in Phys. Rev. Lett., Nucl. Phys. B. and Phys. Lett. B. Actually it would be 10-20 if you count hep-th/0206135. I haven't submitted that to a journal, since at this point I don't much see the point of journals. If the arXiv moderators want to set a standard of 10-20 peer-reviewed publications by a blogger before allowing links to their blog, they should say so. I don't think a few more peer-reviewed publications on my part would make any difference.

Your characterization of my blog is quite inaccurate. There are postings on a wide variety of topics of scientific interest and many physicists and mathematicians, including quite a few string theorists clearly find them worth reading. The evidence for this comes both from what people have told me and from the large number of daily connections to the blog, very many of them from leading research institutions.

Yes, I do cover in detail the continuing controversy over the landscape, I think it is an important story. The moderators may agree with you that my emphasis on it is unwarranted, and that would justify their not allowing a trackback to my posting about Weinberg's article. It doesn't justify their decision to censor any and all links to my blog, including the ones about John Baez's paper and about the Freed-Hopkins-Teleman theorem.

31. **woit**
February 25, 2006

Benni,

One other thing. You write:

"When you have real arguments against stringtheorie(for example if it fails to reproduce an observed physical effect, nonlocal quantum effects could be such cases) then write it in mathematical form to a paper and publish it."

This misses the whole point about the problem with string theory: it's not a theory that is "wrong" in a conventional scientific way. It's "not even wrong", i.e. you can't derive an inconsistency or an incorrect physical prediction from it since it isn't really a theory. What you are asking for is impossible, but in this case it very much is legitimate science to give arguments that string theory (as a theory of unification…) can't ever possibly predict anything. Much of the criticism of string theory here consists of a detailed argument explaining why various claims that "string theory predicts X" are incorrect. I suppose I could write such things up in more detail, providing equations, and even get them published in some peer-reviewed journals. I don't think there would be much point to that, and I don't think it would change the views of the arXiv moderators.

32. **A. nonymous**
February 25, 2006

Patrick,

There's a section of the arXiv for biophysics. You'll see papers there by leading researchers in the field, so most likely they read the other papers that appear there too. That means that if you put a paper there in the right section, a reasonable fraction of your peers will see it and it will affect their opinion of your competence, either in a good or a bad way depending on how good your paper is. Also, they might follow up on it if it strikes them as interesting. So it's effectively published.

It's still a kind of a grey area, though, because it's not the done thing in biology to cite preprints in journal-published papers, so unless you publish in a journal as well, you won't get any citations. Whether you can disown a paper that you've put on the arXiv later if you change your mind is a different question. You can withdraw papers, but the attitude of the arXiv administration is that if you thought in advance that there was a possibility that you would later withdraw a paper, then you shouldn't have posted it in the first place.

February 25, 2006

"This misses the whole point about the problem with string theory: it's not a theory that is "wrong" in a conventional scientific way. It's "not even wrong", i.e. you can't derive an inconsistency or an incorrect physical prediction from it since it isn't really a theory."

Which is why string theory, not Petr Woit should be banned from the arxiv.

34. **woit**
February 25, 2006

Patrick,

What I've seen of hiring decisions in recent years has been in math, not in physics, where things are kind of different. For mathematicians, the peer-review process is supposed to determine not only whether a result is of sufficient interest, but whether the author has a valid proof. Mathematicians take this very seriously, and so the peer-review process is of greater importance to them than to physicists. The system is under stress though, as it has become harder and harder to find good people willing to put in the amount of time necessary to carefully check a proof. You hear a lot of complaints among mathematicians that the peer-reviewed literature is much less reliable now than it used to be.

To get hired or promoted, in most cases peer-reviewed publications in leading journals count heavily. This is not always the case: virtually any department in the country would be happy to hire Grigori Perelman based on his arXiv submissions which just give an outline of a proof of the Poincare conjecture and which he shows no signs of wanting to submit to a journal for peer-review.

In physics, it is becoming increasingly hard to understand why the journals survive. No one I know of reads the journals, everybody just looks at the arXiv. The peer-review process has seriously broken down, for evidence of this consider the case of the Bogdanov brothers. They were able to get several papers consisting of complete nonsense published in a variety of peer-reviewed physics journals, including two rather well-respected ones. I'd also be interested to hear from people involved these days in physics hiring/promotion decisions about how the whole journal issue is viewed.

35. **Benni**
February 25, 2006

Peter woit wrote
This misses the whole point about the problem with string theory: it's not a theory that is "wrong" in a conventional scientific way. It's "not even wrong", i.e. you can't derive an inconsistency or an incorrect physical prediction from it

No.
For example, string theory is formulated as a local field theory. But quantum mechanics is essentially nonlocal.

In ordinary field theory, it is physically possible to restrict the behaviour to locality, since in particle physics one does not work with experiments dealing with entanglement.

Entanglement is a macroscopic quantum effect. Even there exists the quantum eraser experiment (here's an example)
http://grad.physics.sunysb.edu/~amarch/
which deals with entanglement at various time ans space points. It seems that that quantum mechanics is a nonlocal system over space time.

String theory wants to deal with macroscopic objects like black holes and universes.
I have seen many entangled quantum systems.

But never an entangled string!

It is simply false, when stringtheorists say, all they have to do is to get the standard model.

I remember, that I have asked this John Schwarz personally in Munich after a lecture two monts ago.
Schwarz looked at the ground, weaved with his arms, uttering some words, and then he rotated to the table that the audience could not see his face.
He said: In stringtheory we assume everything local.

I would be glad, when someone points me to a paper how he wants to implement nonlocal behaviour in a theory which assumes that all necessary about a particle is a very small quantised string.

To implement correlations, he must, I think, set up a kind of hidden variable theory, or make the string as big as the universe.

If I'm not wrong, of course.

36. **woit**
February 25, 2006

Benni,

You are very confused about these issues. And this is now completely off-topic, no more along these lines please.

37. **Benni**
February 25, 2006

OK, what I mean is simply:

Is it not possible, to give a proof that string theory fails to reproduce entanglement?

38. **J.F. Moore**
February 25, 2006

"No one I know of reads the journals, everybody just looks at the arXiv."

This is interesting, because I would say exactly the opposite. I've worked in solid-state physics, materials science, and chemistry groups (all experimental) and not once has the arXiv come up. I've heard of it, but I have never personally looked up a paper there for my own research. I've only followed links from places like this blog just for curiosity. For research, a few times people trade preprints, but it isn't all that common. When an exciting new paper comes out in a journal, then we discuss it. It seems to be a very different culture.

I plan to do some informal polling, concentrating on the physicists. I suspect a lot of them will have no idea about the arXiv or will simply not care. My own feeling is that, frustrations with peer review aside, I don't want to waste my time reading junk. Not that I'm saying the arXiv is full of junk; perhaps 'small lab' experimenters just generate more junk than mathematicians and HEP types so it's more of an issue. Maybe it's just a different local minimum to solving the problem of communication in our areas of study. I don't know.

39. **woit**
February 25, 2006

Benni,

No, this is not possible. If there there are completely consistent versions of string theory (which is plausible, but remains to be shown), at low energies they should just reproduce the same behavior as in the standard quantum mechanics, including entanglement.

One reason people are so interested in string theory is that it seems that at low energies it gives you standard quantum theories that we know and love and are well tested, but at high energies is supposed to give you something different.

40. **woit**
February 25, 2006

J.F. Moore,

It's interesting to hear how different things are outside of particle physics. The HEP theory preprint and arXiv literature has always had a lot of junk, with the attitude being that part of becoming a serious researcher is learning to quickly tell junk from non-junk. It has also often been very faddish, with people trying to jump on the latest and hottest idea. If you ignored preprints and waited for publications, you'd be out of the game.

41. **J.F. Moore**
February 25, 2006

I see. There is certainly fashion in my area, but I think the timescales are much longer. Actually, it can be maddening how long it takes an 'obvious' idea to become accepted by the mainstream.

I should add to what I said above that theorists of my acquaintance in SS/condensed matter/chemical physics seemed to use preprints and the arXiv a fair bit. What you say makes me want to ask them about the junk factor in their fields.

42. **Patrick**
February 25, 2006

From briefly looking around the biophysics and statistical physics areas of ArXiv, there seems to be a pretty strong theory/experiment split when it comes to posting papers. I'm mostly an experimentalist and I'd never heard of ArXiv until I learned about it through physics websites like this one. In the biophysics section there are papers by some pretty big names in the theory and simulations area, but little to nothing by experimentalists. This might simply reflect the fact that the biophysics theorists are likely to have interacted with other theoretical physicists in graduate school and thus be aware of ArXiv in the first place.

43. **Benni**
February 25, 2006

Of course it is possible to attac string theory.

You mention in your own essay, that "a simple argument gives rise to a high cosmological constant". Roger Penrose attacked stringtheory recently in his new book with singularity theorems, and string theorists theirselves put their theory into crisis with mentioning it has 10^500 solutions.

Also, there seem to be indeed problems with nonlocality. Even in ordinary QFT. A workaround seems to be the well known Schroedinger picture, as H.D.Zeh from Heidelberg writes: http://www.rzuser.uni-heidelberg.de/~as3/nonlocality.html

But there are other Problems:
In this (german) manuscript Prof. Dragon at Hannover (he works on relativity and supergravity, some of his colleagues in his department work on string theory)
http://www.itp.uni-hannover.de/~dragon/stonehenge/qm.pdf
writes at page: 100:
"since string theories contain relation 9.34, they are, in opinion of the author, physically untenable"
And on the following lines, and the page before he gives fair grounds for his opinion. And states: "This serious problem is ignored by string-theorists"…..
So, of course it is possible to attack this theory in a scientific way.

But I see no papers in which you are involved, Peter, that raise any questions. That might be the reason why arxiv has blacklisted you.

44. **Alejandro RIvero**
February 25, 2006

I note some catch-22 situation here in some commenters. The owner of this blog does not seem that string theory is a topic worthy to work in, but in order to critiquise it he is asked to give a record of publications on string theory.

45. **Benni**
February 25, 2006

No. What is wanted are scientific publications which criticise string theory.
Penrose was able to for example.
String theorists themselves found, that their theory has 10^500 solutions.

What Peter does is: He waits till string theorists find problematic things and then he gives short comments. The sucess of this blog is based on papers of others. Everyone could do that -waiting till others struggle and then laugh at them.

Peter hasn't found that it is an NP hard problem to find the correct solution.
Peter hasn't found that String theory has 10^500 solutions.
Peter hasn't found that assumed the additonal dimensions were classical, they would collaps (as Penrose writes).
He even has not found the problem which Prof. Dragon raised (which is indeed the most simple imaginable).

All this are scientific things, a real scientist, which criticises stringheorie could have written on his own. A mathematician, he should know that there exists no theory, which is not worth to spend time. It es even physically valuable to show problems of a theory, which put it into question.

But either Peter does not want to produce scientific work or he is not able to.
So there's no wonder, that arxiv which wants to be for science exchange blacklists him.

46. **Geon Oh**
February 25, 2006

Benni is making a very fair comment which I've been trying to say since long ago. I'm not a string theorist nor non-string theorist (just an undergraduate student at the moment) but I must admit, I'm kind of sick of hearing that 'Peter Woit is brave enough to point out string theory is not even wrong!' It's not about being brave, it's an ignorance to decide 'not' to study string theory and yet trying to raise a voice about it. My mentor always told me 'Save your best thoughts, and devise ways to test them', I can't believe how Peter Woit, his history tells me he is a very qualified physicist, yet he is wasing time on posting articles like these and finding links so that 'general public' can read them. Please stop all the nonsense about Witten being the axis of evil who influence people to take up string theory, at least he doesn't waste time arguing 'why am I blacklisted on Arxiv!!', he's smart enough to realise he should rather spend time 'try things out' rather than 'sit and cry'.

47. **Geon Oh**
February 25, 2006

Sorry if I sound upset… I just feel strongly about this.. 😀

48. **Peter**
February 25, 2006

Geon,

If you think I've ever claimed that "Witten is the axis of all evil" you haven't read or understood much of what I've written here. I'd suggest learning a lot more about this subject before criticizing anyone else for their views about it.

Benni,

I don't know who you are, perhaps also an undergraduate, but you don't understand what you are talking about.

There seems to be something about string theory that encourages people who have learned a little bit about it, but don't actually understand anything, to spend their time attacking people who actually do know what they are talking about.

Both of you, please stop posting here until you actually understand what you are writing about. If people who actually understand string theory want to argue with my views about it, I'm glad to do so, but it's absurd to be spending my time answering attacks from undergraduates who don't know understand what is going on here.

49. **Richard**
February 25, 2006

Alejandro has an excellent point:

> I note some catch-22 situation here in some commenters. The owner of this blog does not seem that string theory is a topic worthy to work in, but in order to critiquise it he is asked to give a record of publications on string theory.

There are certain musical forms (i.e., atonal or 12 tone classical, rap, or fill in your own _____) which I feel perfectly qualified to criticize even though I'm neither a musician or a musicologist. I do know enough about music that I feel perfectly qualified to assert that something smells bad and doesn't advance musical culture at all. Can you imagine being attacked by a musician and told that your opinion is invalid because you yourself aren't a practitioner? I'm seeing a lot of this sort of blind us-versus-them elitism in some of these posts. I'm not a physicist, and frankly don't have a strong opinion about string theory, but Peter's criticism of string theory seems remarkably restrained compared to the rantings, attacks, and wild assertions by Motl and others.

> Peter hasn't found that String theory has 10^500 solutions.

This is a criticism of Peter? Are we supposed to jump for joy because there are 10^500 solutions? And solutions to what? Vacuum states? Some of these comments are so inarticulate that I smell real crackpots, in this case, pro string theory crackpots, and why isn't Motl wading in here and wielding his usual machete to these people?

Happily going back to doing math tonight where the tone of politics and discussion is a bit more civilized …

50. **Mar**
February 25, 2006

Hi Benni. It is called "string theory" 😉 . And no, there is no apparent reason why it shouldn't be self-consistent.

Geon Oh: I think you're completely off the mark here. As far as I undestand, Peter (like many, many scientists including, but not exclusivelly, Lubos) is quite a fan of Witten.

Both:

You completely miss the point, which was about trackbacks from the ArXiV. These should be allowed no matter if the blogger in question is a critic or not of string theory, tokamak approaches to fusion or anything else. While it's understandable that the ArXiV should have some sort of "crackpot filter", I think it's plain nonsense that, for example, a trackaback to a paper by John Baez is banned while the author himself comments in this very blog.

51. **Rien**
February 26, 2006

Regarding the arxiv again, I'm a particle theorist and of course I submit all my papers to journals as well. I am a little suspicious of papers more than a year old that have not been properly published, even though the arxiv has been there during my whole career.

I'm becoming somewhat disillusioned by the peer review process though, but this comes more from being a referee. Several times now, I have strongly recommended against publishing papers, only to find that those papers have been published anyway in another journal (and once even in the same journal). It seems impossible to argue against publishing slight papers with a small or negligible amount of new stuff. There are simply too many papers being put out, in my view. Of course you can always say that you never know what is going to be the next thing, but sometimes it's pretty clear that a paper will not lead to anything, when it's just the umpteent small variation of something.

On the other hand I've also had a referee finding an error in one of my own papers, so it is not altogether bad…

52. **Thomas Larsson**
February 26, 2006

Benni and others,

While string theory makes no hard, falsifiable predictions, it makes many soft predictions: supersymmetry, extra dimensions, 496 gauge bosons, proton decay, new long-range forces, a non-positive CC, etc. The most striking thing about these soft predictions is that **every single one** is in apparent disagreement with experiment.

The situation with string theory is similar to that of Ptolemy's epicycle theory. An ellipse, or any closed curve for that matter, can presumably be expressed as circles around circles around circles ad infinitum, just as any periodic function can be expanded in a Fourier series. So epicycle theory is not even wrong, but the fact that its soft predictions are in apparent disagreement with experiments is nevertheless a problem for it.

If you are not impressed by Peter's qualifications, why don't you have a look at what the founder of the string theory group at Rutgers has to say about his former field, see subsection 1.6 of hep-th/0204131.

53. **Swatters**
February 26, 2006

Benni seems more like a graduate student than an undergrad.

I think I can sum up Benni's opinion: If you aren't an approved of and published scientist then the opinion generated by your primitive little mind is pointless. You are free, free to think whatever the "real scientist" tell you to think. Just shut up and sign the check.

54. **Marty Tysanner**
February 26, 2006

I get the impression that people like Benni and Geon Oh are confused about the real issue at hand. They justify the actions of certain moderators of the ArXiv to censor blog trackbacks to Not Even Wrong because Peter is criticizing string theory without actively producing papers (especally string theory papers) of his own. Geon Oh goes even farther, and states that Peter is ignorant of string theory because he is not producing string papers. Evidently he is either unaware of or disbelieves Peter's repeated comments that he has spent a great deal of time studying string theory; he also ignores Peter's repeated reluctance to engage in discussions about technical topics that he does not feel fully qualified to discuss.

My own observations of Peter over the past several years (since he started posting on sci.physics.research, before the days of the "Not Even Wrong" blog) have been different. It was clear that he talked about a sensitive subject, judging from the lively discussions that ensued and the strong emotions he encountered from some string theorists (especially Lubos *"Superstring/M-theory is the language in which God wrote the world"* Motl…). However, I have noticed that Peter has always been clear about the reasons behind his statements so that anyone was free to challenge him on that basis. So if he were making an incorrect claim about string theory others were free to point out his error. Sometimes this happened — occasionally an expert would catch him making a misstatement. But interestingly, I noticed that rather than becoming defensive or making a personal attack on the person who disagreed with him, he would publicly acknowedge his mistake if he was wrong; if he didn't believe he was wrong, he would give a more technical explanation of his position, and then the discussion would continue. He also seemed to soften the way he presented his views over time; as he discused the views of *reasonable* string theorists who argued with him, he was more careful about saying what specific parts of string theory he disagreed with (especially the landscape), while openly acknowledging that there were other aspects of string theory that were worth studying and that deserved to be called science. For some time now, he has openly stated that reasonable people may disagree with his views about the merits about string theory.

At the same time, I have observed that the people with whom he publicly discusses his views usually fall into one of two categories. The largest group acts reasonable; they either try to engage in a discussion of the technical merits of what Peter says, or they may mention that, "Well, you've got to work on *something* unless you want to just give up, and right now string theory is the best there is even if it isn't perfect." The other group doesn't usually bother to argue from logic; these people seem satisfied with personal attacks on Peter, trying to cast him as a marginal character with no scientific standing who is trying to hurt the One True Fundamental Theory for personal reasons or because he is just ignorant. People like "Michael" (a.k.a. "Hmm," I assume) and other more well known characters come to mind… Rather than actually addressing the technical points Peter makes, these people employ ridicule, distortion of viewpoints or past accomplishments, strawman arguments, and the like.

It is very "interesting" to see certain relatively well known physicists and physicist wannabes resorting to emotional tactics rather than reason when it comes to defending their views. And now, using the curtain of anonymity, certain physicists are now even resorting to censorship tactics to make it harder for physicists and graduate students to see dissenting viewpoints when looking at a paper on the ArXiv. These moderators and people who use emotional methods to attack Peter seem willing to risk unintended consequences — that reasonable graduate students who could become the next generation of string theorists, as well as the public that is helping fund such research, might conclude that these string theorists don't believe that string theory is strong enough to stand up on its own merits against reasoned, dissenting views, and consequently the tactics of mud-slinging politicians must be employed to maintain string theory's favored position. Even worse, engaging in censorship for personal reasons and shrill personal attacks with little technical merit are offensive to both the scientific method and the spirit of free inquiry. Any resulting backlash against people who engage in those tactics is bound to cause damage to string theory by its association with them, even though the number of such people is relatively small. This is yet another example where intelligence and wisdom can be orthogonal…

For someone like me who is very interested in fundamental physics, the discussions Peter has had with others (especially physicists) about string theory have been valuable, far more so than some of the uninformed "string theory is bad" comments by others that seem to frequently clutter the comment sections in his blog. Understanding the weaknesses of a theoretical program is crucial for graduate students (e.g., me) to make an informed choice about what research direction to choose. One usually has many opportunities to hear about a theory's positive aspects by those who are actively working on it, but those same people usually don't spend much time talking about the negatives; presumably if they thought it had a lot of negative aspects they wouldn't be working on it themselves.

So the real issue here that I think people like Benni and Geon Oh should consider is not whether or not they can understand why ArXiv moderators might not like trackbacks to Peter's blog. The real issue, it seems to me, is that trackbacks (and beyond that, the ability to submit papers to the ArXiv) should not be prevented on the basis of personal feelings by moderators. Whatever criteria are chosen for allowing or disallowing trackbacks (or paper submission) should be published and uniformly enforced. Otherwise, the system is open to abuse, as outward appearance would suggest has actually happened in this case.

55. **Pudding**
February 26, 2006

"The real issue, it seems to me, is that trackbacks (and beyond that, the ability to submit papers to the ArXiv) should not be prevented on the basis of personal feelings by moderators."

Has Petr been prevented from submit papers to the ArXiv?

An outrage!

56. **Marty Tysanner**
February 26, 2006

Has Petr been prevented from submit papers to the ArXiv?

Not that I know of. I was thinking of a couple of other people who have apparently been blacklisted for no obvious reason. It would be appropriate for what constitutes grounds for being blacklisted and the procedures/requirements for having priveleges restored were made public and enforced uniformly, just as it would be for trackbacks. Why shouldn't this procedural information be documented and transparent?

57. **Tony Smith**
February 26, 2006

Richard said:
"… There are certain musical forms (i.e., atonal or 12 tone classical, rap, or fill in your own _____) which I feel perfectly qualified to criticize even though I'm neither a

musician or a musicologist. … Can you imagine being attacked by a musician and told that your opinion is invalid because you yourself aren't a practitioner? …".

Yes, I can.
IIRC, in the heyday of atonal 12 tone stuff, establishment music critics would deride audience dislike of atonal 12 tone stuff, saying that the members of such an audience were too ignorant and uneducated to understand the inherent beauty of atonal 12 tone stuff.
The reaction (over a time scale of decades) to such arrogance has been a return to use of harmonious structures.

If physics and superstring theory were to follow the historical pattern of music and atonal 12 tone stuff,
then
there may be a few more decades of arrogant superstring excess, followed by a return to experimentally connected physics,
but making use (in ways not permitted by current rigid superstring doctrine) of some of the math techniques of superstring theory

Tony Smith
http://www.valdostamuseum.org/hamsmith/

58. **Benni**
February 26, 2006

At first: Larsson writes:
>While string theory makes no hard, falsifiable predictions, it makes >many soft predictions: every single one is in apparent >disagreement with experiment. end quote

I know. Indeed it seems that string theorists themselves criticise their own field.
It can only be described as criticism, to write a paper that it is an NP hard problem to indentify the correct solution. Want else should it be to write publications which bring their own subject in a crisis. That such publications are written shows the contrary of what peter thinks. It shows that string theorists are actually aware of the problematic taste of their theory and criticising themselves. How else would you interpret the words of Gross recently?

What sometimes is annoying, is the media hype they create and the advertisement with which string theorists hire students.

But Arxiv has nothing to do with media hype. And even, when one protests against media hype. Peter does a well job. For students and graduates who want to start a carrier in theoretical physics. But not for science only for people.

The Problem in the Arxiv, I think is not, that he got blacklisted in a scientific preprint archive. The problem is that Arxiv has no clear moderating rules. Peter got no correct answer why he is blacklisted. The moderator board has no clear "rules" stated ccording to which it works (e.g it should be possible to make a "democratic" process where 30 moderators vote or such). Also, the "endorsement" system is problematic. Because the rules are not clear and very subjective to the endorsers. It could be, that the next Einstein won't be endorsed, because his paper is so original and so complex that no endorser would have time to read through these many formulas which have nothing to do with present day theory.

At second Peter writes:
>I don't know who you are, perhaps also an undergraduate, but >you don't understand what you are talking about. end quote:

I think I understand these comments of Prof.H.D.Zeh in Heidelberg very well, which discuss this aspect of nonlocality and String theory:
http://www.rzuser.uni-heidelberg.de/~as3/nonlocality.html
Quantum theory is kinematically nonlocal, while relativistic quantum field theory requires dynamical locality. How can these two aspects be compatible?
The most general local structure seems to be described by quantum field theory. It may be characterized by the following program:
(1) Find an underlying set of "classical" fields. This endeavor is the major objective of unified field theory such as string theory or "M theory", where often only rudimentary quantum aspects are taken into account.
(2) Define quantum states as wave functionals of these fields (that is, as superpositions of different "classical" field states).
(3) Assume that the Hamiltonian operator H (acting on wave functionals) is defined as an integral over a Hamiltonian density, written in terms of these fields at each space point.

And I don't see your point how string theory alone should reproduce entanglement, until we have not done step 2 and 3. I could go more into detail, even with calculations, but this gets off topic now and I stop.

59. **Benni**
February 26, 2006

an additional note to the Arxiv:
On the page introducing the endorsement system, arxiv writes
http://arxiv.org/help/endorsement
arXiv.org is distinct from the web as a whole, because arXiv contains exclusively scientific content. Although arXiv is open to submissions from the scientific communities, our team has worked behind the scenes for a long time to ensure the quality of our content.

And this is the problem.
What is "behind the scenens"?
On this page, Arxiv states that its content is controlled by a conspirative group of scientists who can do what they alone think.
Explicite rules and democratic moderating process is absolutely necessary here.

60. **robert**
February 26, 2006

Peter

I'm pleased to see that your 'Letter to ArXiv Advisory Board' has prompted such a useful debate of the role of this body. As one whose professional work has been in areas somewhat removed from the frontiers of knowledge, I find myself in sympathy with others outside the hep-th community who find the aggressive and partisan behaviour of stringers slightly bemusing, and quite at odds with more widely held views on what science is about.

61. **Michael**
February 26, 2006

MathPhys,

I don't despise Peter Woit. I'm just being blunt about who I think he his and what I think he's doing. I consider it possible that Peter is a likable guy personally, but it truly doesn't matter.

I am earning my money as a scientist (mathematical physics), in case you're question was sincere.

62. **Thomas Larsson**
February 26, 2006

Benni wrote:
At first: Larsson writes: >While string theory makes no hard, falsifiable predictions, it makes >many soft predictions: every single one is in apparent >disagreement with experiment. end quote
I know. Indeed it seems that string theorists themselves criticise their own field.

While you perhaps know this, and all senior string theorists undoubtedly do so, it is hardly common knowledge. Neither among the general public, nor among the high school and college kids who will become the next generation of scientists, and not even among professional scientists in other fields. Thus, there is certainly a need for public education here, of the kind that Peter is pursuing.

Because we don't want to keep taxpayers ignorant about the fact that all natural predictions of string theory disagree with experiments, do we?

63. **woit**
February 26, 2006

Marty,

Thanks for your thoughtful long comment and for your kind words about what I've been doing. What you describe is certainly what I hope I am doing, so I'm glad to see that in your perception I generally live up to what I aspire to.

64. **Benni**
February 26, 2006

Thomas Larsson Says:
>While you perhaps know this, and all senior string theorists >undoubtedly do so, it is hardly common knowledge. Neither among >the general public, nor among the high school and college kids >who will become the next generation of scientists, and not even >among professional scientists in other fields. Thus, there is >certainly a need for public education here, of the kind that Peter >is pursuing.
1) yes. And this "public education" might be the reason why Arxiv has Banned Peter. Arxiv might not want to have anything to do with public education.

2) Is it so worse in the US?
In Germany, I'm also a little bit in sorrow. Here, folks have looked at the string hype quite sceptical for 20 years. Now even before LHC is working, there seem to grow out "centers for mathematical physics" everywhere. in Hamburg, Munich, Heidelberg, Jena… Chairs which have been sceptical for years (Heidelberg) now working on it. It might be, that well trained postdocs from the US return. Or it might be that averything else in the Standardmodel is worked out, so they jump on this train because own work in quantum gravity might be a hight risk.
But they do this exactly at the point where the theory is a bit declining.

65. **Benjamin**
February 26, 2006

The situation with string theory is similar to that of Ptolemy's epicycle theory. An ellipse, or any closed curve for that matter, can presumably be expressed as circles around circles around circles ad infinitum, just as any periodic function can be expanded in a Fourier series. So epicycle theory is not even wrong, but the fact that its soft predictions are in apparent disagreement with experiments is nevertheless a problem for it.

Please forgive this vanity comment, but as a mere humble engineer interested in physics, I once had this thought too, both the epicycles and the Fourier part, just the way you say it. Since this is fascinating, and something I can grasp, and I don't know who you are, could either you or a qualified physicist please confirm that this is a valid objection, at least as a first or zeroth order concept for the non-physicist (with perhaps a wee bit of poetic license thrown in)? Thanks.

66. **Tony Smith**
February 26, 2006

Benni has made some comments here, with some of which I disagree and some of which I agree, but I think that in two areas his points are useful:

1 – with respect to arXiv:
"… arxiv writes …[at]… http://arxiv.org/help/endorsement … "Although arXiv is open to submissions from the scientific communities, our team has worked behind the scenes for a long time to ensure the quality of our content."
And this is the problem.
What is "behind the scenens"?
On this page, Arxiv states that its content is controlled by a conspirative group of scientists who can do what they alone think.
Explicite rules and democratic moderating process is absolutely necessary here.
…
The Problem in the Arxiv, I think is not, that he got blacklisted in a scientific preprint archive. The problem is that Arxiv has no clear moderating rules. Peter got no correct answer why he is blacklisted. The moderator board has no clear "rules" stated ccording to which it works (e.g it should be possible to make a "democratic" process where 30 moderators vote or such). Also, the "endorsement" system is problematic. Because the rules are not clear and very subjective to the endorsers. It could be, that the next Einstein won't be endorsed, because his paper is so original and so complex that no endorser would have time to read through these many formulas which have nothing to do with present day theory. …".

2 – with respect to string theory and quantum theory:
"… Schwarz … said: In stringtheory we assume everything local. …
To implement correlations, he must, I think, set up a kind of hidden variable theory, or make the string as big as the universe. …".

Benni's "string as big as the universe" might be interpretable as a world-line, and tachyons might be useful in a theory of correlations, so maybe string theory (with unconventional physical interpretations) could be useful in constructing a realistic quantum theory. However,
to the extent that arXiv suppresses posting of material about string theory interpretations that differ from the doctrinaire structure of conventional superstring theory, then possibly useful advances may be impeded.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

67. **woit**

February 26, 2006

Benjamin,

Yes, the epicycle analogy about the problems of string theory is one that has been made by many people (including some doing string theory).

As a general matter of philosophy of science, the thing is that, unless the structure of a theory is very rigid, it is hard to show that it is wrong, since often a theory can be made consistent with observations by making it more complicated. So the way theories often fail is not that they make wrong predictions, but that they become more and more complex in order to try and stay consistent with observations, until at some point people can't stand the ugliness of the theory any more and stop working on it. This seems to me the way the string theory unification program is headed. To avoid this, some people are trying to claim that ugliness is a virtue…

68. **Benni**
February 26, 2006

Tony Smith says
>Benni's "string as big as the universe" might be interpretable as a >world-line, and tachyons might be useful in a theory of >correlations, so maybe string theory (with unconventional >physical interpretations) could be useful in constructing a realistic >quantum theory.

At first, my knowledge in Stringhteory is not too high.
But to my small knowledge non-local Stringhteories in which strings are indeed stretched between different points of spacetime are a nonlocal quantum field theory, which violates causality (As today theorists compute everything some even work on causality violating models).

When I read such entries:
http://motls.blogspot.com/2004/12/causality-in-sft-ted-erler.html
http://arxiv.org/abs/hep-th/0406199
I see, that string theorists do their best, to get a local field theory.
They (Gross here) write:
>Causality is a basic requirement of any acceptable physical >theory; causes should always precede their effects, and if the >theory is Lorentz invariant, >spacelike separated events should >be uncorrelated.
Although they know, that sometimes in quantum mechanics events at spacelike separated points are correlated. That is, (as it seems to me) they construct their theory often against physical experiment.

Ordinary QFT was invented before Bells inequalities. So there was no need to think on correlations at distant ponts and normal QFT obeys locality. Quantum field theory has other problems too. QED for example is nonlinear. Feynman graphs can contain loops.
These problems are solved as such:
One defines a wave functional of the field operators.
In this review, for example decoherence is calculated with QFT (p17): http://arxiv.org/pdf/quant-ph/9803052
The procedure with this functional picture can be used, to get correlations without violating causality.
But one must "insert" the correct "local" QFT. Here's another example of that: http://arxiv.org/abs/hep-th/9306161
As Prof. H.D.Zeh writes, he thinks that normal QFTs, string and M theory included, are local and therefore only "semiclassical": http://www.rzuser.uni-heidelberg.de/~as3/nonlocality.html
Quantum theory is kinematically nonlocal, while relativistic quantum field theory requires dynamical locality. How can these two aspects (well based on experimental results) be simultaneously meaningful and compatible? How can dynamical locality even be defined in terms of kinematically nonlocal concepts?
It may be characterized by the following program:
1) Find an underlying set of "classical" fields (including a metric) on a manifold. This endeavor is the major objective of unified field theory (such as string theory or "M theory", where often only rudimentary quantum aspects are taken into account).

(2) Define quantum states as wave functionals of these fields (that is, as superpositions of different "classical" field states).

(3) Assume that the Hamiltonian operator H (acting on wave functionals) is defined as an integral over a Hamiltonian density, written in terms of these fields at each space point.

If I wrote something wrong, Peter or somebody else may correct me or delete my post.
But I do not know, what happens if one does step 1,2,3 with stringtheory.

1) Assuming the suesskind multiverse is correct.. What has one insert in such a "wave functional?" All the multiverses of Suesskind?
2) Assuming one day, String theory gives one correct solution, wouldn't this make everything much more complex? In the low energy level, one could work, when it is prooved that stringtheory gives the local standardmodel. But what would happen in the High Energy region?

My question to John Schwarz at Munich was simple:
"How is the quantum mechanical concept of nonlocality brought into stringhteory".
Answer: "Hmmmm, Hmmmm, Hmmmm (for 4 minutes), when we do perturbation series, we assume everything local. The correlations in Quantum Mechanics have not to do with causality violation. Entangled systems are very difficult in local stringheory….."
Question: "Could you provide me a reference on methods how one even tries to research on spacelike separated multiparticle correlations"
Answer: Hmm, Hmmm….. and then something about ADS/CFT duality I could not relate anymore to my question.

@Tony Smith:
I don't think that one can use this theory as a realistic interpretation of quantum mechanics. Neither non local stringtheory or all other approaches.

69. **Aaron Bergman**
February 26, 2006

Benni — you're pretty much asking for a nonperturbative definition of string theory. There exist field theories for the open string, for example, that satisfy all your criteria. Life is harder with closed strings although there are attempts along those lines. So, the short answer is that when it's been possible to define things nonperturbatively, string theory has all the same nonlocalities as ordinary quantum mechanics. The only difference is that the "fields" are now string fields defined on the space of string embeddings rather than points.

70. **Scott Aaronson**
February 26, 2006

Peter,

Just wanted to add to the chorus of support for you. I don't see how one could define "reasonable criticisms of string theory" in a way that includes Penrose's and Smolin's (and even some of the IAS particle theory postdocs', when I talked to them alone), but that excludes yours. Some people might say that, regardless of content, weblogs are just not an appropriate forum for scientific disputes. But in that case, why have trackbacks in the first place?

Best,
Scott

71. **Benni**
February 26, 2006

Maybe one should make a petition (online or per letter) to ask Arxiv, if it could create better "moderating rules" than these:

… arxiv writes at http://arxiv.org/help/endorsement … "Although arXiv is open to submissions from the scientific communities, our team has worked behind the scenes for a long time to ensure the quality of our content."

What is "behind the scenens"?
It is not because of Peter, but because of the Arxiv as scientific institution. The worst scientific journals have peer review system where one gets at least a comment why he is not allowed to publish.

Also the endorsement system… It could be, that the next Einstein won't be endorsed, because his paper is so original and so complex that no endorser would have time to read through these many formulas which have nothing to do with present day theory.

Has anyone an Idea of a better "standard ensuring" system?

This could also be subject to a petition.

72. **woit**
February 27, 2006

Scott,

Thanks for your comment. So that explains why my blog gets so many connections from the IAS.

Others,

I've just deleted a bunch of comments about Piet Hut, Witten, Brian Josephson, etc. The institute controversy over Piet Hut has nothing whatsoever to do with the issue at hand here, which is the decision by the arXiv moderators to suppress links to this weblog. I'm not arguing that the arXiv should not suppress things for which a legitimate case can be made that they are crackpot science. From what I have seen of Josephson's work, I think such a legitimate case can be made. The question is whether this blog is crackpot science, a point of view I obviously strongly object to. Please take discusssions of Piet Hut and Josephson elsewhere, and stick to the topic at hand.

73. **Andrew**
February 27, 2006

Dear Peter,

If you are not having any success with dealing directly with the ArXiV, I would have thought the logical step would be to take your complaint to the body funding them, which surely has ethics rules…. Their policies must be answerable to someone.

74. **MathPhys**
February 28, 2006

Michael,

My question was sincere. Your attitude towards Woit and his blog goes straight against the scientific ideal of objectivity and tolerance of free speech.

Woit has something negative to say on a (so far) purely speculative theory. He says it has (so far) failed to make contact with physics, and for that reason he believes it's on the wrong track. Is that a problem?

Why should a scientist have a problem with that? Why should anyone connect to his blog to leave the sort of messages that you and Motl come here to write?

Your attitude gives non physicists who read this a very negative impression of how physicists interact and deal with each other.

Theoretical high energy physics, particularly in the US, has always been nasty and cut throat. But what you are into here goes beyond professional competition. You are intolerant of opinions that are different from yours. And over what?

75. **MathPhys**
February 28, 2006

I also wish to make clear that I am *not* anti strings. In fact, I *want* to see string theory flourish and thrive, as it brings together everything that I have ever learnt and connects it to everything else.

So what I want to see you, Michael and Motl, do, and what I find most disappointing that you are not doing, is to respond to Woit's critiques in a calm and meaningful way. Tell us, very calmly, why he is wrong. Or tell us that (at this moment) you cannot tell us. There is nothing wrong with a scientist saying "I don't know. Things are unclear. I have gut feelings, but I still don't understand." We all say that almost all the time.

But cheap verbal attacks, personal remarks about Woit's career and his publication list, are best left to high schoolers.

76. **Juan R.**
February 28, 2006

I see no problem with that ArXiv-administrators, journals-referees, etc. are selecting scientific material each day, **if and only if**:

a) Are invoked explicit rules for "what is in" and "what is out"
b) There is posibility for publishing the rejected material in another site (maybe considered "second-class" but at least available).

Peter Woit is highlighting the problem (a). He want know why Not Even Wrong is now out from ArXiv trackbacking.

In a related topic, I would note that history of science is full of theories were initially considered crackpot (by some referee of even by entire communities) but broadly accepted at the end.

It has been well documented at least 27 cases of future Nobel Laureates encountered resistance on part of scientific community towards their discoveries and instances in which 36 future Nobel Laureates encountered resistance on part of scientific journal editors or referees to manuscripts that dealt with discoveries that on later date would assure them the Nobel Prize.

A beatiful example of last is rejection letter to Hideki Yukawa meson theory considered by referee of the physical review journal to be wrong in a number of important points: forces too small by a factor of 10-20, wrong spin dependence, etc. But work was not wrong and some years after Yukawa received the Nobel Prize for physics by *that* work.

Hermann Staudinger (Nobel Prize for Chemistry, 1953):

"It is no secret that for a long time many colleagues rejected your views which some of them even regarded as abderitic."

Howard M. Temin (Nobel Prize for Physiology or Medicine, 1975):

"Since 1963-64, I had been proposing that the replication of RNA tumour viruses involved a DNA intermediate. This hypothesis, known as the DNA provirus hypothesis apparently contradicted the so-called 'central dogma' of molecular biology and met with a generally hostile reception…that the discovery took so many years might indicate the resistance to this hypothesis."

Today the dogma in physics is string theory. Anyone contrary to the dogma receives hostility. In this blog, we can see examples of insane hostility Peter Woit receives from Michaels, Motl, etc.

Among the more notorious instances of resistance to scientific discovery previous to existence of Nobels, we can cite the Mayer's difficulties to publish a first version of the first law of thermodynamics. Not forget that even Newton was considered crackpot by the mainstream of the epoque. Do you remember D'alembert evaluation of Newtonian work?

Therefore, a bit of caution with using the word "crackpot" and more clear rules for ArXiv.

—
Juan R.

77. **Florifulgurator**
February 28, 2006

As an ex-academic, my favorite blogs to keep updated to the state of math phys is Baez´ and this. Any other suggestion?

78. **woit**
February 28, 2006

Juan (and others),

Please stop it with the generic anti-scientific establishment rants. I don't think they add anything to this discussion. Sure, there are lots of examples in history of good scientific ideas being discounted and suppressed, but going on about those doesn't have much to do with the case at hand.

I'll leave Juan's last rant up for a personal reason. The chemist Hermann Staudinger was my great-uncle.

79. **Count Iblis**
February 28, 2006

Trackbacks referring to blogs that discuss the contents of papers (in a serious way) should not be censored. That's totally unjustifiable.

Perhaps someone here with a blog that is not censored by arXiv is willing to help to circumvent the ban by posting trackbacks on their blog on behalf of Peter with a link to this blog?

80. **George**
March 1, 2006

"Trackbacks referring to blogs that discuss the contents of papers (in a serious way) should not be censored."

What is "serious"? Who decides what's a serious discussion?

"That's totally unjustifiable."

Why does the arXiv allow trackbacks at all? What purpose are they supposed to serve?

81. **secret milkshake**
March 1, 2006

We are using the Staudinger reaction in medicinal chemistry quite often around here…

With sophistry one could make phenomena fit (Freudist psychoanalysis or Marxist-Leninist did).

Ugliness = the ad hoc constructs invoked, heaped on to make known things fit (after they did not, and without a non-circular justification for it). Wiggle room = bad.

Math complexity: a practical complication but not a sign of ugliness – if all follows from limited, fragile set of postulates + some nontrivial observables are produced.

"It's not a science, it's just a literature" (landscapist literature at that)

82. **Tony Smith**

March 4, 2006

In comments on a Sean Carroll Cosmic Variance blog entry “Crackpots, contrarians, and the free market of ideas”,
Ethan Tecumseh Vishniac said:
“… As a long time reader of Peter’s blog, a journal editor, and a (former) member of the ArXiv advisory board … I enjoy lurking on …[Peter’s]… blog …
I have a few comments. …
The ArXiv instituted a standard that they would allow trackbacks only to blogs run by active researchers.
That excludes Peter … I can’t remember anyone else’s name coming up.
I’m not going to hazard a guess as to the role that existence of Peter’s blog played in settling on this standard. …
When the topic …[of]… characterizing you [Peter] as not an “active researcher”came up I did a quick search under your name and didn’t find much in the published literature. … I checked the World of Science database. …
For reasons that are not clear to me, this standard was not communicated to Peter for some months. I don’t think most of the board was aware that this was the case.
I didn’t realize it until Peter commented in one of his postings that he had never heard back from the board. …
I’m a little surprised to hear that the policy behind the decision was not communicated clearly to …[Peter]. Actually … very surprised. …”.

From those comments, it seems likely to me that :

1 – The arXiv advisory board instituted a “trackbacks only … by active researchers” “standard” based on deliberations about only one blog, Peter’s.
That seems to me to be a rationalization for a personal blackballing of Peter.

2 – The arXiv board determined Peter to NOT be an “active researcher” based on not “find[ing] much” under Peter’s name “in the published literature” by checking “the World of Science database”.
I went to a World of Science web page at http://scienceworld.wolfram.com/ which says “Eric Weisstein’s World of Science – A Wolfram Web Resource – the best resource for math and science on the internet”
and I searched the “Entire Archive” with these results:
for “Woit” – “Your search did not match any documents.”
for “Motl” – “Your search did not match any documents.”
for “Vishniac” – “Your search did not match any documents.”
for “Vafa” – “Your search did not match any documents.”
for “Ginsparg” – “Your search did not match any documents.”
Lest you think that I just don’t know how to search, I will say that a similar search for “Witten” yielded a two-page list of documents.

3 – If “most of the board was …[not]… aware that … this standard was not communicated to Peter for some months”,
then the board’s oversight of arXiv administration is an example of poor management by the board and capricious (at best – actually, possibly even malicious) execution of policies by arXiv administration.

4 – The fact that Ethan, “a long time reader of Peter’s blog”, did NOT post any comment about this matter on Peter’s blog, but quickly posted comments on Sean Carroll’s blog, shows that Ethan (perhaps in order to maintain status among those he considers to be his peers) feels that Sean Carroll is respectable (and maybe even an “active researcher”), whereas Peter Woit is not (and therefore it is respectable only to “lurk…” on Peter’s blog, but not to post comments thereon).

The whole situation seems to me to be more like making membership decisions in old-time private clubs (back in the days when the IAS had to be created as a home for Einstein because some institutions were concerned about him being Jewish)
than advancement of science by open publication, commentary, discussion, and debate.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

83. **woit**
March 4, 2006

Tony,

I agree with you that the “active researcher” standard was just chosen as that which gave the best argument the moderator could come up with for censoring me. In other areas the arXiv moderation policy is, like that of journals and just about everything else in science, about the scientific content, not the credentials of the person involved. The moderators in this case decided they couldn’t argue against the scientific content of my blog, but could try and argue against my professional qualifications. Since I first started raising these issues publicly, string theory fanatics have shown that they have no answers to the scientific arguments I am making, so their only tactic is to insist that I don’t have the right qualifications to be heard on this issue. This kind of ad hominem response long ago convinced me that the field was even more intellectually bankrupt than I initially thought.

I have a different interpretation of Ethan’s decision not to comment here, but to do so at Cosmic Variance. I take him at his word that he reads what I have to say here and presumably often finds it worthwhile and probably even “respectable”. What I wrote here about what the arXiv’s reason seemed to me to be for its decision was intended to try and force their hand and get them to tell me what this reason was. As long as this remained only on my blog, it in some sense was just between me and the arXiv. Sean’s posting made clear that others were finding my interpretation of what was going on at the arXiv plausible, and made some sort of response and explanation seem necessary.

84. **Aaron Bergman**
March 4, 2006

“World of science” was probably a typo for “web of science”, a citation search engine online.

85. **Tony Smith**
March 4, 2006

Aaron Bergman said: “World of science” was probably a typo for “web of science”, a citation search engine online.”.

OK, assuming that Aaron knows what is in Ethan’s mind better than Ethan’s typing hands (no insult intended, as I make a lot of typos in my writings), I went to a “web of science” web page at http://scientific.thomson.com/free/ which is free and described as “an expert gateway to the most highly influential scientists and scholars worldwide”, and repeated the searches described in my comment above, with the following results:
for “Woit” – “No matches found.”
for “Motl” – “No matches found.”
for “Vishniac” – “No matches found.”
for “Vafa” – “Highly cited researcher”
for “Ginsparg” – “No matches found.”

for “Witten” – “Highly cited researcher”

Since Motl, whose blog IS allowed arXiv trackbacks,
and Vishniac, who is “a (former) member of the ArXiv advisory board”
and Ginsparg, who founded the arXiv,
all have the same “No matches found” null result on the “web of science” search,
I find it ridiculous (it would be funny if it were not a symptom of the antiscientific tendencies of the Cornell arXiv) for Ethan to use the “web of science” “gateway to the most highly influential scientists and scholars worldwide” as a criterion for declaring Peter Woit to be “not an “active researcher”” and therefore to be banned from arXiv trackbacks.

Of course, I am only taking Aaron’s word in my use of “web of science”, and it is possible that some arXiv apologist will now comment that it should not have been either Ethan’s “World of science” or Aaron’s “web of science”, but some other list, and if we go through enough lists then MAYBE one of them might list Woit below Motl, Vishniac, and Ginsparg.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

86. **Aaron Bergman**
March 4, 2006

I’m not sure what the point of this is, but the web of science is not a free service and is available here. All the people you list above return listings.

87. **Tony Smith**
March 4, 2006

Aaron Bergman said “… the web of science is not a free service and is available here …[http://scientific.thomson.com/products/wos/]… . All the people you list above return listings. …”.

“web of science” DOES have a FREE component of its service, which is as I said above at http://scientific.thomson.com/free/ , and the results I stated above ARE ACCURATE FOR THE FREE COMPONENT of “web of science”.

“web of science” does also have not-free components, but I do not have access to them, so I did my search on the free component. If Aaron has access to the not-free components and wants to report results of searches on them, he is free to do so. As I said above, “if we go through enough lists then MAYBE one of them might list Woit below Motl, Vishniac, and Ginsparg”.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

88. **Christine Dantas**
March 4, 2006

Following Tony Smith’s investigation, I wondered whether only
endorsers could send trackbacks. My search in the arXiv resulted in the following (including myself in the list):

Peter Woit: Not currently an endorser.
Lubos Motl: Can endorse for hep-th.
Ethan T. Vishniac: Not currently an endorser.
Cumrun Vafa: Can endorse for hep-th.
Paul Ginsparg: Not currently an endorser.
Edward Witten: Can endorse for hep-ph and hep-th
Christine Dantas: Can endorse for astro-ph

According to the rules of the arXiv:

> Endorsers must have authored a certain number of papers within the endorsement domain of an archive or subject class. The number of papers depends on the particular subject area, but has been set so that any active scientist who’s been working in her field for a few years should be able to endorse IF her work has been submitted to arXiv and IF she is registered as an author of her papers.

Dr. Vishniac is of course very well known and has numerous papers, but apparently he has not registred most of his arXiv entries,
so I suppose that is the reason why he is not being considered as
an endorser.

Since Dr. Woit has submitted only 2 papers to the arXiv (as far
as my search is correct), they have judged him as not an endorser.
I guess that was an important measure that they have considered. According to such a criteria, he would not be allowed to send trackbacks.

Ok, that’s a measure, but a very “blind” one for sure.

One test for my hypothesis would be to see whether Paul Ginsparg can send trackbacks.

I would like to send trackbacks myself and test this as well, but according to blogger (where my blog is hosted), I cannot do this… Well, perhaps there is a way that I must figure out, because since Lubos Motl could do it with the same blogger, then there must be a way.

In any case, that is disappointing. The rules are not clear.

Christine

89. **Aaron Bergman**
March 4, 2006

Tony,

I’m trying to tell you what Ethan was in all probability referring to and to help clear up a misunderstanding. If you want to keep playing Perry Mason, please do it without me.

90. **Power Ranger**
March 4, 2006

On the one hand, you claim that the Trackback system at the arXivs is being run for the benefit of a cabal of string partisans: “Note that, besides the blogs run by arXiv moderator Jacques Distler, Lubos’s is one of only a couple particle theory related blogs that the arXiv moderators allow trackbacks to. That trackbacks to this blog are censored, but allowed to Lubos’s (and almost no others not belonging to an arXiv moderator)…”

On the other hand, you claim that the “active researcher” standard was devised specifically to exclude YOU: “I agree with you that the ‘active researcher’ standard was just chosen as that which gave the best argument the moderator could come up with for censoring me.”

Which is it?

On the one hand, you complain that the “active researcher standard” (the same criterion, I suppose, that’s used by journal editors to select referees) is irrelevant: scientific content is the only thing that should count.

On the other hand, you would probably object even MORE strongly if the arXiv moderators were to moderate your individual trackbacks for their scientific merit.

Seems to me that there’s nothing they could do, short of accepting your tracbacks, that would satisfy you.

And if they accept your trackbacks, whose should they reject and on what grounds?

91. **Benni**
March 5, 2006

I think Peter could go around easily. He could
publish
publish
and publish

Sometimes he says that there are mathematically interesting items in string theory, and also few physical ones.
It seems that he knows most in string theory, so he could do some work there. Maybe he could also find an upper bound for the cosmological constant or such…

But it can be understood, that Arxiv wants to be only in the scholarly discussion process. And for this, it is fairly enough when people like douglas write
“maybe this is a nightmare [in stringhteory research]”

This has nothing to do with a “bankrupt” field, I think. But more with the strange “authoritative” behaviour of scientists. In germany, if a student wants to go in an elevator, and also a professor wants in, the professor often would say “Can I go here” and would ran into the elevator and closing the doors, that the student has to wait on the floor. There exists a Joke saying: “You nothing, you idiot, you amoeba, you …. student”. You have simply almost no right to say anything until you have a long publication list.
Ethan writes to cosmic variance, because he is interested in the opinion of colleagues. He writes “Must I say that I don’t consider you as crank” or “I think your blog personally informative”. But he doesn’t consider peter as a colleague. And maybe questions the scientific value of the blog, since a researcher would not find interesting papers which he has to cite in own papers.

This blog has a social value. It makes people clear about the status of stringtheory. But for to be scientific, Peter should publish something. This would also make his critics to be taken more seriously

92. **nigel**
March 5, 2006

Power Ranger,

“Active research” is not just determined by publication rate. We all know the committee-authored papers, where 100 authors all co-author with one another, so that they get 100 citations each just for writing 1 paper each. A nice long list for the CV, but it is group-think.

Group-think is personality-dominated. But science is determined by important results that have been objectively compared to nature, of which none have come from ST yet.

“…you would probably object even MORE strongly if the arXiv moderators were to moderate your individual trackbacks for their scientific merit.”

I don’t see why Peter could or would want to object to decisions based on scientific merit, since science is the aim of ‘not even wrong’. All the critics who see science as a matter of political correctness, seem personally insulted by Pauli’s category for string theory type-hype, ‘not even wrong’, plus objective questions about the failure of string theory to do anything objective for science.

They should remember that in the end science is not a politically correct tea party with results determined by some kind of secret consensus or conspiracy, but it is determined by agreement with nature. It is very short-sighted to shoot the messenger.

93. **Benni**
March 5, 2006

ethan writes:
> I also think the idea behind the policy could use some public >feedback, but I’m going to leave that to others. I’ve said my >piece. Comments from other people, including anyone reading this >thread, would be far more effective.

Which could be merely understood to his colleagues as a note to protest against the decision of the board. This might also be a reason why he posted at cosmic varianc, where smolin and sean are active.

94. **Power Ranger**
March 5, 2006

“‘Active research’ is not just determined by publication rate.”

No, but it’s not determined by saying, “I scribble in a notebook from 10 until 3 every day.” either. One (unpublished and uncited) paper in over 15 years does not constitute an active research career.

March 5, 2006

Power Ranger,

First of all, I'm really tired of having people challenge my scientific credentials from behind the cloak of anonymity. It seems to be a favorite tactic of string theory fanatics and strikes me as cowardly. At least one thing you can say for Lubos is that he doesn't do this.

If you want to argue about whether I'm doing research or not, you have to show that you have some understanding of what I have written. Based on what I've seen of comments written under the same pseudonym here and elsewhere, it seems to me highly unlikely that you have any understanding of either what I've written, or of most of the scientific issues that are discussed on this blog.

I don't see the incompatibility between claiming that the arXiv trackback system is being run mainly for the benefit of Jacques Distler and other string theory fanatics, and that the "active researcher standard" was chosen to give Distler his best argument for censoring me. Both are true.

This "active researcher standard" seems to be ill-defined, since no one can tell me exactly what it means. If it ever does get made more specific, I suspect it will be carefully crafted to exclude me. In other areas, the arXiv doesn't use this standard. From what I recall, its official standard is supposed to be that it accepts postings that are "refereeable", i.e. that an editor of a journal would send out for peer review and not immediately reject out of hand as crackpotism. I'd be perfectly happy if the moderator wanted to accept some of my trackbacks, rejecting others as crackpotism. It would be quite interesting to see which he put in which category.

It would be a lot of trouble to moderate trackbacks on a case by case basis, so I can understand that the arXiv would want to deal with the question of whether to accept trackbacks from a site as a whole. The natural mechanism for doing this is their endorsement mechanism. If one or more arXiv endorsers endorse a site, trackbacks from there would be allowed. They actually seem to have tried this out in my case: at least one prominent scientist was contacted and told them that trackbacks to my site should be allowed. They didn't like that result and realized that I would have no problem coming up with endorsers, so adopted this new, never before used, ill-defined "active researcher" standard.

96. **Benni**
March 5, 2006

peter wrote: at least one prominent scientist was contacted and told them that trackbacks to my site should be allowed. end quote

Is this speculation, or do you know this for sure?

97. **woit**
March 5, 2006

This is not speculation, but first-hand information. The scientist involved does not want to be publicly identified or get further involved in this controversy.

In any case, I think any regular reader of this blog, or reader of the supportive comments posted here and elsewhere, would not have much trouble coming up with a list of arXiv endorsers who would support the inclusion of trackbacks to this blog in the arXiv. Doubtless the moderators involved are well aware of this, thus avoiding using the endorsement mechanism here.

98. **Benni**
March 5, 2006

anyway it would be good for you, to publish a bulk of reviewed papers.
I wish you many scientific results.

99. **Power Ranger**
March 5, 2006

In the case of trackbacks, you say that it doesn't matter who sent the trackback. Only "the scientific content, not the credentials of the person involved" matter.

In the case of blog comments, you have a different standard, apparently. OK …

The research track record is relevant to lots of decisions (hiring, funding). It's also used by journal editors to choose referees. If blog posts about papers on the arXivs play a similar role to that played by refereeing in traditional journals, it's pretty reasonable to apply a similar standard to decide whose trackbacks can appear alongside a paper on the arXivs.

100. **woit**
March 5, 2006

Power Ranger,

Your latest comments here have no apparent scientific content, if they did and they made sense I'd happily take them seriously, no matter what your credentials or even if you desired to remain anonymous (by the way, you're the only person I've noticed so far who takes the trouble to anonymize connections to the web-server here, impressive).

There's nothing inherently wrong with the idea of using research track record to make the decision at issue here, and I've already submitted my argument to the arXiv advisory board that my research track record justifies accepting trackbacks to this site. I am however pointing out that it is not clearly an approriate one in this case, and is quite different than that used in other cases by the arXiv, and the reason for the change in criterion seems pretty clear. By the arXiv's normal criterion trackbacks to here would have to be accepted, thus the desire to find a different, more ambiguous one that could justify rejection.

By the way, I don't think the analogy to refereeing makes much sense. A referee is given some serious power, that to accept or reject a paper. A link to commentary about a paper which the arXiv in no way endorses is something pretty different. In any case, referees are often chosen by journal editors based on their expertise, not their research track record. It is quite common for very junior people with little track record to be asked to referee papers in their specialty, this happened to me more than once when I was just starting out in this business.

101. **nigel**
March 6, 2006

There is a trackback essay by Jacques Distler at http://golem.ph.utexas.edu/~distler/blog/archives/000760.html

102. **Dumb Biologist**

March 6, 2006

These days in the bio-sphere one (me, for example) is often asked to referee papers because one has just had a paper published in the journal for which one is being asked to referee. Long ago my response was to be surprised and flattered, until I realised the journals was so overtaxed by the weight of submissions they were trolling for anyone with a pulse and two brain cells to rub together.

Anyhow, there seems to be no easy way to draw direct analogies between the print world and the arXiv. To my untrained eye, though, as I've attempted to learn more about the issue, it seems like trackbacks might be, in some remote way, at least, part of an evolving form of peer review. Hopefully the concept of "peer" is also evolving.

103. **Justin**
March 6, 2006

Interestingly, the arXiv allows a trackback to Lubos' latest appauling assasination of the "LQG & standard model" paper by Smolin et al.

On the whole I tend to agree with Lubos' opinion of the intellectual merits of LQG… but still, it seems ridiculous that such a rude and humiliating rant would be allowed, while all trackbacks to any of Peter's comments (even helpful and polite ones) are a priori disallowed.

104. **Lead by Science**
March 6, 2006

DB,

> it seems like trackbacks might be, in some remote way, at least, part of an evolving form of peer review. Hopefully the concept of "peer" is also evolving.

In the way Jacque had presented it, it is.

Peter,

Peter don't worry about the trackbacks, you have linking capability and it still works.

Imagine, if you were in China and the Government did not want you to see, other then, the way it had wanted you to see?

Freedommmm……… is nice, is it not?

105. **One R**
March 6, 2006

Justin,

we are not talking about merits of personality, but of science.

106. **Justin**
March 6, 2006

One R,

It is questionable to what degree such rants are helpful to science.
On the other hand, thoughtful and knowledgable critiques can be helpful. Good science and personality are not disconnected.

107. **Dumb Biologist**
March 6, 2006

LbS,

Yeah, well, let's just say I'm not terribly impressed with the direction the evolution has taken so far. That said, if the arXiv (and other things like it) are in an especially dynamic phase of development, perhaps things can and will evolve still further, and the "selective pressure" applied will weed out the suboptimal approaches. I have some hope the issue, being debated in public as it is, will serve the greater good in the end. Lots of things in science are self-correcting, because the whole is always greater (and often better) than any of the parts.

Exceptional MathReviews

February 28, 2006
Categories: Uncategorized

Mathematical Reviews is a publication of the American Mathematics Society that provides capsule reviews of essentially every mathematics research paper that is published. It has been in operation since 1940, and in recent years the entire database has been on-line, with the name MathSciNet. Some of the reviews are rather entertaining in one way or another, and the availability of this database has led to a new form of diversion among mathematicians: searching on promising words (e.g. "plagiarism") to see what turns up. My colleague Kimball Martin has put together a new web-page entitled Exceptional MathReviews with links to the best reviews he has heard about.

One of the most famous such reviews turns out to be apocryphal. In the days before the searchable database, I had heard it claimed that one Math Review contained the following devastating evaluation: "This paper fills a much-needed gap in the literature." It turns out that this isn't actually true. For the real story and more about Math Reviews, see an article from the 1997 Notices of the AMS.

   Herein the author states "her genuine concern" about Wiles's purported proof of Fermat's last theorem \ref[A. Wiles, Ann. of Math. (2) 141 (1995), no. 3, 443–551; MR1333035 (96d:11071)24] which, after all, appeared in an "in-house publication in the Annals of Mathematics at Princeton". Baica's concerns seem to stem from a worry that results concerning elliptic curves "may not be equivalent to the result in the Euclidean geometry". She backs up her concerns by noting that "there is a need to provide Galois' connection from category theory". Of course, she has no such worries about the validity of her own, Euclidean-algorithm-inspired, proof of Fermat's last theorem.

   It is hard to imagine in a single paper such an accumulation of garbled English, unfinished sentences, undefined notions and notations, and mathematical nonsense. The author has apparently read a large number of books and papers on the subject, if one looks at his bibliography; but it is doubtful that he has understood any of them. He speaks blithely of elements of a formal group and claims to prove (!) that two formal groups having the same Lie algebra are isomorphic. One also hears of root systems of a commutative formal group, and of the union of its Borel subgroups, which belongs to the Lie algebra, etc. What is amazing to the reviewer is that such a thing was ever printed.

This paper contains barely a single correct statement. The first proposition is that an elliptic curve $y^2 = x^3 + A x + B$, with $A,B \in Z$, $A \geq 0$, cannot contain a rational torsion point of order 5 or 7. The proof is erroneous, and indeed the curve $y^2 = x^3 +2160 x + 170\,640$ contains the point $(-24,324)$ of order 5, and the curve $y^2 = x^3 +206\,037 x + 80\,423\,334$ contains the point $(219, -11\,664)$ of order 7. (The one-parameter families of curves possessing 5- and 7-torsion are misquoted from tables of Kubert, but the mathematical error lies elsewhere.) The second result (which is actually true) is given a proof containing the line “leads to the equation $x^3+ A x + B = 0$ with no real solution (when $A \geq |B| > 0$, of course)”, where the assertion is false, of course. The final example concerns the curve $y^2= x^3 + 5 x+1$ where “one easily checks that $E(Q)_{\rm tors}=Z/3Z \ (=\{(0,1),(0,-1),\infty\})$”. But adding $(0,1)$ to $(0,1)$ results in $(\frac{25}{4}, -\frac{133}{8})$, so the point $(0,1)$ is of infinite order!

Understanding the Landscape

February 28, 2006
Categories: Uncategorized

Michael Douglas has written up his talk at the recent Solvay conference, with the title Understanding the Landscape. For previous postings about this conference, see here, here, and here.

Douglas's article is mainly a series of excuses for why string theory can't predict anything. He begins with an historical analogy, comparing the present state of string theory to that of quantum mechanics in the period 1913-1926, and the Bohr model of the hydrogen atom to N=4 supersymmetric YM and AdS/CFT. This kind of analogy has some rather obvious problems: it took 13 years to get from the Bohr model to the complete theory of QM, whereas the idea of string unification has been around for about 30 years, with not the slightest sign of success. More importantly, the Bohr model of the hydrogen atom gave a fairly accurate prediction of the spectrum of the hydrogen atom, so it was clear that there was something very right about it. On the other hand, N=4 supersymmetry YM doesn't predict anything that corresponds to the real world. In a footnote, Douglas writes:

A similar analogy was made by David Gross in talks given around 2000. However, to judge from his talk here, he now has serious reservations about it.

but I'm not sure what reservations of Gross this refers to.

Douglas's second analogy is a "chemical" analogy, basically pointing to the fact that deriving bulk properties of solids from the underlying many-particle Schrodinger equation is difficult if not impossible. Again, this isn't a very good analogy. The problem isn't that you have a simple theory whose ground state is hard to identify because of the numbers of degrees of freedom, like in condensed matter physics. The problem instead is that the ground state of the superstring doesn't look like the real world. Douglas describes the current situation as:

Perhaps all this is a nightmare from which we will awake, the history of Kekule's dream being repeated as farce.

He goes on to give the standard argument for the landscape, referring to it by the novel name of the *Weinberg-Banks-Abbott-Brown-Teitelboim-Bousso-Polchinski et. al. solution to the cosmological constant problem*, but notes that:

On further developing these analogies, one realizes that we do not know even the most basic organizing principles of the stringy landscape.

and proceeds to discuss a little bit two topics that he hopes might be related to this problem, but I don't see any evidence for this. One topic is an abstract proposal for a metric on the "space of all CFTs", the other is the classification of D-branes on a Calabi-Yau in terms of a derived category.

He goes on to discuss his recent work with Denef on computational complexity, which indicates that even if our universe corresponds to some local minimum in the landscape, there is no hope of ever identifying which one it is and actually computing anything about the real world. In his concluding section, he admits that there is no evidence of any simple structure in the landscape, and argues that maybe this is just the way the world is:

Still, our role as physicists is not to hope that one or the other picture turns out to be more correct, but to find the evidence from experiment and theory which will show us which if any of our present ideas are correct.

The problem with his invocation of the role of experimental evidence is that he has just finished making an excellent case that there is no hope at all of ever getting any such evidence for string theory. He seems to have completely abandoned without comment his project of the last few years of counting vacua in hopes of making statistical predictions, and is left with not a single idea about how one can ever hope to get a prediction of any kind out of this framework. In this kind of circumstance, standard scientific practice is to acknowledge that this is a failed project and go on to something else. Douglas not only refuses to acknowledge the failure of string theory, he doesn't anywhere even mention the possibililty that the underlying idea might be wrong.

Yesterday's hep-th preprints included another landscape one, Probabilities in the Landscape by Alexander Vilenkin. Vilenkin shows no more evidence of having a viable way of ever making a physical prediction than does Douglas, but like Douglas invokes experimental confirmation at the end of his paper, then closes with one prediction that is sure to be accurate:

It seems safe to predict that we will hear more on this subject in the future.

For some more entertaining reading, take a look at A Comment on Emergent Gravity by Waldyr A. Rodrigues Jr. Rodrigues says that he gave as an exercise to his students to find the errors in Jack Sarfatti's recent arXiv posting Emergent Gravity. Sarfatti had been blocked for many years from posting on the arXiv, but the arXiv moderators recently relented, perhaps because this paper includes a section at the end about the landscape. Susskind's recent book is one of only two references in the paper. Sarfatti's paper has gone through six drafts, three of which are on the arXiv, and the latest of which incorporates some of the objections from Rodrigues. Rodrigues however concludes his paper thus:

Sarfatti's paper we regret to say, is unfortunately a potpourri of nonsense Mathematics. The fact that he found endorsers which permitted him to put his article in the arXiv is a preoccupying fact. Indeed, the incident shows that endorsers did not pay attention to what they read, or worse, that there are a lot of people with almost null mathematical knowledge publishing Physics papers replete of nonsense Mathematics…

A careful reading of shows that his hypotheses are completely ad hoc assumptions, since in our view no arguments from Physics or Mathematics are given for them. Summing up, we must say that Sarfatti's claim to have deduced Einstein's equations as an emergent phenomena is a typical example of self delusion and wishful thinking.

Sarfatti will be giving the closing talk at the 22nd Pacific Coast Gravity Meeting, to be held this coming weekend at the KITP in Santa Barbara.

   February 28, 2006

   This sounds unduly harsh. Not that I'm disagreeing with the basic
   conclusion. To quote the Douglas paper:

   *Are there fruitful analogies between these long-ago problems
   and our own? What is the key issue we should discuss in 2005? What are our hydrogen atom(s)?*

   *If we have them, they are clearly the maximally supersymmetric
   theories …*

What can one say. Interesting that he goes into Cheeger's work. I recently had the good fortune to meet Cheeger. Of course, the physicists present all wanted to know about the sort of thing that Douglas discusses, although not the Stringy version. Cheeger said he hadn't really thought about it, but he did mention a 1980's paper of his:

J. Cheeger, W. Mueller, R. Schrader Commun. Math. Phys. 92, 3 (1984) 405-454

which I haven't had a chance to look at, unfortunately. Maybe in another life.

2. **ObsessiveMathsFreak**
   February 28, 2006

   Sarfatti's paper needs another revision. It's not displaying correctly on my computer!

   To be genuinely honest, if Sarfatti's paper got through with a lot of mathematical errors, it doesn't surprise me. There are not a few academic papers which bandy about mathematical terms in a very terse and sparse fashion, referring to this or that paper or terminology to justify what they put down. To someone who is not *very familiar* with the field, i.e. 99.9% of undergraduates, a paper filled with nonsense is indistinguishable from one filled with correct but sparely documented terms.

   For example, from the Sarfatti paper:

   > The superfluid velocity field in Galilean relativity is the 3D Cartan closed inexact 1-form
   > v = (h/m)d(theta)

   Is this right? Is it wrong? I know nothing about any of this. I personally do not know what the following terms really mean: "superfluid", "Cartan closed inexact 1-form".

   This statement could of course be correct, but as someone new to the field, I'm basically taking most of this on faith. I don't think I'm alone here. Papers do this. A Lot. Not just physics papers either.

   I actually think this obfuscated and/or terse presentation style is a serious problem in scientific academica. Authors are not making the effort to make their discoveries accessable to a wider audience. Their papers can only be understood by a handful of other people. This doesn't help science. It just creates a huge barrier of entry into any paticular field. And of course, it also means it is easier for papers containing errors to slip through.

   I follow Feynman's philosophy on this: If something cannot be taught to in first year undergraduate course, then it is not fully understood yet. Sorry about the rant, but I've had to put up with a lot of rubbish papers and books lately.

3. **Peter**
   February 28, 2006

   Kea,

   Cheeger's a very good geometer. I first met him when I was a postdoc at Stony Brook, where he was for many years. He's now here in New York, at NYU. The theorem that Douglas refers to corresponds to the intuitive idea that if you have a manifold of a fixed size, to make it more topologically complex you need to make it more curved. If you bound the curvature, you bound the number of topological types.

   But I really don't see at all why he is bringing that up. While you want to bound the curvature to make sure the low energy supergravity approximation is valid, if you're doing string theory, why should you insist on such a curvature bound? And I really don't see at all what this has to do with his proposed metric on the space of CFTs.

   OMF,

   Unfortunately it really isn't possible to write every paper in a way that any undergraduate can understand it. Mathematics is a language, and like any language takes a significant amount of effort to absorb. You really need to immerse yourself in this stuff, think about it a lot and take the time to become comfortable with it. This can take quite a while and is not easy, but once you do this, you really can quickly tell the difference between someone speaking gibberish, and someone who has something interesting to say.

4. **Kea**
   February 28, 2006

   Peter

   Yes, it does look suspiciously like Douglas was rambling on about a dream for a metric that he hadn't thought about too much. He refers to the 1970 Cheeger paper. At the conference I was attending, Cheeger spoke about things like this [paper with Tian].

5. **Benni**
   February 28, 2006

   the paper of douglas seems indeed very much as expression of a big crisis on the subject. It looks similar to the crisis when it was discovered that general relativity is not renormalisable.
   Or even more, since this was one the reason, why one thought strings might help out.

6. **Troublemaker**
   February 28, 2006

   To someone who is not very familiar with the field, i.e. 99.9% of undergraduates, a paper filled with nonsense is indistinguishable from one filled with correct but sparely documented terms.

   Such papers are not designed for laypersons or for undergraduates. They are designed for people who are indeed very familiar with the field.

   Is this right? Is it wrong? I know nothing about any of this. I personally do not know what the following terms really mean: "superfluid", "Cartan closed inexact 1-form".

   So what? If it's beyond you personally, then it's trash?

Authors are not making the effort to make their discoveries accessable to a wider audience. Their papers can only be understood by a handful of other people. This doesn't help science. It just creates a huge barrier of entry into any paticular field.

The arxiv and the refereed journals are not an introduction to anything; they are (in principle) a place for the high-level, cutting-edge work going on in these fields. They are not supposed to be a tutorial, so it should not surprise you that they do not make a good tutorial.

If something cannot be taught to in first year undergraduate course, then it is not fully understood yet.

Even if this is true, it does not pertain to the situation at hand. These papers discuss areas of active and often controversial research. RESEARCH. If it were fully understood, it wouldn't be a subject of research anymore; it would be standard textbook fare.

7. **Chris W.**
   February 28, 2006

   This idea has probably been considered and dismissed before, but I'll throw it out anyway. Couldn't the arXiv support a declaration of intended audience for submissions, which could be used as a qualifier in database searches? One could then search specifically for reviews, pedagogical articles, research reports, etc. Any comments or elaborations on this notion would be of interest.

   Perhaps there are already some "aftermarket" compilations of preprint links that include such categorizations.

   (Sorry if this is too far off-topic.)

8. **Jack Sarfatti**
   February 28, 2006

   Closed inexact Cartan forms are an elegant way of describing superfluids and emergent phenomena in general.

   fyi

   We live in interesting times! 😉 Waldyr explained to me that he was pressured by some people that his students might suffer, otherwise he would not have written anything had I not mentioned him in the comments. I was, of course, trying to be honest that it was his critique that gave me the idea of 8 Goldstone phases with 6 corresponding to the extra degrees of freedom of Calabi-Yau, the connection to torsion and Shipov's 10D manifold. I was very clear in my acknowledgment that Waldyr did not "endorse" the content of the paper. The "math" in the paper is not important. It's the ideas – mainly both positive and negative vacuum energy at different scales as most of the stuff of the universe w

9. **Jack Sarfatti**

It's the ideas – mainly both positive and negative vacuum energy at different scales as most of the stuff of the universe w less than – 1/3. The math can be fixed where needed. What if I turn out to be right in the long run about LHC and DM detectors being null like the Michelson-Morley experiment?

   On Feb 28, 2006, at 3:37 PM, Tony Smith wrote:

   Jack, Peter Woit's blog has a new entry at
   http://www.math.columbia.edu/~woit/wordpress/?p=355#comments
   that mentions your arXiv posting and Waldyr's critical paper,
   and Peter closes his blog comment with the following statement:
   "… Sarfatti will be giving the closing talk at the 22nd Pacific Coast Gravity Meeting, to be held this coming weekend at the KITP in Santa Barbara. …".

   Due to the wide readership of Peter's blog, and the severe criticism by Waldyr quoted by Peter, your KITP talk may get a lot of attention, and
   it may be a very good opportunity for you to present your physical ideas.

   Here are a couple of lawyer-type bits of advice for your 10 minute talk + 2 minute questioning, scheduled for 17:06 – 17:18 on Saturday afternoon:

   You are the LAST speaker, so if you run over it doesn't hurt anybody else's schedule and there would be no problem if your question period were extended.
   ….

   As to the format of your 10 minute talk, my suggestion is to begin with a short statement saying that your arXiv paper did contain some technical math problems, some of which were mentioned in a critical paper by Waldyr Rodrigues, but that your main ideas are physical, and you only have time here to give a rough outline of the basic physics ideas, which are, as you said in your recent e-mails:

   1 – general relativistic spacetime emerges from Goldstone phases of LOCAL vacuum coherent order parameter in similar way that the superfluid velocity field emerges from Goldstone phase of local helium ground state coherence order parameter.

   Good!

   2 – point defect at center of Sun could explain the Pioneer anomaly as a hollow dark matter (exotic vacuum) mini-halo centered on the Sun …

   Good!

   3 – LHC & local DM detectors will not "click" on DM particles ever to explain OmegaDM = 0.23

   Good!

   Will do. Those are some of the key ideas. Another is taking equivalence principle to the max, i.e. all universal space-time symmetry generators must be locally gauged to induce geometrodynamic fields. If, in addition, there is hidden spontaneous broken symmetry in the vacuum for some of these space-time symmetries the "Meissner" mass gap would explain why curvature dominates over torsion for example at least in most situations.

After stating the 3 main points, then go into more detail, particularly about 1, showing the two forms of vacuum nonlocal coherence forming curved spacetime and incoherent well-known Casimir type effects and
their relationship to /\

Good suggestion but I could not do that in 10 minutes.

At end, plug the possibility that if the Dark Energy can be controlled with Josephson Junction arrays, it would be a vast energy source, a prize even greater than nuclear energy tamed by the Manhattan Project.

That would be way out of their comfort zone. Remember most of these guys who are not senior people are running scared about funding and are afraid to stick their necks out. Most of the hall talk at UCLA DM 2006 was people scared about funding. Even Max Tegmark joked about it in his talk.

Don't mention UFOs in your main talk.

Of course not! 🙂

If asked, say that control of Dark Energy could enable us to build things that do most of the things that UFOs are described as doing, and leave it at that.

If any of the above suggestions don't feel right to you, then don't use them. They are only suggestions, and the most important thing is that you should feel comfortable, and use your Cornell theatrical training to deal with …. et al as you would a heckler in a theater. For 10 minutes, the stage belongs to YOU, if you take it.

On the other hand, maybe the hall will be empty? 😉

10. **amanda**
February 28, 2006

I think that maybe Peter is being a bit hard on string theorists. 🙂
For example, Keith Dienes' latest paper hints that there may be a lower bound on positive cosmological constants on the landscape, and that this lower bound may be way too large. If evidence like this keeps coming in, I think people really will begin to give up, and not make "excuses".

11. **woit**
February 28, 2006

Amanda,

Maybe you're right. But I'm having a hard time figuring out what would possibly cause Douglas to give up on string theory. And he's not telling.

12. **Jack Sarfatti**
March 1, 2006

Regarding Waldyr's comments below, he told me that he was threatened that his students might have trouble getting funding if he did not respond negatively. Note that none of Waldyr's remarks are relevant to the the actual new physical ideas and are not even relevant to the actual final version of the paper. The math problems that may be still there are really quite minor and any real ones can be fixed. The bulk of Waldyr's 21 pages of difficult reading does not at apply to my new conjectures at all, but refers to standard background material I mentioned in a cursory way in the first version. See also further remarks below Waldyr's.

"Sarfatti's paper we regret to say, is unfortunately a potpourri of nonsense Mathematics. The fact that he found endorsers which permitted him to put his article in the arXiv is a preoccupying fact. Indeed, the incident shows that endorsers did not pay attention to what they read, or worse, that there are a lot of people with almost null mathematical knowledge publishing Physics papers replete of nonsense Mathematics…

A careful reading of [Sarfatti's paper] shows that his hypotheses are completely ad hoc assumptions, since in our view no arguments from Physics or Mathematics are given for them. Summing up, we must say that Sarfatti's claim to have deduced Einstein's equations as an emergent phenomena is a typical example of self delusion and wishful thinking."

Perhaps, however, Waldyr missed the beautiful simple analogy that the curved tetrad fields are like the emergent superfluid velocity field and that the world hologram with quantized area bits is essentially the Bohm-Aharonov effect for closed non-exact Cartan forms in the presence of topological defects in the emergent coherent order parameter. This is a wonderful idea that must first be grasped heuristically and the math will follow.

The historical Bohm-Aharonov effect is for quantized loop integrals of closed inexact 1-forms around line topological defects. What we need for geometrodynamics is the quantized closed surface integrals of closed inexact 2-forms around point defects. Waldyr's saying this is adhoc shows he missed the simple intutive idea. It's not adhoc, it's compelling and almost obvious to my mind at least.

On Feb 28, 2006, at 11:02 AM, Jack Sarfatti wrote:

Note that I received from several sources who do not wish to be named about Waldyr's general Wolfgang Pauli "attack dog" style of reviewing papers comments such as:

"But since he knows so much mathematics, he often rushes into criticism, without reading a paper carefully enough. So he thinks that the author has committed an error, whilst this was not the (our case)."

Of course I had some minor (formal at least) ambiguities in the formal expressions in 1st version of
http://arxiv.org/abs/gr-qc/0602022 that Waldyr usefully corrected, but I was also accused of misconceptions I did not make – again from my, perhaps, poor exposition and noting that Waldyr is not a native English speaker. 🙂

On Feb 28, 2006, at 9:34 AM, Jack Sarfatti wrote:

On Feb 28, 2006, at 1:20 AM, Paul Zielinski wrote:

If Waldyr's criticisms are technically correct and your mathematical errors are reparable, then a detailed response to Waldyr's published commentary can only improve the strength of your arguments.

The version up there now corrects some very minor formal flaws in the presentation of STANDARD physics that was simply background material that Waldyr wanted more rigorous. Also he accused me of things that were not so, but that may be because I was not clear enough. For example, I certainly knew that there are 4 distinct tetrad first rank Diff(4) tensor 1-forms e^a and 6 zero torsion spin connection 1-forms S^a^b, i.e.

e^a = e^audx^u

S^a^b = S^a^budx^u

The great bulk of Waldyr's 21 pages has little relevance to the latest version posted now

http://arxiv.org/abs/gr-qc/0602022

The vexing "Yilmaz" issue of locality vs nonlocality of pure gravity energy that Waldyr's general remarks on energy-momentum conservation in GR in his 21 pages pertains to are not at all relevant to my new conjectures, i.e.

I. tetrad field emerges from the several Goldstone phases of LOCAL vacuum coherent order parameter in similar way that the superfluid velocity field emerges from the single Goldstone phase of the local helium ground state coherence order parameter.

That's the key idea. I now seem to recall that Hagen Kleinert has 4 phases associated with the tetrads, but not specifically in connection with vacuum coherence? I will have to look at his book – it's a vague memory.

i.e. the PHYSICAL IDEA is that smooth c-number tetrad field is a vacuum coherence effect – not a random ZPF effect.

II. LHC & local DM detectors will not "click" with "the Right Stuff" ever to explain OmegaDM ~ 0.23. Looking for real DM particles whizzing through space is like looking for Earth's motion through the old mechanical aether (distinct from CMB Doppler shifts relative to FRW Hubble flow of course).

III. Bekenstein-Hawking and 't-Hooft-Susskind ideas point to a 2D quantized period DeRham integral from point defects in the vacuum coherence i.e. area quantization and volume without volume from a closed non-exact "area density" 2-form emergent from the Goldstone phases.

Bohm-Aharonov effect is "area without area" i.e. S1 non-trivial first homotopy – quantized loop integrals of closed nonexact 1-forms around line defects

World Hologram is "volume without volume" i.e. S2 non-trivial second homotopy – quantized closed surface integrals of closed non-exact 2-forms around point defects, e.g. one at center of Sun in Pioneer anomaly? This would be a hollow dark matter (exotic vacuum) mini-halo of the Sun.

Also, you may not have expressed yourself as clearly as you might have in presenting some of your points. Some disambiguation in response to criticisms appearing in Waldyr's paper might be a good thing.

Sure. These are all new ideas not found in literature.

I agree with Tony that Waldyr's charges of "ad hocness" are questionable. You evidently have a clear intuitive understanding of the basic physical model you are proposing. However, while I entirely agree that mathematical rigor is secondary to the physics, it does appear that several of Waldyr's points are not merely a matter of "rigor mortis", but are concerned with the proper definitions of important mathematical terms.

Yes, I think the current version is essentially OK in that regard. I basically eliminated all reference to what Waldyr found objectionable in the background stuff that is not essential to my thesi.

As for Waldyr's intemperate language, perhaps it would have been better if you hadn't cited him at all in later versions of your paper?

I thought I was being polite and honest and I made it clear that it should not be construed that Waldyr agreed with my new ideas. In fact Waldyr's contribution is forcing me to confront the need for 8 Goldstone phases instead of only 2 and then I associated the extra 6 with Calabi-Yau and massive torsion fields, i.e. both locally gauge Lorentz group and then hide its symmetry in the vacuum – i.e. non-Abelian Meissner effect for the torsion fields whose mass gap prevents us from seeing it easily.

IV. Extended local equivalence principle, i.e. locally gauge ALL universal space-time symmetries of the physical action to induce geometrodynamic fields beyond the original 1915 curvature field.

Note that at the square root tetrad level the curvature and torsion gauge potentials are SPIN 1 just like in Yang-Mills theory. When you go to geometrodynamic level

ds^2 = e^a(Minkowski)abe^b

Then you get a COMPOSITE spin 2 from entangled pairs of "subspace" SPIN 1 tetrad level fields.

Jack Sarfatti wrote:

…

My key physical idea is dark matter is same as dark energy with difference only in scale and the sign of the energy density and w less than -1/3 and from a distance it mimics w = 0 CDM.

It is obvious to me that the curved tetrad & Bekenstein-Hawking quantized area is like the superfluid circulation and that t Hooft-Susskind world hologram "volume without volume" is like Bohm-Aharonov "magnetic field without magnetic field" even if I did not get the formal math completely right on first try working alone outside of academia – Einstein needed Grossman to get his tensors right and he took ten years. I only took a few weeks so far and have not found my Grossman I guess? 🙂

Remember what Feynman said about "rigor mortis". Are Feynman integrals rigorous? Is M theory? I hear some new math is coming from M theory however. I think Waldyr is making a general point about lack of mathematical rigor in many physics papers. Waldyr is actually a Professor of Mathematics I think and there is a cultural difference. To me the math is secondary to the heuristic ideas.

Instead of some of the alleged "Dirty Dozen" threatening Waldyr that his students might not get funding because it appears that he "endorsed" my paper when I explicitly wrote that he did not do so, why don't these brave professors allegedly in search of the truth publish their own specific objections to the actual final version of the paper for all to see and for the historical record? What equation numbers in the actual version now up there are objectionable? Why do they choose to hide behind Waldyr? Remember what will be recorded IF in fact what I say about the LHC and the DM detectors comes to pass – that they forever remain silent except for false alarms. What I predict is easily falsified by an "ugly fact."

Ode on the remains of a Dark Matter Detector! 😉

Ozymandius
by: Percy Bysshe Shelley

I met a traveler from an antique land
Who said: "Two vast and trunkless legs of stone
Stand in the desert… Near them, on the sand,
Half sunk a shattered visage lies, whose frown,
And wrinkled lip, and sneer of cold command,
Tell that its sculptor well those passions read
Which yet survive, stamped on these lifeless things,
The hand that mocked them and the heart that fed;
And on the pedestal these words appear:
My name is Ozymandius, King of Kings,
Look on my works, ye Mighty, and despair!
Nothing beside remains. Round the decay
Of that colossal wreck, boundless and bare
The lone and level sands stretch far away.

On Feb 28, 2006, at 10:54 PM, Tony Smith wrote:

Jack, did you get a copy of the message from Waldyr dated Tue, 28 Feb 2006 to Zielinski with copy to me in which Waldyr said in part:

On Feb 28, 2006, at 11:23 PM, Jack Sarfatti wrote:

No I did not. How the "Dirty Dozen" could construe from what I wrote that Waldyr endorsed my paper is beyond me. I was very clear to say specifically that he did not endorse it at all. Well no more Mr. Nice Guy eh? I bent over backwards to credit Waldyr's effort. That's what one gets by being "collegial" I suppose? 🙂

The "math" is the least important part of my paper. I was not writing a "math paper." Math is not physics. So far no one has said anything at all about the PHYSICAL IDEAS in the paper. Waldyr has not. No one has. None of Waldyr's math points are relevant to the these physical ideas that I can see.

Here is what is in my paper about Waldyr

"Acknowledgment

I would like to thank Professor Waldyr Rodrigues, Jr of UNICAMP, Brazil for pointing out mathematical deficiencies in the first version of this paper that is really a progress report. The reader should not infer that Professor Rodrigues endorses all of the ideas of this paper or that he thinks the mathematics is up to his rigorous standards. I remind the reader that important new physics has been created with bad mathematics that is usually patched up later. A case in point is the history of the Feynman diagrams and the path integrals, which are still non-rigorous from the point of view of the top mathematicians."

What's wrong with these "dozen" Paragons of Omniscience? Can't these Victorian Station Masters read plain English? Look at this sentence:

"The reader should not infer that Professor Rodrigues endorses all of the ideas of this paper or that he thinks the mathematics is up to his rigorous standards."

Shame on that "Dirty Dozen."

Waldyr allegedly wrote:

"… It is true that I [Waldyr] said to him [Jack] sometime ago that I did not intend to post or publish the notes for the time being. I changed my mind (after almost two weeks) due to a comment that he inserted in the sixth draft of his paper and which to an eventual reader seems to suggest that I made corrections to that version of his paper, something which is not the case.

And indeed, yesterday before deciding to post my notes I received dozen of mails from all around the world asking: how could you endorse that paper?

Well, after that it remained no other alternative as the one I followed
which was to post my notes in the arXiv.
…

Concerning arXiv, endorsers and blacklists I have to say the following.

I think that the arXiv must eventually accept any possible paper it
receives subject to the rules:

(a) Every article should receive a signed review, which is to be posted
together with the article.[1]

(b) Any author could post a reply to the signed review. The reviewer can
write a treplic, and so on.

(c) A blacklist must exist: dishonest people who are plagiarists or invent, e.g., false affiliations must be punished, i.e., they must not be allowed to post any paper. The penalty eventually may not hold for ever, but for a time long enough for them to have time to reflect.

(d) the blacklist must be public. The reason for someone to be in the blacklist must be given. …”.

———————————————————————

Tony

PS – It might be interesting to know who were the authors of the “dozen of mails from all around the world”

I can guess who some of them are.

and exactly what they said, particularly in light of your statement that Waldyr told you “that he was threatened that his students might have trouble getting funding if he did not respond negatively.”

> Such papers are not designed for laypersons or for undergraduates. They are designed for people who are indeed very familiar with the field.

And this is a problem. Even if someone is interested in learning more about a subject, a terse presentation will be confusing and offputting. Are references to pertinent papers or textbooks too much to ask?

> So what? If it’s beyond you personally, then it’s trash?

No, but it creates a barrier to me if I want to learn more about the field. There were’t even any explanations as to what these terms were. The author has assummed that only persons skilled in the field will read the paper, and it becomes a self fulfilling assumption.

> The arxiv and the refereed journals are not an introduction to anything; they are (in principle) a place for the high-level, cutting-edge work going on in these fields. They are not supposed to be a tutorial, so it should not surprise you that they do not make a good tutorial.

I don’t expect a tutorial, but I am disappointed by how inaccessable a lot of scientific papers are. I mislike the Ivory Tower effect that this type of writing gives off, however unintentional it may be. I am an applied mathematics undergraduate with a reasonably detailed knowladge of physics and mathematical physics, but I am frequently thrown off by authors who write for a closed shop.

There was a post in this blog a while back about public engagement in science, and how people were dumbing things down with string theory violin shows and cookery classes. Really, well, trite and condescending presentations of science which I think the public sees through.

My point here is that if scientists cannot even hope to enage and interest scientists in different fields, what hope is there of eliciting general public interest and engagement in our research? If papers are being published with mistakes, perhaps this is another symptom of the same underlying issue.

15. **Steve Myers**
March 1, 2006

On “difficulty” of technical papers: they’re meant for experts in the field and so use the short hand of jargon. Of course, math is not a special language — everything in math can be expressed in English, but once you’re used to the short hand you can read the math directly without translation (for example, since I seldom use vector calculus, I still have to translate del into partials). It is true that the jargon is often used as a way to exclude outsides but without an appendix of definitions, etc., there’s no way around it. Does Sarfatti need to explain cartan forms?

16. **nigel**
March 1, 2006

‘…how people were dumbing things down with string theory violin shows and cookery classes. Really, well, trite and condescending presentations of science which I think the public sees through.’ – OMF

What matters is that most students see through it. It acts like a filter: emphasising the weirder parts of a non-tested speculative mainstream “theory” only few mathematical competent students into physics. In Britain, where string theory was loudly emphasised in best-selling books by Stephen Hawking, a 4% per year drop in A-level physics followed, which continues today.

The normal reaction of the teaching establishment to this is just to demand more propaganda, or better quality stuff, to attract students into physics. You don’t need the landscape controversy to see where physics is going wrong.

String theory is a tiny component of physics, but because it so hard to test and yet so over-publicised, it casts a dark cloud over physics. If string theory looks right, it is only because it is the conquest of free thought by censorship of alternatives.

Compare general books written about the search for a unified theory in physics when it was a popular subject in Britain (before the 1985 ST revolution), to those today when it is unpopular.

Before 1985, the future of physics was open, there were many exciting possibilities. Today, there is widespread prejudice in favour of one speculative model, with no objective predictions let alone evidence. It is defended by obfuscation, which is unethical.

17. **ObsessiveMathsFreak**
March 1, 2006

I feel there is a difference between a terse presentation and a readable one, even if the topic is highly advanced. A simple note at the begining of any document telling th ereader that familiarity with concepts X,Y and Z is assummed would in itself do a lot for ease of access. Then at least the reader knows where to look if they are lost.

In humanities, if one makes reference to an opinion or analysis, they make a big deal about citing properly. Obviously I’m not suggesting that absolutely everything must have an explanatory reference. But yes, it would be helpful if when mentioning cartan forms, the author could provide a succinct reference explaining what they are. That is, if one wants to make the paper more accessable.

18. **Alejandro RIvero**
March 1, 2006

About evidence, well, what I collected in the last three years is evidence that physicists are not intereested on evidence (a recent example I have already told: I was the first one -after six months- telling the ODG that their file http://pdg.lbl.gov/2005/mcdata/mass_width_2004.csv has a wrong value for the muon lifetime and others; the file is still (1/March/06) there but at least you can now get the corrected file by privately emailing to the pdg people; the point here is not a couple erratas, but that nobody noticed them, thus nobody had plotted the thing). At least not interested if it is not evidence for their theory; evidence is not anymore an starting point for research except if it is against SM beyond four sigma… there is a rare feeling of completeness, of impossibility to get anything new from the already measured data.

I find an interesting counterexample -or just a different way to do things- on the approach of Connes-Lott, that took pains to start with the standard model Lagrangian, and I remember Alain kept asking every practicioner about the differences between pole masses, running masses etc to be sure about how all the experimental thing could fit inside the model.

Also hep-ph people have different approach that hep-th, the -ph people keep launching models (either for the love of play or as tickets for Helsinki, you choose), but they do an effort to check against some main parameters.

19. **Theorist**
March 1, 2006

In the last week there were some papers where string theory makes strong predictions about the real world (check on the hep-th and you will find them). So things are moving, little by little string theory will overcome the landscape obstacle.

20. **woit**
March 1, 2006

Theorist,

I've looked at the recent hep-th papers and haven't seen anything like what you describe. It would be major news if there were recent strong predictions from string theory. What papers did you have in mind?

21. **ksh95**
March 1, 2006

ObsessiveMathsFreak, I really feel your pain. I clearly remember thinking the same things when I was an undergraduate.

But not to worry, there is light at the end of the tunnel. A Ph.D means that the government, or some other funding agency, has spent hundreds of thousands of dallors teaching you the precise definitions of those obscure terms. By the time you're done you will be able to read the vast majority of the literature like you read the newspaper.

Also, after completing a Ph.D you will understand that most of the things you found obscure as an undergraduate are actually trivial and writing (reading) those things would be a waste of your (the readers) time. Just think about it. To understand the term *superfluid* one should have taken a course on quantum fluids, which require courses on critical phenomena and field theory, which require courses on Statistical Mechanics, Classical Field theory, Mathematical Methods, and Quantum Mechanics, which require courses on classical mechanics and thermodynamics, which require classes on calculus and algebra…Or, put another way, go get Dr. in front of your name.

But, the main thing you'll come to understand is that everyone thinks about things differently. This means that while an intuitive wishy-washy explaination may make perfect sense to you, it may not make sense to others (especially if the others read the paper 100 years from now). For this reason it's necessary to have a set of well defined ideas, procedures, and their associated vocabulary. This way when Jack Sarfatti says

> The superfluid velocity field in Galilean relativity is the 3D Cartan closed inexact 1-form
> v = (h/m)d(theta)

we know precisely what he means; there is no ambiguity. Without this people like Rodrigues would never be able to "po-po" all over the paper.

22. **ksh95**
March 1, 2006

ObsessiveMathsFreak, I just thought of a better way to think about things. Imagine your in freshman calculus and your instructor decides to teach classes so elementary school children can understand (college freshman is to elementary school as Ph.D is to college freshman).
This instructor starts of by saying a derivative is the time rate of change of a function. A function is a mapping from one variable X to another variable Y, a variable is an abstract representation of some number, a number is an inumeration device, a mapping is…

Every freshman who already understands high school algebra just went to sleep.

23. **Troublemaker**
March 1, 2006

ksh95 has already responded very well to **ObsessiveMathsFreak**, so I will not embellish too much. The point is that yes, it is too much to ask for preprints and journal articles to cater in any way to the novice. They are not intended and should not be intended for newcomers to the field. They should not provide introductory material known to every expert, and they should not serve as a guide to purchasing introductory textbooks. If you are "disappointed by how inaccessible a lot of scientific papers are," then get a PhD, because that's who the papers are intended for. They're not meant to be toilet reading for the layperson, and the suggestion that they ought to be is ludicrous.

24. **D R Lunsford**
March 1, 2006

Douglas's "analogies" present an accurate demonstration of the analytical skill of the author.

1) In the period 1913-1930 one saw a continual improvement – by huge leaps – in the performance and sophistication of laboratories. It was hard to say which was advancing faster, experimental technique or theory.

2) The Bohr-Sommerfeld theory was well-founded mathematically and made definite predictions. Also, it provided a proving ground for applying relativity to quantum problems.

Peter did away with the chemical analogy, but this point is so vacuous that it's not even worth discrediting. For a theory with no vacuum, string theory makes a lot of empty claims.

On a happy note, it's good to see Sarfatti's name in the news 🙂

-drl

25. **A.J.**
March 1, 2006

An alternative for OMF: Instead of getting a PhD, read older papers. Many modern papers are inaccessible because they are part of a continuing conversation about some topic of mathematics. You can't pick them up and read them any more than you can expect two guys who've been talking for hours in a bar about some mutual passion to stop and explain themselves to you. But you can go back, and look at how a field got started. Usually, if you have trouble reading a bunch of different papers in a field, you'll find that they all reference some earlier foundational paper, where the basic vocabulary is introduced and explained.

To take two examples from one of my favorite subfields of mathematical physics: 1) Atiyah & Bott's paper "The Yang-Mills Equations on Riemann Surfaces" is more or less required reading if you intend to think about the relations between Yang-Mills theory and the moduli space of principal G-bundles. And you can find in there references to earlier works in the subject, reaching back to Narasimhan & Seshadri, and Mumford. 2) When Witten was writing in the late 70s and early 1980s, he couldn't assume that his colleagues knew very much of the basic vocabulary of differential geometry. So he spent quite a lot of time giving simple explanations of mathematical ideas.

Most mathematical papers do tell you where to look for an introduction to their language. If they don't tell you where to find a concept, you can always just try searching for it on wikipedia. There are some quite talented people (e.g. Borcherds) who've spent time writing expositions there.

Finally: Mathematical jargon was invented to make our lives easier, not to exclude laymen. If we'd didn't use it, we'd talk like treants: It would take days just to get through the first sentence.

26. **h**
March 1, 2006

ksh95 wrote:

"By the time you're done [with your phd] *you will be able to read the vast majority of the literature like you read the newspaper."*

I'm pretty sure that this is simply not true. Certainly not for the average phd student. Most certainly not in mathematics.

"Also, after completing a Ph.D you will understand that most of the things you found obscure as an undergraduate are actually trivial"

While I agree on this…

"and writing (reading) those things would be a waste of your (the readers) time."

…I'm not that sure about this one.
Also, while completing your phd, (hopefully) you will understand that there is at least 10 times as much new obscure stuff you wouldn't even dream about as an undergrad.

Basically I must agree with OMF on that papers should be more accessible in general (of course, I don't think that they should be at undergraduate level, that's impossible), and written with much more care.
Just compare an average preprint/textbook/conference speech with one by (insert names like Witten, Atiyah, Milnor, etc here). Difference in readability is like heaven and earth.

(sorry if this is very offtopic.)

27. **ksh95**
March 1, 2006

Hello h,
I have no problem reading most of the physics literature. Is the situation different in math?

Anyway, I strongly agree that papers should be written with more care, but that issue is an orthogonal issue to the conversation.

Back to the topic at hand. I was always taught that papers should be aimed towards the post-doc level. Any lower you bore people and any higher you confuse people. After all, the whole point is to advance the field. Advancement is optimal when we streamline communication between those doing the *"advancing"*. Of course communication to novices and laypersons effects replacement rates and funding, but these are secondary effects.

28. **Thomas Larsson**
March 1, 2006

Perhaps Theorist is referring to hep-th/0602286, where Dienes claims that a small CC naturally leads to the standard model gauge group.

29. **ObsessiveMathsFreak**
March 2, 2006

> Imagine your in freshman calculus and your instructor decides to teach classes so elementary school children can understand (college freshman is to elementary school as Ph.D is to college freshman).

Ironically, this is actually how first year calculus classes are in fact taught. At least to mathematics students.

There's probably a difference here between physics and mathematics papers, the latter of which I'm more familiar with. Though I understand that a lot of theoretical physics papers are quite mathematical.

My basic point was that many papers are in fact quite obfuscated by terminology and terseness. Obviously you cannot expect everyone to be able to read your paper, but at the same time it's a little unreasonable to expect everyone who reads it to be an expert in the field with a photographic recall of terms and definitions. A paper should, in as far as it is feasable to do so, be as modular and self contained as possible.

30. **J.F. Moore**
March 2, 2006

I think what people are trying to tell you, OMF, is that it just isn't possible. What you get in papers IS the lingua franca that has been established for a given field. Human knowledge in science at least has become far vaster than one person can ever hope to grasp.

A brief tip that works in my field might also apply to maths – read important dissertations (or parts thereof) in your subject. You can get many via UMI if your library has access. I did this a lot in my early years to get a leg up and be able to comprehend papers. Also, you also MUST talk to people about specific papers, preferably ones that you're both interested in. When starting out it's common to have a lot of misconceptions that can hamper understanding, and talking to someone else can often cut through these things quickly.

31. **woit**
March 2, 2006

Thomas,

I'm aware of the Dienes paper. He's looking at the statistical properties of 10^5 models, ones that are unstable beyond tree-level, so they are not even minima of the landscape. In addition, saying anything about the properties of 10^500 models based on looking at 10^5 very special ones of them doesn't make any sense.

On top of this, what he finds is a preference for lots of low-rank factors in the gauge group, which favors things like the standard model group over GUT groups, but he gets lots of these factors. To the extent there's any kind of "prediction" (which there isn't…), it would be for something like 8 copies of U(1) and SU(2), not one of each.

Claiming that any of this is a "strong prediction about the real world" is just absurd.

32. **Theorist**
March 2, 2006

I was refering to some papers which appeared last Friday. They might be harder to read and understand but they contain very solid results, not assumptions and guesses…. Solid mathematics and solid physics are used in at least one of them and the pheno predictions based on string theory are testable at LHC.

33. **woit**
March 2, 2006

Theorist,

If you'll be so good as to tell us which papers you are referring to we can discuss this further. I took a quick glance at last Friday's papers, and none of them seem to contain anything like a solid prediction of string theory testable at the LHC (and if they did, this would be big news). I'm not going to waste any more time trying to guess what it is you are talking about.

34. **Juan R.**
March 2, 2006

Obviously, Douglas talk is wrong in several historical, epistemological, and technical details. Some points were cited here therefore i will not repeat them.

Douglas's chemical analogy is rather outdated if one interprets it in a traditional reductionist way, especially when he uses the word "deriving"… Their perception is a beautiful example of why string theory is in the very wrong way. The lot of funding for obtaining a TOE from string theory is just lost money…

As stated by Jean-Marie Lehn (Nobel Prize for macromolecular chemistry), one cannot derive chemical phenomena in bulk from a knowledge of constituents; Lehn clearly states there is not reduction of a hierarchical level to the other, just integration between the different levels [1].

Douglas cites condensed matter physicists; well, P.W. Anderson [Nobel prize for condensed matter physics] said that condensed matter physics, for example, is NOT applied particle physics [2]. A full understanding of atoms (atomic physics) is not sufficient understand solids, and doing progresses in the field. It is more, Anderson cites examples of mainstream atomic knowledge leading to wrong conclusions in condensed matter.

Anderson's "More is different" has become a common "mantra" in condensed matter physics but is often ignored by particle physicists, stringers, and other reduccionists. It is natural to read Anderson's criticism to believe on string theory as The Final Theory (the main "mantra" of stringers). Anderson considered string theory "a futile exercise as physics" the last year.

Even the "reduccionist" Murray Gell-Mann (who is often cited by stringers as supporting the "beauty" of string theory) said that string theory -even if finally correct will be NOT a theory of everything [2].

The analogy with chemistry is rather surprising. Douglas says: "On further developing these analogies, one realizes that we do not know even the most basic organizing principles of the stringy landscape. For the landscape of chemistry, these are the existence of atoms, the maximal atomic number, and the facts that each atom (independent of its type) takes up a roughly equal volume in three-dimensional space and that binding interactions are local."

What is really the link of above with string theory except as prose for more funding on string theory during another ineffective 40 years?

Chemistry is a science; string theory is not. Moreover, knowing Douglas CV, I seriously doubt that Douglas knows that and atom is, maybe the union of an attractor and its basin Michael? 🙂

About Landscape, very little can be said those days. Landscape just reflects the desperation in the field. People took wrong ways in the past and now are in a dead end. There is not possibility for computing the CC from the Landscape, and even if they was done (via a new "revolution"), the prize would be too high for science.

I personally would prefer computing billions of things from standard science and leave the CC as a mystery before computing the CC via Antrophic/Landscaping arguments and then to predict nothing of the rest of the world.

Douglas states in his conclusions that

"We believe string theory has a set of solutions, some of which might describe our world."

That is all science behind stringers work. "We believe… might…".

1) These kinds of arguments are being repeated since 40 years ago. We are a bit saturated and is time for the research in other directions.

2) String theory does not work, it newer worked, point. M-theory is not even formulated (if they nonperturbative regime really exists).

3) Mass media, public, undergraduate students, funding agencies are misguided about real success of string theory (i.e none).

In short, we obtain a "theory" (string theory) is not theory (M-theory is even undefined), the "theory" explains/predicts nothing can be explained using GR+SM, offers wrong experimental bounds for many phenomena (e.g. wrong causalitty structure for GR, wrong basic symmetries for the SM at low energies, wrong non-zero T bosonic behavior, etc) and, for obtaining certain bounds on the CC, it needs completely break that satisfactory item we call science.

Understanding the landscape that created the landscape…

http://www.opinionjournal.com/extra/?id=85000550

-drl

36. **Chris W.**
March 2, 2006

This paper should be widely read, and I expect it will be:

Lorentz Invariance Violation and its Role in Quantum Gravity Phenomenology, by John Collins, Alejandro Perez and Daniel Sudarsky [hep-th/0603002]

The authors also make some important general observations about Lorentz invariance violation (LIV), or rather the apparent lack thereof, and the foundations of quantum field theory.

Thanks to Christine Dantas for posting about this. See the excerpts in the comments on her post.

[I know this is off-topic, but the Landscape is so depressing I felt compelled to change the subject (again).]

37. **Chris Oakley**
March 3, 2006

There is another paper (http://arxiv.org/abs/hep0603010) today about Lorentz invariance violation. It was not so long ago that anyone who said SR was wrong was considered a crackpot. But then again, it was not so long ago that one would have been considered a crackpot for suggesting that we live in one of the few universes out of 10^500 that support life.

38. **Thomas Larsson**
March 3, 2006

Douglas has at least created a great new metaphor – a nightmare.

39. **D R Lunsford**
March 3, 2006

This talk about Lorentz violation is silly in this context. In the regime where we abandon Galilean invariance, the reason is not symmetry breaking, but "decontraction", which is very different. So if Lorentz symmetry doesn't hold up, the reason will not be another shell game of symmetry breaking, rather, recognition of another regime for matter and spacetime considered jointly.

-drl

40. **D R Lunsford**
March 8, 2006

I notice no one here is sharp enough to even offer an argument with what I stated, that is, you don't even understand the problem. The problem with the world is, it's filled with mediocrities.

-drl

41. **Chris Oakley**
March 8, 2006

Hi Danny,

I may well not be sharp enough to offer an argument: I did not really understand what you were saying. Can I repeat my suggestion that you collect your best thoughts on physics and put them on a web site, like I did?

42. **D R Lunsford**
March 10, 2006

Chris, you were not in mind, and if anyone could understand it, you could – it goes like this…

One can violate a given symmetry by making more symmetry in a larger context, and then assigning the several old symmetries to their own rooms in the new one. If we make a door between rooms, one room from two, we "decontract" the original symmetries. See here:

http://arxiv.org/abs/hep-th/0106273

The key point is that, contractions are associated with dimensional parameters assigned to groups (Lorentz->Galilei = speed of light; Poincare->Lorentz = Planck length, etc.) while decontractions are associated with assigning a group to a dimensional parameter, not a one-to-one process and so inherently observational. Superficially this is like symmetry breaking – the difference is that instead of adding fields (Higgs mechanism) we “push back” the idea of vacuum itself by introducing a new fundamental symmetry, incorporating the originals by allowing a contraction to recover them. The decontraction looks like the original in some regimes (again like symmetry breaking) because the enlarged vacuum is “stiff” in the dimensional parameter (speed of light is very large; Planck length is tiny etc.)

This is really why string theory is so lame – instead of pushing back the vacuum to incorporate matter as we know it from experiments, it makes matter even more obstreperous by removing its locality.

All Sorts of Stuff

March 3, 2006
Categories: Uncategorized

Harvard mathematician Barry Mazur has many new things up on his web-site. These include an expository article on motives (this via David Corfield), and a foreword to a forthcoming popular book called Fearless Symmetry : Exposing the Hidden Patterns of Numbers. This book looks to be the first popular book to deal with the modern use of group representations in number theory, explaining what reciprocity laws are and a bit about the Langlands program.

The concept of a motive and that of using representations of Galois groups constructed using things like motives are two of the most important ideas in modern number theory. Some of the latest developments in this field concern extensions of the Langlands program involving p-adic modular forms. Mazur and Buzzard are teaching courses on this topic, and Mazur has put some lecture notes up on his course web-site. These courses are part of a special semester on Eigenvarieties at Harvard.

Mazur also has a revised version of his expository piece on category theory, a short piece about Serge Lang, and some very non-basic notes for a "Basic Notions" seminar.

Nature has a short article entitled Physicists told to confront those big questions about the Foundational Questions Institute call for proposals. There's a very positive quote about this from Lee Smolin, who is on the advisory board, but also a much more skeptical one from Paul Steinhardt: "Metaphysics is running rampant through string theory and cosmology," he says. "I would like to see things go a little bit in the other direction."

Kimball Martin's web-site of Exceptional MathReviews includes one by Robert Oeckl about a paper of the Bogdanovs. For more about them see here, here, here, and here. Remarkably, they seem to have some support from at least one string theorist.

Via Bitch Ph.D., perhaps the strangest math-related web-site I've ever seen.

The High Energy Physics Advisory Panel (HEPAP) is meeting today and tomorrow in Washington. Presentations there will include one from Bush's science advisor, John Marburger, and should be available on-line soon.

This weekend, the Mathematical Sciences Research Institute (MSRI) will be dedicating its new building, named after Shiing-Shen Chern. As part of the festivities, Roger Penrose will be giving talks, including a public lecture Sunday on Fashion, Faith and Fantasy in modern theoretical physics.

The second LHC Olympics were recently held at CERN and the talks are available on-line. This is a rather unusual exercise designed to get string theorists and other not-so-hardcore phenomenologists involved in analyzing simulated LHC data. There seem to me to be two big problems with this. First of all, there are no backgrounds in this simulated data, and understanding these backgrounds is going to be the main problem with the LHC data for quite a while. It will be the experimenters who will have to do this, and they may need help from theorists, but help of a very different nature than what this exercise is aiming at. Secondly, once backgrounds are understood and potential signals are extracted, I doubt that the LHC experimenters will be releasing the kind of data simulated here for use by theorists. I suspect they'll be doing the kind of analysis going on at the LHC Olympics themselves and releasing the results as papers under their own names. For more about this, see postings by Lubos here and here. The first of these drew the following comment from a European phenomenologist:

Phenomenology has been always been strong in Europe, hundreds of ppl work in this field since decades, and most consider this contest as child's play. Guess why no European team took part in this activity, right within a truly European institution which has scores of local phenomenologists? It is a bit like if a few phenomenologists decide to learn string theory and organize a contest in Princeton about who can build the best string model….

While this exercise is unrealistic, it may at least clarify various issues about how testable certain specific scenarios really will be at the LHC.

The latest Seed Magazine has some interesting articles. One about mathematical proof discusses problems with proofs in mathematics that may be too complicated to be properly refereed, especially the recent work by Thomas Hales on the Kepler conjecture. It ends with a depressingly silly comment by Keith Devlin:

I see a parallel between the uncertainty of these proofs and developments in physics like string theory, where we're developing mathematical theories of matter that may forever remain elusive to experimental verification.

This is the same kind of foolishness as the comment that "physicists may have to rethink what it means for a theory to explain experimental data" because of string theory (see here).

Another Seed article that has gotten a lot of attention because of it's topic is one called Getting Physical about physicists and sex. See commentary here, here and here. This last link is to Jennifer Ouellette's new blog Cocktail Party Physics, which is of independent interest.

Comments

1. **Dumb Biologist**
   March 3, 2006

   I'm confused. I see nothing especially bitchy about sarongs.

   Also, that physicists get it on is hardly news. Shrödinger was famous for carting both is wife and mistress along with him long ago, and Feynman, having developed considerable expertise on the subject, published advice on how to pick up girls in one of his books. Carl Sagan wrote about sex and drugs, specifically how the latter impacted the former. I hear some lovers of boyish, brainy men openly lust after Brian Greene, so a few also seem to have a bit of that rock star mojo. My wife certainly expressed her admiration after seeing the jacket of my copy of "Elegant Universe". C'mon Seed, tell us something we don't know…like, maybe, Hey, what are we biologists, chopped liver?

2. **Dumb Biologist**
   March 3, 2006

   Oh, I forgot Kinsey. Never mind.

3. **ObsessiveMathsFreak**
   March 3, 2006

   A great amount of mathematical proofs are often presented in a terse and reticent fashion, and the resulting proofs, though they may be correct, can only be understood by those who have already reached a deeper understanding of the topic.

The problem here is that people are misinterpreting the meaning of the word “prove”, in mathematics. To prove means to demonstrate, through argument or evidence, the validity of a statement or proposition. What that means, is that you have to convince another human being that what you say is true.

If your proof is too convoluted, too terse, or too complicated and no one is able to understand it, then you haven’t proved anything. You’ve just scribbled some symbols on paper and said they were true. If you simply brow beat people into submission, through complicated proofs or your intellectual reputation, then they have only accepted that your proof is true. They haven’t accepted the proof itself, And in this case, you haven’t proved anything at all except human fallability.

To prove something, another human being has to be able to read, understand and follow every single step of your argument, from propositions and assumptions all the way to your conclusions. And if no one can do that, your proof is not a proof. It’s just ink on paper, and science is getting nowhere.

Doubt is the worst of all problems to be faced with in mathematics. If you doubt something, even one thing, in your equations, the whole structure begins to teeter and topple in your mind, and every result you produce becomes tainted with reasonable doubt. In other words, you’ve stopped being a mathematician, and even a scientist, and you’ve just become a philosopher.

Certainty is the key. Without it, without assurred falsifiability, mathematics isn’t a real science anymore. It becomes, like psychoanalysis, a subjective endevour, where people accept what they want to accept, and there are no absolute truths anymore. This can happen to any branch of science, including physics, if falsifiability is abandoned.

4. **Dumb Biologist**
March 3, 2006

I wasn’t aware that the gold standard for mathematical proof was falsifiability. Rather, I thought it was logical consistency based upon accepted axioms.

5. **Eric Dennis**
March 3, 2006

“Metaphysics is running rampant through string theory and cosmology”

There’s an unfortunate equivocation on the term “metaphysics” that tends to pop up. Sometimes it’s supposed to suggest a Rube Goldberg mechanism of questionable verifiability, like the 19th century ether models, and other times it refers (loosely) to philosophical or foundational questions about the meaning of important theoretical concepts, e.g. “measurement”, or the precise definition of theories. String theory involves much of the former, but not much of the latter.

I take it Steinhardt is against the former, and Smolin is for the latter.

6. **Aaron Bergman**
March 3, 2006

Sometimes [metaphysics is] supposed to suggest a Rube Goldberg mechanism of questionable verifiability

Anyone who uses it that way is wrong. I’m fairly sure Steinhardt is against the proper definition. It’s all too easy to spend your time thinking about “big questions” and writing lots of papers with few formulae in them. It’s almost always a better idea to go out and calculate something.

7. **Eric Dennis**
March 3, 2006

Going out (or shutting up) and calculating can be a smart move if you’ve got a solid theory that’s been pumping out a lot of impressive results. But when the flood becomes a trickle and twenty years later the trickle has dried up, maybe it’s time to start questioning the shut-up-and-calculate mantra. You don’t even have to write lots of papers with no formulas. Just write one. And if you can’t muster enough interest to spend an afternoon in your basement, don’t pretend that wishing and praying and calculating will keep the termites away.

8. **Aaron Bergman**
March 3, 2006

One quickly learns that anyone can have lots of “deep thoughts”. Nobody cares. Until you have deep thoughts about which you can calculate something, people generally and rightfully aren’t going to be interested.

9. **Chris W.**
March 3, 2006

And then there are shallow (or incoherent) thoughts made to look deep by cloaking them in sophisticated calculations, and formalism in general. Einstein once said about an irksome minor colleague that “the man can calculate but he can’t think.” Excessive emphasis on calculations tends to encourage such people, while discouraging people who can really think—ie, those who are trying to arrive at important insights into what *ought* to be calculated, and why (and in many cases, how).

In a reminiscence about Einstein during the centennial year (1979), Chern once remarked that their conversations and his own study of Einstein’s work had led him to conclude that the singular difficulty of research in physics—and perhaps in any empirical science of real depth—is arriving at the right *formulations* of questions and problems. (Mathematicians, he said, generally start by selecting from among several clearly stated problems, hopefully demonstrating some good taste in their choices.)

10. **Aaron Bergman**
March 3, 2006

The point of physics is to calculate stuff. If you can’t do that, then you’re doing philosophy. Figuring out what to calculate is sure one of the most difficult problems out there, but you’ve already conceded in that formulation the necessity of the calculation.

11. **Anonymous**
March 4, 2006

Chern once remarked that their conversations and his own study of Einstein’s work had led him to conclude that the singular difficulty of research in physics—and perhaps in any empirical science of real depth—is arriving at the right formulations of questions and problems. (Mathematicians, he said, generally start by selecting from among several clearly stated problems, hopefully demonstrating some good taste in their choices.)

Umm. Grothendieck, anyone? Finding the right formulations of things in mathematics is crucial and drives a lot of important research.

12. **Thomas Larsson**
March 4, 2006

The shut-up-an-calculate approach works great, unless something is missing in the usual calculation schemes. E.g., if Feynman had followed that philosophy as a young man, he would have found that electron g-2 was infinite and given up. Instead, he invented path integrals and coinvented renormalization, which certainly were creative acts rather than rote calculation. Of course, once the new calculational scheme was in place, you could go back to turning the crank.

OTOH, it is unlikely that deep thoughts about the meanings of diffeomorphism invariance or quantum measurements will lead to progress by themselves. Some hard modification of the formalism itself also needed, and that can be found even if the interpretation is only approximately right.

13. **A Phenomenology Grad Student**
March 4, 2006

Peter,

Your criticisms of the LHC olympics arise frequently, and they are facile. It is easy for an outsider to criticize, but the "hardcore phenomenologist" critics who have seen the details of what goes on at these meetings seem to have been convinced. (For instance, I understand that Tao Han was initially skeptical, but was very pleased with the recent meeting at CERN.) So let me offer some responses:

This is a rather unusual exercise designed to get string theorists and other not-so-hardcore phenomenologists involved in analyzing simulated LHC data.

Well, partly, yes. But look at who put the most effort into these things: two string theorists, Verlinde and Rastelli, at Princeton (who showed impressive awareness of collider physics issues), a large group of Harvard phenomenology grad students with varying degrees of experience in thinking about collider physics, a couple of Cornell phenomenology grad students with a fair amount of experience thinking about collider physics, and Matt Strassler, who manages to be both a string theorist and a collider phenomenologist. So, your characterization is only halfway accurate. The goal is partly to educate the string theory and model-building communities, but not everyone involved was as ignorant as you imply.

There seem to me to be two big problems with this. First of all, there are no backgrounds in this simulated data, and understanding these backgrounds is going to be the main problem with the LHC data for quite a while. It will be the experimenters who will have to do this, and they may need help from theorists, but help of a very different nature than what this exercise is aiming at.

Yes and no. Early in the LHC run it will be very important to calibrate the machine, to "rediscover" the Standard Model, and so on. But important discoveries tend to be made in channels where detailed knowledge of background is not needed. Resonances will be pronounced. Events with certain configurations of leptons and missing energy are very non-SM like and one can read off kinematic features. And so on. It's really an incredibly difficult computational challenge to produce a similar exercise with backgrounds (though hopefully this will occur to some extent with the next LHC Olympics), but it's not as if issues of background were totally ignored. Most of us tried to focus on features of the signal that would not be obscured by background.

You are of course correct that there are other issues if we need to rely on background-heavy parts of the data to extract information. This is a very difficult field and it demands focused effort on better loop calculations, better Monte Carlo, better PDFs, and all sorts of other things. No one denies this.

However, one thing that you find when staring at simulated signal samples is that sometimes it can be *very difficult* to interpret features in them. Lots of "hardcore" phenomenology involves taking models and discussing how to make measurements in them. The *real* problem of the LHC is to take measurements and make models, and it can be complicated. Kinematic features can arise in multiple ways. Certain apparent features of the data can lead you in the wrong direction. And so on. This exercise is not the trivial one that those who haven't attempted it make it out to be.

Secondly, once backgrounds are understood and potential signals are extracted, I doubt that the LHC experimenters will be releasing the kind of data simulated here for use by theorists.

Almost certainly true, I think. People tend to make this objection as if it defeats the purpose of the exercise. But it doesn't, at all. Partly there is the aspect of this that we are educating ourselves, as theorists, about what information the experimentalists will tell us and how to interpret it. But another important aspect, as I noted above, is that these sample analyses can be surprisingly challenging. And so far we've basically known we're looking at SUSY scenarios. See Matt Strassler's talk for an example of how the data can lead you astray. These exercises are not trivial. Sometimes good theoretical intuition is useful in figuring out what signatures one should try to isolate, given other signatures one sees. This is not obviously something that experimentalists would be as good at, though certainly some experimentalits could do this. If we see something other than vanilla MSSM, though, it becomes a much more pressing issue.

But the most important thing, at least from my perspective, is that we can hope for genuinely useful new ideas to come out of this. There's a somewhat limited toolkit of kinematic distributions to analyze, plots to make, and so on. The exercise shows these tools are very useful in some cases and in others they're probably not optimal. Getting a bunch of reasonably intelligent theorists to stare at data and run up against various surprises and challenges will, hopefully, lead some of those theorists to start creating new tools, suggesting unorthodox approaches to data, examining signals no one has bothered to think about so far, and writing papers on such things. And I think it's clear that there's a pretty rapid change taking place: collider phenomenology is being pursued by more people, it's becoming more respected, it's reshaping the theory job market. These workshops are a small but not negligible part of all of this.

Of course my defense of the LHC olympics sort of assumes a certain bias. If the world at the TeV scale really is just SM + Higgs, or if it is just the MSSM in a particularly nice well-studied part of the parameter space, none of this is necessary and the experimentalists probably have what they need. But if you think there might be interesting surprises, there is a strong need for original thinking about how to approach the data, how to discriminate different models that have similar signatures, and so on.

Anyway, I've rambled on for too long.

14. **D R Lunsford**
March 4, 2006

Speaking of data that isn't here yet – whatever happened to the second release of WMAP data?

"Bitch PhD" – right. Wow. A banner with a smart ass little kid giving me the finger. OK then. Have a nice day!

-drl

15. **EUPH**
March 4, 2006

Dear Ph Grad Student,

your post can be perceived as: "unless understanding LHC data is just running MSSM codes, intelligent theorists should do the job". This sort of attitude partly explains why LHC olympics at CERN was attended almost only by US theorists.

16. **Aaron Bergman**
March 4, 2006

Instead, he invented path integrals and coinvented renormalization, which certainly were creative acts rather than rote calculation.

Who's arguing for "shut up and calculate" or "rote calculation"? It would be nice if people actually read what I said.

17. **A Phenomenology Grad Student**
March 4, 2006

your post can be perceived as: "unless understanding LHC data is just running MSSM codes, intelligent theorists should do the job".

I have as much respect for good experimentalists as anyone, but if the data contain puzzling surprises (as we all hope will be the case, I think), it's good to have feedback between theory and experiment. I'm not claiming theorists will do everything, I'm claiming it's good to have theorists suggesting new interpretations, other signals to study, ways to cut out background, etc. Just look at the more complicated experimental situations we already have, e.g. issues of meson spectroscopy in B physics or charm physics. There is a lot of useful feedback between experimentalists and experimentally-aware phenomenologists in those fields. This isn't like discovering the W or Z where you know exactly what to look for.

In any case, what is clearly useless is bickering on the Internet, so I'll shut up now.

18. **QWERTY**
March 4, 2006

I LIKE BARRY MAZUR'S STYLE OF EXPOSING – IT IS POETIC AND ERUDYTE AND SCHOLARLY AND FUNNY. IT REMINDS ME OF HERMANN WEYL, WHO SAID FUNNY THINGS ABOUT "THE YOKE OF A FOREIGN LANGUAGE WHICH WAS NOT SUNG AT MY CRADLE". MAZUR IS TRUELY A GENTLEMEN OF THE FOUR MOST DISTINCTIONS.

19. **woit**
March 4, 2006

EUPH,

I think you're being kind of unfair to Ph Grad Student, accusing him of an arrogance that isn't really there.

Ph. Grad Student,

Thanks a lot for your long and thoughtful comment, it's the kind of response I hope to get here to issues like this that I bring up. I didn't comment extensively on the LHC Olympics mainly because I'm not a phenomenologist (although long ago spent time working on HEP experiments) so not expert on these issues. One reason I did write something brief here was that I saw from Lubos's blog that others seemed to share some of my reaction to this. It certainly wasn't my intention to imply that anyone involved was "ignorant". However, my initial reaction when looking through the web-pages about this was kind of negative for a couple reasons, but mainly that the emphasis on looking for MSSM signatures seemed to me misplaced. Part of this is that I think it is very unlikely that this is what the LHC will find, but more generally this particular problem is one that I suspect has been already beaten to death. Phenomenologists and Tevatron experimentalists have been working on this intensively for more than 20 years and by now I assume the experimentalists have a high degree of expertise built up on this problem. Going from the Tevatron to the LHC should introduce some new issues, but those don't seem at all to be the ones considered here.

The fact that things are going badly for string theory and that the LHC start-up is coming soon appears to be causing the attention of many particle theorists to move from string theory to phenomenology. Some of this is a good thing, but I hope some of the unfortunate characteristics of string theory research (trendiness, arrogance, unrealistic and wishful thinking) don't just move into this area. The whole idea of calling this sort of educational exercise for theorists an "Olympics" and surrounding it with hoopla kind of puts my teeth on edge, and I gather others share this reaction.

I'm sure that the people involved learned a lot, and maybe it will lead some of them to ultimately be in a position to make real contributions to LHC physics, that would be great. But I also hope the whole field won't move into this. It may be much more important to have some good theorists continuing to come up with new speculative ideas for things to look for at the LHC, rather than immersing themselves in the minutia of looking for MSSM signatures. I'm sure Witten could do well at this kind of exercise, but I think it would be a waste of his most impressive talents, which lie elsewhere. The same may be true for many of the best string theorists.

20. **A Phenomenology Grad Student**
March 4, 2006

Peter wrote:

Unfortunately this is largely a technical limitation. Tools for generating Monte Carlo data for the MSSM are very well-developed (though they still lack certain desirable features). Tools for generating MC for other models are in a much more primitive state. They are improving, and I think they will play a role in the next round of these workshops.

However, even in the MSSM a lot of the effort has focused on certain limited regions of parameter space. The Michigan black box in the LHC olympics exhibited an unusual spectrum, where the main signal was events with 4 b jets and missing Et and the LSP was Higgsino. This isn't the sort of thing one finds many studies of!

It may be much more important to have some good theorists continuing to come up with new speculative ideas for things to look for at the LHC, rather than immersing themselves in the minutia of looking for MSSM signatures.

Well, as I mentioned it won't be just MSSM. Personally I find a lot of the increasingly baroque models that are being built somewhat distasteful, but in any case it's clear that many people are going to keep trying to guess the right model in advance. The things that I think require more effort are model-independent approaches for the possibility that we see something different from any model that has been built, and studies of degeneracies (i.e. how very different models can produce very similar experimental signatures) and how to design observables that break them. These things have been discussed at these workshops as well.

March 4, 2006

A note, metaphysics literally means "beyond physics". The meaning today it would be better expressed as metascience.

Paul Steinhardt quote "Metaphysics is running rampant through string theory and cosmology" is focusing in the lack of verification of some ideas developed (and asumed to be true) in string theory and cosmology (e.g. inflation).

In rigor, cosmology is not one of natural sciences becasue do not fit all requirements of the corresponding scientific method.

Is there a page where i can see the table of contents of Fearless Symmetry : Exposing the Hidden Patterns of Numbers ?

25. **csrster**
March 6, 2006

I know of one high-flying cosmologist who allegedly ensures dometsic tranquility by insisting not only on conference travel expenses for himself and his mistress, but also for his wife and _her_ lover.

26. **Michael**
March 6, 2006

Peter, your ideas have been scooped. Smolin et. al. present their new model of particle physics, and it is obvious to any educated physicist that it is equivalent to your off-diagonal SU(2) model. Don't say I didn't push you to publish your ideas, or that I didn't offer my help. What are you going to do now? Don't give up. You can still play the GUITAR and become a pop-star. 😉

27. **repulsed by Michael**
March 6, 2006

Michael, it's easy for a nasty, little man like you, a coward who remains anonymous, to mock Peter. What original physics ideas have you ever produced? I bet NONE is the answer. I bet you are a pompous snob with little talent for research. One of those academic politicians/parasites who achieves tenure by never rocking the boat, by studiously brown nosing your peers. I bet your entire ouvre consists of trying to make minor punctuation improvements to Witten's papers.

28. **Michael**
March 6, 2006

Dear repulsed by me,

if I am a coward for remaining anonymous, I trust you will immediately catch up with your little gaffe and post your full identity in a verifiable way.

I'm not here to compete, bragg or be admired, so your guess work concerning my academic contributions is irrelevant. Much less am I here to be nice. Peter needs some serious headwind, because his criticism of string theory is disingenuous. It reminds me a lot of Fahrentheit 9/11, mix a few facts with a lot of lies and make a big PR buzz from it. If his opinions were part of a scientific discourse, he'd probably be in touch with me via less public channels of communication, and the discussion would be evolving with time. What he does instead is to mislead laymen in order to create an audience for himself and satisfy his vanity. His arguments do not meaningfully evolve with time, because he simply attacks anything associated with string theory in a Pavlovian way, often using inconsistent or circular reasoning.

You're line about the politicians/parasites is really cute. How many tenured physics faculty can you count at the big Boston area universities, whose contributions aren't genuinely important? Oh wait, can you count at all?

29. **ObsessiveMathsFreak**
March 7, 2006

> His arguments do not meaningfully evolve with time…

Well that's OK then, because by the sounds of things, the rebuttals don't seem to be in significant flux either!

30. **Michael**
March 7, 2006

How could they? Rebuttals to repetitive stupidity are exepcted to be repetitive. Go figure.

31. **anon**
March 7, 2006

People offer constructive criticism here. Michael would fit in better over at Motl's blog.

32. **D R Lunsford**
    March 7, 2006

    I'm the only person here who despises these synthetic creatures so viscerally that I deserve to have my comments deleted. Don't blame the owner of this joint.

    I am repelled down to my last atom by these clowns, and what they've done to science. I wish to God someone with balls and authority, like Dirac, were alive.

    -drl

33. **Chris Oakley**
    March 8, 2006

    I don't see these people so much as hateful as irrelevant. Maybe they are relevant in the short term, but their impact on physics is likely to continue to be nothing at all, unless you count proving that something that looked like a blind alley as really being a blind alley as adding to the store of human knowledge.

    [NB: Here I expand on a message I sent to Danny yesterday:]

    Peter put his finger on it a while back in comparing the research practices of mathematicians to those of theoretical physicists.

    I think that the problem is that we are still living in the shadow of Feynman. Here was a disorganised, impetuous maverick who could solve problems that no-one else could. He would jump in there, solve the problem and then move on to something else, leaving others to clean up behind him. The reason why he could do this, you will note, was not because he was a disorganised, impetuous maverick, but because he was brilliant. Anyone else conducting investigations in this way including (nay, especially) me would end up with a mess, and nothing more.

    The problem is that Feynman was the ultimate trendsetter for theoretical particle physics research. The smartest people in the subject still try to be like Feynman, looking for the next crazy leap and never being much concerned with rigour, or building the big picture. It reminds me of the sad people working the one-arm bandits in casinos: having won the jackpot once, they think they can do it again and again, not realising that their average returns are less than zero.

    The mathematicians, on the other hand, do not have the gambler mentality, and are content to work quietly away at a problem for years with hardly anyone paying attention to them until they publish. The result of this is slow, but steady progress. The result of the particle physicists' enterprises, on the other hand, is just a series of big, bold ideas that did not work.

    Which philosophy do *you* think is more workable?

34. **D R Lunsford**
    March 9, 2006

    Hi Chris, I didn't receive any mail.

    I'd say the problem is generational mediocrity resulting from a strong tendency toward pernicious societal narcissism combined with overwhelming negative anima projections, resulting in a abandonment of personal intellectual rigor in favor of a phony self-actualization, and a loss of discrimination, the "good taste" and "common sense" that was provided by the lost, projected anima. It's not just science that is suffering. Every institution from baseball to Catholicism seems to be in crisis.

    So I think it has more to do with "me generationism" than it does with a particular scientist.

    Try email again, thanks,

    -drl

35. **Daryl McCullough**
    March 9, 2006

    Barry Mazur's article "When is one thing equal to another thing?" is in memory of Saunders MacLane. I didn't realize he was dead.

    According to the Mathematics Genealogy Project, Saunders MacLane is a direct descendent of Gauss (Gauss was MacLane's advisor's advisor's advisor's, etc. advisor).

36. **D R Lunsford**
    March 10, 2006

    Daryl,

    I still have Birkhoff and MacLane in the Chelsea/AMS edition, a wonderful book!

Yet More On ArXiv Trackbacks

March 6, 2006
Categories: Uncategorized

Several blogs today have discussions of the arXiv trackback issue, mostly spawned by Sean Carroll's posting on the topic.

Jacques Distler has a posting where he explains that the arXiv has instituted an ill-defined "active researcher" criterion for allowing trackbacks to blogs and that:
Peter Woit's publication record doesn't put him anywhere close to "active researcher status"
I've written an extensive comment over there about why I happen to think I am an active researcher and the evident absurdity of the idea the Jacques Distler is capable of making a rational evaluation of this question.

More discussion of this is at Chad Orzel's Uncertain Principles, and Georg von Hippel's Life on the Lattice.

Update: Yet more on trackbackgate from Lieven le Bruyn , Evan Goer and Capitalist Imperialist Pig. The first has the useful suggestion of using Technorati to automatically generate complete sets of links to discussions of arXiv papers on blogs. The second reminds me why it's a bad idea to hit the "submit" button when you're extremely pissed off.

Update: In discussion over at Jacques's blog about what an "active researcher" is, the dicey issue has arisen that Jacques actually doesn't seem to be one himself. One commenter has suggested that this whole issue could easily be resolved by just picking a definition of the term, noting that

Few will object to defining a minimallly active researcher as one who has posted an average of 2 papers per year to arXiv over the last 3 years.

Jacques comes no where near qualifying as "minimally active", since he has only posted 3 papers to the arXiv during the last 3 years.

Personally I don't think the 2 paper/year criterion is very good. It doesn't account for length of papers, or that they may be the product of a collaboration, so the author in question is only responsible for a fraction of the paper. A more accurate measure would be based on counting pages of papers and dividing by number of authors. Under this measure, over the last four years Jacques's research productivity looks like this:

2002: 9.3 pages
2003: 3 pages
2004: 0 pages
2005: 23.7 pages

for an average of 9 pages/year (this count is being a bit charitable, since 15 of the 2005 pages are from a "landscape" paper that may not even be science).

Jacques has made it clear that a certain author for whom this number is 14 pages/year is not "anywhere close to 'active researcher' status", so I guess he is even farther away from qualifying as an "active researcher".

Always seems surprising the way people living in glass houses like to throw stones…

Update: This particular food-fight has even been written up for the on-line component of Discover Magazine.

Update: A couple more people weigh in on this, Jim Hu and Alejandro Satz.

Update: I haven't heard anything at all from anyone associated with the arXiv, but a couple trackbacks to one of my recent postings have appeared, so there seems to have been some sort of change of policy there.

Comments

1. **ksh95**
   March 6, 2006

   Lee Smolin over at cosmic variance very elequontly said:
   If academic freedom means anything, it must mean that the university must do nothing to impede free discussion by professionally competent experts on scientific controversies. Given that Peter Woit is a Physics Ph.D. and a faculty member at a major university, who has published papers and has a book in press on the topic, he is without doubt part of the academic community to which the principles of academic freedom apply.

   End of discussion

2. **Dumb Biologist**
   March 6, 2006

   Dr. Woit,

   Just a suggestion:

   My initial suspicion that it was useless to argue about the "active researcher" criterion, idiotic or no, was I doubted the argument would make any difference. Hopefully I was wrong, and it looks as if maybe I was. Some folks even diametrically opposed to your position on ST clearly don't think much of the policy, and some have even gone so far as to insinuate it's likely a load of b.s. contrived as a pretense to do exactly what you claim: Suppress your point of view on less-than-ethical grounds.

   I'd be having a Catagory 5 conniption were I in your shoes.

   I'd also hope somebody threw a bucket of cold water on me before I fired off too many expressions of indignation, righteous or no, in that frame of mind. It's something I've found out the hard way.

   Anyway, best wishes as always, and I'm really sorry for what is obviously a terribly frustrating experience. I hope things all work out for the best in the end.

   D.B.

3. **woit**
   March 6, 2006

D.B.

Thanks for the wise words. So far I only regret one thing I've fired off today, perhaps by tomorrow I'll have realized that more were a mistake. Will keep your advice in mind the rest of the evening….

4. **ark**
March 6, 2006

I belive that Peter's credentials are more than adequate. For instance, he had recently made a presentation on work by Freed, Hopkins and Teleman, math AT/0206257, which later was elaborated by Atiyah and Segal in math.KT/0510674. I am sure, that majority of physicists either unaware or simply do not have skills to appreciate this important recent work. Peter's presentation is aimed exactly at this type of audience. I found his explanations very illuminating. The problem is certainly not with his credentials but rather in a shallow level of many discussions tolerated at his blog.

5. **X**
March 6, 2006

ark, so you mean the blog has to be well-moderated AND the blogger should be an active researcher with decent credentials. That is known as moving the goal post. Anyway, Lubos Motl's blog has no less shallow level of discussion, and it is permitted to trackback.

6. **ark**
March 6, 2006

I agree, but the issue still remains. I do not have a solution, just an observation. Most likely, there is no solution. The fact that somebody is better or worce is a fact of all our life experiences. But, to move forward with whatever democracy, perhaps, is not the best solution since Brownian motion may or may not lead away from the starting point (all depends on dimensionality of space in which it is taking place 🙂)

7. **Hogg**
March 6, 2006

I'm with Smolin!

8. **Ark**
March 6, 2006

Since the last remark surely supports my earlier statement, that is back to square one, I was thinking that may be there is at least partial solution after all. For example, everybody can suggest a paper at arxiv which is worthy of discussion provided that the person who makes such a suggestion also states very clearly why he or she thinks the paper is worth discussing. This should include some references to earlier paper(s) which given one improves/disproves. This earlier one(s) should have already some noticeable citation/downloads count thus indicating that it is of general interest to many people. Hence, it makes sence to talk about its most recent development. It would be interesting to see (for everybody) if some agreement can be reached on usefulness of any such submitted paper. Personally, I would be very surprised that such an agreement can be reached. And for this reason I was saying earlier that democracy in science is two edged sword. With all disadvantages of the pyramidal scientific system it would be totally pathetic to equate voices of all teaching institutions (recall departmental meetings at your own scool 🙂 !)

9. **D R Lunsford**
March 7, 2006

ark – it's obvious to everyone that Peter has not only brains, but balls.

-drl

10. **jb**
March 7, 2006

Question: How many sites have trackbacks blocked?

11. **Thomas Larsson**
March 7, 2006

Trackbackgate 🙂

12. **JE**
March 7, 2006

It's kind of funny to see how desperately arxiv moderators are trying to throw rationale behind their plain censorship of Woit's blog. They have even come up with an ad-hoc active research policy to support their case. What an awful shame to be perfectly aware of the fact that Peter wouldn't be allowed to trackback even if he started to publish papers on a weekly basis!

13. **Luboš Motl**
March 7, 2006

Dear Ark,

the level of the discussion is primarily determined by those who debate. I am at least trying to inhibit the kind of "discussion" in the direction of Danny Ross Lunsford, Quantoken, Nigel Cook, and so many others. Peter, on the contrary, likes to build on this kind of "discussion" because what these crackpots are saying is very convenient for his agenda. He likes to be viewed as the hero who fights against the evil science and the evil scientists. At the same time, of course, he is trying to pretend that he is not one of them.

Best
Lubos

14. **anon**
March 7, 2006

I can't believe Motl's name-calling ad homini attack by stereotyping commentators with different ideas as 'crackpots' is allowed here.

15. **woit**
March 7, 2006

jb,

I have no idea how many such sites there are. Over at Jacques's blog I asked him for a list, got no answer. Given that it took 3 months of effort to find out that there was a list and that I was on it, and another month to find out why, I suspect that getting this kind of information out of the arXiv might not be easy.

anon,

On the whole I prefer to leave Lubos's comments alone here and not delete them, although I would delete such comments from other people. Seeing what the string theory community considers acceptable behavior by one of its leading "active researchers" and bloggers has a certain educational value.

16. **Dumb Biologist**
March 7, 2006

I found the comment by Dr. Polchinski a bit confusing. I think you were right, Peter, to apologize to him for using less-than-collegial language (I'm also doing my best to be polite and appreciative these days, though I'm sure I'll fail on occasion), but I didn't find the basic message to be, in any substantive way, different from what could be found in the Nature column you linked to (the statement "For something more sensible about the anthropic principle, see a recent column from Nature." was omitted.) Example:

"Why is our Universe so exquisitely tuned to host life? Using the anthropic principle to explain the world might be a tempting alternative to invoking God, but it's not science, says Philip Ball.*"

(To be fair, Ball seems to be mostly summarizing the ideas of Smolin rather than endorsing them, but the overall message still appears to take a dim view of the Landscape, per the header I quoted above.)

Meanwhile, I've seen other bloggers express their own rather unanalytic reactions to the landscape ranging in tone from chilly agnosticism to sneering derision. I'm sure Dr. Polchinski singled out your statement to make an effective rhetorical point, but I'm not sure if it was entirely just to do so.

*Not an "active researcher" but a PhD in physics and an Oxford grad, for what it's worth.

17. **woit**
March 7, 2006

D.B.,

Polchinski was within his rights to pick out the worst of my anti-landscape postings and complain about it. It's not one I'm proud of or want to defend, although its main point that this stuff is not science is a valid one, widespread in the physics community at this moment (my allies on this include many string theorists, including Lubos).

It's interesting that Polchinski chose to write in about this in the context of the arXiv trackback issue. Distler would certainly claim that "trackbackgate" has nothing to do with my opinions about this issue, but I think Polchinski's comment shows clearly that this is what this is really all about.

18. **ObsessiveMathsFreak**
March 7, 2006

This is what happens when the rules are not clear and unambiguous. What's an "active researcher"? Can you define it? Can you give a metric that will, for anyone alive, tell you unambiguously whether they are an "active reseacher" or not.

If you can't do this, if you make rules and definitions subjective things, then you are asking for trouble.

19. **dan**
March 7, 2006

hi pete,
i know you are a particle physicist, i am curious as to what your thoughts are with a recent paper by smolin and markapolou that LQG is relevant to particle physics in this recent paper:

http://arxiv.org/abs/hep-th/0603022

we know your skepticism about string theory's ability to say anything about particle physics.

what are your thoughts about "qg and the sm" deriving the sm from lqg.
do you think it is as promisng, less promising, or more promising than string theory? of course, yours truly, lubos has his negative comments, but he is a string theorist, not a particle physicist.

20. **Kea**
March 7, 2006

Dan

The Sundance+PI paper talks about String type diagrams – hence it is just as much String theory as LQG – despite the authors', and others, points of view.

21. **woit**
March 7, 2006

dan,

Sorry, I just haven't had the time to look carefully at this work. Kea's comment about it is quite interesting. But I know little about it, so don't want to host a thread here on this topic.

22. **Benni**
March 7, 2006

woit wrote:
but I think Polchinski's comment shows clearly that this is what this is really all about.

No. Polchynski maybe quotet that comment which was most enerving to him. If someone would criticise LQG it wouldn't hurt him that much personally. Polchynski wrote that the trackback system should be shut down. This is not, what distler wants, when you read his reply (old news, he is wasting time with that controversy etc.).

For Distler it maybe the case to let you out of Arxiv. But this is due to the fact that one might imagine it is annoying when a string theorist writes "may be this is a nightmare in which the theory is today", recognizes that research struggles and then someone with only about 10 papers who published nothing in the field, writes how ugly the work of the stringtheorist is.
I would not want such person, to build a social success to be known in the field upon my failure.
This may be the reason why somepeople won't led your posts associated with a scientific archive.
They want not write papers and then see automatically generated links to their public demolition from someone who has almost nothing written. This is very good to understand.

23. **Justin**
March 7, 2006

I think that the arXiv should keep trackbacks, but just honestly admit that they will not allow trackbacks to Peter's website. I think that there is a legitimate argument that Peter's criticisms are not made in good faith, but rather seek to undermine the honest efforts of a whole comunity of scientists. Perhaps Peter thinks that string theory is not worthwhile, but that opinion in itself does not contribute to the scientific discussion, it does not show a way forward. In the meantime theorists will continue to make progress on the problems they can solve.

That being said, I do think Peter's blog is interesting, and it is worthwhile discussing string theory's successes and failures on the broadest terms. However, I can appreciate that the arXiv would not want to provide links to comments which only serve to criticize the research of hard-working people trying to solve difficult problems.

24. **Benni**
March 7, 2006

Justin, you made the point completely.
This might be the reason, why arxiv moderators wanted only blogs by an active researcher.
That means, they would allow even peter, if he would work hard to try out and got some results. Even if he would find an upper bound for the cosmological constant in string theory, they would accept this.
Polchinski said, that he often cites a paper which is critical on the landscape. I believe that.

The problem is not about the critics but the problem is that one, who never worked out a serious problem on this theory or has only around 20 papers in other fields published makes the failure of others into his triumph without having at least critical results archived.

For someone working hard, and is struggling this is not of any acceptable level. Even when it is true that the media hype string theorists created is indeed dangerous for theoretical physics. One can criticise that, but this even has nothing to do in arxiv.org

25. **woit**
March 7, 2006

Justin and Benni,

I don't know who you are, but you show no signs at all of understanding what the scientific issues are here. You appear to be students who don't know what this is all about, but somehow feel comfortable criticizing me (very repetitively in Benni's case). I'll delete any further comments from you two unless you have something substantive to say.

26. **J.F. Moore**
March 7, 2006

The criticisms of Woit I keep reading here, particularly Benni's, rub me the wrong way. Perhaps it's a byproduct of seeing CVs filled with mediocre papers churned out by hardworking but not terribly brilliant scientists which they use to propel their careers, or going through mass evaluations solely based on counting impact-factored pubs and invited talks. I don't know. Regardless, someone with Peter's credentials who has taken it upon themselves to ask important questions about a field which is consuming significant public funds, questions like 'is this actually going anywhere?' , 'is there a fundamental flaw in what is being done?' etc (I paraphrase), is doing a very important service to the scientific community and the public trust on which it relies. EVERY field of science should have these kind of questions being asked ALL the time, and in most fields these answers come trivially. (Note that justification based on reduction to technology is not what I am talking about, but the fundamental epistemology that _must_ underpin science.)

His forthcoming book is an important part of this, and I hope it gets at least a fair fraction of the same readership as Kaku's latest crowd-pleaser, but there is also a community of practicing scientists out there that could benefit from at least having the trackback there, to be followed or not. I don't see the point in requiring someone critical of a field to do new work in and publish it in that field, thereby lending further creedence to arguments which just _might_ need to be dismissed out of hand, if everyone involved were being honest about what is going on.

27. **D R Lunsford**
March 7, 2006

What would Fritz Rohrlich say about all this? David Finkelstein? John Wheeler? These people are alive and around, but are as silent as lambs. Even Sarfatti.

Why isn't Roger Penrose making decisions about trackbacks, rather than Distler?

What a crowd. I'm ashamed to be a part of this, however indirectly.

(Did you know that "Distler" means "chinless" in Halb-Plattdeutsch? And "Motl" means "bumbler"?)

-drl

28. **anon**
March 8, 2006

'Why isn't Roger Penrose making decisions about trackbacks, rather than Distler?'

I don't think Penrose would been keen to encourage string theorists who rant and rave about all conceivable alternative programs being crackpot: http://arxiv.org/tb-display/hep-th/0603022

29. **Christine Dantas**
March 8, 2006

Dear Peter Woit,

Allow me to give a brief announcement and a comment. My blog has now the trackback feature by HaloScan, so now I theoretically can send trackbacks to the arxiv (at least, according to Jacques Distler, I could). I have just sent a trackback to the paper *Quantum gravity and the standard model*, by Bilson-Thompson, Markopoulou and Smolin [http://arxiv.org/abs/hep-th/0603022]. I believe that it will take some time to appear my trackback link at the arxiv site, though.

I have offered some suggestions concerning the arxiv trackback policy, my comments can be found among the various others at Jacques Distler´s blog, so I will not repeat them here. According to my understanding of what would be a reasonable criteria for accepting trackbacks, you would qualify. The status of "active researcher" cannot be established by the number of papers alone, in my view.

I must confess, in any case, that I have mixed opinions on the truthful importance of trackbacks. Conventionally, if a researcher wants to criticize a given paper, he would normally write a comment to that paper. Or communicate with the author(s), if that is humanly possible. But now, with the internet, things have changed of course and perhaps trackbacks will start having their weight of importance on the self-regulatory nature of the scientific research (or, at least, the way it is supposed to work).

I wish you all the best of luck and hope you gain your rights to the arxiv trackback system.

Christine

30. **woit**
March 8, 2006

Christine,

Thanks, I'll post some more comments about the "active researcher" issue in a moment. It's kind of a ridiculous issue, since every blogger involved in this discussion is obviously an active researcher, and some of these blogs (like yours) are quite good. This whole thing would not be especially controversial if it were not for Distler's desperate attempts to find some kind of reason for not allowing trackbacks to my blog.

Several physicists object to the inclusion of trackbacks to their papers on various reasonable grounds. It seems to me that this can and should easily be addressed by allowing authors to choose not to allow trackbacks to their papers. This question goes way back to more than 10 years ago when I remember Ginsparg discussing a plan to allow linked commentary to arXiv papers. His plan then was to allow authors to delete commentary they didn't approve of. When asked "what about authors who delete comments explaining why their work is wrong?", he said something like "if no comments are there, the work is either wrong or not interesting, not clear that you should care which".

31. **woit**
March 8, 2006

Updated the text of this posting to include some analysis of the curious phenomenon of stone-throwing glass-house-dwellers.

32. **Christine Dantas**
March 8, 2006

Dear Peter Woit,

I have just checked, and my trackback to hep-th/0603022 can be seen now together with Lubos Motl´s trackback.

Regarding your considerations based on number of pages and collaborators (authors), well, I do not exactly agree that this could be a much improved measure of "active researcher", compared to other purely quantitative ones. See that Einstein´s paper on E=mc^2 was a very short one. Also, what page format are you considering? Sometimes papers are submitted in 2-column format. On the other hand, I agree that the number of authors is an interesting consideration to be made.

The issue of evaluating a researcher´s credentials or "status" is an old one. How do we evaluate things like *quality, impact, relevance*? People today just want to measure your work by blind numbers. But it is quite obvious that quantity does not necessarily imples in quality and the other way around is true as well.

I have gone through this several times before in my career and it is depressing. The system engulfs us. I never got interested in numbers, but in quality. But people are not interested in this philosophy or, if they are, cannot properly measure it. I am happy that I still can do my research despite the fact that I am not really in the best of worlds for such an activity.

Christine

33. **woit**
March 8, 2006

Christine,

There's obviously no good numerical criterion to evaluate whether someone is performing worthwhile research, the one in my posting was chosen purely to make a point. One could make all sorts of different points using different metrics. For the record, I certainly think Jacques qualifies as an active researcher, by any sensible definition of the term. The problem is with his insistence on the concept of some other, non-dictionary definition of "active researcher". He clearly was choosing this so as to exclude me, didn't seem to think much about whether it might exclude him too.

34. **Christine Dantas**
March 8, 2006

Dear Peter Woit,

Ok, I understand your point. Thanks for elaborating. Sometimes I excced myself when this issue on "how to properly evaluate one´s research work" comes up. I´ll stop here, thanks.

Best wishes,
Christine

35. **Christine Dantas**
March 8, 2006

Sorry for the typo ["exceed"]. I´m calming down now. 🙂

Christine

36. **anon**
March 8, 2006

"There's obviously no good numerical criterion to evaluate whether someone is performing worthwhile research"

There is a numerical formula to qualify as an endorser at the arXivs. Since, on Distler's blog, you advocated the endorsment system on the arXivs, why use the same formula:

"The number of papers depends on the particular subject area, but has been set so that any active scientist who's been working in her field for a few years should be able to endorse…"

37. **woit**
March 8, 2006

anon,

I wasn't really advocating an "endorser" system, just noting that that is the one the arXiv already uses, and there was no good argument for why they weren't using it in this case (other than the fact that links to my blog would presumably be allowed under the "endorser" system).

As I wrote over there, I also don't have any problem with an "active researcher" criterion, just with such a criterion that excludes active researchers.

38. **anon**
March 8, 2006

That is the criterion they seem to be using to qualify as an endorser. Maybe it is (or should be) the same criterion to qualify to send trackbacks.

39. **woit**
March 8, 2006

Actually, does anyone know what the current criterion for number and timing of postings to hep-th is to qualify as an endorser?

The discussion of the endorser mechanism assumed that the role of endorsers would be to endorse blogs just as they now endorse arXiv postings.

40. **anon**
March 8, 2006

All I'm saying is that they use the same phrase "active researcher" to describe both. Maybe they mean the same criterion in both cases.

41. **woit**
March 8, 2006

Distler was pretty explicit in refusing to give a precise definition of "active researcher". I would think that if he had the arXiv endorser criterion in mind (whatever it is, exactly) he would have mentioned it.

42. **anon**
March 8, 2006

They don't say precisely what that formula is either.

But, if that's what it is, would that be an acceptable benchmark?

43. **woit**
March 8, 2006

Hard to say, not knowing what the formula is. But this is all besides the point. One just wants to distinguish blogs that have some interesting content from blogs run by crackpots or people who know nothing. It's pretty obvious to me which ones have interesting content, and I think most trained physicists would agree on this. If all of the people running blogs with interesting content were arXiv endorsers, then that would be fine. I'd suspect there are a significant number of interesting blogs run by non-endorsers, so that would be a problem.

44. **Arun**
March 8, 2006

The real problem to be solved is to be able to locate all blogs that discuss a particular arxiv pre-print. This should be possible without track-back, if there is a standard way to label references to the pre-print that do not overlap with anything else that the search engines might index.

If arxiv is trying to screen for high quality, that is not possible when so many physicists host blogs, on which anyone can post comments.

45. **anon**
March 8, 2006

"If all of the people running blogs with interesting content were arXiv endorsers, then that would be fine."

"Interesting content" does not equal "should be linked-to from the arXivs".

That seems to be the whole nub of the dispute.

46. **woit**

March 8, 2006

I have a reasonably high standard for “interesting content”, thus do think it is pretty much equivalent to “should be linked-to from the arXiv”. I think the problem is more that different people will differ about what is “interesting content”.

To me “interesting content” is something I’d find worth taking the time to read if I was interested in a certain arXiv paper. I don’t see the downside here to resolving the question of what different people find interesting by being as inclusive as possible. The main danger with being overly inclusive is that you’ll end up with too long a list of trackbacks to each paper, making it hard to find those you personally are interested in. This doesn’t seem anywhere near to being a problem these days, given the small number of blogs linking to arXiv papers. If it becomes a problem in the future, it could be addressed then, at which point one would have a much better idea of what criteria might work to get rid of less interesting trackbacks.

The other problem is the one of authors objecting to all or certain trackbacks to their work. In particular, an author might reasonably object to links to a source containing comments they consider offensive or incorrect about their work. I think it would be a good idea for them to have the ability to have such links removed, or to not allow any trackbacks if they so chose.

47. **anon**
March 8, 2006

So if all string theorists decided they didn’t want trackback links from Peter Woit appearing next to their abstracts (and were allowed to remove them), how would that differ from the current situation?

“I have a reasonably high standard for “interesting content”, thus do think it is pretty much equivalent to ‘should be linked-to from the arXiv’.”

Apparently, many arXiv authors disagree.

48. **woit**
March 8, 2006

One way it would differ from the current situation is that links to discussions here of non-string theory papers (yes, this does happen…) would be there. It’s also true that quite a few string theorists read this blog and tell me that they find what I have to say worth listening to, even though (or especially because) it challenges what they are doing. I’d be quite happy if the situation were that some trackbacks were there to string theory papers where the author either didn’t care, or better yet, was interested in engaging in discussion of the paper on this blog, but not there to ones where the authors were offended by them. I’m really not trying to piss people off, rather trying to engage in serious scientific discussion.

Yes, certain arXiv authors do disagree about whether what I’m writing here is interesting content of a reasonably high standard, and that’s what this is all about. I’m happy to debate this with anyone, but not amused if they refuse to debate this and instead engage in ad hominem attacks on me, as “not an active researcher” or some such.

49. **Dick Thompson**
March 8, 2006

Why am I reminded of “We have always been at war with Eastasia”?

50. **jb**
March 8, 2006

The answer to me seems clear: get rid of trackbacks. Any filtering system will eventually come to trouble, and you can always just use your favorite search engine if you’re interested in discussion of some paper.

51. **Dick Thompson**
March 8, 2006

Reading Distler’s discussion of the policy, I was struck by this:

One’s first thought is: why not use the same endorsement mechanism used for paper submission? Unfortunately, the experience of the moderation system is that endorsement is not a terribly high barrier to entry. Some endorsers are rather loose in endorsing people to submit papers and one can only imagine that they would be even looser in endorsing people to submit trackbacks. In the case of papers, the second-stage filter of moderation is clearly necessary. But we had already decided that there would be no such second stage in the case of trackbacks.

In other words we have the mandarin attitude that can’t trust the “underlings” to stay with the program. Now, rather than *1984* I am reminded of the Bush White House. Small difference, perhaps.

52. **anon**
March 8, 2006

Oh? So now the arXiv moderation system (for papers) is high-handed censorship, too?

They should just accept every paper and have a “debate”?

There must be thousands of endorsers (clicking around, it seems that anyone with any sort of a publication record is an endorser). I can imagine that, with that number, getting endorsed ought to be a trivial matter.

53. **woit**
March 8, 2006

anon,

I’m not going to try and defend what Dick is saying, since I don’t know what his point of view is and quite possibly I wouldn’t agree with it (I’m a lot more elitist and willing to see suppression of crackpottery than many of my commenters), but I tried to engage Distler in a discussion of this point:

“Some endorsers are rather loose in endorsing people to submit papers and one can only imagine that they would be even looser in endorsing people to submit trackbacks.”

which I think is the one that Dick is characterizing as “can’t trust the “underlings” to stay with the program.”

Distler claimed that endorsers have endorsed papers by people like the Bogdanovs to back this up. I characterized this as a bad endorser and asked whether they couldn't just deal with bad endorsers for trackbacks the way they dealt with bad endorsers for papers. All I got in response to this was an insult, at which point I realized that trying to have a serious discussion with him was a waste of time, certainly not worth it on this particular question which is a side issue.

But the whole thing did show that there is an attitude at the arXiv that even endorsers can't be trusted. I freely admit that, having no access to data about how this system has worked for accepting papers, I can't tell whether lax endorsers are a serious, insoluble problem, or whether the problem is that they represent legitimate points of view that happen to be different than Distler's.

54. **anon**
March 8, 2006

"I can't tell whether lax endorsers are a serious, insoluble problem, or whether the problem is that they represent legitimate points of view that happen to be different than Distler's."

Presumably they're not a serious problem because, as Distler says, the papers are also vetted by the arXiv moderators.

55. **woit**
March 8, 2006

"Presumably they're not a serious problem because, as Distler says, the papers are also vetted by the arXiv moderators."

The current endorsement system seems to work tolerably well, and from what Distler says, involves a moderator sometimes trumping an endorser. What I couldn't get an answer from him about was why not just use the same trumping mechanism when necessary, in this case trumping an endorser who endorses a crackpot blog? This sort of extra level of moderation has nothing at all to do with the fact that it would be too hard to moderate indvidual blog entries. This would be an extra level of moderation on the question of which blogs to accept.

56. **Michael**
March 8, 2006

Peter, comparing your own academic accomplishments with Jacques' and reaching a conclusion in favor of yourself raises your crackpot index to an all-time high.

57. **woit**
March 8, 2006

No Michael, I'm just pointing out that, by the criterion suggested on Jacques blog, he and I have the same lowly status of not being "active researchers". I suspect you do too. Join the party…

58. **robert**
March 8, 2006

I recall that, when the internet first started to have an impact, it was hoped that it might liberate the scientific community from the 'publish or be damned' mindset and the tyranny of the anonymous and vindictive referee. This expectation does not seem to have been fulfilled; self-interest and internecine nastiness still prevail.

59. **Michael**
March 8, 2006

Peter, your misunderstanding is that activity is measured in number of pages or papers per year. Important new ideas per year is more like it. Jacques has already mentioned that the criterion for "active researcher" is somewhat ill-defined. He also explained to you that it's only part of a multi-stage filtering system, which as a whole works far better than its individual components do. This is a point you keep ignoring. Of course, you do it on purpose to advance your agenda. You may not be the greatest researcher, but I don't think you are stupid. I can see behind your mask and others do, too. Only Quantoken and Iman Zumbal take you at face value…

60. **Eli Rabett**
March 8, 2006

How about linking forward? Blogs that want to link to Arkiv should explicity include the report number so it will be picked up by Google, and anyone wanting to see what the comments are could simply search on the report number.

61. **woit**
March 8, 2006

Michael,

I'm well aware that Jacques's criterion for "active researcher" is "somewhat ill-defined", and part of a "multi-stage filtering system". One of the stages seems to be "is this person causing serious problems for string theory?".

Your Quantoken obsession was always a bit weird, but Iman Zumbal?????

62. **Michael**
March 8, 2006

"Iman Zumbal" is a pseudonym a crackpot better known as "Danny Ross Lunsford" recently used on Lubos' blog. Since you probably didn't know that, I can fully understand you found my mentioning that name strange. 😉

63. **Power Ranger**
March 8, 2006

Peter didn't count papers/year. He counted (pages/paper)/(authors/paper)/year.

I've never heard of that measure, till Peter invented it. It would make every single high-energy experimentalist have (nearly) zero level of activity.

Was there any point to the exercise, except to show that he could find SOME measure (no matter how ridiculous), by which he is "more active" than Distler?

64. **woit**
March 8, 2006

Michael,

Glad to have the "Iman Zumbal" business cleared up, I was worried for a moment that you had completely lost it. I do read Lubos's blog, it's one of the funniest things on the net (did you know that most Harvard professors are anti-Semites? I learned that today). And sometimes he has interesting news about things like who will get the Fields medal. But I guess I don't read it as carefully as you. Danny is pretty wacky, but can't hold a candle to Lubos in that department. Unfortunately for you, I delete much of Danny's best stuff.

65. **J.F. Moore**
March 8, 2006

Michael: "I can see behind your mask and others do, too."

You don't speak for me, or necessarily anyone else here. I don't believe Peter Woit is engaging in sophistry at all, as you imply. What I don't take at face value, because it has been made impossible to do so, is the criterion for allowing arXiv trackbacks. I do comprehend it, on the level that I understand that any bureaucrat who makes the mistake of precisely defining such a criterion (or even who specifically is charged with any judgement calls) loses their arbitrary powers related to that criterion.

66. **Michael**
March 8, 2006

Peter, if you need anything else, I'll be at your service. 😉 Why do you think I'm about to lose it? I know I'm inconvenient for you (and you and your friends here would surely find better and stronger words for it), but did I give you any indication that I'm an unstable individual?

I, too, find Lubos blog highly entertaining. Lubos is an incredibly sharp thinker and his judgement, especially when it comes to unfamiliar or vague ideas is almost unmatched. His political posts simply reflect that he is a man with principles, and he's got the guts to speak up. Whether you enjoy his mocking of Smolin articles and other humoristic posts is strictly up to you. Your comparing him with Prof. Zumbal is a stupid cheap-shot.

67. **woit**
March 8, 2006

Power Ranger,

"Was there any point to the exercise, except to show that he could find SOME measure (no matter how ridiculous), by which he is "more active" than Distler?"

No, there really wasn't any point to the exercise except that.

But if you want to stick to papers/year over the last three years, as suggested on Jacques's blog, he's well below the minimally acceptable standard of 2/year for an "active researcher" and flirting with going under half that, 1/year over the last few years. And some of these papers are, well, a bit thin. I don't think he's going to measure up to typical standards for "active researcher" constructed by counting publications. Which might explain why he steadfastly refuses to explicitly construct such a standard.

68. **Michael**
March 8, 2006

Dear J.F. Moore,
I didn't try to speak for you. I said "others do, too", which is more than likely accurate. Today's dedication of this song goes to you:

http://www.carlysimon.com/music/Lyrics/You're_So_Vain.html

69. **Power Ranger**
March 8, 2006

Is there any reason to think the standard is stricter than the "active scientist" standard used to determine who is an endorser on the arXivs (as suggested by "anon")?

I followed his suggestion of clicking around. Pretty much anyone with a pulse (scientifically speaking) who posts papers at the arXivs qualifies as an endorser.

70. **woit**
March 8, 2006

Power Ranger,

We don't know if Jacques's "active scientist" standard is stricter than that of being an arXiv endorser since he refuses to tell us what it is. The only thing definite he's told us about it is that Peter Woit doesn't come close.

71. **Michael**
March 8, 2006

"The only thing definite he's told us about it is that Peter Woit doesn't come close. "

That's what scientists do: when in doubt, stick to the facts…

72. **Power Ranger**
March 8, 2006

But we have a good bit of data: Christine Dantas, Lubos Motl, Matthew Nobes, Urs Schreiber, … all qualify. You, apparently don't.

Somewhere between their levels of productivity and yours must lie the dividing line (presumably, closer to theirs than to yours, if you're "not even close").

73. **woit**
March 8, 2006

Power Ranger,

Yes we have a good bit of data that, whatever the mysterious "active researcher" standard is, Peter Woit doesn't qualify but most other people do. And I'm sure that will remain the case no matter what for the forseeable future. At some point later this year I'll probably be posting some of my more recent research on the arXiv. It will then be very interesting to see how Jacques constructs an "active researcher" standard that allows him, with his barely 1 paper/year to qualify, but not me. I'm sure he'll find a way, but it may be really tough if he actually has to tell us what it is.

74. **woit**
March 8, 2006

Eli,

This already works. If you google on standard arXiv numbering of a paper you'll get relevant blog entries. Problem is you get lots of other stuff to and have to sift through it. Lieven le Bruyn suggests using Technorati, which tracks blogs, but I haven't tried it.

75. **J.F. Moore**
March 9, 2006

"I didn't try to speak for you." – Michael

You said that only two specific people, not including me, take Peter at face value. I do and probably some others who read this blog as well. Too bad if that was so confusing for you to grasp.

76. **anonymous**
March 9, 2006

Micheal: "That's what scientists do: when in doubt, stick to the facts…"

Agreed, but unfortunately that is not what Jacques is doing. He is fixing his conclusion first, and then making rules to justify that. That is what ID folks, creationists, fanatics and string theorists do.

77. **SteveM**
March 9, 2006

Under this totally vague criterion Higgs and Gell Mann don't qualify as "active researchers" either. I can only assume in the unlikely event they start blogs up they too won't get trackbacks. A lot of qualified people get bogged down in administration and teaching and may not publish for a long while but they should still have a voice and the right to participate.

Physics, and all science, is crucially based on debate and criticism. If you are confident in your work and publications–whether you work in string theory or anything else–then criticism, or trackbacks to criticism of your papers (even very severe criticism) should not bother you. As a professional scientist you should be able and willing to provide a counter argument at a technical level, without personal attack/abuse. Physicists have a long history of tearing each others work apart, both formally in the journals and informally at blackboards and the like–this is why physics has been so spectacular successful. Blogs are now a new medium for this debate and a very useful one.

Incidently, when exactly did physics turn into this dick measuring contest about who's publication list is the longest or who has the biggest citation size? Recently, I keep repeatedly reading these obnoxious put downs of Peter Woit's publications and credentials by anonymous characters like "Michael" and "Benni" and the like. So out of curiosity I looked up Woit's papers at slac. Now I am not a "Woitian cheerleader" by any means but the first thing I notice is a paper in Physical Review Letters written by only himself while a graduate student. It has a top citation. Then some papers as a single author in Nucl. Phys. B. and Phys Letts B. The TRUE test of a physicist's mettle is whether they can get papers published as a SINGLE author in elite level paper journals like this, the old-fashioned way, and get through the brutal (yes brutal!) peer review. So before they belittle other's past work some of these younger upstarts should try this–they might find the rejection letters very sobering. Truth is most postdocs and assistant professor now would sink like a lead whale without a lot of co-authors. On your resume one paper in PRL written on your own is worth a hundred latexed submissions dumped in the arxiv, with your name alongside another 5 authors at the top, one of whom is your department head.

The impression I get is that P Woit had the potential for a very good research career but was about 10 years too late by the time he got his Phd and simply missed the Standard Model glory years of the 70s and so never found the right niche that would have suited him. In the mid 80s a lot of guys found themselves in the same position and due to a bad job scene, started companies, went into computing or finance or took teaching posts since string theory had taken hold by then and was not to their taste or way of doing things (and of course it was string theorists who were now being hired and funded.). So please, Michael and the rest can you cut it with the snide remarks and insults? It is really wearing thin. If you think Peter talks crap about string theory then lets hear some concrete professional technical arguments from you as to why. Obviously in the trackback issue we want to block out crackpots, but we have someone here with a strong background, is qualified, has peer-revwed papers, works in a major university, has a book accepted for publication, and has the right to express his opinion. Please grant him trackbacks or else scrap this whole trackback thing. The idea that he is being censored is becoming troubling to me and a lot of other people too.

78. **Pookie**
March 9, 2006

No one disputes that Peter was doing good physics, as a graduate student, 20+ years ago.

Should the arXivs accept trackbacks from anyone who, at some point in their lives, were active physicists (all those guys who "started companies, went into computing or finance or took teaching posts")?

Maybe having once obtained a PhD in physics should be enough?

79. **Thomas Larsson**
March 9, 2006

SteveM: We all know what DistlerCo think is the big problem: Trackbacks attract flies.

80. **JE**
March 9, 2006

Woit said,

"For the record, I certainly think Jacques qualifies as an active researcher, by any sensible definition of the term."

The other way round not being true, which given the lack of experimental evidence for Distler's work, makes Peter much less pretentious or rancorous than him.

Michael said,

"Peter, comparing your own academic accomplishments with Jacques' and reaching a conclusion in favor of yourself raises your crackpot index to an all-time high".

Well, combining the bitter reaction to any criticism of string theory from some of its main proponents (now including censorship) with the lack of experimental evidence supporting it for the time being, I think Peter Woit presently scores far far behind.

Woit said,

“I’m sure he’ll find a way, but it may be really tough if he actually has to tell us what it is”.

Once you meet the quantity criterion, there are still plenty of subjective “relevance or quality standards” enabling someone to block your trackbacks if that’s the purpose. Very sad indeed.

81. **ObsessiveMathsFreak**
March 9, 2006

> Should the arXivs accept trackbacks from anyone who, at some point in their lives, were active physicists (all those guys who “started companies, went into computing or finance or took teaching posts”)?

Perhaps they should. Elsewise, what is the point of the trackbacks?

The point of trackbacks is to let the author of a paper, and the readers, know about discussions and references to their papers online. If someone who was running a company had a blog, and referred to your paper in it, showing its application to industry, wouldn’t you want to know about it?

To the trackbacks make the system more open to ideas, or do they simply cross link within a closed circle. If the latter, there’s really no point implementing the system.

82. **Christine Dantas**
March 9, 2006

Dear Peter Woit:

A suggestion.

You have several research papers published in high standard journals, but they are mostly dated back from the beginning of the arXiv (which was about 1992 I guess). If you can make them available electronically, I believe you could post them on the arXiv, perhaps with complementary notes contextualizing them or comparing them with the present status of research. There are examples of papers published before 1992 or so that were submitted to the arXiv. Select those papers of yours which you believe are of interest and post them there.

Also, I believe you have enough material to publish review and expository papers or comments to given papers that would be of high interest. Work on them and post them on the arXiv.

Perhaps that would give you the “numbers” that the “system” requires. Not that I think you should need to do that to prove anything.

I really think that a discussion on the credentials of a professor in a major university, with a very solid background, is completely anti-ethic and repulsive. But it is an excellent example of people that constantly needs to derogate others in other to find pleasure or reinforce their own idea of how great they must be compared to others.

I will stop here.

Christine

83. **sunderpeeche**
March 9, 2006

When Peter previously wrote on this topic (to say ~ “no trackbacks so far and he hadn’t heard from arXiv for 3 months”) I suggested (approx) “don’t worry about the trackbacks, so what, this blog get enough attention and respect to stand on its own merits”.

But Peter did not follow the suggestion and I am willing to admit his actions have paid off much better. I thought of writing a comment **2 days ago** but decided to wait. I am amazed, not to mention ROTFL.

You can’t pay for comedy like this. The arXiv has gone out of its way to make a fool of itself.

What is my attitude about the trackbacks? None. My main concern is that I don’t burst out laughing in the middle of the office and get sacked for reading this on company time.

I checked Peter’s publication record on SPIRES a long time ago and I noticed that most of the papers are from the 1980s. I would not call him an “active researcher”, but as several people have pointed out, the criterion is both ambiguous and irrelevant.

Well done, Peter, though I have no idea exactly what I am complimenting you for.

84. **Nat Whilk**
March 9, 2006

Power Ranger wrote: “*Peter didn’t count papers/year. He counted (pages/paper)/(authors/paper)/year. I’ve never heard of that measure, till Peter invented it*.”

This, of course, reduces down to pages per author per year. On tenure and advancement issues, something like that measure is used by my institution to measure quantity of one’s output (with this measure being augmented by an assessment of quality of output). I suspect many other institutions do so, too, counting a co-authored paper less than a single-authored one, and counting a short paper less than a long one.

85. **Pookie**
March 9, 2006

Under those conditions, I suppose you would fill every paper you write with a long review of well-known mathematics, confining your own work to a few pages interspersed here and there.

With modern wordprocessing techniques, you could turn every 6-page paper into a 60-page paper with little trouble at all.

86. **Nat Whilk**
March 9, 2006

Pookie:

If you can get away with packing 54 pages of fluff into a 60 page paper, you're submitting your papers to different journals than I am.

87. **Pookie**
March 9, 2006

Submitting to journals?

Oh. Right. Forgot about that step …

88. **Alejandro RIvero**
March 9, 2006

The technorati thing was discussed and discarded in Distler blog time ago, if I recall correctly. Now, a good techorati trick could be to look for the url arxiv.org/abs . This is, including abs and not including www so we cover mirror references.

Alternatively click here
http://www.technorati.com/mini/index.html?s=arxiv.org/abs

I suppose we could include this technorati window inside an iframe, llets see:

89. **Alejandro RIvero**
March 9, 2006

hmm the iframe does not appear in the visualization, the html is filtered during posting. if someone wants to test in his website the command is
<iframe height=500 src="http://www.technorati.com/mini/index.html?s=arxiv.org/abs"> </iframe>

90. **woit**
March 9, 2006

SteveM and Sunderpeeche,

This whole experience of having to engage in a detailed public defense of my credentials as a researcher, including responding to a large number of nasty attacks on this subject from people who have no credentials of their own, has been a rather trying experience. But the process has left me (and I gather most people who have been following it) with a lot of evidence that this is all about suppressing my criticisms of string theory, and I think the behavior of some of the people involved has been deeply disgraceful and unprofessional. It also has often been pretty damn funny.

Christine,

Thanks a lot for your comments. One possible good effect of this whole thing might be that it has provided some encouragement for me to get things written up. If Distler can ever be convinced to provide a definite standard for how many papers it takes to me an "active researcher", that would be helpful. I strongly suspect he won't though, purely because any standard he sets that would pose any challenge for me to meet would be one he is incapable of meeting himself.

All of this has caused me to think for the first time in quite a few years about my older papers from the 80s. Although people have done this, I'm not sure it's a great idea to try and post them now on the arXiv. There is at least one unpublished manuscript from that period which I was never happy with so didn't pursue publication. If I have time I might work more on that and post it. The things I was doing back then are still actively being pursued by others. For instance the latest posting at Georg von Hippel's blog is about simulations of theta-dependence in SU(N) lattice gauge theory. The first calculations of this were done for N=2 by me, with collaborators including Nati Seiberg back in 1983.

I haven't spent much time keeping up with the details of work in this field, and it's far from my current interests, so I haven't written about it here. Maybe at some point I will do this. My original work was based on what I still think is a quite beautiful idea about dealing with topology of lattice gauge fields, maybe at least I'll try and find the time to write a blog entry here some time explaining it in simple terms.

91. **amused**
March 9, 2006

"On your resume one paper in PRL written on your own is worth a hundred latexed submissions dumped in the arxiv, with your name alongside another 5 authors at the top, one of whom is your department head."

This is not actually true, unfortunately. It is more like the other way around: for career advancement in theoretical HEP, papers written with influential senior coauthors trump single-author PRL publications any day (unless the latter contains a truly spectacular result, which is rarely the case). The reason is simple: to survive long-term in this business you need the support of influential senior people, and generally you only get this if they have something personal at stake in whether you succeed or not. Young people working independently will quickly discover that their single-author PRL publications are effectively worthless on the job market.

To make this comment semi-on topic, let me just add that I think the club mentality alluded to above is also what is ultimately behind the banning of trackbacks from this blog.

92. **Benni**
March 9, 2006

Woit wrote: One possible good effect of this whole thing might be >that it has provided some encouragement for me to get things >written up.

This is the only correct conclusion existing. It should be no problem for you, even if it is a scientific critisism on stringhteory. Simply publish some serious work.

93. **woit**
March 9, 2006

Benni,

The work I'm talking about writing up has nothing at all to do with string theory. As I've tried to explain to you over and over and over again, the problems with string theory are not the sort of thing it is appropriate to write a standard scientific paper about. You can do this to show that a wrong theory is wrong, you can't do it when the theory is "not even wrong".

94. **Dick Thompson**
March 9, 2006

Peter my standpoint is that there is a wide difference between someone like Sarfatti, who got in, and Tony Smith, who didn't. Sarfatti's contribution was evaluated as mathematical gibberish, while Smith's although way off the main road, and maybe presented with "attitude", seem to be mathematically sound – I haven't seen anybody say otherwise.

Bottom line, the circle the wagons attitude is overdone, if only by a little bit.

95. **Christine Dantas**
March 9, 2006

Dear Peter Woit,

I am glad to know that my suggestion will be somewhat useful.

I very much look forward to your upcoming book.

I also look forward to your continual criticisms of string theory and hope that any rebuttals of them from the ST community will come in educated, technical language.

Christine

96. **woit**
March 9, 2006

Dick,
I agree with you about the Tony Smith/Sarfatti question.

One problem with the increasing prevalence of pseudo-scientific stuff being done by smart, respectable people is that it makes it harder and harder to maintain some reasonable standards of what is legitimate science and what is crackpottery. When this happens, standards start to devolve from focusing on content, to focusing on the credentials of the people involved.

97. **Benni**
March 9, 2006

woit wrote: The work I'm talking about writing up has nothing at all to do with string theory. As I've tried to explain to you over and over and over again, the theory is "not even wrong".

Well, you said that your current interests lie now elsewere and not in the topics you published in the past.
So I thought, as your interests lie in criticising stringhteory, you should come with something like
http://arxiv.org/abs/hep-th/0309170 which is obviously a critisism.

Even the endorsement system of Arxiv is based on the idea of an "old boys club". The thinking was "researchers only endorse researchers".
To belong to a club of researchers, I think, despite what the rules and opinions of other people are about, what a researcher is, or who they exactly want in that club, it would be best to research on something. Regardless what it is. When you find your old papers interesting you should obviously go there.

98. **Benni**
March 9, 2006

Here is even more scientific criticism:
http://arxiv.org/abs/hep-th/0402101
From the abstract:
Assuming this "landscape" exists, anthropic explanations of some quantities are almost inevitable. I explain that this landscape is likely to lead to a prediction of low energy supersymmetry. But we argue that many features of low energy physics are not anthropic and, as currently understood, the landscape picture will get them wrong.

Why don't you come up with papers like this?

99. **Alejandro RIvero**
March 9, 2006

Woit Comment 9112 wrote:

All of this has caused me to think for the first time in quite a few years about my older papers from the 80s.

This is a good news. We have got a continuous loss of people going industry, computers, math, (er… and astro-ph); generically leaving particle physics towards elsewhere.
Now tell me that Stephen Wolfram is coming back to study weak decays and I will consider the week complete 🙂

100. **woit**
March 9, 2006

Benni,

The reason I don't come up with papers like the one you quote is that it is just wrong, it's exactly the kind of paper I've been critiquing here on this blog. In this particular case, what is wrong with it is right there in the abstract:

"I explain that this landscape is likely to lead to a prediction of low energy supersymmetry."

At the time this paper was written, it was fairly clear that this kind of argument was highly dubious, that the landscape did not allow this kind of prediction. I've written about the technical issues surrounding this extensively on the weblog. I'm just not going to start adding papers to the arXiv devoted to criticizing bad arguments in "not even wrong" papers. For the 101st time, I think a blog entry about this is much, much more appropriate than writing a scientific paper and filling the literature with something purely devoted to pointing out an obviously bad argument. Since I don't think the arXiv should be filled with posted papers of this kind, I'm not about to write one. Both you and Polchinski are promoting as examples of what I should be doing papers containing incorrect claims for one method or other of extracting physical predictions from the landscape. I don't believe this can be done, for reasons many people complain that I've repeated endlessly here, but that you don't seem to understand.

101. **Chris Oakley**
March 9, 2006

> Now tell me that Stephen Wolfram is coming back to study weak decays and I will consider the week complete.

Nothing so sane, I'm afraid.

102. **Matti Pitkanen**
March 10, 2006

I think that the trackback issue is much less serious than the censorship against posting to arXiv which in practice means a professional death.

For a decade it become impossible for me to post anything to Physics Archives. Mathematical Subject Classification Tables of American Mathematical Society has alink to my homepage about Topological Geometrodynamics in the section devoted to Mathematics of Quantum Theory. Recently I was invited in to Marguis Who's Who in Science and Engineering. One might think that on this basis I should not be regarded as a non-crackpot by any person possessing IQ above 100 but the wise men in the board seem to think differently.

Certainly I am not the only one. There is large number of active researchers publishing in refereed journals who suffer arXiv.org censorship

Matti Pitkanen

103. **MathPhys**
March 10, 2006

I found Lee Smolin's comment (on Cosmic Variance) on this matter to be most eloquent.

Distler and co are discrediting themsleves and their discipline by this little stunt.

104. **Chris Oakley**
March 10, 2006

Hi MathPhys,

I could not find it. Did you mean Christine Dantas's blog?

LS seems not to be especially bothered by the latest attack from Lupine Lubie.

105. **Christine Dantas**
March 10, 2006

I believe MathPhys refers to this comment (#26) over at Cosmic Variance:

> If academic freedom means anything, it must mean that the university must do nothing to impede free discussion by professionally competent experts on scientific controversies. Given that Peter Woit is a Physics Ph.D. and a faculty member at a major university, who has published papers and has a book in press on the topic, he is without doubt part of the academic community to which the principles of academic freedom apply.
> …Lee Smolin

In my blog, Lee Smolin has commented over a discussion involving his recent paper, to whcih there is now a trackback link from my blog together with Lubos Motl´s.

Best wishes,
Christine

106. **MathPhys**
March 10, 2006

Thanks, Christine. That's the comment I had in mind.

I like it because I believe that it gets to the heart of the matter. There is an element of suppression of free speech going on at arXiv.

107. **D R Lunsford**
March 10, 2006

OK, I have a question.

In this paper:

http://arxiv.org/abs/hep-th/0106273

Do I qualify as an "active researcher", insofar as I induced both a footnote and a reference in the work of *demonstrably* active researchers?

Thanks in advance,

-drl

108. **Jack Sarfatti**
March 11, 2006

Setting the record straight.

Almost all of Waldyr's comments had nothing at all to do with my paper even in the first version. Currently the 11-th version I think corrects and/or clarifies those minor nitpicks Waldyr made for which I am grateful. Most of Waldyr's 21 pages had to do with energy conservation in GR, which has nothing directly to do with the new ideas in my paper. Waldyr wrote his review in a panic that funding would be withdrawn from his students if it was perceived that he supported my ideas. Of course I made it clear in the acknowledgement that Waldyr did in fact NOT support my claims.

WMAP Data Release Imminent?

March 9, 2006
Categories: Uncategorized

Following up on the spectacular first year of data reported by the WMAP experiment in February 2003, results of analysis of the next year's data were initially planned to be released a year later. The release of this data has been repeatedly delayed; for speculation about why, see here and here.

Over the last two years there have been a large number of scheduled colloquia by WMAP scientists that have been cancelled at the last moment. One relatively recent one was an astronomy colloquium at Caltech by Gary Hinshaw with the title "New Results from WMAP" that was initially scheduled for January 4, but was cancelled and now is scheduled for March 22.

From March 23-25 the new Center for Cosmology at UC Irvine will be hosting a workshop on Fundamental Physics With Cosmic Microwave Background Radiation. On the 23rd four WMAP team members are scheduled to speak with titles: "WMAP 0, WMAP I, WMAP II, and WMAP III."

Over at CosmoCoffee (where I first noticed this), Alessandro Mechiorri is spreading the rumor that data will be released next week, on March 14. There's also discussion of this at the Bad Astronomy and Universe Today Forum. So, looks to me like it's maybe next week, and if not, almost certainly the week after.

Update: More news about the state of WMAP from Urbano Franca here.

Update: Looks like it definitely will be very soon now, possibly some time this week. The WMAP Mission Status page says:

Second Data Release

While the first-year results were based mainly on temperature measurements, the continued mission operations are now primarily focused on the much weaker polarized signals – an invaluable "stretch" goal of the extended mission. Analyses of these weaker signals are more difficult. The calibration and systematic error analyses have been completed, and the data files have been documented for use by researchers. For an overview see RESULTS.

This last link is to a New Three Year Results page which right now just says:

Stay tuned for the release of the most recent results from the Wilkinson Microwave Anisotropy Probe (WMAP). Very soon now….

Update: It's official, the release will be on Thursday. Here's the announcement:

Dear colleagues:

We are pleased to announce that the next release of WMAP data, along with papers describing the results, are expected to be available on LAMBDA this coming Thursday, March 16 at 12 noon EST.

http://lambda.gsfc.nasa.gov/

There will be no televised press activity associated with this release, so in an effort to reach as wide as possible an audience, please forward this announcement to colleagues of yours whom you think may be interested.

Thank you very much – we look forward to seeing your analyses of the data!

Sincerely,
Gary Hinshaw
NASA/GSFC

1. **Alejandro RIvero**
   March 9, 2006

   WMAP is the "big mover" in the SPIRES table of citations. astro-ph/0302209 is now in the 7th place, jumping from a 37th last year.

2. **Dumb Biologist**
   March 9, 2006

   I was, as soon as I heard of it, intrigued by the notion that the universe might be finite, non-Euclidean at the largest scales, and that its topology would make it "multiply connected". I guess, beyond the quadrupole and octupole anomalies (which I've read might suggest interesting topology, but, pessimistically, could likely rather suggest some kind of directional bias in the measurements, as they align with the ecliptic), the evidence points to flat and infinite. Which is kind of depressing (if I understand things at all correctly), as it might mean we really have no idea what else is out there beyond our horizon, and never will. Seems reasonable to me the delay is due to attempts to get a firm grip on the source of the anomalies, and determine whether or not it's a foreground issue.

3. **woit**
   March 9, 2006

   Alejandro,

   Thanks a lot for generating that list and for the link to it. Do you have any idea about how to generate a list of most heavily cited papers not of all time, but just for 2005? I wrote to the people at SLAC asking if they will be doing this, but haven't heard back.

4. **Alejandro RIvero**
   March 9, 2006

   Peter, sorry I have tried (I had tried yesterday) but I can not see how to calculate the 2005 most cited from only the. Neither the email interface to SPIRES nor the web one give a hint about how to access the citation count fields. I think that the yearly calculation needs some special script running on the database.

The Spires people is usually hepful, er, helpful. It is only they take its time to answer. But I got finally a good feedback when doing my genealogy projects, and they even implemented the genealogy posibility to hepnames (it has problems with name duplicates, so again it seems is not so easy to interface hepnames from the web).

5. **Alejandro RIvero**
   March 9, 2006

   "from only the available indexes"

6. **Christine Dantas**
   March 9, 2006

   (…)data will be released next week, on March 14.

   Nice date. Einstein´s birthday (and also mine [grin]).

   Thanks for bringing these rumors to our attention.

   Christine

7. **Alejandro RIvero**
   March 9, 2006

   Now I think about, it could be possible to use the difference between current and 12/2004 citation counts to get an estimate of the "only2005"; the problem should be about new papers in the list, that should get a default "999" or so, or to approximate from citebase plots. Hmm, to much time needed.

8. **andy**
   March 9, 2006

   Dumb Biologist and Everybody,
   Could the results from the WMAP change our ideas about whether or not the universe is finite? I am just ignorant on what questions it is aiming to answer.
   -Andy

9. **amanda**
   March 9, 2006

   "the evidence points to flat and infinite"

   The evidence can point to flat, but obviously it cannot point to infinite, though a lot of people who ought to know better will try to tell you otherwise. There are some people who have a theoretical bias in favor of infinite spatial sections, but [a] these arguments are very dubious indeed and [b] there is no possible way that the observations can ever give us any reason to believe in infinite sections. In fact, many of us regard infinite spatial sections as a version of the landscape……

10. **Dumb Biologist**
    March 9, 2006

    Andy: Being a dumb biolgist, I kind of have to trust the astrophysicists on this one a bit, and others with the head for maths to cast the actively critical eye that I lack. I'm not sure if I have many ideas to change, just an active and enthusiastic interest in what I can only characterize as "awesome" ideas like the universe having a doughnut topology, or some other such mind-bending sort of concept.

    Amanda: Can you elaborate? Because part of the reason I find such infinities a little discouraging is precisely because it smells like Landscapology. In fact, I recall reading a Scientific American article some time ago on the subject of an infinite universe that kind of disconcerted me. The bacis gist was even if the laws of physics are the same throughout this infinite section, as you put it, there are other Earths out there, with other copies of myself. Perhaps many. I guess there just have to be if the chance of such a configuration is non-zero. And maybe on some of those other Earths I'm a leading String Theorist. The whole time I was reading this I was thinking "Oh, *come on*." That's the annoying thing about infinity. Anything that can does happen. How can you deal with that scientifically?

    Now that I think about it, Andy, I guess I have to admit I do have some biases…and yeah, I probably would have to change my mind about some things. Oh well.

11. **andy**
    March 9, 2006

    Dumb Biologist and Others,
    The reason I was directing the question to you was that you mentioned evidence about "flat and infinite." I was thinking that you don't have to be a researcher in the area to know what "the party line" is about what the WMAP data is addressing and maybe you had read something where they explained that this is what they were addressing with the WMAP data. From Amanda's post it seems that the idea of an infinite universe isn't even on the table. After I posted my question I thought about it and I thought that they would have to be questioning the big bang if they thought the universe was not finite. I didn't think they were doing that. So maybe Amanda will tell us some more or maybe somebody else will.
    -Andy

12. **Aaron Bergman**
    March 9, 2006

    One can never tell that the universe is infinite because we can only see a finite fraction of it. It's always possible that nontrivial topology is just beyond the horizong.

13. **Dumb Biologist**
    March 9, 2006

    Andy:

    Well, what can I say? I keep reading over and over that the WMAP data is reported to fit pretty darn well with a model of the univers that is "flat and infinite". Now, sometimes folks say the Universe (by "Universe" I mean, of course, what is within our horizon) is infinite in the sense that it will continue to expand forever. Sometimes they seem to be saying "The Universe" (meaning that which is not necessarily within our horizon) really is *infinte*. Always was, always will be. So, certainly all that we see now once occupied a space no bigger than an atom, but that's obviously not all there was in this version of the idea. The visible region of space expanded (and continues to do so), but maybe the same was going on beyond our horizon, as far beyond as you like. Or maybe something else is going on. I keep thinking "well how can we *know* that?", and, per Aaron Bergman's statement above, I don't understand how anyone could assert anything other than "We can't. Not really."

14. **Antonio**
March 9, 2006

Hi all,

I'm a mathematician and my knowledge of physics and it's terminology is feeble, so I have to questions:

1) When you are saying infinite or finite in this discussion, you mean non-compact or compact spacetime respectively?

2) It makes any physical sense to spacetime being a manifold *with* border? If the answer is yes, the border is (+++) or (++-) and why so?

Thanks in advance

15. **Dumb Biologist**
March 9, 2006

Well, don't take my word for it, but my understanding is the WMAP data (among other things) implies an "open" universe, which is, I guess, by definition, non-compact, i.e. unbounded.

16. **Aaron Bergman**
March 9, 2006

It's a bit trickier than that, unfortunately. Space*time* is always noncompact because time seems to be infinite in the future. So, what one ought to mean is that *space* is compact or not. The problem with that, however, is that there usually isn't a distinguished foliation of spacetime by spacelike hypersurfaces. Worse, you can sometimes foliate the same spacetime by compact and by noncompact spacelike hypersurfaces.

Nonetheless, you can still ask things like does any closed spacelike surface (w/o boundary) exist. You can also look at the spatial curvature. If it's positive everywhere, then you better have a compact manifold if I remember my math correctly. If you could, for example, shoot yourself in the back, that has consequences when you look at the sky and people look for those effects.

Or something like that.

17. **D R Lunsford**
March 10, 2006

Can we trust this data to be free of neoconservative spin, so to speak? And why the f=ck has it taken so long? One hopes there was an apparent anomaly that could not be ignored, and has now been assigned an unknown physical cause because the anomaly is real and can't be ignored (correlation with the ecliptic plane for example).

-drl

18. **amanda**
March 10, 2006

What I'm going to say is my understanding after speaking to a real expert — ie, modulo possible misunderstandings on my part:

Aaron Bergman said:

"It's a bit trickier than that, unfortunately. Spacetime is always noncompact because time seems to be infinite in the future."

You're assuming that it will always accelerate. We don't have any reason to believe that it will….but anyway, to be really strict about it, a spacetime with a bang and a crunch is non-compact even though its total age is finite [open intervals and all that….]

"So, what one ought to mean is that space is compact or not. The problem with that, however, is that there usually isn't a distinguished foliation of spacetime by spacelike hypersurfaces. "

Actually, usually there is: the spacelike sections in which one sees isotropy. The main exception is deSitter, which contains nothing but vacuum energy anyway so it looks isotropic to lots of different observers!

"Worse, you can sometimes foliate the same spacetime by compact and by noncompact spacelike hypersurfaces."

I think I would say "various parts of the same spacetime", eg you can't foliate *all* of deS with non-compact spacelike hypersurfaces [I think!]. Remember that *all* of dS has the topology of a line times a sphere….

"Nonetheless, you can still ask things like does any closed spacelike surface (w/o boundary) exist. You can also look at the spatial curvature. If it's positive everywhere, then you better have a compact manifold if I remember my math correctly. "

Assuming they are complete, yes.

"If you could, for example, shoot yourself in the back, that has consequences when you look at the sky and people look for those effects."

People look for such things, but they have not seen them [yet?]. But absence of evidence is not evidence of absence…

"Or something like that. "

Agreed. 🙂

19. **csrster**
March 10, 2006

So the most likely result is that space is _locally_ infinite?

🙂

20. **Dumb Biologist**

March 10, 2006

Please forgive my ignorance…

Now I know a manifold is something that might look Euclidean up close, but globally could be more complex. A foliation is…? Looks like it's something with a bit more variety globally, yet locally describes the manifold. Is this at all correct? If you don't mind helping me a little with pictures, if I were to take a spherical manifold and foliate it in some allowed way (I assume not any sort of foliation is allowed), what would those foliations look like, and what would/could they tell me about the sphere?

21. **woit**
March 10, 2006

D.B.,

We're getting off topic here, but in this context a foliation just means that you can globally choose hypersurfaces of constant time that can be interpreted as "space".

More generally a foliation of a manifold is something like a choice of families of submanifolds that fit together to fill up the manifold. One simple example is a fibration, i.e a foliation where all the "leaves" (in this case called "fibers") of the foliation are isomorphic, and locally the manifold looks (fiber X nbhd. of point).
A famous example is the Hopf fibration of the 3-sphere, a foliation by circles. The general story of what foliations of spheres can look like is quite intricate.

22. **Aaron Bergman**
March 10, 2006

You're assuming that it will always accelerate.

No. Just that there's no big crunch. (Although, as you say, there are compactness issues associated to singularities that I was ignoring.)

Actually, usually there is: the spacelike sections in which one sees isotropy.

I was speaking generically; most spacetimes are not isotropic.

"Worse, you can sometimes foliate the same spacetime by compact and by noncompact spacelike hypersurfaces."

*I think I would say "various parts of the same spacetime", eg you can't foliate *all* of deS with non-compact spacelike hypersurfaces [I think!]. Remember that *all* of dS has the topology of a line times a sphere….*

You can, however, take a quotient of dS so that you've covered the whole thing, IIRC.

People look for such things, but they have not seen them [yet?]. But absence of evidence is not evidence of absence…

As I said above, there's always the possibility that these things are lurking just behind the horizon. All we can do is observe what we've got and talk about that.

23. **Dumb Biologist**
March 10, 2006

OK, sorry to get off topic, and thanks for the brief lesson!

24. **Dumb Biologist**
March 10, 2006

drl: I can't imagine any other reason for the delay that makes sense, given what is known so far. It appears they've already seen enough to know there's either some kind of foreground contamination they can't get rid of without great difficulty, or there's new physics of some sort. It seems quite reasonable to expect they're working hard to make whatever data they release be of the highest quality so they have the highest confidence possible it's either one or the other.

25. **D R Lunsford**
March 10, 2006

Db, let's hope.

Something I'm working on predicts an EM field whenever there is a gravitational field (that is, EM is part of the geometry). If there is a definite correlation with ecliptic, I get a way to determine the effective coupling and so a completely new way to determine the CMB temperature.

How are the raw data handled? Are they available to all "active researchers" who wish to study them?

-drl

26. **woit**
March 10, 2006

Danny,

Data from WMAP is made available at

http://lambda.gsfc.nasa.gov/

How "raw" it is, you'll have to decide for yourself.

27. **Urbano**
March 10, 2006

Peter, I have also commented about that here.

28. **Dick Thompson**
March 10, 2006

For those of us who can read it Padmanabhan's new paper "Dark Energy, Mystery of the Millenium" http://www.arxiv.org/abs/astro-ph/0603114, is relevant to the finite/infinite question. He takes our limited access seriously: every class of observer has a horizon, and every 2-surface in spacetime can be the horizon for some class of observer, so what can we deduce from that? And he deduces quite a bit!

29. **Urbano**
March 10, 2006

Thanks for the update, Peter :-)!

30. **Dumb Biologist**
March 10, 2006

From D.T.'s cite:

"…it is obvious that the cosmological constant is telling us something regarding quantum gravity, indicated by the combination Gh-bar. *An acid test for any quantum gravity model will be its ability to explain this value*; needless to say, all the currently available models— strings, loops etc.—flunk this test."

That's gotta be irritating to somebody…

31. **Michael**
March 10, 2006

Peter, you mentioned that you would like to publish some of your latest research, probably later this year. Would you mind telling us what you have been working on? Any amount of detail you're comfortable with would do.

32. **woit**
March 10, 2006

Michael,

This is completely off topic, and given all your other comments here, I doubt you actually have any real interest in the answer.

I've mentioned this several times, but the main thing I've been working on is the relation between 2d quantum Yang-Mills theory coupled to chiral fermions and representation theory. The Freed-Hopkins-Teleman theorem is a part of this story, and one of the main conceptual problems I've been struggling with is that this seems to require a different way of thinking about BRST than is usual. If I get the BRST issues completely sorted out, I'll first write that part of this up separately.

At some point in the next few months I'll try and write some longer blog postings at least explaining some of the mathematics background, stay tuned. But I'm not going to discuss this anymore here in a comment section of a posting on WMAP. If you have a serious interest in it and want to discuss it, feel free to contact me via e-mail.

33. **Kris Krogh**
March 10, 2006

WMAP isn't the only NASA physics experiment where the release of data has been delayed mysteriously. Gravity Probe B was launched in April 2004 and finished collecting data last August. NASA's post-launch schedule called for announcing the results next month. That's been pushed back a full year.

The $700 million experiment is an extremely sensitive gyroscope in a drag-free polar orbit, whose orientation is compared to a guide star by an on-board telescope. It's designed to measure two effects predicted by general relativity: One is a geodetic precession of the gyro axis in the plane of the probe's orbit. The second is the Lense-Thirring effect — a dragging of inertial frames caused by Earth's rotation, causing the axis to precess in its rotational plane.

The precise outcome won't be known until the probe's data is combined with measurements of the guide star's motion, from a separate group. Those have been embargoed — so it can't be said the gyro analysis was influenced to give a particular result. Still, the guide star's approximate motion is known from previous measurements by the HIPPARCOS satellite. And if the Lense-Thirring effect is absent (which I'm predicting) that would be apparent already.

It's interesting that while NASA is forced to drastically cut science programs to fund the Bush Mars initiative, they've chosen to extend this one. According to the Gravity Probe B web site, not all the additional time will be needed for data analysis. That should be finished by summer's end. Until the following spring they'll be having the results vetted by various experts. (And maybe garnering support for an unexpected result.)

This additional one-year delay comes on top of many years of others in the probe's launching. And those of us who've staked our futures on the experiment's outcome are left hanging that much longer.

35. **wolfgang**
March 11, 2006

Kris,

> NASA's post-launch schedule called for announcing the results no later than next month. That's been pushed back a full year.

As far as I remember, it was always clear that no results would be announced after just one month. Gravity probe B is a unique experiment which will probably not be repeated any time soon. Thus it is very important to get data analysis (by different independent teams) right, which simply takes some time.

There is already a lot of evidence for the Thirring-Lense effect and I would not expect a negative result. But it will be very interesting to see the details of their report.

36. **Brett**
March 11, 2006

The strongest evidence for gravitomagnetism comes from binary pulsar measurements, and this is quite compelling. The Lens-Thirring prcession is really nothing more than the most elementary consequence of gravitomagnetism. It is possible that there might be a discrepancy between the observed precession rate and the one predicted by General Relativity; that would be tremendously interesting, although I still think it's unlikely. However, it would be amazingly improbable that no dragging of frames at all was observed by Gravity Probe B.

The odds of seeing no Lens-Thirring precession at all, is based on evidence from other areas, practically nil. I do not believe this because I have some vested interest in accepted theories being proven true; indeed, precisely the opposite is true. I believe the GR gravitomagnetic predictions will be borne out simply because the evidence is so good in other sectors.

Got this from cosmocoffee.

News of the Multiverse

March 13, 2006
Categories: Multiverse Mania

When I was reading Susskind's book The Cosmic Landscape, I was paying close attention to the main problem with the whole multiverse/anthropic string landscape idea: is there any sort of experimental prediction that emerges from this that would justify calling it science? One thing that kind of mystified me was Susskind's claim, in the Introduction and Chapter 12, that the "cosmic horizon" beyond which other parts of the multiverse live is like a black hole horizon and in principle information about what is beyond the horizon is accessible in the analog of Hawking radiation. This seemed to be a rather vague idea, which Susskind goes on to drop, never mentioning it in the chapter he devoted to possible experimental tests of the landscape. Since I'd never heard of anyone claiming this anywhere else, and Susskind didn't seem himself to take it very seriously, I just ignored it.

Cosmologist G. F. R. Ellis, in a new preprint entitled On horizons and the cosmic landscape has decided to take it seriously, and show that it is wrong. Ellis's paper is rather peculiar; I've never before seen an arXiv paper that argues against not another scientific paper, but some vague statements in a popular book. I haven't tried to follow Ellis's argument, partly because it seems rather vague itself, with not a single equation in it. Perhaps this is unavoidable, given the vagueness of Susskind's argument that he is challenging. Anyway, at the present time, the situation seems to be that neither Susskind nor anyone else has come up with a calculation that would show how to detect information about other parts of the multiverse hidden in some sort of Hawking radiation from a cosmic horizon, and now we have an argument from Ellis that this is in principle impossible.

Some people have been giving me grief about writing blog entries with no equations, but here no one seems to have any.

If you want to hear more from Susskind about the multiverse, he's giving the colloquium next week at MIT with title The Landscape and the Megaverse, and the abstract of this talk is:

A new paradigm for the origin of the laws of physics may (or may not) be emerging out of observational cosmology and theorists efforts to understand string theory. The ordinary 15 billion light-year universe is being replaced by a vastly bigger "megaverse" consisting of a huge number of what Guth calls "pocket universes." If this is true then many of the Laws of Physics that we normally think of as "written in stone" will be local environmenal facts. I will explain the evidence for this controversial view, its implications, and the various views of leading physicists and cosmologists.

Susskind is also giving a talk here in New York on April 10 at the New York Academy of Sciences. The description of the talk tells us that

Several decades ago, Susskind introduced the revolutionary concept of string theory to the world of physical science. In doing so, he inspired a generation of physicists who believed that the theory would uniquely predict the properties of our universe. Now Susskind argues that the very idea of such an "elegant theory" no longer suits our understanding of the universe….

…Susskind believes that string theory, rather than reaching a dead end, has led to a vastly expanded concept of the universe, which he calls "the lanscape," where the anthropic principle makes perfect sense.

Attending the talk would cost $20, so I think I'll skip this one.

The last issue of the NYAS publication Update Magazine has an article by Lee Smolin on all of this entitled A Crisis in Fundamental Physics. Later this year Smolin will have a new book out, entitled "The Trouble With Physics".

There is something I would very much like to attend, but will be out of town so will have to miss. The American Museum of Natural History each year organizes a debate in honor of Isaac Asimov. This year the topic will be Universe: One or Many?, and the blurb goes:

Join a panel of cosmologists to argue and debate the possibility that our Universe is just one of many universes that comprise the "multiverse." This notion invokes dimensions beyond our everyday experience and draws from the leading edge of our conception of the cosmos. The presence or absence of data in support of these ideas forms a central theme for the evening.

I'm not sure who is going to argue for the presence of data in support of these ideas since I've never heard of any. The panelists are Michio Kaku and Andrei Linde, presumably pro-megaverse, Lawrence Krauss, who I'm guessing is on the anti-side, and Lisa Randall and Virginia Trimble, about whose views on the subject I know nothing.

Comments

1. **Aaron Bergman**
   March 13, 2006

   Ugh. Kaku again.

2. **Tung**
   March 13, 2006

   In that article, Smolin is saying that the pragmatic style (the American style) of doing physics is posing great harm to the current progress of physics.
   In Einstein's words, our generation is one that filled with mere artisans rather than real seekers of the truth.

3. **Chris Oakley**
   March 13, 2006

   It seems that the anthropic evangelists would rather destroy the subject altogether than forego the opportunity to preach their foolish philosophy.
   Let us be clear on this: the public may not understand Calabi-Yau manifolds or heterotic strings, but they certainly understand the basics of scientific reasoning, and are perfectly capable of identifying situations where certain people choose to abandon such principles. If Susskind *et al* manage to convince people that fundamental physics has now ground to a halt, how can this be good for funding?
   A lot of string theorists seem to want to silence Peter, but it seems to me that the anthropists are the ones who are desperately in need of censorship.

4. **anon**
   March 13, 2006

   Peter, the relationship between black hole information loss, assuming the universe is a black hole, and Hawking/Susskind/t'Hooft was discussed in a here on this blog last July, although the link from Google doesn't work.

My recollection is that Hawking first showed in say c1976 that information gets lost in black holes. He gave a lecture in San Francisco a couple of years later, that Susskind and 't Hooft attended. They bought Hawking's idea and applied it to the universe, on the assumption the universe is a black hole. Recently, say c2004, Hawking found an error in his original argument.

It is sweet that Susskind is under attack now from G. F. R. Ellis, who is co-author of Hawking's major treatise, "The Large Scale Structure of Spacetime".

5. **Anon.**
March 13, 2006

Peter, I find it strange that you are harshly critical of string theorists but allow others to make sweeping and ridiculous claims without comment. I found Smolin's article to be highly disingenuous. For instance, he says "Theories of quantum gravity include twistor theory, causal set models, dynamical triangulation models, and loop quantum gravity. One reason string theory is popular is that there is some evidence that it points to a quantum theory of gravity."

On the other hand I think it is clear to most theorists that, despite its (many) problems, string theory *is* a quantum theory of gravity. Smolin's "there is some evidence" is vastly understating the case. However, it is *not at all* clear that loop quantum gravity is a *theory* in the technical sense in which physicists use the word "theory." Naively quantizing gravity, one runs into the problem of nonrenormalizability, i.e. of infinitely many undetermined couplings, so we say that this is not a theory. It is not at all clear that LQG avoids this problem, and in fact it appears quite likely that it does not. Even Lee admits that he does not know whether there are infinitely many undetermined couplings or not!

Here is a thread from your blog in which this is spelled out pretty explicitly.

So, given that it is not clear that LQG is a theory at all, whereas string theory is at least that, I find Lee's article troubling. If LQG eventually proves to contain some new principle that restricts possible interactions and creates a sensible theory, that would be exciting, and the community would not ignore it. But until then it is justifiably ignored by most of the community. Appealing to non-experts and claiming to be part of a grand philosophical tradition are moves that I find distasteful.

(I find the landscape equally distasteful, but clearly that receives plenty of attention already. I just fail to see why you appear to encourage one sort of non-scientific hype while frowning on others.)

6. **woit**
March 13, 2006

Anon,
The LQG/string theory war is off-topic here, it has nothing to do with this posting. I mentioned Lee Smolin's article in passing because it is mainly about the multiverse and was published in a NYAS publication, thus relevant to the topic at hand.

I strongly disagree with your characterization that string theory is a theory, LQG not, and don't see anything wrong with what you quote from Smolin. There are serious questions still up in the air about both of them. In the case of string theory, no, it is not a consistent quantum theory of gravity in 4d, since all we have is a divergent perturbation expansion.

The current situation is that no one has anything that I would call a really satisfactory theory of quantum gravity, one that is completely consistent and well understood, and either makes testable predictions or explains in a convincing way how the standard model is related to quantum gravity. As long as this is the case, my point of view is that people should be trying as many different kinds of ideas as possible. The problem with string theory is not that some people are doing it, but with the way it is being fanatically pursued, despite its by now obvious failures, driving out people who try and work on other ideas. If you think ideas about quantum gravity should be "justifiably ignored" because they have problems, you need to ignore everything.

Personally I see some of the ideas the LQG people are investigating to be much more promising than the ones used in string theory, others will differ. Until either side comes up with a completely consistent theory that makes testable predictions that are then checked, reasonable people can differ about this.

Please, take the polemical string theory/LQG arguments somewhere else. They don't belong in the comment section to this posting.

7. **Christine Dantas**
March 13, 2006

I do not know about Trimble's views on this issue, but I have
found an interesting passage that she quotes:

> We understand the concern of cosmologists that unbridled speculation should not take over the field, that it is better to persist with the standard model, warts and all, than for opinions to become splintered, with the decline of professional standards which would then almost inevitably ensue.
>
> Our response to this point of view, with which we have some sympathy, is that undesirable fragmentation has been permitted already, through the invasion of cosmology by Particle physicists. If the invasion had the precision and the certainty of earlier invasions of astrophysics by atomic theory and nuclear physics, the consequences would obviously be positive. However, one can have reservations about the advantages of becoming caught up in speculations from a different field, especially when those speculations are announced with an air of authority that will probably turn out to have been taken too seriously.

[Attributed Sir Fred Hoyle, Geoffrey R. Burbidge, and Jayant Narlikar, according to Trimble´s article *"Can't You Keep Einstein's Equations out of my Observatory?"*, BeamLine 29, No. 1, p 21-25 (1999).]

Interesting enough, as she points out, these researchers are well-known for their relatively non-mainstream contributions to cosmology.

But I must restate: I do not know her present opinions on the multiverse issue.

8. **Another Anon**
March 13, 2006

I agree with the other Anon that Smolin's article is a bit distasteful and self-serving. He seems to be seizing on the multiverse/landscape situation as an opportunity to knock string theory off the throne and replace it with LQG and related approaches, exchanging one brand of hype for another. Not much in this for peasants like me working on such mundane topics as ordinary gauge theory (boring things like trying to construct nonperturbative chiral gauge theories, so as to have a chance of determining whether that tedious hypothesis about sponaneous gauge symmetry breaking in electroweak theory is true or not.) Doesn't sound like there would be any more crumbs for us if King Witten were to be replaced by King Smolin.

9. **woit**
March 13, 2006

Another Anon,

Undoubtedly Smolin would like to see less resources and attention flowing to string theory and more to LQG. Given the current huge imbalance on this issue in favor of string theory, this is not at all unreasonable. I don't see the slightest danger any time soon of a "King Smolin" controlling the bulk of resources in the field and suppressing alternative points of view.

I think I share your point of view that the problems I care most about are being addressed neither by string theory nor LQG. But, again, this really is not the place for more battles about string theory vs. LQG.

10. **Aaron Bergman**
March 13, 2006

This is pretty off-topic and Peter's welcome to delete it if he wants, but….

You know, I'm trying to be polite to Lee over on another blog, but my god. That article is so unbelievably tendentious, self-aggrandizing and condescending that it passes into the realm of dishonesty. You want to know why you get such a bad reaction from other physicists, Lee? It's not because string theorists hate LQG. It's because of supercilious articles like that.

11. **woit**
March 13, 2006

Aaron,

You're right that this is both off-topic, uncivil, as well as stupid to boot, and I should delete it. Instead I'll leave it up as yet another indication of the kind of ugly behavior that string theorists insist on engaging in these days.

Look, Lee is someone who has always been completely civil to everyone, in his comments on blogs and in everything he writes and does elsewhere. He has maintained this civility in the face of absolutely appalling behavior towards him by Lubos Motl (behavior that no one in the string community sees fit to publicly denounce or take any action against), as well as a less than civil tone from you, Jacques and others. For you to be complaining about Lee's behavior as "so unbelievably tendentious, self-aggrandizing and condescending that it passes into the realm of dishonesty" and "supercilious", given the tone and content of the way string theory has been promoted and the behavior of your string theory colleagues, both close ones and not so close ones, is completely ridiculous.

Just knock it off with the personal attacks, I'm sick to death both of being the target of this kind of shit from people like Lubos, Jacques (and many others), and of seeing you throwing it at people like Lee, and anyone who dares to point out the problems with string theory. If you think something someone writes is inaccurate or you have a scientific criticism to make, go ahead and make it in a civil fashion. If you can't do that, shut up. In any case, stop polluting this field with this kind of nastiness.

12. **Aaron Bergman**
March 13, 2006

Lee's "civility" has begun to feel to me to be tremendously superficial and political. He keeps a tone of civility while being substantively dishonest. It's getting to be offensive. At least Lubos doesn't hide his disrespect for others behind a false guise of comity.

You accuse me of "throwing [personal attacks] at … anyone who dares point out the problems with string theory." Please give me an example. I'm quite googleable. If you can't, don't foist on me the actions of others. Perhaps you've forgotten the various times when I've agreed with various criticisms of string theory?

As for the scientific criticism of Lee's tired points, that's been done a zillion times both here and on Cosmic Variance. That Lee seems to not have listened to any of it at all is part of the problem.

And WTF am I supposed to do about Lubos? I lost the code to the orbital mind-control satellites a few years ago, and I think it would be clear by now that Lubos isn't going to listen to anyone. I'm open to suggestions.

13. **Who**
March 13, 2006

Aaron, I was surprised by your latest comment, in reference to Smolin's NYAS article *A Crisis in Fundamental Physics*. I re-read the article and could find nothing that I could imagine calling "unbelievably tendentious, self-aggrandizing and condescending" or "supercilious " or smacking of "dishonesty".

The article has very little to say about LQG and the imbalance in theory research funding. It really is about what it says in the title: a crisis in fundamental physics.

I urge anyone who can to take an objective unemotional look at the article. It is clearly targeted at a passage by Steven Weinberg which Smolin quotes. Weinberg depicts a major foundations crisis situation–a "turning point" in the "history of science" (not merely the history of physics, he would have it, but science as a whole)—and suggests that humanity may have to relax the standards by which science is done and the criteria of what is science. In particular, Weinberg refers to the current tendency to "legitimate anthropic reasoning as a new basis for physical theory".

The main things Smolin does in the article are simple to state: he describes Weinberg's position, and he opposes it. He describes the circumstances which have brought matters to a head. He takes Weinberg's statement as a confirmation that there is a (philosophical) crisis in physics—a crisis having to do with foundations—and he gives an historical account of how he thinks this crisis came about.

Then he states his main thesis in this key paragraph

"**I believe we should not modify the basic methodological principles…Science works because it is based on methods that allow well-trained people of good faith, who initially disagree, to come to consensus about what can be rationally deduced from publicly available evidence. One of the most fundamental principles of science has been that we only consider as possibly true those theories that are vulnerable to being shown false by doable experiments.**"

Smolin says we should NOT change the basic methodological principles. Theorists, in his view, should continue the practice of proposing theories that are "vulnerable to being shown false by doable experiments." This is what allows the scientific community to function, by making differences empirically resolvable.

I think that to sustain this precept is not self-serving on Smolin's or anyone's part. I rather think it is a service to physics and the scientific community in general.

It seems to me that you can disagree with Weinberg and Smolin about the magnitude of the unresolved foundation issues and the seriousness of the present situation in physics. You can argue that there is no crisis, and there is no major "turning point". Or, you can concede the gravity of the situation and come down on Weinberg's side, against Smolin.

But I don't think you gain respect by simply bad-mouthing Smolin's article—calling it "supercilious" and "condescending" etc.

Nor do I suspect that you speak for very many string researchers when you say such things.

14. **Anon.**
March 13, 2006

Who says:

The main things Smolin does in the article are simple to state: he describes Weinberg's position, and he opposes it.

You seem to have read a different article than Aaron and I did! There was a bit about that, yes — a few short paragraphs in the middle. But I see this as sort of a diversion from the main thrust of Lee's article, which is stressing the need for thinking about "conceptual puzzles" and "foundational issues." I don't mean to be off-topic and polemical, I'm just trying to respond to what I see as the central focus of Lee's article: namely, his assertion that most physicists don't care about conceptual or foundational issues, whereas he does. This is what I see as condescending, and I think it's what Aaron was referring to as well. The implication that no one else is willing to think deeply is made pretty bluntly, and it is offensive. Lee explicitly links his own work — and that of his collaborators — with that of "Einstein, Bohr, Mach, Boltzmann, Poincare, Schrodinger, Heisenberg." Is this not self-aggrandizing?

Peter, if this is off-topic, feel free to delete, but I think I'm clearly replying to the text of one of your links…. Just because (some) string theorists often make overhyped and arrogant statements, it doesn't excuse similar statements from those opposed to string theory.

15. **woit**
March 13, 2006

I'm not going to tolerate a stupid off-topic flame war here, so will delete any more comments on this thread (after exercising my prerogative as blog owner to have the last word). If someone has an intelligible scientific point to make, make it, but I won't tolerate either personal attacks or repetitive and tendentious LQG vs. string theory arguments.

You're perhaps right Aaron that I have unjustly accused you, however "tendentious", "supercilious", and "condescending" are words that seem to me to apply to some of your postings, most recent example the ones over at the blog belonging to Christine Dantas. But you're right that you don't ever behave like Lubos, and most of the time avoid behaving like Jacques.

I reread Lee's article, and found it perfectly reasonable (although I disagree with him at some points: I'm much less optimistic than him that work on the foundations of QM will get him what he wants, and less convinced that LQG now leads to solid, testable predictions). The main point he is making is both very true, exceedingly important, and rarely said in public by a theorist: if one believes that string theory leads to a landscape such that there is no plausible way of testing it, it is one's duty as a scientist to abandon work on it, not to start promoting some new paradigm of how to do untestable science.

I see not the slightest evidence the Lee is being dishonest at any point, whereas the vast promotional string theory literature at this point just reeks of dishonesty. As you might guess I also happen to feel that I've been personally treated in an exceptionally dishonest and unethical way recently due to my opposition to string theory.

What can you do about Lubos or others who behave badly? Come on, when he posts something offensive, write in a comment saying so. If you and all the other string theorists reading these blogs did this regularly, he might actually change his behavior, or at least you would make it clear that the string theory community doesn't support him. Instead, his idiotic nastiness goes unchallenged, with string theorists doing things like writing comments supporting what he has to say, except perhaps noting that he is a bit "undiplomatic". And he's not the only string theorist whose behavior people should challenge, just the craziest.

16. **Aaron Bergman**
March 13, 2006

Feel free to delete this one, too, Peter. If it does get you can leave that "Who" is welcome to e-mail me or tell me of another forum in which I can respond.

In addition to Lee repeating various incorrect claims about string theory and 'background independence' (something pretty much guaranteed to make me irate), this paragraph was particularly bad:

> Meanwhile, many of those who continue to reject Einstein's legacy and work with background-dependent theories are particle physicists who are carrying on the pragmatic, "shut-up-and calculate" legacy in which they were trained. If they hesitate to embrace the lesson of general relativity that space and time are dynamical, it may be because this is a shift that requires some amount of critical reflection in a more philosophical mode.

I don't appreciate being told that I'm "reject[ing] Einstein's legacy", and hesitant to "embrace the lesson of general relativity" because this "requires some amount of critical reflection". This isn't an attack on string theory; it's an attack on the people who research string theory.

Rereading the essay, it's true that the majority of it probably does not justify my reaction (as I said, repeating the same incorrect claims about background independence got me angry), but that paragraph is particularly offensive. The self-serving aspect of this essay is how Lee continually sets himself as the defender of Einstein, background independence and deep physics as if no one in string theory ever thinks of such things. Plenty of such discussion occurs, although it usually doesn't end up in papers. One person who does publish papers with discussions along those lines is Tom Banks.

I think it's interesting that, Lubos excepted, most of the critiques about LQG by string theorists have to do with how the theory could match up with the real world, ie, anomalies, the semi-classical limit and, somewhat more loosely, black hole entropy. On the other hand, the critiques of string theory seem to be more philosophical, complaining that it's not background independent or that it has too many vacua to be predictive.

The latter critique is certainly legitimate (although still somewhat permature in my opinion *contra* both the anthropists and the anti-anthropists). But it is still a metaphysical complaint.

So, I think that Lee's dichotomy between the deep thinkers doing "background independent" quantum gravity and the "shut up and calculate" stringers leaves a lot to be desired.

17. **Eric Dennis**
March 13, 2006

By the same token, Smolin is "linking" the shut-up-calculate crowd's work with that of Feynman, Dyson, Gell-Mann, and Oppenheimer. His point is not to play "my guys are smarter than your guys". It's to note an interesting ideological division among physicists and ponder its relevance to the future progress of the field.

18. **woit**
March 13, 2006

Other comments came in while I was writing the last one, so I'll leave them.

No, Aaron, complaining that string theory can't predict anything and thus is not legitimate science is not "metaphysical", it's scientific method 101. What is "metaphysical" are the arguments used to justify continuing work on the landscape and string theory unification.

But I really don't want any more of this nonsense here. Just stop it. At this point I'll delete anything at all about this that anyone tries to put here.

19. **ObsessiveMathsFreak**
March 13, 2006

> Ellis's paper is rather peculiar; I've never before seen an arXiv paper that argues against not another scientific paper, but some vague statements in a popular book.

Interesting. This sounds like the kind of paper you would find in the humanities, where views on books are regularly discussed. Might this be the start of a new trend in physics publishing? The phrase "natural philosophy" comes to mind.

20. **Dumb Biologist**
March 13, 2006

I really don't understand Dr. Smolin's assertion that the "shut up and calculate" approach has somehow led science to the Lanscape. I rather thought the oringinal sentiment was to avoid wooly philosophizing about an approach that, while defying human comprehension, nevertheless made perfectly accurate and testable predictions. As Landscapology apparently addresses problems that are neither calcuable (i.e. NP-hard and intractable) nor testable, I'm not sure how "shut up and calculate" is even relevent. It's not at all clear to me how more wooly philosophizing is supposed to help when experimental verification of its fruits are no closer than what can be attained with any other approach. I'd say if the experiment isn't doable (which apppears to be true of any current approach to unification physics or quantum gravity), "shut up and do something else" might be good advice.

I'm not even a physicist, and I simply can't wait for some humongous collider to come along and give scientists something else to argue about besides philosophy. Like data.

21. **Chris W.**
March 13, 2006

This one is *meant* for deletion, and is inoffensive and helpful (I hope):

Typo alert: *…which he calls "the lanscape,"…*

22. **Chris W.**
March 13, 2006

One more typo: *…local environmenal facts…*

(Sorry for not including it the previous comment.)

23. **Another Anon**
March 13, 2006

Thanks for your reply above, Peter. The stuff I wrote about "King Smolin" was of course exaggerated for theatrical effect. But as someone who doesn't have anything at stake in the outcome of any strings vs LQG fight I still found parts of the article a bit objectionable. In particular toward the end where Smolin writes:

"So, while the new foundational approaches are still pursued by a minority of theorists, the promise is quite substantial. We have in front of us two competing styles of research. One, which 30 years ago was the way to succeed, now finds itself in a crisis because it makes no experimental predictions, while another is developing healthily, and is producing experimentally testable hypotheses."

At the risk of being paranoid, this sounds a lot like "The previous bandwagon has ended in a ditch, so now it's time to build a new bandwagon". (I'm no expert on the current state of LQG etc, but that last bit smacks of propaganda hype a la string theory.) I would have preferred a conclusion more along the lines of "Since the previous bandwagon ended in a ditch, perhaps bandwagons themselves are not such a great idea". Instead of trying to predetermine which philosophy or research program will turn out to be the best, how about encouraging people to follow their own ideas, and rewarding them purely according to the progress they make without preferential weighting for any particular research program. For many years the rewards for making progress in string theory have been way out of proportion with other areas. My worry after reading this article is that, if Smolin had his way, that would simply be changed to preferential weighting for progress on the "new foundational approaches" he advocates.

24. **woit**
March 13, 2006

Chris W.,

The typos are in the original, so I'll leave them. This whole subject is characterized by incredible sloppiness, why not sloppy spelling too?

Dumb Biologist,

My interpretation is that Smolin is arguing "shut up and do something else", the something else being thinking about foundational issues, ones that are neglected in string theory. The hope would be that if you do this you'll get some insight into a different, more promising direction than string theory, at which point you can shut up and calculate again. I have a somewhat similar view, but replacing studying foundational issues in QM, by looking for a deeper mathematical interpretation, and I prefer to start with the standard model rather than gravity.

Another Anon,

I think Smolin would agree with you that this is all about "encouraging people to follow their own ideas, and rewarding them purely according to the progress they make without preferential weighting for any particular research program" and your opposition to bandwagons. The problem with the way research is currently structured is that it is very hard to get attention for any formal research if it's not string theory. He's just making the argument that this is not good and pointing to one kind of research that he sees as having suffered because of the way string theory has driven everything else out. If miraculously he manages to get people to listen, becomes power-mad and constructs a new bandwagon designed to drive other ideas out of business, that would be a bad thing. I just don't see the slightest danger of that happening in the forseeable future.

25. **Zelah**
March 13, 2006

Reading this Blog has discouraged me about how High energy physics is conducted.I mean, crying foul at a webarticle? By String Theorists?

It seems to me that Lee is just politely speaking his mind. A totally legitimate thing to do! Most probably there is some sort of hidden insult that Lee is giving out to his fellow high energy physicist theorist?! Cannot take the heat Stringers? I say if you want to dish it out like say Lubos, then you have to take it on the chin!

My final thoughts. As an amateur, it seems to me that there is a whole lot of data waiting to be explained! Like Dark Matter / Energy.Surely, it is a serious indictment of String theory if it has NOTHING TO SAY on these matters? Worst in my book is to ask higher standards of ones competitors!

26. **Who**
March 13, 2006

The typos are in the original, so I'll leave them. This whole subject is characterized by incredible sloppiness, why not sloppy spelling too?

IIRC Susskind once posted something on arxiv about "Sting Theory",
You had a thread relating to it here, I believe. It was funny (not only the Freudian spelling, the whole thing).

A propos. Baez just gave a talk at Rovelli's CPT—he posted a link in yesterday's TWF #227—and at the end of the talk Rovelli asked him "doesn't this mean that the physics of the last 25 years is junk?"

and Baez agreed. this is from someone who was there and just posted it on PF. Baez talk and Smolin's essay are parallel in some respects, both illuminate embarrassing problems in fundamental physics

27. **Another Anon**
March 13, 2006

Thanks Peter, although it seems your reading of the article is quite different from mine. I guess we'll just have to agree to disagree.

28. **vb**
March 13, 2006

You've got an excellent blog, which I regularly read (via Google Reader, so I skip the replies most of the time, but anyway) and share similar sceptical views, but similarity between the Darwin theory of natural selection and the landscape idea is appealing. In your own opinion, what web site or blog would be the most antagonist to your blog? Thanks, vb.

29. **Lee Smolin**
March 13, 2006

Dear Aaron and others,

I apologize if you found what I said to be "condescending" and "offensive". My point is not to insult anyone and it is certainly not to support one trendy fashion against another. I meant what I wrote in the Physics Today article, which is that intellectually independent individuals with something original and important to contribute always deserve priority, even over people pursuing my own research program. This is what I do in practice, as I think those who know me will attest to.

The point of this article was not to make a polemic for LQG, which is mentioned just once (and then just in a list of theories) but to offer a new hypothesis as to why physics is in a crisis. To the people I inadvertently offended, I would ask you to look beyond labels to the facts I describe. It is just true that there is a small community of people whose scientific work is centered on "foundational issues." By this I mean those questions usually labeled such, for example the measurement problem in quantum mechanics, the problems of time or what is observable in quantum cosmology, or the relational/absolute debate about the nature of spacetime.

I don't think there is anything arrogant about pointing out that there are different communities, or that these communities have different styles and evaluate research according to different values. The foundations community, in my experience, values intellectual independence and depth of thought more than many people in more mainstream fields. This is partly because one needs acquaintance with the philosophical tradition to make a contribution here, and also because there being almost no professional opportunities in research universities for such people, they tend to be intellectually independent people who value their independence more than they do the usual sorts of professional success.

Nor is it "self-aggrandizing" to mention that this foundational tradition owes a great deal to and feels itself to be connected to Einstein, Bohr and other foundational thinkers of the first half of the 20th Century. Again this is just a fact. You are much more likely to find someone who has actually read the original writings of Einstein, Bohr, Boltzmann etc among the foundations community than you are among more mainstream communities.

There is nothing wrong with a theoretical physicist not having an interest in foundational problems. Most don't, it's a choice about where you think the answers to the questions you want to solve are going to come from. I choose to go to meetings in foundations of quantum mechanics, because I think they are relevant. I've seen very few people at these meetings who also contribute to string theory-I only recall Brian Greene and Gerard 't Hooft. So it's just a statement of fact to say that most string theorists don't think the foundational issues are relevant for their field. Another piece of evidence for this is that there are few if any papers by someone considered a leading string theorist proposing a new solution to one of the foundational problems I listed above. But many of the leaders of the non-string approaches to quantum gravity have written such papers, such as Crane, Dowker, Finkelstein, Hartle, Isham, Markopoulou, Penrose, Rovelli, Sorkin.

The point of my essay is to propose that it is an intellectual mistake to separate the problem of quantum gravity from the foundational issues. This implies that more attention and scope needs to be given to those who understand and care about the foundational issues and have ideas of how they relate to the problem of quantum gravity. This could be right or wrong. If you don't agree with it, that's fine, but please don't be insulted just because your style of research is labeled "non-foundational," when in fact you have not focused on the problems that are called "foundational".

As for rejecting Einstein's legacy, this is again just a fact. If you study the work of historians such as Stachel and Barbour, who are intimately familiar with Einstein's work and its historical context, you learn that background independence is the core of what they consider Einstein's legacy to be. I don't understand why this bothers anyone. If you have thought about the issue and decided to reject background independence then you are in disagreement with Einstein. But this should hardly bother most contemporary theorists as very few of us agree with Einstein's views on quantum theory, which puts almost all of us outside of his legacy.

Is it arrogant to say that shifting one's view on these issues requires a certain amount of critical reflective thinking? Perhaps, but all I can say is that this is what it took for me to make the switch, having been trained originally as a quantum field theorist and having done all my early work on perturbative quantum gravity. It took sustained interactions with Barbour and Stachel, as well as close study of their and Einsein's work, over several years, to come to their point of view.

Finally, thanks to WHO, who made several points better than I could have.

Thanks,

Lee

30. **woit**
March 13, 2006

I gave Lee the last word here since there was a significant amount of criticism here and he deserved the right to respond to it. But, please restrict comments to the topic of the posting (the multiverse, remember?). There's a lot of interesting things to debate about foundational issues, but I'd rather people not do it here and now. For one thing, such a debate is exceedingly hard to properly moderate, and I'm way too busy for that right now.

31. **woit**
March 13, 2006

vb,

Depends what you mean by antagonist. There's Lubos Motl, who goes nuts when my views are mentioned, except that he and I kind of agree on the landscape. I don't know of any blog that actively promotes the landscape point of view regularly from the point of view of someone doing research in that field.

32. **vb**
March 13, 2006

Thanks for the answers. Yes, youve guessed right in your second part, "antagonist" in this sense, as you've said, who: "…actively promotes the landscape point of view regularly from the point of view of someone doing research in that field." — not aware of any site, which, btw, tells a bit of story: perhaps it's easier to be sceptical; "poking around" controversial hypothesis [landscape] publicly by an established scientist [e.g. Susskind] can make him vulnerable to "not even wrong" kind of opinions (on the other hand, for a non-well-known scientist, it may be an opportunity). Science has no other way but to advance though; and someone has to make first steps, even if they fall…

33. **woit**
March 13, 2006

vb,

One interesting aspect of the landscape idea is that it is significantly less popular among younger researchers without much of a reputation, which is also the same population that is most likely to start a blog. My interpretation is that this is because adopting the landscape point of view is a kind of giving up which is much more likely to appeal to older people who have spent more than 20 years struggling to get a prediction out of string theory. Younger people who haven't been at this as long are more likely to believe that giving up is not necessary, that some nice vacuum state of the right kind can still be found.

I do wish Susskind would start a blog though, that would be interesting.

34. **Jimbo**
March 13, 2006

I think everyone should read Smolin's paper, ref'd by Peter. It is an outstanding delineation of the crisis impending in theoretical physics. The reason that Ellis' comment is devoid of math is that all the calculations supporting his claim that Lenny is wrong about horizon distinctions, are done in the paper he ref's by Davis & Lineweaver. Sounds to me like Susskind was trying to slip the public a `mickey', vis a vis, particle v. event horizons, in order to bump sales.

35. **Who**
March 14, 2006

The reason that Ellis' comment is devoid of math is that all the calculations supporting his claim that Lenny is wrong about horizon distinctions, are done in the paper he ref's by Davis & Lineweaver.

That was my impression too: Ellis didn't need to include equations since he is dealing with established concepts familiar to cosmologists, and he gives ample references.

BTW the paper he cited by Davis and Lineweaver is one of several by those authors about cosmological horizons.

To amplify Jimbo's remark, contrary to Susskind's claim, what cosmologists call the particle horizon is not analogous to a black hole event horizon, except in a verbal or poetic sense. Moreover the cosmic microwave background is not coming to us from the particle horizon (but from the surface of last scattering), and it is not produced in a way analogous to Hawking radiation. Even if one were to grant for the argument's sake that information about matter eaten by a black hole is encoded in the Hawking radiation, this would not imply that information about other universes ("pocket universes" and the like) is present in the CMB. The exerpts from Susskind's book which Ellis includes in his article are extraordinary—I recommend reading the Ellis article (all 3 pages of it) just for the quotes.

36. **csrster**
March 14, 2006

Ellis has obviously misunderstood Susskind's argument, as no-one with a primary school education could have made such an absurd blunder as the one Ellis attributes to Susskind.

37. **Eli Rabett**
March 14, 2006

It may be time to reconsider)after a few centuries of success(the proposition that the universe can be understood at all levels by humans. Perhaps there is some level at which this cannot be done, and attempts to do so only lead to madness and ill tempered posts.

38. **woit**
March 14, 2006

Eli,

I don't know about "at all levels", but at the level string theory is trying to understand, there's no evidence yet that this can't be done. String theorists at the moment are trying to promote the idea that since string theory leads to a complicated mess that can't be understood, the world must be a complicated mess that can't be understood. That string theory is just a wrong idea is a much simpler explanation.

39. **Who**
March 14, 2006

[csrster: *Ellis has obviously misunderstood Susskind's argument, as no-one with a primary school education could have made such an absurd blunder as the one Ellis attributes to Susskind*.]

Your guess is understandable (because what Susskind claim is so absurd) but unfortunately you would seem to be mistaken. Ellis quotes passages from Susskind's book which are explicit, and gives a link to longer exerpts providing context.

The case is quite clear. Please do not rely on my imperfect paraphrase, but read the quotes from Susskind in Ellis original paper. It is only 3 pages and no trouble to read.

[url]http://arxiv.org/abs/astro-ph/0603266[/url]
[b]On horizons and the cosmic landscape[/b]

Abstract: "Susskind claims in his recent book The Cosmic Landscape that evidence for the existence and nature of 'pocket universes' in a multiverse would be available via detailed study of the Cosmic Blackbody Background Radiation. I point out that apart from any other queries one might have about the chain of argument involved, this claim is invalid because it rests on a confusion between the nature of a particle horizon and an event horizon in cosmology."

Ellis gives this link to exerpts from Susskind's book containing the questionable claim:
[url]http://www.twbookmark.com/books/28/0316155799/chapter_excerpt22014.html[/url]

Some quotes from Susskind are:
"…The very same arguments that won the Black Hole War can be adapted to cosmological horizons. The existence and details of all the other pocket universes are contained in the subtle features of the cosmic radiation that constantly bathes all parts of our observable universe…"

40. **Christine Dantas**
March 14, 2006

Very interesting paper by Ellis, with excellent references.

He writes,

> In reality, the limit is even stronger: no significant cosmological information reaches us at the present time from beyond the *visual horizon* – defined by the world-lines of the furthest matter from which we receive electromagnetic radiation today.

As far as I understand, however, another horizon could be set by a primordial gravitational radiation background. The observational aspects of this possibility, in classical and string theory contexts respectively, can be found in astro-ph/0504290 and hep-th/9907185. Another interesting paper is by Craig J. Hogan: astro-ph/9809364. However, I do not know how far these studies could be extended to the multiverse issue in the sense that information coded in the primordial gravitational radiation background (observed from WMAP or LISA) could be used to infer on the existence of these "other universes".

41. **Anon1**
March 15, 2006

Hi,
For pple who r confused about 'particle' and 'event' horizons..(actually, u can add the hubble radius to this list..these 3 are often mixed up) look at this paper.. Ofcourse, this is much before black hole radiation etc.. but this is one of the first to spell out the differences clearly. Hope it helps..

42. **Eli Rabett**
March 17, 2006

Peter,

True there is no evidence that we cannot understand the universe at the level of string theory, but equally well there is no guarantee that it can. Moreover it is not even clear that the methods that have been used to characterize nature up to this point can continue to work ad infinitum.

I offer this thought in the same spirit as the anthropic principle was created. The level of string theory is so far from human experience that the universe may not be explicable to or by us at that level.

Two Years Later

March 13, 2006
Categories: Uncategorized

This week is the second anniversary of this weblog, so perhaps a good moment for some reflections on what has been happening over the past two years.

In many ways, the weblog has been successful far beyond my wildest dreams. My original expectation was that there would be a handful of people with similar interests who would regularly read it, and it would be quite a success if I ended up with a couple hundred readers. I don't have completely accurate recent statistics, but recently each day at least several thousand people are checking up to see what is going on here. This is quite gratifying, and makes the significant amount of effort and time I've been putting into this seem worthwhile. It has been interesting to note from looking at some other blogger's publication records that starting an active weblog seems to correspond to starting to write many fewer papers. My one regret is that the time spent on this has definitely taken away from time that could be devoted to finishing and writing up various research projects. In the future I hope to find a better balance on this issue.

One of the main topics covered on this blog, and by far the most controversial, is the ongoing story about string theory and its dominance of theoretical high energy physics. The public perception of string theory seems to me to have changed significantly recently, as more and more science journalists have started to realize that things are not going well. Many of them have moved from a stance of uncritical acceptance of the claims of string theorists to a more skeptical and balanced view of the subject. The kind of overhyped popular string theory article that was a staple for 20 years is increasingly unlikely to be written by professional science journalists. Such things now occur most often in places like university press releases, authored by people with no experience in the subject.

I'd like to think I had something to do with this, but there are much larger forces at work. The field of string theory has suffered a remarkable intellectual collapse, one that is not just a matter of opinion, but can be quantified in various ways. For many years Michael Peskin has written up a discussion of the yearly list of top cited HEP articles. I wrote up postings discussing the 2003 and 2004 lists. By 2004 there were only two post-1999 string theory papers among the list of 50 most heavily cited (the early 2002 Berenstein et. al. PP waves paper, and the early 2003 KKLT paper), and Peskin seems to have stopped writing up a discussion of the list, possibly because there was virtually nothing new to discuss. SPIRES has not yet produced a 2005 list and I don't know if they ever intend to, but from some data gathered at physicsforums.com it would appear that the only two string theory papers likely to have accumulated the 150 or so citations needed to make the top 50 in 2005 are exactly the same two as in 2004. The subject has come to nearly a dead stop, and that rather than the complaints of its critics is behind the sense of crisis felt by many of its practitioners.

The panel discussion at Strings 2005 in Toronto was rather remarkable. For the first time, members of the audience started to raise real questions about what was going on in the subject and the panel members had difficulty in putting a positive face on the situation. It will be interesting to see if a similar discussion occurs at Strings 2006 this summer in Beijing.

The two post 2000 papers that are widely cited reflect the two main topics that string theorists are still working on. One is AdS/CFT, which many, many people work on since it is the best thing to have come out of the string theory project. There doesn't however seem to be much significant progress in this area. The second paper, by KKLT, is the one that really launched the whole landscape business. The fact that it is the most recent hot area of activity in string theory is something that even most string theorists find very disturbing. Over the last couple years, the original implausible hopes that something could be gotten out of the Landscape have been pretty convincingly crushed. Leading figures in the field have abandoned the Landscape and moved out into the swampland of theories that have nothing to do with the real world and may or may not be low energy limits of a string theory. It remains very unclear what the point of this is.

The most active string theory blogs are becoming ever more bizarre, with increasingly strange behavior of all sorts from Lubos Motl, and Jacques Distler following the lead of others into the swampland while firmly sticking to the idea that my criticisms of string theory are some sort of illegitimate crackpotism. While most string theorists are well aware of what bad shape the field is in and casting about for something new to do, the true believers are exhibiting something more and more approaching religious fanaticism.

Unfortunately, leading figures in particle theory show no signs of being willing to publicly address the increasingly disturbing state of the subject. Part of my problem with the arXiv is the feeling of many that I do not have the stature in the community necessary to justify being allowed to make the kind of critical comments I have been making publicly. I'm willing to agree with this point, but it remains unfortunately true that those whose responsibility it is are doing little to address the situation. The whole field of particle theory is becoming increasingly damaged by these problems, and only one aspect of this is the problem of public perceptions, which is going to get a lot worse before it gets better.

I have no idea where this story is going next. The general attitude seems to be to hunker down for the next few years, try and wait out the crisis and hope that LHC results will save everything. This doesn't seem to me to be the right way to address the serious problems that are all too obvious right now.

Update: Some anonymous person really has too much time on their hands. But I'm honored.

Update: One or more people definitely have too much time on their hands. Besides the Not Even Wrong parody mentioned above, there's another one, and also Cosmic Variance and Lubos Motley's Stringy Climate Theories. This last one informs us that

Recent fake blogs have brought shame to the Internet:

(1) http://motls.blogspot.com pokes fun at Dr Lubos Motl, by posting a mixture of insane climate drivel, interspersed with attacks on theoretical physicists. I can reveal it is fake.

Comments

1. **Garrett**
   March 14, 2006

   String theorists will work on something. (And no, not burger flipping, as much as you might wish…) It is a gradual revolution. People will work on things that aren't strings, but keep referring to strings, or say their work is "string inspired." Eventually, someone will find something cool, maybe tenuously connected to past string work, and everyone will jump on that. Then, after awhile, people will see that the connections to strings are superfluous. And that multi-decade endeavor will be relegated to the dustbin of history. Such is the way of crowd dynamics, even really frickin' smart crowds.

2. **Garrett**
   March 14, 2006

   Oh, and yes, nice job Peter — congrats on your anniversary and much deserved blog success. I think you're playing a bigger role than you're willing to admit.

3. **a**
   March 14, 2006

   String theory predicts nothing, and LHC might find nothing.

In a few years we might have to reconsider anthropic models more seriously.

4. **Ijon Tichy**
March 14, 2006

> The public perception of string theory seems to me to have changed significantly recently, as more and more science journalists have started to realize that things are not going well. Many of them have moved from a stance of uncritical acceptance of the claims of string theorists to a more skeptical and balanced view of the subject.

One would think they would strive for a skeptical and balanced view of all areas of science, not just string theory. Unfortunately, much of science journalism is of the mindless cheerleader variety, uncritical and unquestioning, leaving the largely disinterested public with a rather distorted view of the enterprise. Science needs its critics, especially in highly speculative fields like high-energy physics and cosmology. So you can understand why I believe that this blog is carrying out an important role. Keep up the good work, Peter Woit.

5. **Chris Oakley**
March 14, 2006

I sometimes wonder whether some HEP researchers really understand what research is all about. An interesting but speculative idea did not work. So what? Move on and try something else. Brand loyalty makes no kind of sense in this game: there are just models that are good at describing nature and models that are not. Nature and Occam's razor are the arbiters. Distler (the "flaming spear in the stringy god's left hand") and Motl (the "hammer in the stringy god's right") seem to think that criticism of ST is a personal attack on themselves. That is not how it works. We are all Sherlock Holmeses, rooting around the dustbins of reality for clues as to how the universe works. Some hypotheses fit the facts well, some do not. Some hypotheses can be stretched and squeezed in an unattractive way to fit the facts, but why bother? Why not just try something simpler?

6. **Thomas Larsson**
March 14, 2006

Happy anniversary, Peter.

7. **anon**
March 14, 2006

'… Lubos Motl, and Jacques Distler following the lead of others into the swampland while firmly sticking to the idea that my criticisms of string theory are some sort of illegitimate crackpotism.'

What someone should do is expose some of belief systems of these 'defenders of the faith'.

None of them are as holy as you Peter. I know Lubos is a deviant of mainstream views on climate change, so he's a 'crackpot' in that sense. Then you just apply his own brand of guilt by association, and hint that if he has eccentric views on climate, he's ST work is probably guilty by association with a cranky brain.

Since Jacques is moderator of trackbacks and allows them from Motl's blog which is as full of crackpot climatic postings as it is ST, Jacques is guilty by association too. I won't mention Kaku's interests in UFOs, but sincerely someone should make the public aware of their guilt by association to loony ideas. BTW, does anyone know any deviancy of Susskind (apart from physics)?

8. **Juan R.**
March 14, 2006

Congrats for your contribution to light in this nigthmare called string "theory".

March 14, 2006

Have you seen the lunatic stuff distler posts on his blog?

By comparison, motl seems positively sane.

10. **robert**
March 14, 2006

Your blog has made vey interesting reading over the past two years. And to think I stumbled upon it, having been thoroughly impressed when watching 'The Elegant Universe'. Keep 'keeping it real'.

Best wishes

11. **Joao Leao**
March 14, 2006

Being a long time lurker to your blog I take this oportunity to thank you and congratulate you on what you have accomplished here. Besides the obvious fact that it takes guts to point out a "naked emperor" in any court, I think the success of "Not Even Wrong" owes much to your level-headedness and your gift for clear writing. Though I cannot claim that I always agree with you, I am probably more radical than you in what I consider conceptual and critical failures in today's fundamental (super)physics. You are surely right in pointing out that the recognition of the general *malaise* is spreading through the ranks! This is also underscored by the increasing "prickliness" of the "defenders of the faith". (Arrogance and insecurity often go hand in hand!) These are hard times for physics and, as much as it may hurt you, your time is well spent in providing and "driving" this critical vehicle. And it should be noted that you try your damnest to keep it constructive.

Hang in there!

12. **Who**
March 14, 2006

the empirical science ethic (only theories vulnerable to test by a do-able experiment) is almost 400 years old
your blog is 2 years old
and upholds that ethic
bravo Peter

Novum Organum (1620)

13. **Zelah**
March 14, 2006

Happy anniversary Peter.

14. **Urbano**
March 14, 2006

Congrats. And keep it going :-)!

15. **Dumb Biologist**
March 14, 2006

Happy 2nd!

16. **Dick Thompson**
March 14, 2006

Happy anniversary from a daily peruser. You have performed and are performing a valuable service.

The string theory community is better than the likes of Motl, Distler, and the anthropic landscape crew, and we can hope it will come to its senses shortly. There is hope there, for example in Lisa Randall's models and the higher category approaches promoterd by Urs Scheiber and John Baez, among others.

17. **Kea**
March 14, 2006

Happy anniversary to you and the WMAP release!

18. **Ron Avitzur**
March 14, 2006

Happy anniversary!

Thank you for providing a forum for so many educational discussions, and for a fascinating glimpse "behind the curtains" into the human side of the process of science.

Keep up the great work! (And good luck striking a balance between all the time this takes, and continuing your own research.)

19. **Dumb Biologist**
March 14, 2006

They say you've finally arrived (where I can't say) if you've been lampooned. One of course would hope for a *good* lampooning…

20. **tommaso dorigo**
March 14, 2006

Peter, congratulations for this endeavour. Two things.

One, you know very well that this blog is not just a blog. It is in places like this that science makes progress sometimes. Public arenas are scarce, hampered by good manners, and people will not speak up too easily with the first thing that springs to their mind. It is in a successful blog such as yours, ran by a respected scientist such as you are, and frequented by lots of silent listeners as well as by a few vocal individuals, that the scientific debate becomes hot, useful, and constructive (well, not always, but signal to noise seems good). So thanks! for running it, and if you think about ramping down the blogging for that other paper you wish to write… Well, write it here. You'll get more attention and constructive criticism in the making.

Two, as an experimentalist in HEP I feel I have been left driving blind. I have spent the last ten years of my life constructing tools to find the Higgs boson, and I do not even know for sure if I would prefer if it was there or not after all. Many colleagues are so into Susy they think it is just a matter of time until they bump in spectacular cascade signatures. I wish I was convinced by it myself, but no, cannot see the real appeal. String theory looks so far out to me I never even ventured into trying to understand it. In a word, I need guidance, or I will lose interest. Will the good old days when the world was either S-T or V-A, and we physicists only had to go figure it out, ever come back ?
I hope by reading your blog I will keep some inspiration…

21. **woit**
March 14, 2006

Tommaso,

Thanks for the encouragement! I do hope in the future to try and write some things here that will be ultimately part of a paper I'm writing (although I fear this may drive away much of my audience….)

It's a tough time to be an experimentalist, but, it could be worse, you could be a high-energy theorist, which has really been a frustrating business for quite a while now. Good luck in your hunt for the Higgs!

22. **Kris Krogh**
March 14, 2006

Peter,

Thanks for your courageous stand these two years, that the job of physicists is not to tell us about the imaginary but the physical.

23. **Hooman**
March 14, 2006

Congradulations Peter on your second year of this SUPERB blog. Every branch of scientific endevour needs sharp and rational, criticism. But I believe this blog is much more than a simple 'anti-string' voice. It is a wealth of interersting information and a source of inspiration for all people who are interested in "modern Natural Philosophy".
Pauli would be have been very pleased with your efforts….;-)

24. **Justin**
March 14, 2006

Congradulations for your contribution to the continuing decline of high energy particle theory.

25. **Michael**
March 14, 2006

Peter, if you find running this blog "gratifying", what word would you use to describe a successful academic career?

26. **Santo D'Agostino**
March 14, 2006

Peter,

Congratulations on producing a valuable scholarly contribution.

All the best wishes,
Santo

ps: Michael, you are acting like an ass. Smarten up, will you?

29. **Who**
March 14, 2006

speaking of presents, Bert Schroer posted an article today that discusses among other things Peter's book "The Failure of String Theory"—-and has a fair amount of complimentary things to say.

I gather Schroer is a respected elder statesman algebraic QFT guy, friend of Ray Streaters since 1960 according to Streater, Schroer's papers go back to 1961. he is worried about the state of physics and he has ideas of what needs to be done—and he compares and contrasts his views with those in Peter's book. So it is kind of a nice thing to have happen on your blogbirthday.

Schroer's paper that he posted today is
http://arxiv.org/physics/0603112
String Theory and the Crisis in Particle Physics

It has a funny fourline poem in German that originated in Prague sometime before 1940 at a time when a maestro named Motl used to conduct Wagner operas.

" … after a performance of Wagner's Tristan and Isolde…. an art critic wrote instead of the usual critical review in next days newspaper the following limerick….:

Gehe nicht zu Motl's Tristan
schau Dir nicht dieses Trottels Mist an,
schaff dir lieber 'nen viertel Most an
und trink dir mit diesem Mittel Trost an "

it is a tradition in our family that people should get poems for birthdays and is this really so off-topic as all that?

30. **D R Lunsford**
March 14, 2006

It may be flattery, Peter, but it's lame and misses the real point. No one reads the masters. I lived in the journal stacks – haunted them. I saw the evolution of physics almost first hand – the only trouble was, the authors were dead or scattered, so direct questions were impossible.

No one reads journals now. They hang around the archive like a pack of goth girls at a record store. Like string theory, the archive is a failure not only in fact, but in concept, because it is too easily subverted by priggish martinets.

"Not even wrong" is, above all, an homage to Pauli, the great unread and misunderstood hero of physics. When I saw that title, I rejoiced, because I knew that anyone who really loved Pauli also really loves physics, and would defend it against subversion whatever the cost.

Here's to Pauli, and here's to Peter.

33. **Bourgeois Nerd**
March 15, 2006

Happy Blogoversary from a daily reader! Some of what you write is waaaaaaaaaaaay over my head (I'm just a useless English major with a fetish for cosmology and particle physics, after all), but it's always interesting and often wryly funny. I don't always agree with your views, but you've really articulated what had been a vague dissatisfaction with string theory; I never really "got" the "beauty" of it and just didn't like it. I'm glad others share this view and back it up with some actual evidence and knowledge instead of my non-empirical feelings. Plus, I'm also happy that there's someone out there being a gadfly and sticking it to THE MAN. He always needs that. Keep up the good work!

34. **robert**
March 15, 2006

Peter

Please free to delete this, but I cannot restrain myself from commenting once more that 'Michael' continues to reveal himself to be a complete shit. Lubos and Distler may take things a little too far from time to time, but at least they make it clear who they are and, especially in the case of LM, produce blogs that contain a great deal of interesting material when they are not going OTT.

35. **anonymous**
March 15, 2006

Robert, Santo & others,

Please, I would really urge you to just ignore Michael. He's a troll, out on baiting, and any attention to him is what feeds him.

Ignoring Michael is easy enough, but now its getting irritating to read such replies are yours.

36. **Haelfix**
March 15, 2006

Wasn't Shroer the Professor who was harping about DDF/Pohlmeyer string quantization a few years ago? I glanced through his paper and he still seems to have issues with stringy localization.

Afaik that question is still debated, particularly in the context of string field theory. Is anyone aware of whether its settled now or not?

37. **Chris Oakley**
March 15, 2006

A non-literal translation of the poem, that I hope at least captures the spirit:

Don't go to Tristan of Motl's,
Don't appear at this zombie excrescence,
It's better just to get some bottles:
And have a much more pleasant acquiescence

38. **Paradigm**
March 15, 2006

Michael: this year there is a summer school about "Strings and Branes: The present paradigm for gauge interactions and cosmology". Do you think it is a honest title? Don't you agree that this blog can help students?

39. **David Cobden**
March 15, 2006

I want to add my voice to the chorus. This is my favorite blog. I am a condensed matter physicist, presently at the March meeting in Baltimore along with about half the other physicists in America. I see many problems with the way physics is going nowadays, and one of them is the situation in particle theory, which has become detatched from reality. My particle theory colleagues would not agree with this (I hope they don't take offence and vote against my tenure), but everyone I know in condensed matter would. The particle theory situation is particularly irksome because it gets such a disproportionate share of the limelight, and because many of us who are passionate about physics see this degradation of the traditional scientific method happening at the very core of our discipline. The situation is not going to get better unless we talk about it! Your blog is the healthiest, most coolly moderated discussion physics forum I know of, given the limitations of bloggery. Though there are other good blogs, they seem to skirt around these deepest problems. We need something like Not Even Wrong in condensed matter. I hope you keep it going!

40. **Robert**
March 15, 2006

Happy B'day!

Come one, Peter, say something on physics/0603112 don't be shy! Lubos already had his go.

41. **woit**

March 15, 2006

Thanks to all for the blog-bday greetings!

Robert,

I'm in the middle of writing something about this. Lubos is just too fast, I can't beat him on speed.

42. **Who**
March 15, 2006

Lubos comment on the poem is not perceptive.
he knocks the rhyming—-suggesting it is dumb technically.
it is not. Lubos reflex contempt misleads him in this case.

the rhyming is an example of a rather technically challenging
German light verse form called the **schuettelreim**
which has to rhyme on actual Spoonerisms
(permutations of the syllables which result in other words of different meaning)

there are German websites devoted to schuettelreim—-to "switch rhyming", or spooner-rhyming

Motl should show respect for the poem's technical competence (and wit). Dont knock it til you try it.

the verse would be more perfect if one phrase—-viertel Most—were changed to
drittel Most
the better to permute into Mittel Trost

The viertel (a quarter-liter wineglass) being more common than a drittel (a third of a liter glass or mug) would have occasioned the artistic compromise.

43. **Bert Schroer**
March 17, 2006

To Who says
You are perfectly correct, now I remember that it must have been a "drittel". It is one of the best schuettelreims in German I know. Most of them only have two lines like:
Es klapperten die Klapperschlagen
bis ihre Klappern schlapper klangen
or
Es sprach der Herr von Finkenstein
die Harzer Kaeschen stinken fein
or (if you don't mind one with a boy scout flavor):
Sie zogen aus mit bunten Wimpeln
und kehrten heim mit wunden Pimpeln.
But please don't think that the beauty and perfection of the 4-liner was the main reason for writing my article.
I will be back on the radar screen with some (hopefully) enlightening remarks on the role of differential geometry and topology in quantum field theory (Schroer versus Woit, but no polemics) only on coming tuesday.

44. **Who**
March 17, 2006

I will be back on the radar screen

It's a pleasure. I look forward to seeing you.

45. **John A**
March 21, 2006

I read both this weblog and Lumo's. Sometime I agree with one of you and not the other, sometimes both, sometimes neither.

Like String Theory, the consensus on climate science is rather less than the hype put upon it by some of its more famous protagonists.

I do not care for theories which have no testable results or which cannot be replicated. So for Lumo to support String Theory (majoritarian) and climate skepticism (minoritarian) and this blog to do the reverse, is satisfyingly ironic.

Can I make a suggestion? Try to dial down the rhetoric on Lubos and focus on the substance of the argument.

Having setup quite a few blogs myself, I can say that I get more scientific content through them (or even despite them) than from peer-reviewed journals. They're not a nirvana, but they have definitely changed the way academic discourse is conducted.

I look forward to another couple of years of interesting commentary. I am sure the truth will out.

46. **woit**
March 21, 2006

Thanks John.

One correction. This blog takes no position at all on climate change and I delete comments from people who try and start debates here on issues like that. I'm a firm believer that my blog should stick to topics that I have some expertise in.

Focussing on the substance of an argument with Lubos is really not possible, I've sometimes attempted it and never gotten anywhere. He is however highly entertaining, and the fact that a Harvard faculty member string theorist is so loony is a truly remarkable one to observe, so I don't at all intend to ignore him.

Baez and Schroer

March 15, 2006
Categories: Uncategorized

John Baez's latest This Week's Finds is out. As in other recent issues, he starts with some of the most fantastic astronomical pictures around. He also links to his recent non-technical talk Fundamental Physics: Where We Stand Today, which also has fantastic pictures. In the talk he describes how, since the 80s, "many physicists feel stuck", and "continue to make predictions but they are usually wrong or not yet testable. This has led to a feeling of malaise. Why are they failing?" He partially answers this question with

But when their theories made incorrect or untestable predictions, many theorists failed to rethink their position. It is difficult to publicly retract bold claims. Instead, they focus more and more attention on the mathematical elegance of their theories… some becoming mathematicians in disguise. (There are worse fates).

Someone who was at the talk reports that afterwards Carlo Rovelli asked Baez "whether what he had just presented didn't imply that the theoretical physics of the last 25 years was 'junk'", and that Baez "replied after some hesitation 'You said it'".

A physicist who has been concerned for quite a while about the sociological changes in how particle theory is done and the ever more critical situation that the field finds itself in is theorist Bert Schroer. His specialty is in the area of algebraic approaches to QFT, especially conformally invariant ones. More than a decade ago he was writing review articles on QFT well-worth reading that included warnings about what has been going on. For some examples, see his Reminiscences about Many Pitfalls and Some Successes of QFT Within the Last Three Decades and Motivations and Physical Aims of Algebraic QFT.

Schroer has just posted three new articles on the arXiv. One of these is entitled String theory and the crisis in particle physics and is well worth reading if you have any interest in the ongoing controversy over string theory. Schroer has many interesting points to make on the subject, and one of his main concerns is that a great deal of knowledge developed about QFT during the last century may be effectively lost as the training of young theorists focuses on string theory. This article has already drawn Lubos Motl's trademark rant accusing anyone skeptical about string theory of being an incompetent crackpot.

The second of his new articles is called Physicists in times of war and begins with comments on the Iraq war and Schroer's profound disappointment at the refusal of Witten and others to join him in a public campaign against the war before it began. The second part of the article tells the story of Pascual Jordan, one of the founders of quantum mechanics who joined the Nazi party. Schroer's politics are diametrically opposite to those of Jordan, but he is highly sympathetic to Jordan's scientific point of view, from the earliest years of quantum mechanics, that it is necessary to think about quantum systems in a way which doesn't depend on starting with a classical Lagrangian and "quantizing".

The last of Schroer's new articles should appear on hep-th tonight and is entitled Positivity and Integrability. It tells some of the history of the QFT group at the Free University in Berlin and has a lot of interesting things to say about reflection positivity and the Euclidean approach to quantum field theory.

Update: I haven't heard anything at all back from the arXiv about the trackback issue, but just noticed that trackbacks to the two recent Schroer articles mentioned here have appeared. The ways of the arXiv are highly mysterious….

Update: Baez has a clarification here of his response to Rovelli.

Comments

1. **Robert**
   March 15, 2006

   Peter forgot to mention that in the first paper Schroer advocates an approach that dumps all geometric parts from our treatment of quantum physics as it is inherently classical. Not quite in line with Peter's favourite alternative direction.

2. **woit**
   March 15, 2006

   Robert,

   Schroer definitely favors an algebraic, non-geometric approach to QFT, while I'm starting from a very geometric direction. However, one of the basic lessons of mathematics is that to understand a mathematical structure at the deepest level you often need to simultaneously use algebraic and geometric insights, and understand how they are related. I still think the geometric starting point is most promising, but over the years I've become more and more aware of how important it is to also think about these questions from a more abstract, algebraic point of view (have you heard me go on about K-theory and representation theory?).

3. **DMS**
   March 15, 2006

   Well, Bert is wrong in lumping all American physicists on the Iraq war; see for instance

   http://physicsweb.org/articles/news/7/1/14/1

   Nobel laureates oppose war against Iraq

   29 January 2003

   Forty-one American Nobel laureates have signed a declaration opposing war with Iraq. The declaration was organised by Walter Kohn, a theoretical physicist at the University of California at Santa Barbara, and former adviser to the Defense Advanced Research Projects Agency at the Pentagon. The signatories include 19 winners of the physics prize.

   The declaration reads:

   "The undersigned oppose a preventive war against Iraq without broad international support. Military operations against Iraq may indeed lead to a relatively swift victory in the short term. But war is characterized by surprise, human loss and unintended consequences. Even with a victory, we believe that the medical, economic, environmental, moral, spiritual, political and legal consequences of an American preventive attack on Iraq would undermine, not protect, US security and standing in the world."

   The signatories include Norman Ramsey, who worked on the Manhattan Project, and Charles Townes, a former research director of the Institute for Defense Analyses at the Pentagon. Townes was also chairman of a federal panel that studied nuclear warheads.

Kohn expects more laureates to sign this week but the current list of signatures is:

Physics

Philip W Anderson, Hans A Bethe, Nicolaas Bloembergen, Owen Chamberlain, Leon N Cooper, James W Cronin, Val L Fitch, Sheldon L Glashow, Leon M Lederman, Arno A Penzias, Martin L Perl, William D Phillips, Norman F Ramsey, Robert Schrieffer, Jack Steinberger, Joseph H Taylor Jr., Charles H Townes , Daniel C Tsui, Robert W Wilson

4. **A.J.**
March 15, 2006

Two comments:

1) I was the last person to edit the wikipedia paragraph that Schroer quotes as "string-theoretical adulation in its purest form", and I completely disagree with his characterization of the writing. The paragraph is hardly the praise he makes it out to be. Frankly, I saw dwelling at length on the variety of things the "M" might stand for as a way of correcting a common misconception on wikipedia, namely that anyone has much of a clue what M-theory actually might be.

2)

5. **A.J.**
March 15, 2006

2) … Schroer's been banging on now for some time about the conceptual superiority of the algebraic approach to QFT. I think it's about time that he included in one of his polemicals an explanation of how renormalization theory fits into the AQFT conceptual framework. The techniques of effective field theory are essential to anyone who actually does computations or makes connections to experiment, and it's difficult, to say the least, to take seriously a proposed framework which seems basically to ignore and/or dismiss these tools.

6. **Peter Shor**
March 15, 2006

What I found astonishing is the idea that young string theorist are not learning a lot of quantum field theory. How can you possibly hope to generalize QFT when you don't completely understand it?

7. **Igor J.**
March 15, 2006

RE: DMS – Nobel laureates oppose war against Iraq

As I read the declaration, it does not seem to me as a categoric oposition against the Iraqi war, but rather they point out that this war is not in US interest… Eg. see the excerpts:
"…oppose a preventive war against Iraq without broad international support. "
"…Even with a victory, we believe that …"
Which I would read as: "If the world is with us and we have a quick and politically correct victory, we have no problem with the war….".

I believe that Schroer was looking for some strict refusal of the war (or any war in general), this would be clearly not enough for him…
[[If you read the article it is clear that he basically does not understand how any physicist could support any war at all etc…]]
Igor J.

8. **woit**
March 15, 2006

Peter,

I think Schroer's point is that quantum field theory remains a poorly understood subject, about which we still have a lot to learn; no one completely understands it. Certain parts of it are well-understood, are in standard textbooks, etc. Most string theorists know those, and also know quite a bit about the more advanced parts of the subject that are relevant to string theory. But there is a lot about quantum field theory that isn't relevant to string theory, and it is knowledge about those parts of the subject that I think Schroer fears may get lost.

9. **Who**
March 15, 2006

Update: I haven't heard anything at all back from the arXiv about the trackback issue, but just noticed that trackbacks to the two recent Schroer articles mentioned here have appeared…

one trackback being to NEW

!

10. **Chris Oakley**
March 15, 2006

I could be that Schroer's attitude toward String theory and string theorists was not helped by Lubos's reviews of two AQFT books on Amazon, here and here, especially as these are the same (negative) review pasted in two places. Having said that I think that Lubie is right to point out that a lot of people seem to have worked on Axiomatic/Constructive/Algebraic QFT for a long time and yet still cannot calculate cross sections or decay rates.

11. **Chris W.**
March 15, 2006

Wouldn't it be fair to say that at some point the effort to understand quantum field theory becomes *inseparable* from the effort to formulate a quantum theory of gravity, or at the very least, how quantum field theory should be understood in the presence of gravity? It seems to me that this has always been implicit in the understanding that gravitation is not just another physical field, notwithstanding the many formal connections that can be made between the mathematical structure of general relativity and gauge theories. More precisely, it is—to use Julian Barbour's term—the *frame* within which all physical processes happen.

The study of quantum field theory in curved spacetime seems to reinforce this conclusion. Note that in physics/0603112 Schroer discusses (on page 27) a recent paper of

Stefan Hollands and Robert Wald, **Quantum Field Theory Is Not Merely Quantum Mechanics Applied to Low Energy Effective Degrees of Freedom**.

12. **Arun**
March 15, 2006

Since Schroer skewers Motl at a rather personal level, I think Motl's ire is understandable.

13. **Who**
March 15, 2006

Since Schroer skewers Motl at a rather personal level, I think Motl's ire is understandable.

LOL

Spooner-rhymes are hard to forget

Gehe nicht zu Motl's Tristan
schau Dir nicht dieses Trottels Mist an,
schaff dir lieber 'nen viertel Most an
und trink dir mit diesem Mittel Trost an

several people have tried to translate but they did not provide
a simple literal translation—just to give the meaning of the words. I will try:

don't go to Motl's Tristan
do not consider this idiot's manure
rather get yourself a glass of apple wine
and drink comfort by this means.

Trottel = imbecile
Mist = manure
Most = hard cider, new wine
Trost = comfort, consolation
anschauen = contemplate, consider

14. **Haelfix**
March 15, 2006

AQFT is something people need to work on, but at this point its really of mathematical interest moreso than physical interest. This could and probably will change eventually but I just don't see many young physicists staking their tenure trying to reproduce cross sections that people have known for 30 years. As such its really the domain of tenured proffessors as its a very difficult problem with absolutely no guarentee of quick results.

If something really new and exciting came out of the field, people will jump on the bandwagon, but until that time its similar to working on the measurement problem, read probably career suicide

15. **Thomas Larsson**
March 16, 2006

What struck me in Schroer's article was his comment on AdS/CFT on p 14. Apparently he claims that it cannot be correct because the number of degrees of freedom on the two sides do not match. Does anyone know more about this?

Of course I strongly disagree with Schroer's statement (on p 26) that loop groups do not admit higher-dimensional counterparts. Both the Kassel algebra (multi-dimensional affine) and the Larsson-Rao-Moody algebra (multi-dimensional Virasoro) have been around for many years, and their beautiful representation theory is now being converted to physics (hep-th/0504020). There are of course errors and omissions at this stage (the worst errors are being weeded out, however), but progress has been surprisingly rapid. The most important conceptual conclusion is that the observer must be integrated seemlessly with the formalism, something which in a sense was anticipated by Rovelli's relational QM.

Schroer's ignorance about this development shows that I must increase my M-arketing efforts.

16. **Chris Oakley**
March 16, 2006

Who,

I'm not arguing with your translation, but in being literal you have foregone the sublime rhyme of "Motl" (as mispronounced by anglo-saxons) and "bottle".

Haelfix,

You are not quite right there. There are active AQFT groups in Hamburg, Zurich and Basel and probably at other European universities as well. Working on this is not quite professional suicide. Suicidal tendencies are more likely as a result of trying to keep up with their research output, which, like Superstrings, gets more detached from reality year on year. I am not sure that they are really interested in calculating cross sections anyway – if you want proof, have a look at the correspondence I had with a referee (who presumably belonged to the AQFT camp) on my web site from 1986/1987.

17. **ObsessiveMathsFreak**
March 16, 2006

Another humanities style paper in arXiv. How many of these are there?

18. **Sam**
March 16, 2006

Woohoo! AdS/CFT is wrong? The one development in string theory that Peter had to grudgingly admit was worthwhile. Now that Schroer has demolished AdS/CFT, we can truly say that string theory is a failure!

19. **woit**
March 16, 2006

Thomas and Sam,

Schroer doesn't say "AdS/CFT is wrong". My reading is that he is just pointing out the obvious fact that it isn't a precise relationship between two standard QFTs, but a relationship between a standard QFT (4d N=4 supersymmetric YM), and a 5d theory which is not a standard QFT (although you get a QFT, supergravity, in the low energy limit).

I don't think any of the positive things I've had to say about AdS/CFT are said grudgingly. But I do think it's important to remember that what is going on with AdS/CFT is still poorly understood. Lacking a non-perturbative definition of one side of the correspondence, one can't even precisely say what the conjecture is. There's something very interesting going on here, and a lot is known, but a lot isn't.

20. **Aaron Bergman**
March 16, 2006

Schroer is probably referring to Rehren's work relating an AQFT on AdS space to an AQFT on Minkowski space in one fewer dimension and Arnsdorf and Smolin's follow-up hep-th/0106073. There were discussions of it on spr at the time. My recollection of the upshot is that the AQFT's produced by Rehren's procedure have aren't physically useful (bizarro thermodynamics, for example.) It's not particularly clear what this relation has to do with Maldacena's duality between a QFT in four dimensions and *quantum gravity* in five dimensions (well, ten dimensions really).

21. **urs**
March 16, 2006

Maybe the applications of AQFT most relevant to interesting applications in physics concern AQFT of 2-dimensional conformal field theory.

For instance Antony Wassermann's discussion (math.OA/9806031) of representations of loop groups and the fusion of these reps (hence relevant to WZW models) is based on methods borrowed from AQFT.

Furthermore, representations of AQFT operator algebras are known to be one source of modular tensor categories from which 3D TFTS and 2D CFTs are constructed (http://golem.ph.utexas.edu/string/archives/000747.html).

22. **Benjamin**
March 16, 2006

"but he [Schroer] is highly sympathetic to Jordan's scientific point of view, from the earliest years of quantum mechanics, that it is necessary to think about quantum systems in a way which doesn't depend on starting with a classical Lagrangian and "quantizing".

As a mere engineer interested in physics, please indulge a naive comment. I was delighted to read this, since I have also been puzzled by what seems to me like 'blind adherence to formal recipes' in quantum theory, such as simply assuming commutation relations among operators instead of deriving them from observation.

So in superstrings, as I understand it, they assume an open or closed string, instead of a traditional point particle, associate position and momentum operators with this so-called 'string' (I mean, is it really like a little piece of spaghetti?), and then simply assume commutation relations 'by analogy' with point particles. But since the idea of a string is so different from a point particle, why blindly follow the same formal procedure and assume (hope?) that it works? Obviously, I'm missing a great deal, probably almost everything. But it does seem somewhat like a case of robotic imitation of a formal procedure that somehow worked in a different context.

In a similar vein, one could criticize formal procedures in 'orthodox' quantum theory, as the quoted authors do, even if the agreement with experiment is good. I like to be able to picture what is going on, just as Maxwell's 'abstract' equations correspond to Faraday's 'lines of force'. Just because a formal recipe produces valid predictions of data doesn't impress me so much per se. One could consider it jerry-rigged to do so. One could say that the formal procedures are 'parroting' reality, without really shedding light. I guess this line of thought is either too stupid or too philosophical for real physicists…

23. **Bert Schroer**
March 16, 2006

Some remarks about the various comments on my 3 papers of yesterday and today are in order.
Having lived in Brazil for the last 4 years, my flux of information is very incomplete. Concerning the Iraq war, my main source of information comes from sites of international newspapers, but I am detached from the sociology of US physics departments. It seems that I had the bad look to encourage Ed Witten in an email to start an anti-war campaign and I interpreted his negative answer in a too sweeping way. Actually I am sharing an office with Walter Baltensperger who is a good friend of Walter Kohn, but unfortunately he never told me about Kohn's anti-war activities. Baltensperger is basically apolitical and he is presently trying to get a documentary about "the Power of the Sun" (with Walter Kohn the main presenter) adapted to Portuguese to be afterwards distributed to schools in Brazil.
Concerning my string theory…essay I think that one should use a polemic style in physics only in situations of utmost emergency. Polemics, if it is good, sometimes has the power of opening frozen minds and leads to a scientific light bulb moment, but it is of course totally useless with people who allowed fundamentalism to take over. A perfect example of scientific polemics at its best is Res Josts's article in Helvetica Physica Acta 36, (1963) 77. This was written at the hight of the S-matrix bootstrap fashion and I think it did something to clear the air. The situation is much harder now, and if my efford is in vain it is probably not only because it lacks the elegance and coherence of Jost.
By the way the limerick which I remembered from my student times (maybe because it is as far as limerinks go the most perfect I ever run across, I think it is a delightful jewish flavor) was not meant personally against Lubos Motl. I just looked at his site and got the impression that he also did not misunderstand my intentions (although scientifically we are in different boats). Looking at his photo it remined me of how my former FU (younger) colleague Hagen Kleinert looked like when I met him the first time in Boulder (Colerado) where he was enthusiastically preaching the virtues of infinite component fields. When we are young we all go through a Sturm and Drang period. I also experienced this in connection with physics&differential geometry and this has a lot to do with my present more critical view and the differences in opinion with Peter Woit on this matter. Since this is quite interesting and needs some more time, I would like to come back to this (I have an appointment right now) soon.
That there is nothing as a gauge principle is the conclusion of algebraic field theorist for a long time. I became aware of this in connection with different ways present certain 2-dim. models. Recently I run into an interesting observation from Wigner's representation point of view (see the recent paper with Jens Mund and Jakob Yngvason).
No I did not say that the Maldecena conjecture is wrong, I only pointed out that there is a mathematical theorem which says that if you want a supersymmetric gauge theory on the conformal side (that's what most people want) than the AdS side cannot be a QFT for which you can write down a Lagrangian (algebraic QFT envisages a vast territory beyond the Lagrangian setting with which many string theorists unfortunately identify QFT). The best mathematically controllable illustration can be given in terms of so called generalized free fields which have to many degrees of freedom for a lagrangian formulation (I think a good reference is a paper of Duetsch and Rehren which should be easy to find). I am not saying anything which is not (at least implicitly) already in the literature but which may have been lost in thausands of publications on the subject. My statement was somewhat provocative since I proposed to use the Maldacena statement as a vehicle to get some intrinsic understanding of what string theory is. I think without an intrinsic understanding of string theory you cannot hope to prove the conjecture.

24. **Peter Shor**

March 16, 2006

Peter (Woit) says:

"But there is a lot about quantum field theory that isn't relevant to string theory, and it is knowledge about those parts of the subject that I think Schroer fears may get lost."

This still boggles my mind. In my experience of mathematics, it has become quite clear that anything mathematical has a chance of being useful for anything else. So I don't how see can string theorists say that any part of quantum field theory is irrelevant to string theory, especially when the paths that they currently think are relevant to string theory appear to be leading into a vast swampland. Is this arrogance or just a fad mentality?

25. **woit**
March 16, 2006

Peter,

Some parts of QFT really are quite important to string theory, others don't seem to have much to do with it. While there is plenty of arrogance and fad mentality among string theorists, they certainly have tried all sorts of things to get string theory to work, including using many ideas from QFT. But I don't think that there is some idea about QFT out there which will fix the problems of string theory. What's remarkable about string theorists and their descent into the swampland is not so much that they're not willing to try new ideas from QFT to fix string theory, but that they're unwilling to abandon the idea that the answer to the problem is a string theory.

26. **Arun**
March 16, 2006

Is the superstring an extended object or not?
Bert Schroer writes:

> It was already mentioned before that whereas it is true that the extension of the classical Nambu-Goto string (whose canonically quantized version is the "mother" of the string-theoretic reformulation of Veneziano's dual model) is really a relativistic spacetime string, this is not the case for its canonically quantized counterparts.
>
> The only intrinsic notion of a quantum relativistic localization is that obtained by translating this object into other positions and checking whether its commutator with the original object is nonvanishing once the second would be string shape enters the causal influence region of the first. This test was made (even by string theorists) and the result was negative [7][8]; the commutator is just that of two pointlike objects localized at the center of mass points of the imagined strings.

27. **Aaron Bergman**
March 16, 2006

Quantum field theory means different things to different people, for what it's worth. At the risk of generalizing too much, it's a widespread opinion that the axiomatic approach to quantum field theory hasn't been particularly fruitful. Most don't look at it as ignoring "part of quantum field theory" so much as ignoring an *approach* that is not viewed as useful.

Dr. Schroer obviously disagrees.

28. **Juan R.**
March 17, 2006

Benjamin said,

"So in superstrings, as I understand it, they assume an open or closed string, instead of a traditional point particle […]"

There exists many misconception around string "theory" hype. I carefully recommend to anyone does not believe even a 10% is said in popular treatises about string "theory".

The objects called strings play a fundamental role in an asymptotic regime of the branescan. However, once outside the asymptotic regime, one finds a sea of new objects called p-branes, with p taking values from 0 to 9. The 2-branes are usually identified with the traditional superstrings.

There is a joke claiming that now string theory is not about strings!

The history of the subject is full of historical twists. One of more interesting I know is that after of decades "explaining" us how "stupid" the pointlike particles of the standard model were and why a concept of extended objects (the strings) was "cool", we have finalized that string theory is not fundamental and we need some thing new called "M-theory" by now.

The (M)atrix version of M-theory (only known at my best current knowledge) is based in D0-branes as fundamental entities. The D0-branes are pointlike particles… The strings are considered derived objects in the new approach.

Therefore, in some sense, stringers are returning to the "old" (but effective) quantum field theory of pointlike particles but they do not say in that way of course 🙂

March 17, 2006

Schroer listed some legitimate complaints against string theory. Since no one knows what the M stands for (Mystery, Membrane, Mistake), in the future, let's refer to M-Theory by its initials. M-T as in empty.

30. **Dumb Biologist**
March 17, 2006

Holy cow! I completely missed the note about the trackbacks! Mysterious indeed. It strikes me as a bit of an anticlimactic resolution to what looks to have been a rather painful and/or irritating episode for all involved, this sudden and silent reversal.

I sincerely hope the end result is not just a reasonable acknowledgement of your *bona fides*, Dr. Woit, but refinement of arXiv policies that allows everyone, including the moderators, to avoid future headaches.

George Mackey 1916-2006

March 16, 2006
Categories: Obituaries

It was sad to see an announcement today on the Harvard math department web-site of the death earlier this week of emeritus Harvard professor George Mackey.

Mackey's mathematical work is dear to my heart, since its central concern is the relationship between quantum mechanics and representation theory. He began his career in functional analysis, getting his Ph.D. in 1942 under Marshall Stone. Back in 1930 Stone and von Neumann had proved a crucial theorem about quantum mechanics, a theorem which essentially says that once you choose Planck's constant, up to unitary equivalence there is only one possible representation of the Heisenberg commutation relations. This uniqueness theorem is what allows one to just define quantum theory in terms of the operator commutation relations, and not worry about which explicit construction of the representation of these operators on a Hilbert space one uses. The theorem is only true for a finite number of degrees of freedom, and thus doesn't apply to quantum field theory, one reason why quantum field theory is a much more subtle business than quantum mechanics. Stone and von Neumann put their work in the context of representation theory of the Heisenberg group (actually due to Weyl) and this was of great interest to mathematicians since it was one of the first results about the representation theory of non-compact Lie groups. For an excellent history and introduction to this subject, see the paper A Selective History of the Stone von-Neumann Theorem by Jonathan Rosenberg.

Mackey seems to have been the person who gave this theorem its name, in his important paper of 1949 "A Theorem of Stone and von Neumann" which generalized it. Over the next few years Mackey extended this much further in a series of papers on induced representations (representations of a group G "induced" from representations of a subgroup H). The foundation of this work is now known as the Mackey Imprimitivity Theorem, and it provides a powerful tool for studying representations of a large class of non-compact groups, including especially semi-direct products.

Mackey was a wonderful expositor, and over the years I've learned a great deal from some of his expository books and papers. His 1963 monograph *Mathematical Foundations of Quantum Mechanics* is very readable. In 1966-67 he gave a course at Oxford on representation theory and its applications, the notes of which were published in 1978 as *Unitary Group Representations in Physics, Probability and Number Theory*. This is a fantastic book, covering a wide range of topics relating quantum mechanics, representation theory and even number theory. A later collection of expository material, from 1992, was published by the AMS as *The Scope and History of Commutative and Non-Commutative Harmonic Analysis*. It contains what is perhaps the best of his expository work, an historical survey first published in the AMS Bulletin in 1980 entitled "Harmonic Analysis as the Exploitation of Symmetry".

While I never took a course from Mackey, I did get to talk to him on several occasions. I especially remember a conversation in which he described his technique for speaking French during the time he spent in France. He decided to speak his own rationalized version of the language, eliminating extraneous and confusing structure like genders of nouns. Not clear what the French thought of this. He was an original, and I'm sad to hear he's no longer with us.

Update: Stephanie Singer has put up copies of letters from Mackey on her web-site. A memorial service for Mackey will be held in Cambridge on April 29.

Comments

1. **Who**
   March 16, 2006

   He came to Berkeley one semester in late sixties (anyway around 1970) and I took his course on Group Representations. The large hall was always packed. A lot went by too fast for me. Left a vivid impression though. He had so much verve.
   Would like to hear others' recollections.

2. **Stephanie Frank Singer**
   March 17, 2006

   George Mackey's daughter, Ann, was my roommate in college and remains one of my closest friends. When I was a sophomore in college, interested in both mathematics and physics, I sent him a short note asking him what his field was, and requesting advice. He responded with two long handwritten letters that I am reading with interested after rediscovering them in my files this morning. I can't imagine that I understood much of it at the time. Here's a sample, from near the end of the first letter:

   > This description of what my field is and how I got into it is rather longer than I expected it to be and I apologize if I have tried your patience. On the other hand it is probably a bit unintelligible without some further explanations. What are topological groups, Hilbert spaces and group representations and why do I find them so interesting? Actually when properly understood they are rather central topics and I think it will help me give you a picture of what pure mathematics is all aobut and how it relates to physics if I give a brief historical sketch including definitions of some related concepts….

   What is astounding is that nearly twenty-five years later these forgotten letters hidden in a drawer describe exactly the mathematics that is most important to me. It never would have occurred to me to think that George Mackey sent me on that path, since I got there (like Alice through the looking glass) by heading in what seemed to me the opposite direction.

   Also astounding is the generosity of a man who would handwrite twenty or more pages in response to a student he had never met.

   Another memory: George supposedly spent eight hours each day on his research, in addition to his teaching and other obligations. He told me once that his method was to work for forty-five minutes of each hour and then spend fifteen minutes of each hour reading a nonmathematical book or taking some other kind of break. Knowing this has always helped me to pace myself.

   Thank you, George.

   Alice Mackey, George's wife and Ann's mother, supported him and put up with his foibles. The French, at least, had the option of sending him home! Alice gave him the space and time to do his work and letter-writing. In the last several years, Alice supported and loved George through a difficult period of declining health. Thank you, Alice.

   There will be memorial service for George at Harvard on April 29, 2006, in the afternoon.

3. **woit**
   March 17, 2006

   Stephanie,

   Thanks a lot for your memories of Mackey.

I'm guessing we both arrived at an interest similar to Mackey's in QM and representation theory via symplectic geometry and its relation to quantization. I recommend Stephanie's books "Symmetry in Mechanics" and "Linearity, Symmetry and Prediction in the Hydrogen Atom", to anyone who wants an introduction to these subjects.

4. **MathPhys**
   March 19, 2006

   I highly recommend Stephanie Singer's book "Symmetry in Mechanics" to all students who wish to read about symplectic geometry and related topics for the very first time. People should write more such books.

5. **Santo D'Agostino**
   March 20, 2006

   I heartily agree with both Peter and MathPhys: Both of Stephanie Singer's books are very good, very clear introductions. I wish they were available when I was learning these subjects for the first time, but at least I can recommend them now to any interested beginners who cross my path.

   Warm congratulations to Ms. Singer, and I do hope you keep writing!

6. **harsha**
   March 20, 2006

   to stefanie :
   as someone who is precisely trying to find what mackey describes, i was wondering if maybe you could type or scan these letters onto your website. (i realise they are pretty long and a lot of it might just be defining lie groups, hilbert spaces, etc. so, maybe atleast some excepts which talk about motivations). it would prove to be very useful, specially for younglings like me who dont know too much.

7. **MathPhys**
   March 20, 2006

   Stephanie,

   There is an incredible amount of material on integrability that remains to be explained to students. Why not write sequels to "Symmetry in mechanics"?

8. **Stephanie Frank Singer**
   March 20, 2006

   Well, wow, folks, thanks for the feedback. I'm feeling the love! Don't hesitate to repeat your opinions at Amazon.com.

   I will post George Mackey's letters as soon as I get ten quiet minutes. I'm incredibly busy in 2006, starting two businesses (real estate development and election data consulting) and working to get Chuck Pennacchio elected to the US Senate. Also, I'm working with activists around the state of Pennsylvania to fight the installation of unauditable, unaccountable voting machines. I'm starting to wonder how many Americans really believe that democracy is worth fighting for. I'm talking about fighting laziness, established power brokers and bureaucracy here on the home front.

   So I haven't even found time to post the errata that Tudor Ratiu so kindly sent me for *Linearity, Symmetry, and Prediction in the Hydrogen Atom*, much less to write a new book. But do send me ideas of what you'd like to read. The next book I've thought of is the story of the *real* Kepler problem, that is, the problem Kepler devoted most of his energy to (according to Koestler's *The Watershed*): why are the planets where they are? I heard a talk by Jerry Marsden a few years ago announcing that there was a geometrical explanation: once Jupiter's orbit is given, then the positions of the other planets can be predicted geometrically. That's the book I'm daydreaming about these days. But it will have to wait.

9. **woit**

   A link to Mackey's letters at Stephanie's web-site was added.

Three-year WMAP Data Now Out

March 16, 2006
Categories: Uncategorized

Data from the second and third year of the WMAP satellite experiment has just been released a few minutes ago. There a press release and other general information page. The scientific paper explaining what this new data tells us about cosmology is Three-Year Wilkinson Microwave Anisotropy Probe (WMAP) Observations: Implications for Cosmology. This is a good time to admit that I'm no cosmologist, and thus not the person to get information from about the significance of these results. However, I expect some of the earliest informed discussion of them should take place on various blogs, and I'll be linking to those as I see them.

Update: Comments from Sean Carroll and Steinn Sigurosson. Discussion at CosmoCoffee and Bad Astronomy and Universe Today Forum. Also a posting from Lubos. I'm no expert here, but Lubos's comments seem to me to be nonsense (I find it hard to believe that in the three-year data set they're resolving structure 100 times smaller than in the first year, and I think he's just completely wrong to say that this data rules out ekpyrotic or cyclic models).

Update: Christine Dantas also has more about this.

Update: Amazingly, Lubos still is maintaining that the 3 year results have 100 times better angular resolution than the 1 year results. This kind of fanatical inability to ever admit that one was wrong about something goes a long way towards explaining the current state of string theory.

Comments

1. **Dumb Biologist**
   March 16, 2006

   I think the 100x estimate is actually correct. However, according to a new article in the NYT here:

   http://www.nytimes.com/2006/03/16/science/16cnd-cosmic.html

   But Paul Steinhardt of Princeton, who has lately championed an alternative to inflation, in which the universe begins and ends cyclically in a collision between a pair of island universes, know in string theory as branes, pointed out that the new data are also compatible with his theory. Calling the results "extremely important," he noted that they were in agreement with the simplest models of these theories.

   'It rules out need for anything exotic," he said.

   I haven't the remotely foggiest idea about any of it, I only pass this along…

2. **woit**
   March 16, 2006

   D.B.,

   Do you have any reference for the 100x claim? It may be right, I'm just having a hard time believing that tripling your data size allows you to increase your resolution 100-fold. But maybe they did something much more clever with the later data.

   I notice that Lubos edited somewhat his statements about cyclic models being ruled out, and added a statement that Peter Woit knows nothing about cosmology. More recently he seems to have deleted the attack on me, maybe he's about to do more editing on the cyclic models claims. He's hilarious.

3. **woit**
   March 16, 2006

   D.B.,

   Thanks for pointing out the NY Times article, I hadn't seen it. I think the "100x" number is referring to being able to detect much smaller signals in order to get the polarization data (not smaller patches of sky). Lubos seems to have completely misunderstood what this has to say about cyclic models. Cyclic models predict no visible B-mode polarization. If WMAP had seen this kind of polarized signal, it would have ruled them out, but it didn't.

4. **Dumb Biologist**
   March 16, 2006

   I don't think this is the first place I saw the "100x better" thing, but…

   http://www.space.com/scienceastronomy/060316_wmap_results.html

   This new signal is roughly 100 times weaker than the signal we analyzed three years ago and about a billion times less than the radiant warmth we feel from the Sun," said Lyman Page, a WMAP team member from Princeton University.

   Now, I don't know if getting 100x better signal is really the equivalent of saying you're looking at structures 100x smaller, but there's a 100x improvement in something.

   I'm sorry I can't do better. I've been kind of sneaking in glimpses of reading between time points and basically behaving like an ADHD-addled channel surfer when I should be paying more attention to what I'm doing. I find stuff like this almost unspeakably cool, so I get a little worked up…

5. **Dumb Biologist**
   March 16, 2006

   D'OH! Simulpost!

6. **Alejandro RIvero**
   March 16, 2006

   Perhaps some topologist will give us someday a hint about why the universe is flat for the current bigbangy solution. Meanwhile, I do not understand the fuzz about WMAP in theoretical blogs. Except that some of you had got a hidden idea to explain flatland.

Did I already suggested to read astro-ph/0601168?

7. **Christine Dantas**
March 16, 2006

Dear Peter Woit,

Perhaps he is referring to section 4.1.3 (paper on Implications for Cosmology), where the WMAP data is combined with small scale CMB experiments, which probe smaller angular scales than the WMAP.

As expected, the paper on polarization measurements is quite involved. I am always concerned with the fact that you have to use a model of the foreground emission to subtract from the data. It is not a trivial thing at all to separate the intrinsic polarization signal from the foreground emission. So I would say that we must interpret these results with great care. In any case, I am just starting to effectively read these papers, it will take time to digest the details.

I will try to call some of my colleagues at INPE who are specialized in CMBR (we have a ballon experiment here in Brazil) to add their comments to my blog page, where you can find also a brief post on the new WMAP data.

Christine

8. **woit**
March 16, 2006

Christine,

Thanks, I've added a link to your posting and look forward to hearing anymore you learn about this.

Hard to tell what's going on with Lubos. He keeps changing his posting, now he's got some WMAP pictures up there which he claims show that 3-year WMAP can resolve solid angles 100th the size of 1-year WMAP and 1000th the size of COBE. But as far as I can tell, the resolution of both 1-year and 3-year WMAP is the same: 13 arcminutes, 33 times smaller than COBE. No idea where he's getting his numbers from, they don't seem to make sense.

9. **Dumb Biologist**
March 16, 2006

I just can't get over the idea that physicists can say something rather concrete about, and hence test models of, what what was going on about a trillionth of a second after the visible universe started expanding. That's so impressive it's absurd. Sorry for the fanboy slobberfest, but all hail physics! I know there are some crises in subsets of the field, but if results like these don't reveal something vital, vibrant, and important overall, I don't know what does.

10. **Luboš Motl**
March 16, 2006

Dear Peter,

it would be a great idea for you to stop spreading the noise and nonsense that you keep on spreading.

Open one of the 74 news articles here

http://news.google.com/news?hl=en&ned=us&q=wmap+patches&ie=UTF-8&scoring=d

and read the paragraph that contains the word "patches". After you read this paragraph, and maybe the whole article, correct the order of magnitude error that the journalist introduced, if you're capable to do so, then reread my blog article to be sure what I mean, and check the pictures that I linked to see why I say what I say.

The maximal designed angular resolution of WMAP is fixed but more data and a much better statistical treatment has allowed to create these much finer maps and everyone who has looked at the 2048-pixel-wide pictures (or who read some of the basic articles released today) knows that.

I have always had the comment that the "modern" models of ekpyrotic/cyclic Universes try to be indistinguishable from inflation. This is the uninteresting part. The more interesting part is that they predict blue gravity waves that must eventually come into the game. At any rate, no one except for the authors knows exactly how to derive the magnitude and frequency-dependence of the tensor perturbations from the ekpyrotic scenarios, so I think it is fair to write what I wrote.

Best wishes
Lubos

11. **Christine Dantas**
March 16, 2006

I will try to understand this.

For the moment, all I can say, from the *Mission Explanatory Supplement paper*, is that the WMAP experiment can reach a 13 arcminute FWHM resolution for the temperature anisotropy of the CMBR. Also, that "the skymap data products derived from the WMAP observations have 45 times the sensitivity and 33 time the angular resolution of the COBE DMR mission".

Christine

12. **woit**
March 16, 2006

D.B.,

The WMAP results are truly amazing, and this is a really healthy subfield of physics. But the results about inflation are a bit overhyped. This is giving us very little information about how inflation may have worked, although of course it's remarkable you can say anything at all. The next generation satellite, Planck, should have the sensitivity to see the effects of gravitational waves if they're there, which would be something a lot more substantial.

13. **Christine Dantas**
March 16, 2006

Sorry, in the previous post, where I wrote “experiment can reach a”, replace this by “experiment has a”.

Thanks
Christine

14. **woit**
March 16, 2006

Lubos,
I don’t understand what you’re trying to accomplish by pointing me to a popular news story with obviously incorrect numbers in it (100 billion light years??). If you can point to somewhere in the WMAP scientific papers where they explain about the 100 fold increase in resolution, please do so. It still seems to me that the “100” at issue here is an increase in sensitivity. They’re able to extract much smaller temperature differences from the noise, but this doesn’t at all mean that they have 100 times higher angular resolution.

And your comments about ekpyrotic scenarios make no sense: “blue gravity waves”? no one but the authors knows what the theory predicts? Sorry, but I’ll take Steinhardt’s claims about this over yours.

15. **Dumb Biologist**
March 16, 2006

Oh, I know. I guess to me it’s just a bit mind-blowing that quite possibly now there’s a rather compelling “smoking gun” indicating, that, for real, inflation happened. I understand (I think) that the whole “inflaton field” thing is something of a gigantic black box, and that lots of folks find this deeply disatisfying. Some of the articles I’ve read seem to allude to this reality, though I agree the limited scope of our knowledge about inflation (even with this news) gets short shrift.

16. **woit**
March 16, 2006

First year data:
http://lambda.gsfc.nasa.gov/product/map/dr1/map_images/pub_images/ILC_Maps/ILC_b.jpg

Three year data:
http://lambda.gsfc.nasa.gov/product/map/current/map_images/ilc_gal_moll_2048.png

Note the hundred-fold increase in resolution.

17. **Chris W.**
March 16, 2006

Lubos, thanks for reminding us yet again that you’re the smartest guy in the room. We just can’t seem to get it through our thick little heads.

18. **D R Lunsford**
March 17, 2006

This is my last comment for this blog, I’m done with all of this. You can read me in forthcoming papers if you’re interested. Otherwise, my last comment is this:

Penrose completely destroyed the idea of inflation using nothing but entropy, yet we are supposed to believe, after years of looking and a long wait, that the octupole anomaly magically cleared itself up (and not a word was said about the ecliptic anomaly, so there was nothing to clear up). In fact, the work of Huterer, Copi, and Starkman was not even mentioned. Instead, we got a dissertation on applied inflation theory.

So, who should I believe? An authentic genius, or a star chamber of people with, shall we say, vested interests?

Science is dead. Nice job y’all.

-drl

19. **lmot**
March 17, 2006

There is absolutely no evidence of global warming in this new data.

Also, that plot everyone is showing has several wiggles, and everyone knows wiggles are a property of strings.

2006 Templeton Prize

March 16, 2006
Categories: Uncategorized

The 2006 Templeton Prize of $1.4 million was awarded yesterday to cosmologist John Barrow. Barrow is the author of about 400 scientific articles and nearly 20 popular books. In recent years, one of his interests has been the possibility of time-variation of fundamental constants. At a press conference in New York yesterday, he said that new data on quasars expected within two months may provide evidence of such variation.

Science and Spirit has an article by Barrow written for the occasion and called The Unexpected Universe. It also has a report on the press conference that goes on at length about the string theory anthropic landscape and credits Barrow (and Tipler) with writing a "highly influential book for the interface between science and religion" back in 1986 entitled *The Anthropic Cosmological Principle*. The report includes the following gibberish:

String theorists also assume that other universes, which collectively compose a "multiverse," exist in other dimensions outside of our observational parameters. Our own very limited experience suggests that finely tuned universes might be more likely to exist than more randomly constructed universes, at least over the long term. If this is true, then fine-tuning may be a guide that cosmologists can use to one day locate and observe an alternate universe.

Barrow himself however doesn't seem to have much to say about the string theory landscape.

Maybe if Leonard Susskind hadn't said unfriendly things about having no use for religion in his recent book, he could have been $1.4 million richer instead of Barrow. The New York Times headlines its story about this Math Professor Wins a Coveted Religion Award. A mathematician friend of mine is kind of outraged at this and wants to write to the Times to complain about the description of Barrow as a "math professor".

Comments

1. **john e gray**
   March 17, 2006

   Barrow is a math professor at Cambridge. By UK standards he is a mathematician where they treat theorists who work in GR no differently than other types of applied mathematics. Stochastic geometry, which has orgins in GR, is one of many types of math applications that are explodiing in various domains that have come from the exploration of GR. By the way, his "undergraduate degree " is in math. He is I would bet that he has more papers listed in MathNet than your friend has or will have in 30 years. By what criteria is someone a mathematican these days, working in a subfield that has less than a hundred people who publish papers in that field?

2. **Robert**
   March 17, 2006

   Not only GR is math at Cambridge, UK but even string theory: DAMTP, the Department of Applied Mathematics and Theoretical Physics, is the department not only of Barrow but also of relativist Stephen Hawking, and Michael Green, Paul Townsent, Garry Gibbons, Fernando Quevedo, Nick Dorey, David Tong amongst other. All these people write papers about string theory but in Cambridge's view are members of the maths department.

3. **csrster**
   March 17, 2006

   In Cambridge even a semi-maths-literate ex-astrophysicist like me
   can count as a mathematician 🙂 I tell people that Stephen Hawking works in my old department.

4. **anon**
   March 17, 2006

   A previous recipient of this prize is Paul Davies. It is quite an event, held in a cathedral. In his acceptance speech, Davies said:

   'A world freely created by God, and ordered in a particular, felicitous way at the origin of a linear time, constitutes a powerful set of beliefs, and was taken up by both Christianity and Islam. An essential element of this belief system is that the universe does not have to be as it is: it could have been otherwise. Einstein once said that the thing that most interested him is whether God had any choice in His creation. According to the Judeo-Islamic-Christian tradition, the answer is a resounding yes.'

   – http://www.firstthings.com/ftissues/ft9508/davies.html

5. **Chris Grant**
   March 17, 2006

   As a followup on John E. Gray's point, the ' "math professor" ' Barrow has 100 items indexed on MathSciNet.

6. **woit**
   March 17, 2006

   Personally I'm all in favor of blurring the boundaries of math and physics so that in many cases there's no useful distinction, but here I'm with my friend that the NYT headline is misleading, given local American usage about what is math and what is physics. Barrow clearly falls on the physics/astrophysics side of the physics/math divide. MathSciNet is very inclusive and has lots of papers by physicists (a good thing), but the relevant point is that 3/4 of Barrow's papers are not in MathSciNet.

   In any case, my suspicion is that the headline writer used "Math" rather than "Physics" because, with 3 characters less, the headline fit better. Most readers of the newspaper can't tell the difference anyway, not that there's anything wrong with that.

7. **damtp_dweller**
   March 17, 2006

   To Robert and those discussing Barrow's position at Cambridge:

   John Barrow is Professor of Mathematical Sciences here in Cambridge. Although he (and Gibbons, Hawking, Quevedo, Perry, Green, and others) works in the Centre for Mathematical Sciences, they are technically members of DAMTP, the Department of Applied Maths and Theoretical Physics. We inhabit the CMS with our colleagues from DPMMS (pure mathematics and statistics). However, given the fact that papers from both departments are usually given the affiliation "DAMTP/DPMMS, Centre for Mathematical Sciences," it's perhaps understandable that there's confusion.

I do agree that Barrow is a physicist rather than a mathematician (and I think that's how he would describe himself), especially given the content of the majority of his papers.

8. **secret milkshake**
March 17, 2006

gibberish or not, at least they are not giving this money away to Bogdanov brothers or some God-damned televangelist.

(ID is wooly thinking but I do not have problem with it when it is presented honestly – and it could make for engaging literature, in Dyson case)

9. **MathPhys**
March 18, 2006

Barrow (and Hawking) are in DAMPT: that's in dept of 'applied mathematics' (that's the fluid mechanics and nonlinear PDE people) and 'theoretical physics' (that's the GR, string theory, and theoretical high energy physics) people.

None of these people would call themselves 'mathematicians'. Michael Green would never call himself a mathematician. Same goes to Quevedo, Townsend, and all the others. The most mathematical work at DAMPT is probably done in Fokas' group (I think he's at DAMPT).

It is true that their students dp parts I, IIA, IIB and III of the 'maths tripos', but 'maths' here has historical origins peculiar to the Cambridge system. In Oxford, they would all be physicists. In Edinburgh, they could be either in maths or in physics.

No, Barrow is *not* a mathematician in the sense that Andrew Wiles, for example, is a mathematician.

10. **damtp_dweller**
March 18, 2006

It's DAMTP, not DAMPT (although it is, for some bizarre reason I've never quite understood, pronounced "dampt").

11. **Not a Nobel Laureate**
March 18, 2006

"What mighty contests rise from trivial things"

— "Canto I; The Rape of the Lock", Alexander Pope

12. **MathPhys**
March 18, 2006

damtp_dweller,

You're right. My mistake. I was writing phonetically. By the way, what became of the old building on Silver St? It was charming.

13. **damtp_dweller**
March 18, 2006

The old location at Silver Street is now used by (I think) the graduate union and various university admin departments. I think Darwin college may also have taken some of it. I guess it did have a certain character but the new location is much, much better suited to the size of the department.

14. **MathPhys**
March 19, 2006

I haven't been in the new location, but from the pictures that I see, the architecture horrifies me. Can you open the windows for ventilation? or are the offices air sealed? How far walking is it from Churchill College? How far from St John's?

15. **damtp_dweller**
March 19, 2006

The place grows on you after a bit. I was a bit concerned by the style of the buildings at first too, particularly the outside. However, it's actually a really nice place in which to work (apart from the food, which is typically Cambridge: hugely over-priced, bland, and sometimes inedible). The windows open in all of the offices that I've seen, although the automatic blinds are a bit unnerving on first sight. Oh, and parts of the place are very confusing. I still manage to get completely disoriented by the circular staircases in Pavillion B 🙂

It's less than two minutes walk from Churchill (you simply go north and walk across Madingley Road. St. John's is a bit farther but still less than ten minutes on foot.

16. **Alex**
March 19, 2006

The award seems a little overgenerous and somewhat dubious in its purpose. If the aim is to try to reconcile religion and physics, I can't say that I've found Barrow's arguments particularly relevant to such a project.

"The Constants of Nature"2002 is quite a thought-provoking book, which examines the fine tuning of physical constants to create laws of physics which are conducive to the evolution of life.

In particular, Barrow is interested in the fine structure constant, the ratio between the energy needed to bring two electrons from infinity to a distance of s \against their electrostatic repulsion, and (ii) the energy of a single photon of wavelength 2 \pi s \.

This is one of the few dimensionless constants in nature and Barrow seems to believe there is evidence that it has changed over time.
His evidence comes from the Oklo 'natural reactor' in West Africa and the study of Quasars using multiplet sampling.

The implications of his views are that the universe in its current phase (not just at inception) is particularly fine tuned for life. He also examines the views of Linde on "eternal inflation" and Lee Smolin's arguments about black hole universes being naturally selected.

As to his suggestions about the changing fine structure constant: there is counter evidence which suggests that it's NOT changing, and furthermore, he provides no theoretical explanation about why it would change, or the atom become slightly larger since 14 billion years ago.

However, even though he is something of a court physicist to Number 10 and the Vatican, I can't say I noticed any strong religious arguments in this book.
I suppose a potential one is that some "intelligent designer" was responsible for the "initial conditions" of inflation, although he isn't crazy enough to suggest this.

To me, the anthropic principle argument is tautological and leads to not very interesting theoretical musings. In a similar vein Eddington and Dirac spent a lot of time in semi-mystical investigations of large number theory.

17. **Alejandro Rivero**
March 19, 2006

Eddington was a bit more semi-mystical than Dirac. The later was betting more on evolving constants than on a special coincidence. By the way it is interesting to nocice that a lot of crackpot ideas on gravity and masses around in the net are just variants in disguise of Dirac's large number idea.

About this kind of research, let me to remember that we took a whole year in physicsforums clasifying the numerical coincidencies around. Some famous ones are even published. For instance, Lubos happened to rediscover m(electron) / m(proton), which probably is the shortest article ever published in the Physical Review, decades ago.

18. **island**
March 19, 2006

At least Barrow is looking for real first principles.

The structure of our universe is the most natural configuration for the big bang to produce, per the least action principle… because… [infinities, multiverses, and "cosmological selection effects" don't go here, jack].

Please.

19. **MathPhys**
March 19, 2006

Thanks, damtp_dweller.

By the way, what do you do for research? What are people up to in Cambridge nowadays? The place is a bit too quiet as compared to a few years back. (Don't worry about hijacking a thread. It's all for the good.)

20. **Incompetent**
March 20, 2006

"It's DAMTP, not DAMPT (although it is, for some bizarre reason I've never quite understood, pronounced "dampt")."

Blame it on the peculiarities of what English speakers consider 'pronounceable'. For obvious reasons, 'mtp' at the end of a word is deemed unpronounceable, so the 'p' is ignored, giving 'damt'. But the combination 'mt' is also unusual, so this is resolved by inserting a 'p' in the middle. In a similar way, many English speakers will say and even write 'hampster', even though the word is actually 'hamster' (borrowed from German, hence the un-English 'mst').

I tend to say 'damt', but then again I have enough experience of German that 'mt' doesn't feel unnatural.

21. **Alejandro Rivero**
March 21, 2006

I think that phonemes are defined via the possibility of differentiating words, thus this combination is not only unpronounceable, it plainly does not exist. Just as a colored hadron.

2005 Topcites

March 20, 2006
Categories: Uncategorized

The SLAC SPIRES yearly list of [most frequently cited papers in 2005](#) is now available. I commented [recently](#) on what this was likely to show, quantifying the intellectual collapse of string theory since 1999.

There are exactly three post-1999 particle theory papers among the top 50 in the list. Two of these are about flux compactifications and have moved up significantly since last year reflecting the increasing popularity of landscape studies. At number 18 (up from 29) is the KKLT paper from early 2003, and at number 34 (up from 54) is an earlier paper from 2001 by Giddings, Kachru and Polchinski. The only non-landscape post-1999 paper to crack the top 50 is the 2002 Berenstein, Maldacena and Nastase paper on PP waves (which is part of the AdS/CFT story). It just barely makes it at number 49 (down from 32 last year).

The highest ranked post-2003 paper is the Arkani-Hamed and Dimopoulos 2004 paper on split supersymmetry. It's at number 106, with a total of 103 citations.

There's also a new 2005 [All-time topcited list](#). Maldacena's AdS/CFT paper from 1997 remains very near the top, with 3881 citations. There is nothing post-1999 on this list, which includes the top 186 papers. If recent trends continue indefinitely, it seems entirely possible that no post-1999 particle theory paper will ever make this all-time top-cited list, allowing historians of science to conclusively pinpoint the death of particle theory as having coincided fairly precisely with the end of the 20th century. This is optimistically assuming people lose interest in the landscape. It is also possible that landscape studies will come to dominate the field, with landscape papers then climbing up into the all-time topcited list. This doesn't really change the conclusion about the death of particle theory.

Comments

1. **Who**
   March 20, 2006

   This doesn't really change the conclusion about the death of particle theory.

   LOL

   (agree of course)

   A bunch of us made predictions about the topcites 2005 list.
   Here are the forecast poll results:
   http://www.physicsforums.com/poll.php?do=showresults&pollid=580

   I see that your (notevenwrong's) guess proved correct. Congratulations.

2. **ObsessiveMathsFreak**
   March 20, 2006

   > It is also possible that landscape studies will come to dominate the field, with landscape papers then climbing up into the all-time topcited list.

   Philosophy. The last refuge of the hypothecator.

3. **Jimbo**
   March 20, 2006

   No critique is as devastating as a quantitative one ! Kudo's to Peter for calling it as it is. One wonders, how many hundreds of string papers are still pending review at Nucl.Phys.B, PhysRev D, etc ? How many grad students will join the `String Army' this year ?
   Like the `war' in Iraq: Massive inertia*snail's pace = business as usual.

4. **JustAnotherInfidel**
   March 20, 2006

   Perhaps one could find another six year period where very few papers made the topcite list (say, 1987-1993 where the top cited papers are pretty far down the list, not to mention few and far between). Looking selectively at the data really doesn't prove much.

5. **woit**
   March 20, 2006

   JustAnotherInfidel,

   I strongly disagree that I'm looking selectively at the data. I think that if you ask virtually any particle theorist who has been in this business for many years what they think about how many new ideas have come along over the last six years compared to other periods in their lifetime, they will tell you that the number of such ideas in the past six years has been unusually low. I'm putting forward the most honest and objective way I know of quantifying this. If you have a better one, let's hear it.

6. **arnold**
   March 20, 2006

   Maybe there have been good ideas, but if you're not a big name….nobody pays attention.

   The big names decide what is good physics and what is not.

   Maybe we are close to the end of physics.
   In science in principle you should not worry what the big names think, but what the experimental measurements say.

7. **JustAnotherInfidel**
   March 21, 2006

   Dr. Woit–

I feel that one must take other things into account when making claims like “the death of particle physics is nigh”–the set of string theorists who understand, say, twistor strings is a very small subset of all string theorists, so naturally there will be fewer citations of that work. Papers like RS1 or AdS/CFT represent huge steps in understanding (or misunderstanding, if you like) of physics that don’t just happen everyday. Some of the papers listed on this list (just the theory papers apply) represent really revolutionary ideas (inflation, Beckenstein/Hawking radiation, asymptotic freedom…).

One should look at the theoretical papers (not things like WMAP data) which represent ground-breaking ideas (judged by the number of citations), and look at the years in which they were published. If you can show that the current six year lapse in theory is longer than any other before, then I will accept your claim that particle physics is in a dark ages.

8. **MathPhys**
March 21, 2006

I recall the years from the mid 70’s to 1983 (so that’s more than 6 years) when basically nothing was going on in theoretical HEP (except for Witten’s papers on Chern Simons theory, non abelian bosonization, global anomalies, etc, which were too mathematical to be called high energy physics proper). The standard model was fully established and people started playing mundane games with Kaluza Klein, SUSY, etc.

The situation changed completely in 1984–1985 which were revolutionary years: superstring theory, conformal field theory, quantum groups, knot invariants, and RSOS models in stat mech, and probably more. Probably the most revolutionary years since quantum mechanics and/or quantum electrodynamics, in terms of the number and quality of new ideas floating around.

So yes, I’m hopeful that something will come along.

9. **Alejandro RIvero**
March 21, 2006

As I see, these people at SPIRES are he(l)pful. And jointly with arxiv and KEK, it is a resource to be proud of.

10. **woit**
March 21, 2006

Because of some of the comments here, I took a closer look at some of the topcites data, even making a histogram of the time distribution of the all-time topcited papers.

The results for 1975-86 agree with my memory of the period. There were lots of new ideas that people were working on: supergravity, lattice gauge theory, instantons, GUTs, 2d models, etc. (Chern-Simons-Witten was later), although some level of frustration at how difficult it was to either solve QCD or get beyond the standard model. The topcites data show a consistent average of 5-6 papers/year for this period, with a peak of 9 in 1985 corresponding to the advent of strings.

The period from 87-93 does contain many fewer papers, just seven, an average of one/year. This is significantly more than the post 99 zero/year, but more to the point, research during this period was largely driven by new developments in a way that is very different than recent history. If you look at the earliest SPIRES yearly top-cites compilation, covering 92-94, and ask how many of the top-cited papers were from the six years just before this (1987-93), you get 13 out of 40, even though most of these papers are on things like CFT results that were very popular then, but haven’t made the all-time list since people have lost interest in them. This number of 13 out of 40 is very different than the similar number for 2005: 3 out of 50 (or 2 out of the top 40). While people in 1993 felt things were in a lull, the situation was very different back then, there were plenty of quite recent results that large numbers of people were working on.

Also, while 1987-93 was a fallow period for string theory, it was the period when the whole field of topological quantum field theory got going, and Witten did his Fields medal winning work on Chern-Simons. There’s nothing remotely similar to this in the last few years.

Citation counts don’t reliably identify important new ideas, they reflect what the community is working on. Famously, Weinberg’s electroweak paper received no citations for several years, but now is the most cited theory paper of all time. Maybe there is some important idea out there in the recent literature, but its significance is not understood, so hardly anyone else is working on it. Witten’s twistor string paper has received relatively few citations, but that seems to be not because people don’t understand it, but because it has not led to as much as originally hoped, so few people continue to work on it.

11. **JustAnotherInfidel**
March 21, 2006

Dr. Woit–

Thank you for your detailed analysis. Absent any other indicators, your analysis does seem to indicate that ideas are fewer and further between. It does seem to quantify the dark ages of particle physics you alluded to in the original post. Perhaps we have been “sidetracked”, so to speak, on ideas like RS1 and AdS/CFT, or that the field is more dispersed than at other points in the past.

12. **David B.**
March 21, 2006

Dear Peter:

It takes many years before a paper can gather 1000+ citations (this is the magic number that makes it to the top-cited papers of all time, 990 is no big step down from this). This never happens immediately. Claiming that because no such thing has happened in the last 6 years that theoretical particle physics is dead is a wrong conclusion and does not take into account historical data on the subject.

To make such a statement you have to wait (at the very least) about 15 years and then look back. You also have to wait and see what happens after the LHC is taking data to declare that theoretical particle physics is dead, because if anything unexpected is found, I can guarantee that it will be a very interesting time for theoretical physics.

To judge a field by how many papers from the previous year have gathered 100+ citations is probably more correlated with having fashionable theories/mechanisms. On the other hand, if a subfield is more technical and it requires a lot of hard work to get results, then you would be extremely happy if a paper got 50+ citations in that year. One should always judge by quality, not just quantity.

The fact that experimental physics is dominating the list is actually very healthy: there is very interesting new data (neutrino masses, cosmological precision experiments) and there is a strong effort to fit these observations with our understanding of the standard model and physics beyond the standard model (like inflation).

13. **A. Torok**
March 21, 2006

David B.: I strongly agree with your statements.

14. **woit**
March 22, 2006

David B. and A. Torok,

Obviously I was making a provocative statement about the "death of particle theory". We don't know yet how it will turn out, maybe the LHC will change everything. However it's not going to be telling us much for at least another three years or so, at which point the period of zero progress that I am identifying will have stretched out to about a decade.

As for your comments about the all-time list, you're just refusing to look at the data. If someone comes up with a new idea that is recognized as important in this field, it tends to get a lot of attention quickly. There are a lot of smart people out there everyday looking at new papers on hep-th, ready to jump on anything new they see. Historically, it is not at all unusual for important papers to accumulate nearly 1000 citations within 2-3 years (the most heavily cited papers generally get 3-500 citations/year). I picked one recent year at random (2002), and looked at the SLAC all-time list which that year included the top 104 papers. Eight of these were from within the previous 5 years. It doesn't take 15 years for most important papers to show up on the all-time list. Please look at this data, and don't just assume you know what it says. And no, the reason for this data is not that the list is being overwhelmed by a huge number of important new experimental results. Besides WMAP, which dominates the list, this has not been a period of unusually many or important HEP experimental discoveries, although HEP experiment is in better shaper than HEP theory.

As far as I can tell you're both students and lack historical perspective on this issue. If you ask anyone who has been working in this field for twenty years or more, paying close attention to new developments as they arose, I think you'll find that virtually all will tell you that the dearth of recognizable new ideas during the last six years compared to earlier periods has been dramatic. If you don't want to believe me or other people who have this experience, look for yourself at the SLAC data.

I think it is extremely unhelpful for people to try and deny the facts of the matter here. Particle theory is in a bad way, and the community needs to figure out why this is true and whether something can be done about it. Denying that this is true won't make the problem go away.

15. **David B.**
March 22, 2006

Dear Peter:

I am not a student and I have been in the field for more than 10 years, so I have some historical perspective. Furthermore, I am not in "denial". I was just pointing out that it is too early to make concluding statements like that. You have an undeniable right to have a negative opinion of the current state of theoretical particle physics and nobody is trying to rob you of that fact.

Looking at the papers on the topcited list that have between 1000+ and 1200 citations you will quickly realize that the grand majority of them have been around for more than ten years, so my estimate is broadly correct.

To make a point: the paper of Faddeev and Popov that introduced
ghosts and gauge fixing in 1967 took until after the year 2000 to get to the top. Are you telling me that their work is unimportant because it didn't make it to the top in three years (as it obviously should have)?

It is not true that you generically get to that number within three years. That is truly exceptional, even today.

You also failed to mention that many of the topcited papers that accumulated 500+ citations per year for three years in a row around 1997 were very closely related to each other, and not completely independent ideas either. The year 2002 is not random.

Why don't you make the experiment with the year 1995? Not a single theory paper from the previous five years is in the topcited list.

The theoretical high energy community is waiting for new data. The extreme precision of current data places enormous constraints on new ideas. The big breakthroughs you are probably referring to (circa 1997) are related to new paradigms to avoid these constraints based on ideas of extra dimensions, etc.

New ideas that people are waiting to "pounce on" require two ingredients: avoiding current phenomenology constraints in a clever way and most importantly: a simple calculation attached to it. Without the second fact you can not hope that there will be 500+ citations within a year, no matter how important your idea is.

16. **woit**
March 22, 2006

David,

My apologies for mistaking you for a student, I was going by the e-mail address you gave and very quick results of a google search.

As for the points you make:

1. Sure, at all times most top-cited papers are older ones, but that's irrelevant. What I'm trying to get at is the number of recent ideas recognized by the field as significant. Often these will appear on this list within a few years of when they come out.

2. As I noted earlier, historically there are examples of papers whose importance was not recognized for quite a few years. Weinberg's "A theory of leptons paper" was a dramatic example of this. The Faddev-Popov paper of 1967 was another. When it came out, very few people cared about non-abelian gauge theories (they were too busy working on the predecessor of string theory…). It was only after 't Hooft showed renormalizability in 1971 and asymptotic freedom was discovered in 1973 that gauge theories became popular. If you're going to compare citation counts of papers from the sixties and ones from nearly forty years later , you need to take into account two factors. The number of papers being written was many fewer forty years ago, and, unless you are looking at a different data source than me, the SLAC all-time lists from years ago are much smaller and nowhere near as deep as the current ones. The latest all-time list (2005) that has zero papers from the last six years on it is 186 deep. The lists from 1995 and 2000 that you refer to have only 47 and 87 entries respectively.

3. The year 2002 was randomly chosen as a recent year that would pick up the pre-2000 period before the point at which I claim brain-death set in. Sure, among the 8 papers on that list, there are correlations. I wasn't making much of that absolute number, just that it is very different than zero. I'll also point out that I wasn't comparing numbers, just responding to your incorrect argument that recent papers don't appear on the all-time list.

4. Let's discuss 1995. As others have remarked, 1987-93 was considered by most people the previous low point of new ideas in particle theory, so 1995 should be the worst previous year in terms of numbers of new ideas showing up on these lists. The 1995 all-time list doesn't include any recent papers, but it is only 47 long. If you can get ahold of a list of the top 186 papers, which is what you need to directly compare to 2005, I'm willing to bet it will have a significant number of recent papers in it. The 1995 list of top papers recently cited (in this case 93-95, there is no data for just 1995) includes in the top 40 eight from the period 1990-95. Compare this to 2005, where the top 40 includes just the two recent landscape ones. Also note that 1995 was the year of the second superstring revolution, and the year after Seiberg-Witten. Anyone looking at these numbers at the end of 1995 would also be well aware that there were quite a few papers from late 1994 and 1995 that were accumulating citations at a very fast rate. The 1995 situation was just radically different than that of today. If you know of any papers too recent to make the 2005 top 40, but that are accumulating

citations very quickly like Seiberg-Witten, let me know.

5. The new ideas that dominate the late 1990s list are not just extra dimensions. Many of them have to do with AdS/CFT and other aspects of string theory, which have nothing to do with the precision of current data.

6. Making the top 40, or the top 186 all-time list doesn't require 500+ citations in a year. To make the top 40 just requires about 150 citations/year, to make the top 186 all-time list over five years would require 200 citations/year. Historically, in all previous periods, there have been many papers getting cited at these rates (although as you go far back in time, you have to rescale for the significantly smaller number of papers being produced). My point is that the only recent papers from the last 6 years in this league are landscape papers: the KKLT paper (223 citations last year), and the Giddings et al paper (169 citations).

7. People don't just pounce on phenomenology papers, they also pounce on string theory papers. I don't think of KKLT as a phenomenology paper. If someone had a decent new idea about string theory, even if it had zero phenomenological implications, it would get pounced on.

Finally, what is the point of trying to make these tendentious arguments that you are using? Do you really believe that the last six years has been a healthy period for particle theory? If you believe that, let's hear some examples of important ideas from the last six years, of a number even remotely comparable to previous six year periods. If you agree that this has not been a healthy period, why try to come up with quantitative arguments for the idea that it's not so bad?

17. **David B.**
March 22, 2006

Dear Peter:

The last few years have been a healthy period in high energy theory. They are definitely not as intense as during the 1990's, and I don't feel like there is nothing to do or work on, quite the contrary. My "counting" is just as tendencious as yours. I picked 1995 exactly because that was another period where particle physics had been declared dead a few years back (I had been told that there was no future in high energy particle physics before entering graduate school).

There have been very interesting recent results (they might not make it to the topcite 1000+), but here are a few of extremely high quality results of the previous five years (apart from the ones you have already mentioned) that indicate that theoretical high energy physics is doing just fine:

Minahan and Zarembo hep-th/0212208 provided new tools to address the AdS/CFT. They showed that one loop computations in the AdS/CFT gave rise to integrable spin chain models. The presence of an integrable structure in the calculation of anomalous dimensions in N=4 SYM was unexpected.
The follow-up work is very technical, but it is extremely exciting and of very high quality.

Dijkagraaf and Vafa in a series of papers in 2002 made a conjecture relating matrix models and non-perturbative effects in supersymmetric gauge theories. Although they were inspired by string theory, these results hold regardless of this motivation and permit one to calculate many results exaclty, as was proved later. You might complain that they relate to supersymmetric theories, but then, it is very hard to come by with exact calculations in any context.

Arkani-Hamed, Cohen and Georgi hep-th/0104005 introduce the ideas of deconstruction and show how we might be fooling ourselves into thinking we live in higher dimensions if the high energy theory has the right set of discrete symmetries.

Witten gave a huge push to the computation of helicity amplitudes in QCD in hep-th/0312171. Many of the techiques devised since then on these ideas are extremely efficient at computing gluon scattering. This is the dominant source for uncertainties in the LHC.

I can keep on going. Most of the interesting works of these previous five years involve computations that require a lot of work. I don't see any reason to believe that because calculations are harder that progress has stopped. It just moves slower and that is reflected in the number of citations per year that a paper receives.

The above are a few of my favorite papers of the past five years, and you might appreciate that none of them are directly related to the landscape. Even though I try to keep up to date in high energy physics, there is not enough time in the day to read everything that comes out, so I can not give you an in-detail presentation of what is going on everywhere, but for me, personally, it feels like a healthy environment to be working on right now.

18. **woit**
March 22, 2006

David,

I think you've identified the best work in particle theory during the past few years, but I also think that it is very clear that these are results that are of much less significance than ones in any similar list that people would have generated in the past when asked to produce a list of the most important work during the past 5-6 years.

To have a serious discussion of the significance of those papers, one would have to go into a long discussion of what exactly is in them, what one could in principle hope they might lead to, what exactly they have led to, etc. They are all papers that have received a great deal of attention, and are certainly not things that have been ignored or not understood. The relatively modest number of times they were cited by other papers during 2005 reflects the fact that other theorists find these results of limited interest and have not been able to get very much out of them. The only one that has more than 100 citations is Minahan-Zarembo, because many people are trying to find a useful integrable structure in N=4 SYM, partly because of the relevance to AdS/CFT. It will be interesting if that goes anywhere, but progress seems limited, and this is still a very long way from leading to something that you can do any physics with.

The Dijkgraaf-Vafa results give very limited information about certain supersymmetric models, again, a long way from being useful for physics. My impression is that many people have looked at this, but few people are still working in this area.

The twistor string again is an idea that seems not to have led to as much as people had originally hoped. Again, many people have looked at this (probably most serious particle theorists), but very few people are still working on it.

Those are general impressions from listening to talks, scanning hep-th papers, reading conference talks off the web, etc., but they are borne out by the quite small number of citations those papers have been getting compared to the leading papers from previous periods. Take a look at the total number of citations of these papers so far:

Witten, twistor string: 206 citations in 2.25 years, 92 citations/year

Dijkgraaf-Vafa: 322 citations in 3.6 years, 89 citations/year

Minahan-Zarembo: 283 citations in 3.25 years, 87 citations/year

Arkani-Hamed, et. al: 300 citations in 5 years, 60 citations/year

I think it is extremely unlikely that any of these papers will ever reach 1000 citations or the all-time topcited list. The only one of these where there still seems to be sizable interest is Minahan-Zarembo, and whether people keep citing it depends on whether the search for integrability in N=4 SYM goes anywhere. Maybe interest in this topic will grow significantly, or continue at the present rate for the next seven years necessary to get to 1000 citations, but I find that hard to believ.

All in all, I'm sorry, but I think the evidence that you've given that this is a healthy period just doesn't stand up to scrutiny. It's always true that there is "something to work on"; one can always calculate something, the question is how interesting the result of the calculation is. The SPIRES data I've quoted conclusively show that the theory community sees these results as much less interesting than the results achieved in any other similar period in our lifetimes.

New Top Quark Mass

March 20, 2006
Categories: Uncategorized

Via Tommaso Dorigo of the CDF collaboration, the news that the Tevatron Electroweak Working Group has released a new analysis of combined CDF and D0 data with the most accurate result so far for the top quark mass: 172.5 +/- 2.3 Gev. Last summer this value was at 174.3 +/- 3.4 Gev (see a posting here), an improvement over the earlier value derived just using Run I data of 178.0 +/- 4.3 Gev.

The paper describing these results is available now here, and will soon be on the arXiv as hep-ex/0603039. This new result represents a determination of the top quark mass to 1.3% accuracy, and the paper claims that further Run II data should ultimately allow an accuracy of better than 1%.

For a talk about the significance of the top quark mass, see here.

Comments

1. **Tony Smith**
   March 20, 2006

   Peter said "… the Tevatron Electroweak Working Group has released a new analysis of combined CDF and D0 data with the most accurate result so far for the top quark mass: 172.5 +/- 2.3 Gev …".

   I think that it should be noted that the "172.5 +/- 2.3 Gev" value applies only to one of three peaks in Fermilab t-quark data.

   For example, the original 26 April 1994 paper FERMILAB-PUB-94/097-E contained a 26-event histogram for W+(3 or more)jets, without b-tags, that is Figure 65, and which (with an x for each event in each 10-GeV T-mass bin)looks like:

   80

   90

   100
   x
   110

   120
   x
   130
   x
   140
   xxxxxxxx
   150
   xx
   160
   xxx
   170
   xxxx
   180
   xxxx
   190

   200

   210

   220
   xx
   230

   240

   In addition to the broad central peak around 170 GeV or so,
   there is a small high peak around 220 to 230 GeV,
   and a tall narrow low peak around 140 to 150 GeV.

   In that paper, Fermilab dismissed the tall narrow low peak, saying "… We assume the mass combinations in the 140 to 150 GeV/c^2 bin represent a statistical fluctuation since their width is narrower than expected for a top signal. …".

   Nevertheless, the low and high peaks persist in later data for which they are not excluded by cuts etc, and in my opinion all three peaks should be taken into account in analyzing the T-quark data.

   If it is assumed that the T-quark is a simple quark just like all the others, and if one if forced to pick only one of the three peaks and reject the rest, then perhaps the Fermilab consensus view that "the" T-quark mass is "172.5 +/- 2.3 Gev" might be justified (but the other two peaks would still be unexplained, as they do not appear to be accounted for by conventional background).
   However, I do NOT think that the simple T-quark assumption is accurate.

   Kent W. Staley, in his book "The Evidence for the Top Quark" (Cambridge 2004), mentions on pages 295-296:

   "… hints that the simplest hypothesis that the top candidate events are just the ttbar events and SM background may not be entirely correct such hints 'should be monitored carefully, as they may be offering us glimpses of new physics' …

Even when experimenters find that they have acieved experimenters' success, they look more closely to see the interesting flaw in their achievements – the discrepancy that will mean, not failure … but the possibility of some new success …".

Staley's book contains detailed references and context that I will omit here.

Possible clues about the three peaks might come from such sources as:

hep-ph/030713, by Froggatt, that studies the interrelationships of the T-quark, the Higgs, and the Vacuum; and

hep-ph/0311165 and hep-ph/9603293, by Yamawaki et al, that describe T-quark condensate models, including:
Nambu-Jona-Lasinio models with mt about 145 GeV
Kaluza-Klein (8-dimensional) model with m_t about 173 GeV
Bardeen-Hill-Lindner models with mt about 218 GeV.

Please see the papers themselves for details.

In deference to Peter's wish to exclude discussion of non-standard physics models, I will stop here.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

2. **Bourgeois Nerd**
March 20, 2006

So is this just a refinement of the Standard Model or something interesting? I'm afraid I'm too much of a layman to tell.

3. **woit**
March 20, 2006

Bourgeois Nerd,

In some sense, this is just a more precise determination of one of the standard model parameters. But it's a very important one: the Higgs couples to fermions according to their mass, so it is by far most strongly coupled to the top quark. So, if you want to detect the Higgs, either directly or indirectly, knowing the top quark mass as accurately as possible is important.

4. **Thomas Larsson**
March 20, 2006

How does the new top mass change limits on the Higgs mass and other things?

5. **andy s.**
March 20, 2006

Taking these three values together makes the TQM in the range
[173.7 – 174.8] (or 174.25 +/- 0.55).
That's the lowest of the three maxima and the highest of the three minima.

Although I suppose it doesn't really work that way.

6. **Dumb Biologist**
March 20, 2006

In Dr. Tait's presentation, he suggests the mass of the top can tell physicists something about electroweak symmetry breaking. I know a tiny bit about the Higgs mechanism giving mass to the W's and Z, and obviously if the top couples most strongly to the Higgs, there's some kind of circumstantial relationship. But beyond the mere fact that the vector bosons and the top all are mighty heavy, weigh about the same, and hence have similar couplings to the Higgs, what deeper principles are being revealed?

7. **Alejandro Rivero**
March 21, 2006

Ah, I also had a prediction for the top quark, but it was exactly at 175 Gev (188 u), hmm. (well, it could be a prediction for top+charm meson).

Seriously, what matters is not 175 or 173, even Tony's 145 peak. What matters is why it is at the electroweak symmetry breaking scale.

8. **Luboš Motl**
March 21, 2006

Dear Bourgeois Nerd,

the top quark mass is important because it is important for the existence of supersymmetry and the minimal supersymmetric standard model.

Thomas Larsson: yes, the Higgs mass in the minimal supersymmetric standard model depends sensitively on the top and stop masses.

More generally, the exact top quark mass is important because it affects string theory phenomenology. Click the PDF file that Peter Woit linked in the last sentence of this article – with the word significance – and go to the middle of the PDF file.

Of course, without supersymmetry, the top quark mass is not too significant, and the Higgs mass is independent of the top quark mass.

See my blog for more details about this issue.

Best wishes
Lubos

9. **stan**
March 21, 2006

This blog post is indeed remarkable. Lubos writes:

“Its mass used to be thought to be 178 GeV. It was lowered to 175 GeV and now to 172 GeV, with error margin around 2 GeV. [..]

At roughly the same time, Faraggi included some loop corrections which made the agreement worse because the physical mass he obtained [using string theory] was 192 – 200 GeV. [..]

this story is an example that string theory can predict properties of particle physics and it can even give us the right predictions.”

It is encouraging that superstring-theorists tried (try?) to predict particle properties. But the Faraggi result was obviously *falsified* by the experiment.

10. **Luboš Motl**
March 21, 2006

Dear stan,

you forgot to quote my sentence about the crackpots who form the core of the readership of Peter Woit’s blog. It was inconvenient for you, was not it? The tree level calculation from 1991 was confirmed by experiments, the loop-corrected calculation from 1995 was falsified by experiments. At any rate, you should better be careful in saying that the loop-corrected prediction was falsified because the owner of this blog does not like those who disagree with his thesis that string theory etc. is “not even wrong”.

Best
Lubos

11. **Alejandro Rivero**
March 21, 2006

So, string calculations do not need loop corrections?

12. **The Anti-Lubos**
March 21, 2006

Luboš Motl: *you forgot to quote my sentence about the crackpots who form the core of the readership of Peter Woit’s blog*.

Well, you’re here all the time. Sounds like a case of the crackpot calling the crackkettle black.

13. **Lubos Motl**
March 21, 2006

Alejandro Rivero, your dumb questions convinced me that I must simply put you in the very same group as Nigel Cook, Tony Smith, Danny Ross Lunsford, Quantoken, and many others. Sorry but it will probably be hard for you to reverse this policy.

The full calculations of course include loops. But the tree level calculations don’t. Saying that tree level calculations are worthless, which is what you are essentially doing, is incredibly stupid. Most of the key calculations in physics, including those in the discovery of the electroweak theory, were tree level calculations.

The full calculation needs us to clarify many more extra details, and it is completely conceivable that the 1995 loop calculation is simply further away from the correct answer than the 1991 tree level estimate. Experimentally, it is clearly the case.

Best
Lubos

14. **woit**
March 21, 2006

I definitely recommend Lubos’s blog entry

http://motls.blogspot.com/2006/03/peter-woit-recommends-supersymmetry.html

It really has everything:

1. delusional thinking about string theory: “string models predict the exact masses of all particles”.

2. bizarro ideas about the scientific method: see his discussion of the Faraggi “prediction” of the quark mass.

3. lunatic rants about string theory skeptics, e.g. yours truly.

As for his comments about the top mass being not significant if there is no supersymmetry, this is just misinformation.

In the standard model itself, precision electroweak measurements depend both on the top quark mass and on the Higgs mass. Knowing the top quark mass, these measurements give significant constraints on the Higgs mass. See page 6 of the Tait talk I quoted. I don’t know of a source for updated numbers on these constraints using the latest top mass.

In the MSSM, at tree level the Higgs mass has to be less than the Z mass, which is wrong. Loop effects allow a higher Higgs mass, and the one-loop calculation strongly depends on the top mass. One can push up the Higgs mass, but doing this requires increasing degrees of fine-tuning. People are already uncomfortable with the degree of fine-tuning required to get the Higgs mass above the LEP experimental lower bound of 114 Gev. See page 12 of the Tait talk.

15. **The Anti-Lubos**
March 21, 2006

Lubos Motl: *Saying that tree level calculations are worthless, which is what you are essentially doing, is incredibly stupid*.

Saying that he said this or even implied it when he did not is incredibly stupid.

16. **Lubos Motl**

March 21, 2006

Dear Peter Woit,

1. the statement that a particular background in string theory predicts the masses of all massive particles ia a mathematical fact, and only people who are un-educated in theoretical physics misunderstand why

2. a prediction means a calculation of a certain observable that will be observed in the future, which is what Faraggi (and many other people) did. His calculation could have been imperfect but it was definitely a prediction, and once again, only complete ignorants like you and your crackpot fans are unable (or unwilling?) to understand this fact

3. the lousy intellectual quality of your society of cranks is being proved by virtually every posting you have ever made, and almost every comment that your crackpots fans ever added to your postings

4. the Higgs mass itself can't be affected or deduced theoretically from the top quark mass if you have no supersymmetry simply because there are quadratic divergences correcting the Higgs mass that are not cancelled automatically unless one has SUSY, but can be freely cancelled by (nonSUSY) counterterms. The value of the top quark mass influences various high precision measurements but does not, in any way, decide about the existence of the theory if the theory is non-supersymmetric; any value is equally OK theoretically

5. you exactly explained why top and stop are important for MSSM – because their large one-loop corrections make the predicted Higgs mass plausible. This fact is the main reason why studying the top with a better accuracy is a scientifically justifiable enterprise. The large one-loop top corrections are in no sense "fine-tuning" because the top Yukawa coupling is not a small number. On the contrary, it is experimentally proved to be around 1/sqrt(2), so your whining about "fine-tuning" in the one-loop corrections is just another, 9325th evidence of your complete ignorance about particle physics.

I recommend you to avoid commenting on things that you have no idea about, such as particle physics, string theory, cosmology, and many other fields.

Best
Lubos

17. **Alejandro Rivero**
March 21, 2006

It could be worthwhile to quote also here the paper Lubos brought into focus: http://ccdb4fs.kek.jp/cgi-bin/img_index?9110375
I am not sure if it is the first estimate running down to the 175 range; I have seen some this range quoted in other ocassions, but also in higgs estimates, so memory is fuzzy here. Perhaps Tony can remember better, as top is in his focus.

18. **woit**
March 21, 2006

Lubos,

You're missing the main point in the non-supersymmetric case. High-precision electroweak measurements depend on the Higgs mass, so they indirectly are measuring it. This measurement is highly sensitive to the value of the top mass. For latest results, including the latest top mass, see

http://lepewwg.web.cern.ch/LEPEWWG/plots/winter2006/

For the fine-tuning I'm talking about in the supersymmetric case, see the discussion at

http://golem.ph.utexas.edu/~distler/blog/archives/000336.html

and maybe you can write in to the author to inform him how ignorant he is on this issue.

19. **Alejandro Rivero**
March 21, 2006

It is perhaps remarkable that Tait's slides still carry a plot from a 1993 article: the one in page 14 comes from page 9 of http://arxiv.org/abs/hep-ph/9311269 . Incidentally it can be noticed that it is still adjusting to a top quarks mass of 150 GeV (is it the second discontinous line counting from the bottom left corner?). Those interested on predictions should note also figure 5 in page 29 of this preprint.

On a different matter, I was thinking about aplying to the graduate program of Harvard. Do you know any professor there able to write a recommendation letter?

20. **anon**
March 21, 2006

Lubos is such a crackpot. According to Lubos, (Lubos Theorem 1)measuring the mass of the top quark is a scientifically important endeavor iff supersymmetry is true. (Lubos Theorem 2) For any theory X, If you cite a reference that talks about X, then you believe everything X says is true. (contrapositive of Thm2: If you do not believe everything that X says is true, then you do not cite a reference about X)

21. **Lead by Science**
March 21, 2006

Maybe Peter and Lubos should remain confronational with each other, for "information" that was just supplied by that "energy" expenditure. 🙂

22. **Thomas Larsson**
March 21, 2006

A story dedicated to Yellow Michael.

An anthropic string theorist, a non-anthropic string theorist, and a physicist were discussing the experimental status of string theory.

Anthropic string theorist:
– String theory is in complete disagreement with experiments, but that is OK because God created the universe to be compatible with human life.

Non-anthropic string theorist:

– String theory is in complete disagreement with experiments, but that is OK because Witten has won the Fields medal.

Physicist:
– String theory is in complete disagreement with experiments.

23. **tommaso dorigo**
March 22, 2006

Hi all,

wow there is a lot to learn by reading these comments… People who trust recent advances in theoretical physics and people who eat sausage should not ask what there is inside. (One might rightly add people who blindly believe in experimental errors – but that's another story).

Just a remark: I accept non-experimentalists being speculative about background fluctuations in principle – the charm meson started off as one at the very beginning, and so did other important discoveries in particle physics as well as other disciplines. But claiming that there are three peaks in the top quark mass distributions CDF and D0 isolate, based on a plot of a very background-rich sample isolated with a tenth of the statistics available today, is plain nuts.

Ah, and the top mass did not "use to be 178, then 175, then 172 GeV". CDF measured it at 174 GeV in 1994 (!) in the "evidence" paper, one year before we decided to go observational. Later, more precise determinations have brought the value around a bit, but world averages have stayed in the 171-178 GeV range, and always within 1-1.5 sigma from 174.

24. **Tony Smith**
March 22, 2006

Tommaso Dorigo said, about my comment: "… claiming that there are three peaks in the top quark mass distributions CDF and D0 isolate, based on a plot of a very background-rich sample isolated with a tenth of the statistics available today, is plain nuts. …".

I agree. However, that is NOT what I said. I did specifically mention only one plot (1994 CDF untagged semileptonic), but I also went on to say: "… the low and high peaks persist in later data …".
I did not give specific references to the later data for space and exposition reasons, but, since the question has been raised, here are some of them (note – of the three peaks (low, central, and high), the central peak is the one around 173 GeV):

the 1997 D0 untagged semileptonic histogram at hep-ex/9703008 showing all three peaks;

the tagged CDF semileptonic events in hep-ex/9801014 showing the low peak;

the tagged D0 semileptonic events in hep-ex/9801025 showing all three peaks;

the CDF dileptonic events in hep-ex/9802017 showing the low and central peaks;

individual D0 dileptonic events described in the thesis of Erich Varnes at http://wwwd0.fnal.gov/publications_talks/thesis/thesis.html including the following events:

Run 84676 Event 12814 (2-jet analysis gives low peak)
Run 58796 Event 417 (low peak)
Run 90422 Event 26920 (low peak)
Run 88295 Event 30317 (low peak)
Run 84395 Event 15530 (3-jet analysis gives high peak);

individual D0 dileptonic events described in hep-ex/9808029 using the matrix-element weighting algorithm that "… is an extension of the weight proposed in [R.H. Dalitz and G.R. Goldstein, Phys. Rev. D45, 1531 (1992)] …", including:

e mu #1 (low peak)
e e #1 (low peak)
mu mu (showing low and high peaks)

which events were also described using the neutrino weighting algorithm, with these results:

e mu #1 (low peak)
e e #1 (low peak)
mu mu (high peak)

I hope that the above makes it clear that a reasonable analysis of later data shows that all three peaks do continue to show up.
Of course, you can argue about interpretations, and indeed (as Fermilab has done) argue that since the low and high peaks involve fewer events, they should be thrown out. However, it seems to me that the 3-peak point of view is also reasonably arguable, and that work on theory and future data analysis should include work on all three possible peaks instead of designing cuts etc that exclude the high and low peaks from data analysis.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Please note that the above is only an outline indicating some of the later data, and that extended discussion of relevant subtleties (see my web site) is beyond the scope of blog comment discussion. I would like to think that the above is extensive enough to refute the blog characterizations of me as "just plain nuts" (by Tommaso Dorigo) and "moronic crackpot" (by Lubos Motl).

25. **Juan R.**
March 22, 2006

Lubos Motl Said,

1. the statement that a particular background in string theory predicts the masses of all massive particles ia a mathematical fact, and only people who are un-educated in theoretical physics misunderstand why

2. a prediction means a calculation of a certain observable that will be observed in the future, which is what Faraggi (and many other people) did. His calculation could have been imperfect but it was definitely a prediction, and once again, only complete ignorants like you and your crackpot fans are unable (or unwilling?) to understand this fact

3. the lousy intellectual quality of your society of cranks is being proved by virtually every posting you have ever made, and almost every comment that your crackpots fans ever added to your postings

[…]

Excuseme my complete ignorance and my obvious lack of brilliance (i am not a Fields medallist and never will become one) Dr. Motl, but i am unable to understand above 3 points (really i am unable to understand the rest of points also, but this is not a journal :-).

3. How can one measure the crank level of any posting here? I am just curious! Please do not cite Baez ranks or similar, since none of them has been experimentally proven! From a historical point of view, i also find interesting all past genius of physics (including Isaac Newton) was named cruncks by their then colleagues. Is not this a lesson for all of us?

Moreover, whereas i disagree with some comments posted in this blog, i agree with many others and, by now, *the net balance is clearly positive*.

2. I think that none manual on epistemology or experimental methods (i know) agree with you.

A prediction does not mean a calculation of a certain observable that will be observed in the future, as you are saying. A clear example is computation of size of hidden dimensions on string theory. One can calculate that "observable" and obtain any result from zero to infinite.

Yes, the mainstream claims that hidden dimensions "are" of Planck scale but arguments are easily rebated from chaos (microstructure from sub-Planck scale spacetime modifies correlations and the physics *over* the Planck [There is a good QM example worked in Nature by Zurek and methods can be adapted to a generalized string theory formulation in Liouville space similar to that of Nanopoulos and coworkers]).

Not forget also that in certain cosmological-string models the hidden dimensions are infinite in size (FAPP).

Therefore, any measure of the size of any hidden dimension (if any) and agreement with string theory (any value from zero to infinite) is not a prediction.

1. You claim it *is* a mathematical fact that a particular background in string theory predicts the masses of all massive particles.

Perhaps i am un-educated (in your own words) but, sincerely, I fail to see that from both a physical and a mathematical point.

See the point from set theory. If you are claiming that string theory is a collection of different sub-theories/models each one with diferent "parameters" (background), then if a particular background in string theory "predicts" -this is not a correct word by point 1- the masses of all massive particles, then many other backgrounds do not and offer us wrong results. That is also a mathematical fact you forgot cite above.

It is also interesting to note that if X string models are compatible (the word "predict" is as said incorrect) with values of masses, and Y are NOT compatible. The ratio X/Y is either very close to or equals to zero. Therefore, from a Landscape point of view, string theory is not compatible with masses.

But if you are claiming that only one of those backgrounds correspond to the "real" (physical) string theory (with the rest of a pure mathematical interest), then your above phrase cannot be correct. Instead of a particular background in string theory… you would say just "string theory" (meaning with its only physical background, THE background, that nobody knows) …

—
Juan R.

26. **Alejandro Rivero**
March 22, 2006

Lead, yes it is true that interesting information appears even if with the pityful waste of confrontational energy. All this issue of SuGra Electroweak Breaking, from the plot in Tait's slides, is worthwhile to be contemplated. I was unaware of the trick of generating a phase transition by just running down the constants in such a way that the uncolored mass (the higgs) hits the change of sign.

Of course a collateral benefit of this confrontational show is that all the participant can hope get more visibility for their own papers. I expect the silencious espectators will consider it and jump to the arena some day.

27. **Steve Myers**
March 22, 2006

A note on crackpots & data: Just last night I discussed this iossue with my two sons (one a computer scientist who refused fellowship & got MS in less than a year; the other, a construction supervisor who got his degree & went into industry) & both agreed with me that the test for crackpots was whether or not their stuff worked. I now work in data acquisition & analysis (so I understand Tony Smith's concerns) and any theory I have must fit the facts & predict future behavior of equipment. My computer scientist son said he thought this throwing of "crackpot" at people & attacking their intelligence is a result of the scarcity of positions available & the fight for funding (one reason he left academia). I think it's very sad. Was Einstein right: is being a plumber the best option (or electrician or carpenter)? And finally, Lubos, of course Woit is right about Higgs mass by way of the top and precision electroweak measurements.

28. **Alejandro Rivero**
March 23, 2006

An update about the prediction of top mass Lubos was proud of. It was bases in the techique of infrared quasi-fixed points for the top quark yukawa coupling, a technique that was resuscited in the eraly nineties and at that time involved SuGra and string based models. But it comes from ten years before; most people quotes a paper of C.T Hill of 1981, Phys Rev D 24 p 691, which in turn attributes the idea to Pendleton and Ross in some paper written down at the end of 1980 and published as B. Pendleton and G.G. Ross, Phys Lett 98B p 291 (1981). The paper of Hill does not claim string or susy inspirations, and I can not tell of P&R now because it is an offline paper. But here goes one half of the string-susy-fundamentation of top mass.

The another half is the trick for Radiative "infrared" Electroweak Breaking used in Sugra. It is that because the Higgs is uncolored but the top is not, the RG equations can be adjusted in such a way that as one run them down from M_GUT to low energy, at some instant a critical point "a la Curie" is crossed and the Higgs field gets the negative mass square it needs to break electroweak symmetry. I can not tell if this idea is original of SUSY theories; Tait seems to imply it, and I can not find it argued in other kind of papers. In fact it is a very elegant idea.

Letter From Schroer

March 21, 2006
Categories: Uncategorized

Bert Schroer has sent me a very long and interesting comment for posting here. I've put it into a separate web-page. It includes both a lot of history and many different ideas. Unfortunately I don't have the time right now to write much about it in response, but just will make one point about the part that he explicitly addresses to me.

Schroer claims that geometric methods in QFT have so far only been useful in dealing with free fields in a fixed background gauge field or metric. This is largely, but not completely true. Most of our reasons for believing the standard model are based on perturbative quantization of gauge fields, and for this it's true that geometrical methods are not strictly necessary. But for QCD, we need a non-perturbative quantization of the gauge fields, and here lattice QCD is the best we've got. It is based upon discretizing a geometrically formulated path integral, preserving as much of the gauge field geometry as possible. My own guess is that there is still a lot to be learned about non-perturbative quantization of gauge fields, based upon the geometrical formulation of the problem given by the path integral approach and I have been working on speculative ideas of how to do this (some of which even involve gerbes and algebraic geometry…). This is still work in progress, maybe I'll someday find it really can't work, but for now I'm quite optimistic.

There's also a new survey paper on QFT from Fredenhagen, Rehren and Seiler. The authors discuss the current state of understanding of QFT, with some points of overlap with Schroer. Like Schroer, they also discuss string theory in detail, and are critical of the inability of the string theory research program to come up with precise statements about what the theory is supposed to be. They are however, much less forceful in their criticisms than Schroer.

Comments

1. **Alejandro Rivero**
   March 21, 2006

   Uff!

   And at the end the finger points to Weinberg. Indeed he left the field jumping into the astrophysics wagon. And sure it seems to favour the "effective" approach to QFT, but this is a blame on QFT in general, not on AQFT only. Hmm.

2. **Dick Thompson**
   March 21, 2006

   Schroer's letter is fascinating stuff. Aside from the geometric issue (or maybe you regard it as part of the same story) is his criticism of functional integral methods. Frankly I think the rush to use path integrals here there and everywhere has been a downer for particle physics. If algebraic methods can do the calculations and be rigorous too, that would seem an advantage.

3. **Lubos Motl**
   March 21, 2006

   These attempts to return physics to the 1930s or even further to the past are completely pathetic. Path integrals have rightfully become the dominant way to describe physics of quantum fields and their strength turned out to be even more obvious in theories with non-Abelian gauge symmetries (Yang-Mills symmetries much like conformal symmetries on the worldsheet etc. – we can't really live without these things today). It would be extremely awkward to do physics without the FP-ghosts and path integral in this case which is very important today.

   In the same way, it is impossible to undo the insights of the Renormalization Group from the 1970s – considered by many wise people to be the most important insights in physics in the second half of the 20th century. Quantum field theory is an important stuff. Some of them may be UV complete but even if they are UV complete, they should be used as effective field theories describing physics at some energy scale. Eventually we know that all QFTs break down at the Planck scale or earlier.

   Complaining about QFTs being used as effective QFTs with respect to an energy scale, and complaining about the use of path integrals in physics of 2006 is a soft type of crackpotism that only differs from crackpotism that rejects the theory of relativity by a factor of 3 (counted by the number of years of developments in physics that the crackpots decide to ignore).

   The whole concept of AQFT has become an unproductive line of reasoning because the basic philosophy of AQFT contradicts many things that have been demonstrably successful in the last 40 years: cutoff dependence and effectivity (non-exactness, in a sense) of QFTs, path integrals methods including ghosts. These methods had nothing to say about physics above 2 (or 3?) spacetime dimensions and the success of similar reasoning in 2D should be thought of as the maximum that can ever be extracted from this type of reasoning.

4. **Brett**
   March 21, 2006

   I think that Schroer has a number of interesting things to say about the problems with path integrals, and to a large extent, I agree with him. I too learned from Roman Jackiw to be very careful when dealing with functional integrals. However, I think that functional integrals can be fabulously useful tools. Their weakness is that they can easily fool us into thinking that we are working with mathematical well-defined and unambiguous objects, when in fact, we are not.

   People have, of course, tried to fix functional integration's problems. This would mean placing it on a firm mathematica footing, most probably in algebraic geometry. Then the usual "functional derivatives" would be reinterpreted as functors, whose representations could be studied, and so on. The problem with this idea is that it's proven to be impossible thus far (although people I know are still working on it). A rigorous formulation of path integrals would automatically entail a rigorous formulation of renormalization–already a tremendously difficult task. And the very fact that these problems are so difficult is a significant reason that many people, such as myself, choose not to work on them.

   I am somewhat mystified by Schroer's idea of what "algebraic" QFT is. With "axiomatic" QFT, it's reasonably clear what that means. And note that in axiomatic QFT, one cannot calculate any cross-sections. Schroer says one can do this in algebraic QFT, by means of ordinary Feynman diagram perturbation theory. However, such perturbation theory cannot be used in an "axiomatic" approach, because the resulting power series are asymptotic, and no rigorous estimates of their rates of divergence exist. In other words, this is an uncontrolled approximation, something that cannot be sensibly used in an "axiomatic" framework.

   So my question is: What exactly does Schroer's "algebraic" QFT encompass? Where does it end? Many (maybe most) papers in QFT do not explicity make reference to any path integrals but merely use the perturbation series as a starting point. What disqualifies these papers as "algebraic" QFT?

   I said above why I think few people work on axiomatic QFT–because the really interesting problems are prohibitively difficult. The tractable questions are just much less interesting. Blaming one stupid commenter who made a bad impression on Weinberg just seems bizarre, and I think Schroer does the physics community a disservice with this (essentially ad hominem) accusation.

5. **Kea**
March 21, 2006

Schroer: "Isn't it ironic that string theorists accuse the AQFT of the use of gratuitous mathematics when they themselves are using structures like gerbes and algebraic geometry?"

Oh no! Doesn't he even realise that rigorous non-Abelian localisation leads that way?

6. **Kea**
March 21, 2006

Just noticed gr-qc/0603079 by Brunetti and Fredenhagen.

7. **Eugene Stefanovich**
March 21, 2006

I strongly agree with the following Schroer's statement:

"…Lorentz covariance, quantum theory and the cluster property do not lead to QFT. .. These so-called "direct particle interaction" models fulfill the cluster-decomposition property yet they do not have a
representation in terms of a second quantization setting…With other words this claim by Weinberg … is incorrect"

There are few examples which do not fit within usual local QFT:

1. "direct interaction" theories mentioned by Schroer (see papers by W. N. Polyzou)
2. non-local QFT: M. I. Shirokov, "On relativistic nonlocal quantum field theory", Int. J. Theor. Phys. 41 (2002), 1027
3. A beautiful series of papers by H. Kita in 1966-1973. The last paper in this series is "A realistic model of convergent quantum mechanics of interacting particles" Prog. Theor. Phys. 49 (1973), 1704 where you can pick up the other references if interested.

8. **Thomas Larsson**
March 21, 2006

Dear Prof. Schroer:

In any case considerable progress to find analoga of those structures which one has in chiral theories (energy-momentum virasoro structure, current algebras) are well on their way in recent articles of Todorov et al.

In recent years the only papers of Todorov that I have read are his biographies of Einstein and Hilbert, and Heisenberg.

The mathematical problem of generalizing the Virasoro algebra to higher dimensions was settled a decade ago. The diffeomorphism algebra in N dimensions has two non-trivial cocycles by the module dual to closed (N-1)-forms, found by Rao and Moody (Comm. Math. Phys. 159 (1994) 239–264) and myself (J. Phys. A 25 (1992) 1177–1184), respectively. It may be worth pointing out that Bob Moody is somewhat famous, e.g. for the codiscovery of Kac-Moody algebras. Note that when N=1, a closed 0-form is a constant function, so the Virasoro extension is central when N=1, but not otherwise. In fact, all extensions of the diffeomorphism algebra were classified by Askar Dzhumadildaev (Z. Phys. C 72 (1996) 509–517); I spent a considerable time to understand his paper, which resulted in the review math-ph/0002016.

It is of course widely recognized that the standard axioms in LQP, in particular, the strong emphasis on the Poincare algebra, cannot hold in quantum gravity. The Poincare group has two properties in flat space:
1. it is the group of isometries.
2. it is the spacetime group which acts on the physical fields alone.
It is unclear to me if the isometry property plays any useful role in QG; it seems more appropriate for QFT in curved space, which is another problem. The second property in QG is subsumed by the spacetime diffeomorphism group. This is nothing but background independence, which is widely regarded to be the key conceptual lesson from GR.

A digression on LQG. I agree with the LQG people that manifest background independence (the formalism should not depend on any reference background structure, be it a flat metric or a preferred foliation) is necessary in QG, but I don't think that the LQG implements this deep idea correctly. In particular, LQG methods apparently fail when applied to the harmonic oscillator (hep-th/0409182), which in my opinion is a show-stopper. There are theorems which show that background indendence is incompatible with Fock quantization (in 1D, the only Virasoro rep with c=0 is the trivial one), but a no-go theorem only shows which axioms must be relaxed (here: anomaly freedom).

The generalization of the Virasoro algebra to 4D is thus the branch of mathematics which deals with background independence, quantum mechanically. The key insight from its representation theory, initiated in the Rao-Moody paper above and understood geometrically in math-ph/9810003, is that all fields must be expanded in a Taylor series around an operator-valued curve prior to quantization. This operator-valued curve, which can be identified as the observer's trajectory in spacetime, plays a crucial role; e.g., it enters into the relevant extensions. Without it, it is impossible to deal with gauge or diffeomorphism symmetry on a genuinely quantum level.

The paper I mentioned in my previous comment was a first attempt to reformulate QFT to incorporate this insight. That paper contains (at least) one error and one omission already for the harmonic oscillator: there is an overcounting, and no inner product was defined. These problems have now been solved.

Best regards,
Thomas Larsson

9. **D R Lunsford**
March 21, 2006

I want to say, sorry for overstaying my welcome, since I bowed out, but in light of the fudged WMAP data, to see Schroer and Larsson and others really talk physics – it does my heart some sorely needed good!

Thanks again, Peter.

Not Even Wrong wipes out the Reference Frame.

12. **Bert Schroer**
March 22, 2006

I just now typed a 4 page letter answering most of the questions, but as a result of a wrong klick on my laptop I lost almost two hours of work; I am too frustrated to continue, maybe I will get to the sceen on the weekend again.
cheers
Bert Schroer

13. **Thomas Love**
March 22, 2006

Schroer ends his response with

"Isn't it ironic that string theorists accuse the AQFT of the use of gratitious mathematics when they themselves are using structures like gerbes and algebraic geometry? I cannot think of more useless mathematical structures for quantum theory (which deals with operators and states) than those. Hypocricy? Hubris? Double standards?"

Like it or not, physics is based on advanced mathematics. While I believe that string theory is based on faulty physics, one cannot fault the mathematics. Robert Hermann called it "experimental mathematics", learn some new mathematics and see if you can apply it to physics. Who knows what will work until we try it? I beleve the problem with AQFT is paradigm paralysis, keep trying the same thing. The impossibility of combining the Poincare group with internal symmetries should have led to a rejection of the Poincare group in favor of the de Sitter group or something bigger. I use U(3,2).

14. **woit**
April 6, 2006

Now that I'm back, I've turned back on comments here in case anyone wants to continue this discussion.

Hiatus

March 22, 2006
Categories: Uncategorized

I'm leaving tomorrow night on a trip that will take me away from internet access for a week or more. During this time I won't be posting anything, or able to manage the comment section, so I'll be shutting off comments late tomorrow afternoon, turning them back on when I'm back on April 4th.

The trip will take me to the middle of the Sahara, in Niger, where I hope to see the total solar eclipse next Wednesday. I'd like to be able to claim that this is some sort of scientific expedition, involving perhaps testing GR by measuring the deflection of starlight during the eclipse. But that's not the case; this is really just an excuse to go to an exotic location for a much-needed vacation. I thought for a moment about renting a satellite phone with a modem, and blogging from the desert, but decided that would seriously impinge on the important vacation aspect of this trip.

Another reason for the hiatus is that I haven't been able to come up with an inspired idea for an April 1 posting, and this gives me an excuse for giving up on trying to do that again this year. If I get any good pictures, maybe I'll finally get around to putting something more visually appealing here.

Comments

1. **Luboš Motl**
   March 22, 2006

   Enjoy the trip. Otherwise, there is no problem that you will turn the comments off. I will create a special article under which the discussion that would otherwise occur at Not Even Wrong can continue. Thanks. You're welcome, Peter.

2. **lmot**
   March 22, 2006

   I've got a better idea Lubos. How about you and Peter have a contest to see who can go longest without posting?

3. **woit**
   March 22, 2006

   Hi Lubos,
   Thanks. I guess… Why do I suspect you'll delete all the comments I would have kept, and keep all the ones I would have deleted? Oh, well, have fun!

4. **Arun**
   March 22, 2006

   Enjoy your vacation!

5. **weichi**
   March 22, 2006

   Enjoy the trip! I was in India for the total eclipse in 1995; it was a stunning experience. I hope the weather is perfect for you!

   March 22, 2006

   Wear sunscreen!

7. **MathPhys**
   March 23, 2006

   How will you get to Niger, Peter? Any respectable airlines (allowed to land in EU) flies there?

8. **Bert Schroer**
   March 23, 2006

   Dear Peter,
   after my frustrating experience of loosing more than 2 hours of work yesterday evening (in answering various questions/comments using directly the reply system of your weblog), I prefer to wait up to your return for a continuation. Today I have a replacement hep-th/0507038 on the server which addresses a quite interesting point about localization-entropy. I hope that I finally managed to make a clearer presentation of this in my view important point (which by the way also shows the structural power of algebraic methods).
   Have I nice trip and above all nice weather
   Bert

9. **Alejandro Satz**
   March 23, 2006

   I have an idea! Many blogs have taken up the idea of "Opposite Day", in which you are supposed to defend, with the best possible arguments and no parody, a view completely opposed to yours. (An example is here.) So why not have, after Peter comes back from his holiday, an Opposite Day in which Peter defends string theory and Lubos attacks it? *That* would be interesting to read!

   Good luck in your trip!

10. **anon**
    March 23, 2006

    '…perhaps testing GR by measuring the deflection of starlight during the eclipse…'

    Eddington in 1919 didn't avert the contraction of the telescopes due to cooling, and this distorted his data: 'During a total solar eclipse, day becomes night for a few precious minutes. The temperature drops, birds stop singing, and bees return to their hives for a premature rest.'

Hope you can capture some of the atmosphere of this event, perhaps not the sounds of birds and bees, but at least the effects of the lighting on the desert landscape?

11. **Alejandro Rivero**
March 23, 2006

Have a nice travel. I guess you could find some internet shops around; if you check how full of inmmigrants are the ones in Europa, you can guess there is a way to get the connection at the other side in Africa and SouthAmerica.

12. **woit**
March 23, 2006

MathPhys,
Getting to Niger via charter flight from Paris to Agadez. Will have to spend a day or two in Paris on either end of the trip. Life is rough.

Bert,
Sorry you're having trouble with the comment system here. If you're writing a long comment, best probably to write it in some other software and cut and paste.

13. **Dick Thompson**
March 23, 2006

Peter: Envy – envy – ennnnnnnvy!

Have a great time!

14. **Doug**
March 23, 2006

Peter,

Please don't think that you need to add visual appeal here. No pictures can match the intellectual appeal of your blog. I am so glad that you stick to the topic of physics and haven't turned "Not Even Wrong" into a travelogue. I get so tired of having to sort through cultural posts in hopes of finding a nugget of science. That's why I always come to your blog first. It's a winner.

15. **svelte**
March 23, 2006

Peter, I'm just curious, why Niger ? There are quite a few other countries in West Africa that are slightly richer and slightly safer than Niger.

16. **Arun**
March 23, 2006

Maybe the change in scenery will give some inspiration w.r.t. to the landscape 🙂

17. **woit**
March 23, 2006

Doug,
Don't worry, no intention of turning this into a travelogue, I kind of agree with you. This posting and maybe one after I get back will be the full extent of it.

Svelte,
Several reasons for Niger
1. Maximum length of eclipse is in the desert near the Niger-Libya border
2. Best chance of not getting clouded out is in the desert. Clouds are unlikely, although there are sandstorms.
3. I like deserts in general, also quite looking forward to getting the chance to see some of Niger.

The eclipse track across the Sahara goes through Niger, Chad and Libya. I doubt many people are going to Chad, partly because of the safety issues. I was considering going to Libya, and many people will be there, but the Libyan government has been causing difficulties with visas.

18. **Alejandro Rivero**
March 23, 2006

It will be hard to get from Niger airport to the Libyan border, will it be?

19. **woit**
March 23, 2006

Not going all the way to the Libyan border, but still, quite a few hundred miles from Agadez. Will mostly be camping and travelling by 4 wheel-drive, perhaps some camels will even be involved….

20. **MathPhys**
March 23, 2006

Peter,

From what your description, your trip sounds like the real "getting away from it all".

Have a safe trip.

21. **MathPhys**
March 23, 2006

PS The Libyan/Niger border region is populated by the Tawareque tribes. Must be very interesting.

Back

April 4, 2006

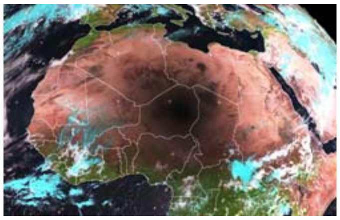
Had an amazing trip, which involved several days of travel through hundreds of miles of spectacular sand dunes in four-wheel drive vehicles operated by impressive Tuareg drivers (no camels). This put me and the group I was traveling with somewhere in between Dirkou and Bilma, about at the center of the shadow seen in this picture:



At some point I may post some links to other pictures. In a day or so after I deal with a couple hundred e-mails we'll return to your regularly scheduled programming.

Update: Fred Bruenjes was at the same eclipse camp in Niger, and has a report on the eclipse here. He also tells about traveling to the site, taking a more leisurely route than the one taken by the group I was with.

The Templeton Foundation: A Skeptic's Take

April 6, 2006
Categories: Uncategorized

Science writer John Horgan has just written a piece about the Templeton Foundation that is causing a bit of a ruckus. It first appeared in The Chronicle of Higher Education, and is also posted a the Edge web-site, where perhaps some further discussion of it will appear.

Horgan participated in a program held at Cambridge as a Templeton-Cambridge Journalism Fellow in Science and Religion, an all-expenses paid gig that came with an additional $15,000 that made it hard to turn down. He had very mixed feelings about the experience, and explains these in detail.

The financial scale on which Templeton operates is unparalleled in this area. As in Horgan's case, the people they invite to participate in their programs are often offered a lot more money than usual for this kind of thing. The foundation has an endowment of $1.1 billion, and is funding more than 300 projects at the rate of $60 million/year, a rate they intend to double. By comparison, the total NSF budget for supporting theoretical physics is also about $60 million/year. The sheer number and diversity of organizations using Templeton money to promote bringing science and religion together is staggering. I keep finding new ones at various places around the web, and also have yet to run into any organization trying to bring religion into science that isn't getting Templeton funding.

One new Templeton-funded project is called Foundational Questions in Physics and Cosmology, and has a very illustrious advisory board of physicists. It has just finished accepting proposals for a first round of grants to total $2 million, and has received a 172 proposals, totalling $23 million, from top institutions including Caltech, Harvard, MIT, Princeton and The Institute for Advanced Studies, Stanford, UC Berkeley, Oxford, and Cambridge. Sean Carroll (who turned down Templeton money since he disagrees with what they are trying to promote) has a posting about this, including a guest blog entry and discussion with Anthony Aguirre, who is one of the physicists running the project.

The ethical questions involved in the question of whether to accept money from a source one is not completely happy with are not at all straight-forward. One can sensibly argue that there is nothing wrong with taking money from someone whose goals one disagrees with, as long as they let you do what you want with it, and one isn't forced to further such goals. On the other hand, publicly associating oneself with an institution to some extent lends ones credibility and prestige to the institution and inherently furthers their goals. It's also true that money talks, and a large amount of money talks loudly. Many scientists in recent years have probably ended up doing one thing or another that they wouldn't otherwise have bothered to get involved in because Templeton money made it rather attractive.

There seem to me to be several different things about Templeton to be wary of. One is that the foundation's leader, Sir John Templeton, is in the process of turning over control of the organization to his son, John Jr., who has a much more politically right-wing, evangelical Christian, point of view than his father. Even if one has no problems with what the foundation has done in the past (e.g., it has not supported creationism), this doesn't mean it won't change what it does in the future.

I personally happen to think that bringing religion into physics is inherently a bad idea. Whatever one's view of religion is, it is inherently a quite different thing than science, and at a time when standards of what is science and what isn't are under attack, a blurring of the distinction between science and religion may be very dangerous. Much of what Templeton supports seems to me rather silly, but not much of a threat to anything important. For example they are funding a project in Vienna that will bring together physicists, philosophers and theologians to study the foundations of quantum physics. I don't believe the theologians will be much help here, but they're not likely to cause much harm. On the other hand, the large amount of Templeton funding promoting symposia devoted mostly to pseudo-science like this one on the Multiverse and String Theory is much more worrying.

Comments

1. **JC**
   April 6, 2006

   Any idea as to whether Mr. John Templeton Jr. is actually a true hardcore religious type, or whether the religion thing is just a convenient political "cover" for him? If it's the latter, he may very well be harmless for the most part.

   For many of the "neo-cons", I get the impression a lot of them use religion largely as a convenient political "cover" for pandering to the religious right voters.

2. **Bill**
   April 6, 2006

   Who are the most prominent religious scientists/mathematicians? Do Witten/Dijgraaf/Ashtekar/Atiyah/Maldacena/Hawking/Serre/Wiles/Tao/Mazur/etc believe in any form of god? How many are atheist? The gossip would be interesting…

3. **dan**
   April 6, 2006

   i agree with bill — i wonder if studying high-level physics (i.e particle physics, quantum gravity, etc.) begets a belief in some sort of deity (ala deism perhaps?)

4. **Lurker**
   April 7, 2006

   Off topic, but, Peter, why don't you have a prominent link to where your new book can be bought?

5. **Fabien Besnard**
   April 7, 2006

   It has been pointed out before by several people
   here including me that Templeton do support ID, if not openly.

6. **csrster**
   April 7, 2006

   The Horgan article is worth reading for the Weinberg quote alone 🙂

7. **anon**
   April 7, 2006

   Peter,

The Templeton Foundation does do some good work. They publish Professor Russell Stannard's book, "Science and the Renewal of Belief", http://www.templetonpress.org/book.asp?book_id=74

"Originally published in Great Britain and now updated and available for the first time in a U.S. edition, this book is a critically acclaimed work by a renowned theologian-scientist.

"Russell Stannard is known for cutting through highly technical data and presenting it clearly and simply. In Science and the Renewal of Belief he sheds light on ways in which science and religion influence each other and can help each other. Science and logic cannot establish belief, he says, but belief can be con-firmed and renewed with the changed perspective of modern science.

"The many reviews of the UK edition of his book cite his lucid presentation of relativity and quantum theory, and the way he uses relativity to explore time and eternity, and indeterminacy to comment on free will. He is also praised for offering fresh insight into original sin, the trials experienced by Galileo, the problem of pain, the possibility of miracles, the evidence for the resurrection, the credibility of incarnation, and the power of steadfast prayer. By introducing simple analogies, Stannard clears up misunderstandings that have muddied the connections between science and religion, and suggests contributions that the pursuit of physical science can make to theology."

Stannard was professor of physics at the Open University a decade ago (he is now emeritus). He was too busy then with his research into the connections of physics and miracles to reply to my letter as a student asking about quantum gravity, but he kindly passed it to a colleague who wrote to me that I need to study string theory (I believe the suggestion was to see if it can be reconciled with prayer). Unfortunately, I failed. (Others claim to have succeeded.)

8. **Chris Oakley**
   April 7, 2006

   Superstring theory has proved that most theoretical high-energy physicists, given a free choice, will work on speculative, quasi-religious nonsense.

   Since the Templeton Foundation sponsors those who investigate the connection between science and religion, it would appear that Superstring theory and the Templeton Foundation are a marriage made in heaven.

   So here is a proposal for a research project: calculate the extent of the 6 or 7 compact dimensions in heaven.

9. **Ben**
   April 7, 2006

   Speaking as a religious person with an interest in (though sadly a lack of deep understanding of) physics, it's always been a bit mystifying for me to understand why the Templeton foundation is so in love with string theory and the multiverse. On a purely aesthetic level, I find the idea that God created a final theory which dictates the physical parameters of our universe much more appealing than the idea of multiple universes spewed out at random. At any rate, I'll certainly agree with Peter and Chris that high energy physics is metaphysical enough these days without adding Templeton's money to the problem.

10. **anon**
    April 7, 2006

    Dear Chris,

    String theory is at a much higher level than you imagine. One Harvard M-theory expert (an assistant professor) said:

    "String theory is the language in which God wrote the universe."

    If you disagree with this statement, disprove it! (And keep your discussion mathematical with physical content.) 😉

11. **Tony Smith**
    April 7, 2006

    Anon said (quoting Lubos):
    "… "String theory is the language in which God wrote the universe."
    and then said:
    "… If you disagree with this statement, disprove it! (And keep your discussion mathematical with physical content.) …".

    Since the statement itself is not "mathematical"
    and
    since it has no "physical content" of calculations of observable quantities (as Feynman said, "The whole purpose of physics is to find a number, with decimal points, etc! Otherwise you haven't done anything."),
    it is a very good example of the unfortunate level of what passes for thought in today's physics establishment.

    Tony Smith
    http://www.valdostamuseum.org/hamsmith/

    PS – Chris said "that Superstring theory and the Templeton Foundation are a marriage made in heaven". Although they are remarkably compatible (with Lenny's Loony Landscape putting huge areas of physics forever beyond human comprehension, and thus creating a huge space for a G-d of the Gaps), I see the "marriage" as being made in Hell by Satan in order to put Humanity into a Dark Age.

    It is amazing to me that a program (fqxi) to grant $2 million for "… unconventional … physics … research that, because of its speculative, non-mainstream, or high-risk nature, would otherwise go unperformed due to lack of available monies …"
    attracted
    "… 172 proposals, totalling $23 million, from top institutions including Caltech, Harvard, MIT, Princeton and The Institute for Advanced Studies, Stanford, UC Berkeley, Oxford, and Cambridge …".
    It seems as though the Dark Age is already here, and that Satan is giving thanks to Templeton for helping him win this round in his fight with G-d.

12. **ObsessiveMathsFreak**
    April 7, 2006

    Bringing religion into physics is like bringing alchemy into chemistry. Imagine if a modern chemist took a foundation's money and began giving talks and writing papers about the four humors and transmutation of elements in the context of modern chemistry. Would you take money from the same foundation that continued to fund this?

13. **Dumb Biologist**
April 7, 2006

Well, their study of the post-CABG impact of anonymous prayer on recovery was a bust by any measure, so maybe they'll be hoisted by their own petard.

14. **anon**
April 7, 2006

Prayers failed to contribute to the recovery of heart surgery patients in the Templeton study because the universe is 96% dark energy and dark matter.

What do you think happens when the universe is 96% dark stuff? Prayers can get attenuated by the factor exp(-x/y) where x is the amount of shielding dark energy/matter, and y is the relaxation length or 'mean free path' of a prayer through the dark stuff (y being the amount which is enough to attenuate prayers by the factor e).

So actually, the 'negative' result of the prayer study is actually best perceived more evidence for the current cosmological model. Sorry Peter, for going off topic a little bit. 🙂

15. **Alejandro Rivero**
April 7, 2006

ObsessiveMathsFreak, that is not accurate. Alchemy has never left chemistry. The basic principle in Alchemy is not around humours (that is medicin) but ying/yang, call it Mercuric/Sulphurous, Acid/Base, Reduction/Oxidation…

16. **Alejandro Rivero**
April 7, 2006

Yes, a funny quote: "I am all in favor of a dialogue between science and religion, but not a constructive dialogue."

Religion is not mostly harmless. On one hand, the belief in an extranatural explanation does not seem compatible with the search of explanation. Religious people can do good observational science, reading Nature as the book of God, but weak theory. If this is bad at individual levels, it is worse when it is amplifyed at politic (which has intervering agendas of its own) and institutional levels. In Spain a good example of such problematic was the rebuilding of Ramon y Cajal's "Junta de Ampliacion de Estudios" as a post-war "Centro Superior de Investigaciones Cientificas" under the control of Opus Dei.

Also, it is not only about guiding and censoring; we have lost important individual people defecting from science to religion. From the past, think about Pascal, hammer of Aristotle, getting that mistical experience and abandoning all the scientific research. Or Isaac Barrow, dead on oppium after leaving math for a mix of religion and academic politics. Perhaps today Money or Politics are more powerful sources of defection, but all of them have mutual synergy, as Hogan's comment shows.

17. **Michael**
April 7, 2006

Science and Religion has been mixing for along time. That is not what worries me. What worries me is irresponisble scientists and /or quasi-scientists writing about questionable science to prove the existance of a god or to prove ID (I am not implying any person or group in this statement). Most scientists and informed public can tell the difference between pseudo-science and real science. However, the general public is relatively uninformed and would rather be spoon fed. This is where pseudo-science does its real damage. I think that this is where the Templeton Foundation can do a significant amount of damage.

18. **Dick Thompson**
April 7, 2006

This may be a new problem for physics, at least in recent times, but it is an old, old one for intellectuals generally, hence the ancient saying "He who would sup with the devil must use a long spoon."

Argumant along the line of "X has done some good work" are also a familiar part of the problem. When I was a kid (during WWII), there was general derision of a saying that had been common a decade earlier; "Mussolini made the trains run on time."

And so is the "The father is moderate but the son is radical". "If the Tsar only knew what his cossacks were doing in this pogrom, surely he would stop it."

As my quotations suggest, I think that history wil not look kindly of the physicists who have sold their birthright for a fat endowment.

19. **steve**
April 7, 2006

Alejandro's comment about religion and theory is way off the beam. Kepler's theorizing was entirely fired by his belief that he was understanding the mind of God (he had a neo-Platonist view of the role of math in the universe). Newton was a pretty religious guy (and also seems to have been interested in alchemy). Galileo seems to have been pretty devout, but more in a modern "non-overlapping magisteria" way, a la Gould, than the straightforward linkage of Kepler and Newton. All of these were mathematical modelers and theorists, in fact the very first in physics.

It should also be pointed out that one strand in the history of science (Houkyas) argues that it was precisely the theological beliefs of the English scientists–specifically their "voluntaristic" doctrine that God could have designed things any way he wanted–that led to empiricism in the first place. Cartesians and other Continentals, in this view, tended to think that God should be constrained by logical principles intelligible to mankind, and so tried to deduce more and experiment less. I don't know the current scholarly state of play on this idea, but it was still being taught to undergraduates at Princeton in twenty-five years ago.

20. **Thomas Love**
April 7, 2006

Theory and Theology have the same root: Theos=God. But why?

21. **The Anti-Lubos**
April 7, 2006

Thomas Love said: *Theory and Theology have the same root: Theos=God.*

Actually, they don't. *Theory* comes from a Greek root meaning "a viewing" or "a contemplation."

22. **Alejandro Rivero**
April 8, 2006

It is amusing to label as NeoPlatonist to the man that put perfect circles off, I wonder from where has this idea come, surely some historian looking at his gravure with the platonic solids (having just five planets, the radiouses of these solids were a logic place to research for a parameter-free theory; it is unrelated to Plato). It is true that the question of God was very live topic in the Baroque age, but note that neither Kepler not Galileo nor Newton can be qualified as orthodox theologicians; surely the inquisicion had found solid points to attack Kepler and Newton had they being at the reach of Catholicism. Note also the extensive printing and reprinting of Lucretius and other propaganda of Epicureism, where gods, even if acepted, were unrelated to the deep workings of Nature. To say that a scientist is trying to understand God if only valid in a sense: he is trying to understand His inexistence.

23. **Benjamin**
April 8, 2006

Peter, this may seem trivial, but I wish you had a date near the top of the page one gets to when one clicks on the comments, just as one has on the main blog page. I sometimes like to save a good posting, including the comments, and when I click on it I like to see the date right away at the top.

As for science and religion, I believe in certain 'metaphysical' principles, but I agree that they should not be brought into science. Feynman is right when he says it is about predicting numbers. However, one should distinguish between harmless 'metaphysical' feelings like Einstein's belief that 'God does not play dice', which can be considered 'motivational' (even if it made Einstein more or less waste his later years), and a subversive theological agenda. For the latter, read Christianity. I am not here to bash Christianity, but there is a noticeable tendency for them to think of their religion as the best or truest, as do the Muslims. The Muslims, at least, are pretty outspoken, but Christians tend to be more subtle, and any sneaky attempt to inject any particular dogma masquerading as science is especially noxious.

24. **Benjamin**
April 8, 2006

Here's a better thought: Mathematics itself can take on some of the pernicious attributes of religious speculation. That's what people here seem to see in string theory. Wasn't Einstein at his greatest in his youth when he was thinking empirically and 'operationally'? Then, when he learned Riemannian geometry and developed a greater appreciation (perhaps awe) for mathematics, he seems to have developed a belief that simply tinkering with the math would produce the truth. Isn't that what the anti-symmetric tensor business was about, which Weinberg said amounted to nothing? (I'm no expert.) Anyhow, mathematics can be pretty seductive! It can acquire some 'metaphysical' or 'theological' characteristics. So maybe religion isn't the only danger to physics.

25. **island**
April 8, 2006

Religion is necessary to science as long as science rejects out of hand interpretations of evidence by scientists which indicate that there is purpose in nature, due to their own personal pre-conceived prejudiced and misconceptions about what's actually known.

Proof:

God does not play dice', which can be considered 'motivational' (even if it made Einstein more or less waste his later years)

Apparently this person has no idea that Einstein's opinion falls from the most natural extension of GR with a cosmological constant as it applies to the observed universe… not from some quasi-religious "feelings" about it.

So hidden variables is a categorically determined matter and you have the quantum gravity and the ToE in your back pocket, right?…

Maybe you can provide some logical proof for infinity while you're at it, so that we can finally know for sure that Einstein was wasting his life believing that *"such a complete resignation in this fundamental question is for me a difficult thing. I should not make up my mind to it until every effort to make headway toward a satisfactory view had proved to be in vain"*.

Taking money from Templeton is necessary and justified as long as creationists are the only ones that carry the torch of purpose in nature.

Don't count Einstein out yet… as nothing has been "uncertainly settled" yet.

26. **anon**
April 8, 2006

'Einstein … rejected the theory not because he … was too conservative to adapt himself to new and unconventional modes of thought, but on the contrary, because the new theory was in his view too conservative to cope with the newly discovered empirical data.'

– Max Jammer, 'Einstein and Quantum Physics,' in 'Albert Einstein: Historical and Cultural Perspectives', edited by Gerald Holton and Yedhuda Elkana, 1979.

27. **island**
April 8, 2006

Thanks, I'll bear that in mind the next time that I think about how Einstein felt about quantum weirdness…

I was indirectly quoting from his 1917 paper, when he attempted to defend his theory against arguments for setting boundary conditions at infinity, because it severely weakens the predictive capabilities of GR by requiring that it be augmented by other principles or a bunch of arbitrary information in order to yield determinate results.

For this same reason, in, "Gravitation", Misner, Thorne, and Wheeler said that GR *"demands closure of the geometry in space as a boundary condition on the initial-value equations if they are to yield a well-determined and unique 4-geometry"*.

There is no uncertainty in this model, period.

28. **woit**
April 8, 2006

Please, this is a posting about the Templeton Foundation and the funding issues it raises. Try and avoid the seemingly irresistible urge to go on about your favorite ideas about cosmology or GR, that's completely off-topic here.

29. **island**
April 8, 2006

Sorry, I agree, but I also felt compelled to defend that my example was correct in context, in order to illustrate why I believe that there are circumstances where it is… *"ethical […] to accept money from a source one is not completely happy with are not at all straight-forward'*.

Maybe I could have done it without the example:

Taking money from Templeton is necessary and justified as long as creationists are the only ones that carry the torch of purpose in nature.

… when science requires that respectable scientists, like John Barrow, cross the line in order to do real science that would otherwise gain little or no support from the mainstream, so in this context, at least, it *can* be very necessary to science even if you don't like the false-idol that forces the issue back to the surface until it is unequivocally decided.

That sounds a lot crazier without the good reason for it tho!… 😉

30. **knotted string**
April 11, 2006

If Templeton were backing heretics who couldn't get funding anywhere, instead of giving million dollar awards to already known and powerful people like Paul Davies, John Barrow, etc., then I'd have sympathy.

They're not interested in helping obscure back-room patent clerk types. They are out to do something political by bribing big names.

31. **Chris Oakley**
April 11, 2006

I must admit that I don't think that I would be so proud as to turn down Templeton's money if it was offered. But one of the many reasons why it would not be on offer is this: *they have an agenda*. Unlike the Bambergers (who founded the the IAS in Princeton) this is not a disinterested attempt to further scholarship. It is an attempt to bring people around to their way of thinking. With more than a billion dollars in the pot they can afford to be patient, but the plan is clearly to "buy" as many eminent scientists and other thinkers as they can in hopes that these people will repeat their message. Although it may be done in the nicest possible way, it still leaves a bad taste in the mouth.

32. **Tony Smith**
April 11, 2006

knotted string said "… Templeton …[is not]… backing heretics who couldn't get funding anywhere … They're not interested in helping obscure back-room patent clerk types. They are out to do something political by bribing big names. …".

Chris Oakley said "… I must admit that I don't think that I would be so proud as to turn down Templeton's money if it was offered. …".

I agree with both statements. I am also not so proud as to turn down Templeton's help. In fact, back in November 2005 I sent an e-mail to hubbard at fqxi.org saying in part:

"… I saw … at … a Templeton statement at http://www.templeton.org/topics_in_the_news/Official_Statement.asp … the following: '… the Templeton Foundation refuses in its programs to blacklist scholars based on their ideological positions. … Blacklisting is ethically inappropriate in academic contexts. … Research scholarship does not proceed by processes of censorship and inhibition of debate. …'.
I am, and have been since around 2002, blacklisted from posting on the Cornell arXiv … I individually do not now need grants or money, and this message is NOT a request for money. However, I do need relief from the oppression of blacklisting, such as opportunities to present my ideas to physicists for discussion and criticism, and also some place where my work could be securely archived for the future. … If you think that it would be useful for me to meet with you or any other representative of Templeton to discuss such matters, I would be happy to do so at a mutually convenient time and place. …".

I have (as of now, several months later) not received any reply whatsoever.

Since I was not even asking for money (just for an invitation to talk about my ideas),
it seems to me that Templeton is indeed not interested in helping heretics, but is in fact interested in furthering a political agenda by buying influential people in influential organizations , as evidenced by the fact that their $2 million grant program attracted (according to Peter) "… 172 proposals, totalling $23 million, from top institutions including Caltech, Harvard, MIT, Princeton and The Institute for Advanced Studies, Stanford, UC Berkeley, Oxford, and Cambridge …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Peter, I want to make it clear that I do NOT want this comment to lead to discussion about my physics model or about me being blacklisted. I only mention my situation because (since I am an obscure heretic) it seems that Templeton's totally ignoring my request for help is a concrete example that shows their high-minded statements such as "… Blacklisting is ethically inappropriate in academic contexts. …" to be merely bullshit window dressing to cover their real agenda, which is (as knotted string said) to "… do something political by bribing big names …".

33. **Alejandro Rivero**
April 12, 2006

how do you say in USA: "put your money where you mouth is"? Tony attemps clarifyes that words and actions do not agree.

I have been thinking on the questions raised in this thread, and I think we should at least agree on an statement:

"that gods, as sentient entities, are allowed to exist and live freely as far as they understand that Their freedom is restricted by the freedom of other sentient beings, and Their rights restricted to the rights of other sentient beings, particularly by those of the human genre".

Is this enough to qualify for Templeton money?

34. **Anthony Aguirre**
April 14, 2006

Tony Smith,

I am sorry that you did not receive a helpful reply from Kirsten Hubbard, our scientific program manager. This may have been, in large part, because FQXi is NOT the Templeton foundation, nor is she a spokesperson for Templeton. FQXi is an independent and independently-run organization with seed funding from the Templeton Foundation (and hopefully soon other donors).

In terms of who is funded by FQXi, note that the quoted web announcement referred to applications received, not applications funded. But in any event FQXi will seek to fund the best foundational, unconventional research in physics and cosmology that it can, whether it is by a patent-office clerk or a Harvard professor. The former is, of course, the exception more than the rule, albeit an important one.

best,

Anthony A.

(FQXi Associate Director)

35. **knotted string**
April 15, 2006

If Tony Smith is too exceptional for your taste, then try funding the Harvard assistant professor who said ‘String theory is the language in which God wrote the universe’. But beware he might spend his time blogging about climatic change being a fraud! 😉

36. **John Harding**
April 23, 2006

I predict that life will continue to reproduce itself at least for the near future because of the anthropic principle. But what do I know? I’m nobody.

Eurostrings 2006

April 8, 2006
Categories: Uncategorized

This past week there has been a conference going on in Cambridge called Eurostrings 2006. It's a bit like the annual "Strings XXXX" conferences, although about half the size and organized just by European institutions that are part of the European Superstring Theory Network, which since last year has been funded by a grant from the EU. Part of the conference consists of a celebration of Michael Green's 60th birthday.

Most of the talks are already available online. There's not much new being reported, but the talks include a nice review talk on topological strings by Robbert Dijkgraaf. There's another talk on recent work on topological strings by Erik Verlinde, and a week earlier there was a conference in Munich devoted to the subject.

Nathan Berkovits talked about work in progress with Nikita Nekrasov on multi-loop amplitudes using his pure spinor formalism. This subject still seems remarkably confused, with Berkovits explaining that they have found a problem they still don't know how to resolve: their regularization causes amplitudes with genus larger than 6 to vanish, violating unitarity. For commentary on yet another new suggested formalism for defining superstring amplitudes due to Warren Siegel and Kiyoung Lee, see this posting by Lubos Motl.

As part of the Green birthday celebration, John Schwarz gave a talk on String Theory Books. He reminisced about the writing of the two-volume book with Green and Witten (his outline refers to a "removed chapter", and "broken vow", what are those?). Evidently the book was written in 9 months back in 1986, a truly heroic effort given its size. Last Monday, Schwarz finally finished up a new textbook on string theory, written with Katrin and Melanie Becker and entitled "String Theory and M-theory: A Modern Introduction". They started writing back in February 2005, planning a 350 page book to be completed by the end of September, but ended up just last week completing a 729 page book. From the table of contents it looks like GSW abbreviated and updated, containg more modern material on branes, dualities, black hole entropy, flux compactifications and gauge/string dualities. It seems rather peculiar that flux compactifications and the landscape get a whole chapter, whereas AdS/CFT is dealt with in one section of one chapter. All in all, comparing the new book to the old one, twenty years later the subject has become a lot more complicated, a lot uglier, and the prospects for using it to predict anything about the standard model have vanished.

The Schwarz talk also has a link to a video of a Berlitz commercial featuring a German radio operator misunderstanding someone radioing in a distress call that they were sinking (the German hears this as "thinking"). I can't at all figure out what this has to do with Schwarz's talk. Is string theory making a distress call as it is sinking, but no one understands this?

Victor Rivelles attended, and has blog entries here, here and here. He reports on a talk by my fellow Princeton student Costas Bachas about using string theory techniques to solve capillarity and wetting problems, then comments that "If LHC provides no proof to string theory string theorists will not lose their job, they can just change to applied string theory!"

Comments

1. **Chris Oakley**
   April 8, 2006

   Applied string theory? What does that mean? The only thing I can think of that fits this description is working for a postal/parcel delivery service. Someone should do a study to see if the postal workers who have "gone postal" in the past (wasting many fellow human beings, and most often themselves in the process) were in actual fact just frustrated Superstring theorists who were unable to cope with the absence of any extra dimensions.

   If only I had know that these guys were staying right opposite the Cambridge University Library, where I often go to work. I could have sauntered along to the college bar afterwards to try to talk them out of making this career move, possibly saving many innocent lives in the process.

2. **Algernon Llewellyn-Twittleton**
   April 8, 2006

   The talks were all videoed and may (?) appear online.

   The `removed chapter' was apparently one on light-cone gauge string field theory that never made it in to GSW. The broken vow was `never again!' – the new book with Beckerx2 breaking this.

   Despite your perhaps overly fond hopes Peter, John Schwarz's talk did not anticipate the demise of string theory. The commercial you found puzzling was used to illustrate a point about ensuring the text of his new book was not like German gewritten.

   vive les cordes

3. **woit**
   April 8, 2006

   Thanks Algernon!

   I did think it was probably too much to hope for that Schwarz was implying that string theory was sinking. For one thing, he probably wouldn't have spent the last year writing a book on the subject…

4. **Luboš Motl**
   April 8, 2006

   The commercial "What are you sinking about?" was mentioned by John Schwarz as an example of sometimes difficult verbal communication between native English speakers and non-native English speakers. Such trivial difficulties can sometimes influence even teams that write books, despite the high intelligence of all the authors.

   But it's still a courtesy from the German speakers to speak English. John Schwarz has a German enough sounding name so that he could also learn German. 😉 In fact, Becker sisters' grandfather was kind of Czech and his name was Jan (=John) Schwarz.

5. **Chris Oakley**
   April 8, 2006

   I don't see any Llewellyn-Twittletons on the list of participants, and yet Algernon here seems pretty well informed about this conference. Could it be that he is posting

under a pseudonym? If so, why? Is contributing to this blog a CLM* for String Theorists? But I notice that he stops short of saying "Long Live Strings" in English, even though I am sure that he must be aware that this the usual language of this forum.
—-
CLM = Career-limiting Move. Another example of an academic CLM is calling your PhD supervisor an "idiot" or "imbecile" before he/she has written your references.

6. **Tony Smith**
April 8, 2006

Peter said: "… John Schwarz … reminisced about the writing of the two-volume book with Green and Witten … Evidently the book was written in 9 months back in 1986, a truly heroic effort given its size.
Last Monday, Schwarz finally finished up a new textbook on string theory, written with Katrin and Melanie Becker and entitled "String Theory and M-theory: A Modern Introduction". … a 729 page book. From the table of contents it looks like GSW abbreviated and updated … All in all, comparing the new book to the old one, twenty years later the subject has become a lot more complicated, a lot uglier …".

The haste with which 1986 GSW was written is evident.
For example:
Volume 1 contains Appendix 5.A "Properties of SO(2n) Groups" that discusses interesting things like SO(8) triality and the spinor representations of SO(2n),
while
Volume 2 (at page 388) says "… It is perhaps surprising* that one can define a second set of gamma matrices …"
with the * indicating a footnote saying
"To the reader who has read the construction of the spinor representation of SO(2n) in Appendix 5.A, this may not seem so surprising.".

When I first read GSW, I found it to be very unevenly written,
with very clear beautiful sections on triality, SO(2n) spinors, the Elements of E8 (Appendix 6.A), etc,
and
with some less-mathematical sections seeming to me to be muddy and obtuse.

At a conference, I had the opportunity to ask Ed Witten why GSW was so unevenly written, and even with some sections apparently written by someone who was unaware of preceding sections.
He said that they (G,S,W) had divided the book into chapters and then each of the three authors had written their assigned chapters independently.

Guess who wrote the clear beautiful math stuff in GSW ? (Hint – his initials are EW).

Therefore, I am nor surprised when Peter says that Schwarz's rewrite/update (without EW as coauthor) seems "a lot more complicated … a lot uglier".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

7. **woit**
April 9, 2006

Tony,

Witten has an incredible command of a lot of mathematics, and he is a wonderful expoeitor, so I'm sure his co-authors had trouble competing with that. But the additional levels of complexity and ugliness I was referring to are inherent to the subject, not due to the authors. All I've seen anyway is just the table of contents, and I was referring not to the exposition but to the properties of the topics chosen.

8. **Robert**
April 10, 2006

JHS's also explained that the G, S and W individually drafted the chapters (and it is indeed quite obvious who wrote what) and only later send them around (using the by then still novel computer network joining Princeton, QMW and Caltech) for the others to edit. He also mentioned that they each worked like 100 hours/week to finish those books but W still managed to work out cubic string field theory simultaneously.

The "what are you thinking about" spot making fun of us Germans struggling with the English language became a running gag for the rest of the conference, not only Paul Townsent refered to it mentioning Michael Gutperle's pronounciation of "Janus".

So, remains one question: How many Germans does it take to change a light bulb?

Vee ask heer se kwestions!

9. **woit**
April 10, 2006

Robert,

"Townsent"? Can't see why anyone is making fun of you Germans with your accents….

10. **Alejandro Rivero**
April 10, 2006

There is some distintion between "sound" and "phoneme". Basically if you understant it , it is still the same phoneme, just different accent or sound. On the other hand, I believe that an insult against scottish is "Yours is not an accent, it is just a different language that happens to have the same written form".

11. **Robert**
April 10, 2006

Ahhhhh. Gotcha! At least I manage to call him Paul, not like the secretary at Strings '99 who even produced a name tag with "Pete".

12. **Bert Schroer**
April 10, 2006

Here is another one
question: Prof. Wigner do you spell your name with vee?

Wigner: 9W

13. **Jenny Attiyeh**
April 11, 2006

Hi Peter et al –
Just wanted to let you know that my ThoughtCast interview with Lisa Randall is finally finished, and online in podcast form at http://www.thoughtcast.org. Thank you all for your input on potential questions for the interview. Feel free to leave a comment on the ThoughtCast website. And please remember that the intended audience for this interview is curious and intelligent, but mainsteam — far less informed than you guys. I think you might nonetheless enjoy listening to her thoughts on string theory.
Thanks again!
Jenny

14. **knotted string**
April 12, 2006

"… Very soon now these [string theory] theories will be tested. …" – Jenny (introducing Lisa Randall).

"Is there any room in your theories for life on any extra dimensions or parallel universes?" – Jenny

Lisa Randall, laughing: "There absolutely is room … in particular if there are other branes … we really don't know what's there …"

🙂

Polchinski on the Landscape

April 9, 2006
Categories: Uncategorized

At the recent Solvay conference there was extensive discussion of the Landscape, and I've already discussed here Michael Douglas's write-up of his talk on the subject, entitled Understanding the Landscape. Now Joe Polchinksi's rapporteur talk on the subject has appeared; it's entitled The Cosmological Constant and the String Landscape. Polchinski is essentially making the same argument as Susskind makes in his recent book, and his argument has pretty much the same problems that Susskind's has, which I discussed in detail in an earlier posting. However, his article is written for physicists, not for the general public, so he is making a much more technical version of the argument. It's probably the best version of the case for the string theory anthropic landscape available, so worth reading carefully.

Polchinski begins by explaining why the cosmological constant problem is difficult. He divides possible solutions to it into ones where the CC is fixed, and ones where it is adjustable. The problem with the idea that the CC is fixed and calculable is essentially that all the contributions to the vacuum energy that we know about give values of the CC that are far too large. These include things like fermion loops and the Higgs potential in the standard model, supersymmetry breaking in supersymmetric extensions of the SM, and Planck scale effects in theories of quantum gravity. He goes on to explain why it is difficult to try and modify the theory of gravity so that it won't couple to these sources of vacuum energy.

There is a wide range of ideas about how to select a small CC in theories where the CC is adjustable, and Polchinski describes several of them and what problems they have. Some of these ideas naturally explain a small CC in an empty universe, but not in our matter-filled universe. Finally he ends up with the anthropic explanation: the CC is small because if it wasn't we wouldn't be here. He does note that:

Of course, the anthropic principle is in some sense a tautology: we must live where we can live.

this carries a footnote comparing the anthropic principle to Darwin's theory of natural selection:

Natural selection is a tautology in much the same sense: survivors survive. But in combination with a mechanism of populating a spectrum of universes or genotypes, these 'tautologies' acquire great power.

Susskind makes the same sort of claim that the anthropic landscape is much like the theory of evolution, and I think this is extremely dangerous and unwise. There is a mountain of scientific evidence for the theory of evolution and none for the anthropic landscape. It is very important that this distinction be made, and trying to blur the difference between these two very different situations is not something a scientist should be doing at a time when science in general and the theory of evolution in particular is under attack by the forces of the religious right. When I was in Niger one of my travel-mates was a creationist who was generally annoyed at what he saw as the arrogant way scientists dismiss his view of the world. We discussed cosmology, and I tried to tell him a bit about inflation and what aspects of the universe it was supposed to explain. In response he asked me why he shouldn't just go with his preferred explanation: it was all the doing of the "Big Kahuna", as he called the deity. I tried to explain about the scientific method: your theory is supposed to make distinctive predictions that you can go out and check by making observations. I think I had some success in getting this idea across, but I don't see any way I could have defended to him something like the anthropic landscape. It's not legitimate science since it makes no real predictions that you can use to see if the idea is right or not. What's at issue here is the credibility of science itself, and physicists who care about this credibility should not be claiming that an idea like the anthropic landscape has the same status as heavily tested and verified theories like that of evolution.

Polchinski goes on to repeat the analogy with evolution a bit later, and I actually don't understand at all what point he is making here, when he argues that maybe only the anthropic principle determines the CC:

Thus we should seriously consider the possibility that there is no other selection mechanism significantly constraining the cosmological constant. Equally we should not stop searching for such a further principle, but I think one must admit that the strongest reason for expecting to find it is not a scientific argument but a psychological one (footnote): we wish fundamental theory to be as we have long assumed it would be.

and the footnote is:

Again, the Darwinian analogy is notable.

Personally I'm agnostic about whether the CC is computable from first principles or not. As a scientist, one's job is to come up with theories and extract predictions from them to see if they are right. If you have a theory that says the CC is not computable, that's fine, but then you have to just forget about the CC and find something that your theory does predict so you can test it. You can't go around claiming that the fact that your theory is compatible with any value of the CC is somehow some sort of scientific success and evidence for the theory. The problem with a theory where all values of the CC are a priori equally likely is that it's vacuous (as far as the CC is concerned). Its implications are exactly the same as throwing up your hands and saying "I have absolutely no idea what determines the CC, it could be anything".

The fact that we are here and observe galaxies does put constraints on the CC, and Polchinski would like to make much of this. He'd like to claim that the anthropic landscape predicts that the CC is a random variable, and then, given the fact we see galaxies, it would have an expectation value about an order of magnitude higher than its observed value. He defends the theory against this mismatch by quoting Galileo's defense that his theory might be inaccurate but was a lot better than Aristotle's, then writes:

This order of magnitude may simply be a 1.5 sigma fluctuation, or it may reflect our current ignorance of the measure of the space of vacua

One problem with all this that Polchinski doesn't mention at this point is that the anthropic constraint is not on the CC but on a combination of the CC and Q, the normalization of the primordial temperature fluctuations. Assuming both are random variables, the observed CC is way off what one expects. One can deal with this by just assuming that the CC is a random variable, but Q isn't for some reason. This gets into the fundamental problem with the string theory anthropic landscape: it doesn't just not predict the CC, it doesn't predict anything at all. As far as one can tell, it's consistent with just about anything. It doesn't make any predictions, so it's really not a legitimate scientific theory at all. One can try and claim that it really is a scientific theory, and that it does predict something: we are at some randomly chosen (according to a not yet understood measure) point in the landscape compatible with our existence. The problem with this (as Polchinski notes) is that there is a long list of properties of the world that appear to be rather special and statistically highly disfavored by any likely measure: the theta-angle is very small, proton lifetime is very long, number of generations is small, etc., etc. If one actually took the string theory anthropic landscape seriously as a theory, one would have to abandon it in face of these falsifying observations.

The crucial question for whether the anthropic landscape is science or not is whether it makes any testable predictions. Polchinski doesn't at all address the question of whether further study of the landscape will lead to any prediction of anything, presumably because like everyone else he has no plausible idea for how this could come about. He does claim that Weinberg's 1987 arguement makes 5 successful predictions or postdictions:

The anthropic argument is not without predictive power. We can identify a list of post- or pre-dictions, circa 1987:

1. The cosmological constant is not large.

2. The cosmological constant is not zero.

3. The cosmological constant is similar in order of magnitude to the matter density.

4. As the theory of quantum gravity is better understood, it will provide a microphysics in which the cosmological constant is not fixed but environmental; if this takes discrete values these must be extremely dense in Planck units.

5. Other constants of nature may show evidence of anthropic constraints.

Calling these successful predictions seems to me a huge stretch. 1. follows from a tautology, 2. and 3. are the same "predictions" I get by saying I have no idea what is going on here (including having no good reason to believe the CC is zero). 4. isn't an experimental prediction at all, and 5. is so vague as to be completely meaningless.

Polchinski ends up his defense of the landscape by quoting Dirac:

One must be prepared to follow up the consequences of theory, and feel that one just has to accept the consequences no matter where they lead.

The problem with this is that Dirac undoubtedly didn't have in mind the idea that if your theory has no experimental consequences, you should accept the idea that you can't ever predict anything. Obviously, you should give up on your theory at that point, and this is what Polchinski and others show no signs of being willing to even consider. Back in 1998, in lectures at the SLAC Summer Institute, he wrote:

On Lance Dixon's tentative outline for my lectures, one of the items was 'Alternatives to String Theory.' My first reaction was that this was silly, there are no alternatives…

and his attitude doesn't seem to have changed since. He and others never discuss the possibility that string theory is simply a wrong idea, a possibility for which the landscape provides overwhelming evidence. This seems to be something he is unwilling to seriously consider.

There's one peculiar reference in his paper. When he refers to the problem that the landscape can't even predict the one thing people originally hoped it would be able to, the scale of supersymmetry breaking, he writes:

An obvious question is whether we can understand the supersymmetry-breaking scale (see and references therein). Is low energy supersymmetry, or some alternative , favored?

is a reference to split supersymmetry, and is a reference to a paper by Fox et. al called Supersplit Supersymmetry. The strange thing about the apparently serious reference to is that the paper in question is actually an April Fool's joke (check the date on it…). The authors were making fun of how supersymmetric phenomenology is being pursued, and specifically of the idea of split supersymmetry. In "supersplit supersymmetry", all superpartners are pushed up to unobservability at the Planck scale, solving all the problems caused by the lack of observation of effects of supersymmetry. For any conceivable purpose, the supersplit supersymmetry model is precisely the standard model. The joke is that particle physicists have become so enamored of supersymmetry that they would happily study a supersymmetric model inherently indistinguishable from the much, much simpler standard model. Part of being unwilling to consider the idea that superstring theory might be wrong is being unwilling to consider the idea that supersymmetry might be wrong, and thus, instead of referring to the standard model, one adopts the supersplit supersymmetry model.

The funny thing about this April Fool's joke paper is that, according to SPIRES, Polchinski's is the sixth paper to cite it. Looking through these six papers, only one of them seems to be aware of the joke, with a footnote to the reference pointing out that the paper appeared on April Fool's day and that the model was equivalent to the standard model. Some of the particle theory community now seems to think that the idea of a vastly more complicated model that is inherently indistinguishable from the standard model but is in some sense "supersymmetric" is a model worth taking seriously and making reference to. Yet another weird thing about this paper is that there is one trackback to it, and this trackback was generated by a comment from LambchopofGod on a Cosmic Variance posting. Presumably it's a bug, not a feature, that any commenter on an approved blog can generate trackbacks at the arXiv, but seeing the way the arXiv handles trackbacks, who knows. In any case we'll see at some point if trackbacks to the Polchinski paper and the Fox et. al. paper get generated from this posting. Hopefully at least a trackback to the Fox et. al. paper will appear, since many readers of that paper don't seem to realize that

IT'S NOT SCIENCE, IT'S AN APRIL FOOL'S JOKE, PEOPLE!

Comments

   April 9, 2006

   Besides Witten defecting from string theory, what else could possibly make Susskind, Polchinski, and others give up string theory? It seems like all this anthropic silliness over the last few years isn't enough.

2. **woit**
   April 9, 2006

   JC,

   I'm sure Susskind and Polchinski will give up on string theory if and when someone comes up with a much better idea and the physics bandwagon changes direction to follow it. The weird thing is that it seems that deciding that the theory can't predict anything doesn't seem to be enough to make them give up on it. If you had told me a few years ago that this would happen, I would have refused to believe it. I'm still having trouble…

3. **JC**
   April 9, 2006

   I've always wondered what would be going through the mind of a retired theorist who had spent his/her entire working life on a theory which turned out to be either wrong and/or vacuous in the end.

   I get the impression that for some folks, the anthropic stuff is almost like a last ditch attempt to salvage their life's work into something meaningful and/or at least to slow down the decline to oblivion and/or meaninglessness.

   I would guess that knowing that one's entire life's work was a huge boondoggle, isn't exactly something to be proud about in retirement.

   April 9, 2006

   "A new scientific truth does not triumph by convincing opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

   — Max Planck, *A Scientific Autobiography and Other Papers*, 1949

   This may also be true about adherents of a non-predictive methodology admitting that they were backing the wrong horse.

5. **JC**
April 9, 2006

Allegedly Lorentz was a true believer in the ether to the very day he died. (I don't have a reference handly offhand).

I wouldn't be surprised to see that other physicists of Lorentz's generation (ie. mid-late 19th century) were all true believers in the ether, all the way to their graves.

6. **Tony Smith**
April 9, 2006

Peter says "… Susskind makes the same sort of claim that the anthropic landscape is much like the theory of evolution …".

I would hope that everyone (even Joe and Lenny) could agree that the "theory of evolution" includes at least the following structures:
1 – a fairly detailed fossil record showing an understandable progession of organisms from early blue-green algae to oxygen production … etc … to dolphins in the sea and humans on land; and
2 – a crude understanding of genetics at the molecular level and that mutations can cause genetic change.

Maybe people can argue about the punctuations in puntuated equlibrium speciation, etc, but there IS a progressive fossil record and there IS a molecular mechanism for genetic change.

My question to Joe and Lenny would be:
Can you show me where the "anthropic landscape" contains ANY comparable structures ?

Where is a string-theory-model of a progressive fossil record,
i.e, a series of states leading from the Big Bang to our present Earth arranged in an understandable progression like the series of fossils in our fossil record ?

Where are the string-theory-model laws (NOT vague hand-waving) that govern how string-theory states can mutate from one to another a la molecular genetics with mutation ?

Unless and until Joe and Lenny can put up such examples, they should shut up about the Landscape being "much like the theory of evolution".
Of course, as long as their audience (present-day superstringers = 90% of USA theoretical particle physicists) is sufficiently sheep-like to buy their stuff, they are not likely to "shut up". Rather, they are more likely to shout louder and attempt to drown out any voices of reason.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – I am particularly disappointed in Joe. Years ago he did calculations that could be compared with experiment, and if he had stuck to his guns, he could have claimed predictions against then-conventional wisdom, which predictions were later validated. For example, in Nuclear Physics B221 (1983) 495-523, entitled "Minimal Low-Energy Supergravity", Joe Polchinski (with Alvarez-Gaume and Wise) said:
"… Weak-interaction breakdown occurs for top-quark masses between 100 and 195 GeV. If we take A to have its value in the Polonyi model … the top-quark mass lies in the smaller range 140-195 GeV. … The renormalization group equation … tends to attract the top quark mas towards a fixed point of about 125 GeV. …".

However, Joe et al lost their nerve and caved when in 1984 CERN claimed to find the T-quark around 45 GeV.
Instead of saying that the CERN 45-GeV "discovery" was wrong (as indeed it was, with CERN embarrassingly "undiscovering" it over the next several years), they seem to have followed the sheepish herd of consensus exemplified by this quote from Mohapatra's book Unification and Supersymmetry:
"… An ingenious … method has been proposed by Alvarez-Gaume, Polchinski, and Wise … It is interesting that m_t lies in the range [between] 100 GeV …[and]… 190 GeV.
The recent discovery of the t-quark in the mass range of 40 to 60 GeV therefore rules out the simple-minded analysis …".

If Joe et al had stuck to their guns from 1983 to 1994, Fermilab data would have vindicated their predictions, and they could have claimed a great success for theory vindication by experiment.

April 9, 2006

Folks that **think** they know and understand Evolution Theory would really do good in reading Ernst Mayr: Ernst Mayr (EDGE) and Ernst Mayr (Amazon).

At least according to what i've read and heard, there's a huge gap between what is being called "evolution theory" and what contemporary neo-Darwinism actually is (the tantalizing evidence goes from fossils to virus and bacteria drug resistence, i.e., from ancient to modern times).

[]'s!

8. **Arun**
April 9, 2006

Most probably it is because of my shortcomings, but I do not see how any of the proposals of Polchinki's talk solve the problem posed at the beginning – namely, the gravitation of the Lamb's shift energy.

9. **woit**
April 9, 2006

Arun,

The idea of anthropic landscape solution to the CC problem is that for some particular points on the landscape all the large contributions to the CC like the ones from electron loops just about exactly cancel, leaving a CC close enough to zero for galaxies (and us) to be able to develop.

10. **LambchopofGod**
April 9, 2006

As you know, I was of course aware that Fox et al is a joke. Furthermore, at the time of the posting I believed, and I still do believe, that Sean thought it was a joke too, and that his reference to it was an extension of the joke. But I have no experimental evidence for this belief of mine……

11. **Sean Carroll**
April 10, 2006

I think that more people got the April Fool's joke than Peter is giving them credit for.

12. **boreds**
April 10, 2006

Yep, citing the paper hardly indicates that he doesn't get the joke.

13. **Arun**
April 10, 2006

Peter,
So there a near-continuum of landscape states, all with our standard model as the low-energy limit, but differing in contribution to the CC by stringy fields, so that in one of them, the CC comes out right? Or is it more that landscape vacua with the wrong CCs also have the wrong low energy physics?

I'd feel a lot less unhappy if it were the latter.

Thanks!
-Arun

14. **Arun**
April 10, 2006

> We can think of Fig. 2 to good approximation as representing the shift of the electron zero point energy in the environment of the atom or the nucleus. Thus we must understand why the zero point energy gravitates in these environments and not in vacuum, again given that our vacuum is a rather complicated state in terms of the underlying fields. Further, if one thinks one has an answer to this, there is another challenge: why does this cancellation occur in our particular vacuum state, and not, say, in the more symmetric SU(2) × U(1) invariant state of the weak interaction? It cannot vanish in both because the electron mass is zero in the symmetric state and not in ours, and the subleading terms in the vacuum energy (1.1) — which are still much larger than the observed V — depend on this mass.

So, either the landscape vacuum does the appropriate CC cancellation at one scale, and we still have the puzzle of which scale, or the landscape vacuum manages the magic of CC cancellation at all scales?

15. **woit**
April 10, 2006

Sean and boreds,

Looking at the six papers that referenced Fox et. al., my guess was that some knew it was a joke, but it is pretty clear that some didn't. I still find Polchinski's reference to it strange. Undoubtedly he knew about the joke, and maybe his reference to it was some sort of self-deprecating humor. But when there's a huge question about the predictivity of your research program, and you're writing an article defending it, ignoring the predictivity problem and putting in a reference to a joke paper where the lack of predictivity is the joke, seems to me exceedingly weird.

16. **woit**
April 10, 2006

Arun,

It's the former. There's no known reason why having the right small value of the CC would imply getting anything else right about low energy physics.

In the landscape, the CC is the same at all scales. There is one section of Polchinski's article where he discusses the possibility of a version of gravity that doesn't couple to the CC at all scales, but this has lots of problems that he explains.

17. **Arun**
April 10, 2006

Peter:
In the landscape, the CC is the same at all scales.

How is that magic accomplished?

18. **woit**
April 10, 2006

Arun,

All I mean is it behaves like a standard CC in Einstein's equations. This is just a constant. Probes of any wavelength see the same CC. This is standard gravity. Polchinski is discussing the idea of modifying gravity.

19. **Who**
April 10, 2006

Going back to your 23 August 2005 post
http://www.math.columbia.edu/~woit/wordpress/?p=245
which is closed so I cannot add a comment,

the book is available for order from amazon.uk for $21

or more precisely 12 pound ster. (hardcover)

http://www.amazon.co.uk/exec/obidos/ASIN/0224076051/026-6340214-9602016

the availability date they give there is 16 march 2006

ordinary US amazon gives a date of 25 april 2006 and has one review, but lists no price so it seems that amazon.uk is already shipping

20. **woit**
April 10, 2006

About the book,

The information on Amazon isn't correct. Last I heard, publication date in England is June 1. A few weeks ago I went over the final proofs, so they should start being able to print books soon, but I haven't seen any yet. Publication in the US should be sometime in September. I'm just starting dealing with the production people here for that version. It will probably have a different preface.

21. **anon**
April 10, 2006

"It will probably have a different preface." Oh, I see. The British version is different to the American one; it has a topless girly on page 3.

22. **Lubos Motl**
April 10, 2006

Peter, you are kind of crazy if you think that Polchinski does not realize that supersplit SUSY is a joke.

23. **Not a Nobel Laureate**
April 10, 2006

To put this anthropomorphic principle in perspective imagine the reaction in the condensed matter community if someone invoked the same principle to "explain" high Tc superconductivity.

Nothing more pathetic than a group of relatively smart people believing their own bullsh*t.

Henry Kissinger sum it up best after his retirement to academia.

"Why are academic battles so fierce?"

"Because the stakes are so low."

So it is with strings and their proponents.

24. **Hech Baan**
April 10, 2006

Dear Not a Nobel Laureate,

Anyone should understand that anthropic principle isn't part of the string/M-theory. It's a temporary way of making sense of some results. When we know more we'll be able to make predictions without relying on the anthropic principle.

Rest assure that if something is obvious to almost everyone then it's obvious to the scientists too.

25. **Scott Aaronson**
April 10, 2006

Peter, there's another difference between natural selection and the anthropic principle, one that to my mind is even more basic than testability. This is that natural selection is an "algorithmic workhorse" — a mechanism for amplifying low-probability events to higher probability. Start it up, and it takes you the rest of the way. It's a tautology with oomph, something any mathematician should recognize. Whereas the anthropic principle is an oomphless tautology.

26. **Not a Nobel Laureate**
April 11, 2006

Hech Baan wrote

"Anyone should understand that anthropic principle isn't part of the string/M-theory."

No, but a number of string/M-theory proponents invoke it to avoid question the merit of having so many in the field pursue this line of research.

"It's a temporary way of making sense of some results."

It's a way of avoiding physical reality.

"When we know more we'll be able to make predictions without relying on the anthropic principle."

That doesn't sound very promising given that you can't make any testable predictions by relying on the anthropic principle.

"Rest assure that if something is obvious to almost everyone then it's obvious to the scientists too."

Not in my experience.

27. **Who**
April 11, 2006

Obviously what gives natural selection oomph is reproduction.
Polchinski's "survivors survive" misrepresents the tautology, which is more like "the prolific proliferate"—-reproductively successful (genotypes) succeed in reproducing.

Polchinski:
Of course, the anthropic principle is in some sense a tautology: we must live where we can live.

Natural selection is a tautology in much the same sense: survivors survive. But in combination with ***a mechanism of populating a spectrum of universes or genotypes****,* *these ‘tautologies’ acquire great power.*

My comment:

One can imagine a centralized “mechanism of populating” a range of possible genotypes which operates randomly—where individuals do not reproduce individually but are produced by a central machine. Each is the expression of a random sequence: almost no individuals are viable—most come out of the machine dead or as unorganized mess.

If I understand Scott Aaronson’s remark, such a scheme has no oomph. It does not amplify low-probability instances of organization.
If his point is valid, then Landscape philosophers won’t get anywhere until they think of a way for nice universes to reproduce and thereby proliferate.

28. **Hech Baan**
April 11, 2006

Dear Not a Nobel Laureate,

Let’s face it string/M-theory isn’t perfect, but it’s the best theory we have today. It’s a pity that the theory is so complex that not everyone can appreciate the beauty and predictive power of it.

Sooner or later we will make a testable prediction without relying on the anthropic or any other questionable principle. At the same time we shouldn’t overestimate the anthropic principle’s role.

My advice to you is: be patient. There are much simpler things we don’t know answers yet (e.g. twin prime conjecture). Understanding physical reality is the most complex problem. Nobody expects quick or short answers. If the anthropic principle will get us there then so be it.

29. **knotted string**
April 11, 2006

Dear Hech,

Your belief that eventually a testable prediction will arise seems to have absolutely no scientific validity. It is just a belief, like the beliefs of religion.

The world has been patient for 20 odd years with various forms of string theory, and you advise us to be patient?

30. **anonymous**
April 11, 2006

Excellent post, “Who”. Nicely expresses the fundamental difference between the two.

31. **Arun**
April 11, 2006

I’m still scratching my head as to how the landscape produces a cosmological constant that is the same at all scales, when the physics accessible to us is not doing so. How does the landscape vacuum arrange for the appropriate cancellations at all scales?

32. **woit**
April 11, 2006

“Peter, you are kind of crazy if you think that Polchinski does not realize that supersplit SUSY is a joke.”

Lubos,

You don’t even bother reading what I write. You seem to have missed my comment about Polchinski:

“Undoubtedly he knew about the joke”

33. **Thomas Larsson**
April 11, 2006

Both Polchinski’s paper and the supersplit paper (v1) were uploaded on March 31. If Polchinski’s paper was also intended as an April’s fool joke, he surely fooled me.

34. **island**
April 11, 2006

Hech Baan Says:

Let’s face it string/M-theory isn’t perfect, but it’s the best theory we have today.

Didya hear the one about the string-tailed cat in a room full of rocking chairs?

… or the one about the stringy-haired hippie who wondered into barber camp?

~

This strongest implication of the anthropic connection to the forces of our universe is through evolutionary theory since the anthropic constraint on the forces indicates that there is very possibly a mechanism that enables the universe to (((convolve))) it’s characteristics inherently forward to higher orders of entropic efficiency, just like we humans did when we evolved from apes to harness fire… and beyond.

This obvious extension can’t be ignored because the TOE becomes the ToE when the anthropic principle explains “why” the forces cannot be unified.

Which has absolutely nothing to do with string theory, but you’d have to a real air-head to think that there is no connection between evolutionary theory and the anthropic principle.

35. **Tony Smith**
April 11, 2006

Who said "… Landscape philosophers won't get anywhere until they think of a way for nice universes to reproduce and thereby proliferate …".

Polchinski, in hep-th/0603249, said "… while it is difficult to select for a single vacuum of small cosmological constant, it is extremely easy to identify mechanisms that will populate all possible vacua –
either sequentially in time, as branches of the wavefunction of the universe, or as different patches in an enormous spatial volume.
… if the many vacua are metastable: inflation and tunneling, two robust physical processes, will inevitably populate them all …
But this is all that is needed! … Thus we meet the anthropic principle….".

In other words, Polchinski and the anthropic / landscape people are happy with reproduction and proliferation by "dumb" processes like inflation and tunneling that don't act to select "nice universes" – Who described such processes as "… a centralized 'mechanism of populating' a range of possible genotypes which operates randomly – where individuals do not reproduce individually but are produced by a central machine. Each is the expression of a random sequence: almost no individuals are viable – most come out of the machine dead or as unorganized mess …".
while
people like Who (and me) think that the processes of reproduction and proliferation should act to select "nice universes",
in the sense that evolution by genetic mutation and environmental requirements acts to select "fit" organisms.

In other words, my view is that nature is built upon processes that, in Who's words, "… amplify low-probability instances of organization …",
and
any landscape, anthropic principle, or whatever that just sort of randomly produces stuff will never produce any physics other than, in Who's words, an "unorganized mess".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – As to how to build a process that will "… amplify low-probability instances of organization …", maybe it might be productive to generalize the quantum computer / spin network viewpoint of Paola Zizzi expressed in gr-qc/0304032.
It also might be nice to look closely at exceptional algebraic structures, because, since they are "special" mathematically, they might be good at selecting/amplifying "special" physics structures.
In my view, it would be nice if such work received funding on the order of the current level of superstring funding. After all, as knotted string said to Hech Baan: "… Your belief that eventually a testable prediction will arise [from conventional string theory] seems to have absolutely no scientific validity. It is just a belief, like the beliefs of religion. The world has been patient for 20 odd years with various forms of string theory, and you advise us to [continue to] be patient? …".

36. **Hech Baan**
April 11, 2006

Dear knotted string and Tony Smith,

I wouldn't call it a belief. I would call it an educated guess. It has the same scientific validity as our confidence that one day we will prove the Riemann Hypothesis. The world was patient for almost 150 years with various approaches to prove the Riemann Hypothesis. And in that case I ask you to be patient too.

Alternatively, join the group of scientists addressing the current problems to appreciate the beauty and complexity of the nature (be it distribution of primes or Quantum Gravity).

37. **woit**
April 11, 2006

Hech Baan,

No, belief in string theory does not have ths same scientific validity as belief in the Riemann Hypothesis. There is overwhelming numerical evidence that the Riemann Hypothesis is true, zero experimental evidence for string theory. In the case of function fields (which are closely analogous to number fields), the Riemann hypothesis has been proven, which is one of several reasons to believe that a proof for the standard Riemann Hypothesis will be found. I've heard this analogy repeated elsewhere, but sorry, it really is complete nonsense.

And please, everyone, if you have something to say about the Polchinski paper, please do so, if you want to rant in an empty way about the anthropic principle in general, do this elsewhere.

38. **LambchopofGod**
April 11, 2006

I think Polchinski's paper raises a lot of interesting issues. I wonder if anyone can comment on what he means by "post-selection" of the cosmological constant [the last paragraph before his conclusion]?
Meanwhile, see the final sentence of
http://arxiv.org/abs/astro-ph/0604242
for an interesting new suggestion as to how the CC problem might ultimately be solved……

39. **Tony Smith**
April 11, 2006

Hech Baan said: "… Dear knotted string and Tony Smith … I ask you to be patient … Alternatively, join the group of scientists addressing the current problems to appreciate the beauty and complexity of the nature …"
and went on to say, further:
"… CC paradox: 'Landscape is huge. The probability that I live in a universe with a small CC is almost zero. In spite of this, I live in one of them. Now how is that?'
A possible solution – Antropic principle …
… If you find a better solution … then you can apply it to the CC paradox. Good luck. …".

To Hech Baan. Please don't assume that only conventional string theorists can deal with the CC paradox. For example (and here I am NOT mentioning my work to get into a discussion of its merits because Peter does not want his blog to get into such things, but am only mentioning it as one concrete example of an alternative to conventional string/M theory),
based on a generalization of Irving Segal's conformal structures related to gravity, I can and have calculated the present value of the ratio
Dark Energy : Dark Matter : Ordinary Matter
with the result 0.73 : 0.23 : 0.04
which is pretty close to the WMAP results.
Calculations are on the web as a pdf file at CERN CDS preprint EXT-2004-013

but they are not on the Cornell arXiv because I am blacklisted there.
They can also be found, with more details, in html format at
http://www.valdostamuseum.org/hamsmith/cosconsensus.html#wmap

Maybe my work is right, maybe it is wrong, or maybe it at least contains some seeds from which a useful theory that can be used to calculate (not relying on anthropic stuff) the CC / Dark Energy : Dark Matter : Ordinary Matter ratios that we see experimentally.

I am NOT saying, as Hech Baan is saying about conventional string/M theory, that my work is "the best theory we have today".

I am only saying that it seems to give a more concrete result than conventional string/M theory, and is therefore a possible counterexample to Hech Baan's assertion that conventional string/M theory is "the best theory we have today".

There may be many other models that may turn out to be more useful than either my model or conventional string/M theory (for example, some forms of loop quantum gravity, spin foams, etc).

My point is NOT to try to sell my model.
My point is that ALL possible approaches should be funded and explored,
and
that it is quite likely (given 20+ years of work by hundreds of very smart well-funded people on conventional string/M theory, resulting in failure to produce concrete results that can be compared with experiments)
that being "patient" and "join[ing] the group of [conventional string/M theory] scientists …" in such things as the anthropic landscape may well only lead theoretical physics into a Dark Age.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

40. **woit**
April 11, 2006

Lambchop,

That paper doesn't offer any way to solve the CC problem. Right now the anthropic "prediction" of the CC is too high by at least one order of magnitude, more if you let Q vary. The argument of this paper seems to be that if you observe planets in certain dwarf galaxies, then you could claim that the CC is too high by as much as three orders of magnitude, even keeping Q fixed.

This doesn't offer any positive prediction about the CC, it just holds out hope for one more piece of evidence against the anthropic explanation of the CC. There already is lots of evidence against the anthropic landscape, even if this particular new piece of evidence turns out to be possible, I don't think it will have much effect.

41. **LambchopofGod**
April 12, 2006

Errr….actually I was mainly referring you to the *last sentence*, where the author suggests that the CC problem will ultimately be solved when we receive an instructional broadcast from a more advanced civilization….. 🙂

42. **woit**
April 12, 2006

Lamchop,

Oops, seems that I sometimes don't read things carefully, and don't get the joke….

43. **a philosophy student**
April 12, 2006

> the anthropic principle is in some sense a tautology:
> we must live where we can live.
>
> Natural selection is a tautology in much the same sense:
> survivors survive.

Since terms are important in this context, this note:
These two terms or principles stand for different things:

When saying: 'we live where we must live' (AP), then on equal terms, concerning evolution, would be: 'we survive where we must survive'. Let's call it, for ease, the 'natural principle' (NP).

Going a bit further, we could modify NP, while keeping it on equal footage qua scope of meaning to AP, to: 'survivors survive because they càn survive'.

If we take this as a pricinple after the example of AP, then now we should try find the reason behind what the principle states, or we are stuck with our tautology.

But the difference between the two is of course that for NP the reason has been found, namely natural selection (NS), while for AP it hasn't, despite the two being put on equal footage here (in the quote), mixing the principle NP with it's reason NS, while for AP there's only the principle.

44. **a philosophy student**
April 12, 2006

I mean 'can' where I say 'must', twice, in:

"When saying: 'we live where we must live' (AP), then on equal terms, concerning evolution, would be: 'we survive where we must survive'. Let's call it, for ease, the 'natural principle' (NP)."

45. **boreds**
April 12, 2006

Peter

I guess lubos is referring to what you say in the posting above:

"the apparently serious reference to [70]"

rather than what you said in the comments, which is clearer.

In any case, I don't think it's that weird that Polchinski made a joke about the paper.

I don't know about the other five citations, but it would be hard to imagine they didn't realise it was an April fools if they'd read the paper.

46. **Who**
April 12, 2006

philos. student,
you might be interested in Scott Aaronson's comment in this thread
http://www.math.columbia.edu/~woit/wordpress/?p=372#comment-9623

I think it has something to do with what you are discussing. Perhaps you saw it and simply didn't think it germane to your points. But I think it does have some bearing. I expanded on Scott's a couple of comments later. See if you can make anything of the earlier discussion and if it fits with what you are saying.

47. **Shantanu**
April 12, 2006

Peter have you seen astro-ph/0604242 ? It talks about an observational
test of antrophic origin of cosmological constant. your thoughts on it?

48. **woit**
April 12, 2006

Shantanu,

I just wrote about that in a comment above, responding to Lambchopofgod, who was actually pointing to the kind of absurd end of the paper. But now, my comment is relevant, as an answer to your question.

49. **Shantanu**
April 12, 2006

Thanks Peter,. Sorry I missed your comment above. anyhow I am not sure how serious about the last sentence.

50. **Aaron Bergman**
April 12, 2006

To the point on the analogy between the anthropic principle and natural selection, it might be an oomphless tautology, but it doesn't need the same oomph as natural selection. As long as there's one universe with life in it, we could be in that universe.

51. **woit**
April 12, 2006

Aaron,

It's also true that we could all be a figment in the imagination of the Flying Spaghetti Monster. I wish someone out there who doesn't think this stuff is indefensible pseudo-science would, instead of defending it by invoking tautologies, give a plausible scenario of how it will lead to the kind of testable predictions that up until now everyone agreed were required before you called something science.

52. **a philosophy student**
April 12, 2006

Who,

My point is that Polchinski, besides like Peter says at other places in his paper, in this quote mixes the resp. situations of evolution and anthropics by his chosing of terms.

AP is a tautology, and as such, states facts. What Peter would like physicists to do is to search for a reason for these facts, a mechanism that explains the state AP refers to.

Now NS is such a mechanism, but of course for a different state of facts, namely for what I above, for easy of the discussion, have called NP.

AP does not have such a mechanism, and it is wrong to put both AP and NP on equal footing, as Polchinski does in the above quote, making it appear they are.

He should have written, instead of 'natural selection', something like 'survivors survive because they càn survive' (NP). This is a statement of facts, which can be, liguistically, and more important: logically, a tautology, but the term 'natural selection' cannot be a tautology for it is an empirical mechanism, nót a statement of facts which can be a logical tautology. But of course doing so would point out AP has no explanatory mechanism.

The correct use of these terms in this is important in (@ least) two respects:

1) in the context of string theory: as Peter points out:

> … trying to blur the difference between these two very different situations is not something a scientist should be doing …
>
> …… physicists who care about this credibility (of science) should not
> be claiming that an idea like the anthropic landscape has the same status as heavily tested and verified theories like that of evolution.

2) these days Darwin is under attack from 'unscientific' corners. It is in this respect that it is very important to be clear in one's choice of words. You cannot describe natural selection by 'survivors survive'. NS is much much more than that. By bringing NS (wrongfully) down to the level of a statement of facts it can be eassily misunderstood and attacked, eg by calling it a tautology.

On Scott's post:

> … natural selection is an "algorithmic workhorse" — a mechanism for amplifying low-probability events to higher probability. Start it up, and it takes you the rest of the way

This makes it appear as if NS is an always-sure way to an always-sure outcome. NS is an algorithm, granted, but one that relies heavily, not to say totally, on external input, ie the environment. This is a highly coincidential matter. Take eg the extinction of the dinos. Whether it was by an asteroid or not, fact is had they lived on, mammals would still be small mouse-like creatures hiding in small holes in the ground.

So, NS also has 'an sich' nothing to do with the probability of events. It will not change the low or high-probability of an event. It's all coincidence. It is a fact that human life is a very low-probability event in the universe, but that it excists here is not,
qua probability, due to NS, but to the occurence of the low-probability fact that after earth was formed, it gave rise to the necessary 'materials' for evolving life. This 'material' is then worked upon by the evolutionary mechanism NS, but the latter has nothing to do with the probability of the correct circumstances for evolving life being present.

Note: of course it's not only the circumstances on earth that are relevant, or low-probable, but also the distance earth-sun, the presence of a big object like jupiter swallowing comets and asteroids, the distance sun-center of the galaxy, aso.

A note on Jupiter: the point of Jupiter swallowing collision-course-objects means that life on earth has got the necessary time to evolve, as the dinos will be happy to point out.

Another note: this whole discussion depends on how you weigh the term 'low-probability'. 1/zillion may be considered low probable, but in an infinite set this still gives rise to an infinite amount. According to this reasoning, if our universe, and/or the multiverse, and/or whatever is infinite, then there are an infinite of worlds with intelligent human-like things on it – even discussing the same things we do now.

Even by this account it's not due to NS that there is a sure outcome of whatever you want, but it is due to the infinity of the 'initial state' it works upon.

So NS doesn't in fact necessarily has 'oomph' – @ least not when not considering the 'basic block', ie the gene, or, in Smolin's case, the black hole – and even in this case, again, it's not due to NS but to the
nature of the material it works upon.

Phew.

Sorry Peter if this is way to off, I only meant to make a humble first post here.

53. **Christine Dantas**
April 12, 2006

The Lithic Principle. The Liquid Principle. The Canid Principle (of course, man´s best friend must have some importance on all this). In summary, a multitude of principles to chose from in order to study the multiverse. I am sure among them there must be a Multiverse Principle (the Universe is the way it is so to allow for the existence of a multitude of others).

Now, seriously, I am deeply intrigued that I exist and see the Universe around me. I really would like to know why things are like that. The Anthropic Principle is fruitless to that end, in my opinion, by its own definition.

Christine

54. **Aaron Bergman**
April 12, 2006

Peter, we *really* don't have to go through this yet one more time.

Cosmological natural selection doesn't have the "oomph" that the real thing does, either, because nothing ever dies.

55. **Who**
April 12, 2006

because nothing ever dies

entire universes die

Aaron you brought up CNS. Scott did not mention it, nor did I. Is this because you have some new ideas about it, like "nothing ever dies", and want to discuss them?

56. **Aaron Bergman**
April 12, 2006

One can read between the lines in your comments.

The point is that one does not need a way to populate the landscape, a way for "nice universes" to reproduce or anything. Once you have a mechanism that produces a single universe which can support life, the anthropic principle holds.

There are a zillion different ways one can put some sort of measure on the space of vacua, if you feel like engaging in some sort of principle of mediocrity, but that's not the anthropic principle.

57. **Who**
April 13, 2006

You already said that Aaron, and Peter rebutted it. You said
… As long as there's one universe with life in it, we could be in that universe.

Peter replied*…give a plausible scenario of how it will lead to the kind of testable predictions…required before you {call] something science*
——————

Scott's original point was:

…natural selection is an “algorithmic workhorse” — a mechanism for amplifying low-probability events to higher probability. Start it up, and it takes you the rest of the way…

It is a powerful means of generating complex organization. (Perhaps the most effective mechanism we know of for doing this.)
Mere happenstance is not. Therefore, I think Scott’s point was, Polchinski made a poor analogy.

Do you think Polchinski made a correct analogy? So far your comment does not support this, but has been to repeat that a natural mechanism for self-tuning or amplifying low-probability events is NOT NEEDED, which is not quite on the mark. If you would like, please think up a reason why Polchinski’s comparison of biological Natural Selection to string thinkers’ Landscape speculation should not be considered far-fetched.

58. **Aaron Bergman**
April 13, 2006

Peter’s statement, true or not, is not a rebuttal.

I don’t really care all that much about how good the analogy between the anthropic principle and natural selection is; it’s obviously not a precise analogy. I’m just trying to clarify a few issues along the way.

59. **ksh95**
April 13, 2006

Peter Said:

> …”give a plausible scenario of how it will lead to the kind of testable predictions that up until now everyone agreed were required before you called something science…”

Didn’t Smolin do precisely this? All one needs is for the “*Universe-Creating-Mechinism”* to be dependent on a few measurable parameters.

60. **Aaron Bergman**
April 13, 2006

It depends on what you mean by predictive. There are a variety of way to populate a landscape of vacua; common examples are some sort of quantum mechanical superposition, tunneling, Smolin’s idea, etc. These will give different distributions of the population of vacua. The fundamental leap, however, is whether this population translates into a probability measure. If you make that leap, a sort of principle of mediocrity, you can make probabilistic predictions. Otherwise, one is simply left with the binary question of whether a particular vacuum gets populated or not.

61. **Chris W.**
April 13, 2006

The most galling thing to me about drawing the analogy with natural selection is that the variation upon which selection operates in biology is an inescapable empirical fact, whether or not you understand the underlying mechanism (and Darwin didn’t). This *observed* variation was Darwin’s logical starting point. He knew that it was the raw material with which animal and plant breeders worked, and realized that the essential logic of selective breeding applied even when the relevant contingencies—selective conditions—were not consciously arranged but arose accidentally, or as a result of the internal dynamics of an ecosystem.

In contrast, the multiverse is a purely theoretical construct. It is taken seriously mainly because it seems to follow from the joint application of quantum field theory and general relativity in cosmology. However, even this line of argument seems to have degenerated, insofar as the putative existence of the multiverse is now being taken to imply that observed laws in our “pocket” of the multiverse are “frozen accidents”, perhaps anthropically selected. This strikes me as self-defeating to the point of silliness, inasmuch as it was the ramifications of those laws that led us to assert the existence of the multiverse in first place.

(Lately I’ve been wondering why these points aren’t made more often. The self-undermining implications of the multiverse idea have occasionally been pointed out by other commenters on this blog.)

Memorials

April 9, 2006
Categories: Uncategorized

The May issue of the Notices of the AMS has memorial articles about two great mathematicians who passed away recently. The first is about Serge Lang and includes contributions from many people, including my Columbia colleague Dorian Goldfeld. When Lang died last September, I wrote a short posting here, but didn't want to go into much detail. He was a remarkable man, with many facets, but also famously difficult. The Notices article does him justice and is well worth reading.

In the same issue, Loring Tu has the first part of a long article about Raoul Bott, who died last December. It's a wonderful article concentrating on Bott's mathematical career and describing in detail the setting of some of his most important work.

Today I also ran across the sad story of the death of John Brodie. Brodie was a theorist who got his Ph.D. from Princeton and worked on gauge theory and string theory. Evidently he suffered from bipolar disorder, which was a contributing factor in his death. I never met him, but had seen some of his papers. Perhaps some of the readers here knew him personally.

Comments

1. **Derek**
   April 9, 2006

   Whut? No mention of Carleson winning the Abel?

   AMS Notices is really going down the tubes recently – in content, timeliness, character and sadly even readership (just look at the idiocy spouted on the letters page for examples).

   Are there any better magazines in the same genre out there?

2. **woit**
   April 9, 2006

   Derek,

   The Notices is definitely the best thing of its kind I know about. They're not especially timely (now there is news on the AMS web-site, including the Carleson news), but the articles are of high quality, and this takes time. I kind of agree about a lot of the letters….

3. **Jimbo**
   April 11, 2006

   I never knew nor met JOHN BRODIE, but I read Peter's post about his death.
   I would urge everybody to clik on the Rutland Herald link to the story surrounding BRODIE's life & death. It is a superbly written article about an extraordinary human being of the highest order, the stuff of which a movie could easily be made. Stephon Alexander, who knew BRODIE is quoted in the article.
   Someone needs to make sure a slightly compactified version of the Herald's obit is sent to Physics Today.

4. **Lurker**
   April 11, 2006

   Peter et al, I don't mean to spam, but what's the difference between "Not Even Wrong : The Failure of String Theory & the Continuing Challenge to Unify the Laws of Physics" and "Not Even Wrong: The Failure of String Theory and the Search for Unity in Physical Law"? I discovered this blog only recently, so I'm sorry if this is a FAQ.

   Lurker

5. **woit**
   April 11, 2006

   Lurker,

   The first is the UK edition, supposed to be released about June 1 by Jonathan Cape. I'm surprised it is on the US Amazon site, since Cape just sell in the UK and British Commonwealth. The second is the US edition, put out by Basic Books, should be released sometime in September. The two books will be mostly the same, except the US edition will probably have a somewhat different preface (and different cover, and perhaps slightly different subtitle).

6. **Pindare**
   April 12, 2006

   Thanks for the links, really interesting.

   Off-topic: a paper by John Conway and Simon Kochen on their "free will theorem" is out today http://arxiv.org/abs/quant-ph/0604079

7. **Tony Smith**
   April 12, 2006

   Jimbo said "… the Rutland Herald link to the story surrounding BRODIE's life & death … is … the stuff of which a movie could easily be made …".

   The Rutland Herald article said "… Brodie … took the supermarket job to escape the complexities of physics, he told friends, only to find his mind spinning with questions about bagging efficiency. ….".

   The article reminds me of scenes in the movie "A Beautiful Mind" such as, for two examples:
   those in which John Nash visualizes math ideas and in which such things as flocks of pigeons inspire such ideas; and
   those in which John Nash fled from police-type people.

The most recent four papers of Brodie that I saw on arXiv are:

hep-th/0301138 (with Damien Easson of Syracuse as co-author), entitled "Brane inflation and reheating", in which he "… construct[s] an inflationary brane world scenario from Type IIA string theory …" and goes on to say "… Using observational (COBE) data, we placed constraints on the parameters of the model … we can get more dark matter th[a]n visible matter. However, this dark matter will not be dark because it couples to the Standard Model gauge fields which we have taken to live on the D4-branes. To solve this problem we could put the Standard Model gauge fields on the D6'-branes, but this would modify our cosmological analysis. We leave the details of this model of dark matter for future work. …".

hep-th/0208191, entitled "Vortices under S-duality" dealing with QCD confinement;

hep-th/0107178 (with O. Bergman and Y. Okawa), entitled "The Stringy Quantum Hall Fluid", in which they say that the "… brane picture naturally explains various aspects of the quantum Hall fluid, such as the quantization of the filling fraction, and the charge and statistics of the quasiparticle and quasihole excitations …"; and

hep-th/0101115, entitled "On Mediating Supersymmetry Breaking in D-Brane Models", in which he "… present[s] a method for having first and second order phase transitions in brane constructions which might be relevant for modeling the Standard Model Higgs field …".

Note that these papers all deal with things (COBE inflation bounds, Dark Matter, QCD confinement, Quantum Hall effect, and the Standard Model Higgs field) that are subject to experimental / observational tests,
so
it seems to me that John Brodie's approach to physics was the type of approach that is needed to advance understanding of physics.

Since it has been over 3 years since he put a paper on the arXiv, I wonder whether he left any unpublished notes. If he did, I hope that someone will write them up and put them on the arXiv for posterity.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – The Rutland Herald article said "… people started talking … Why didn't the homeowner who heard the doorbell let it go rather than calling police? Why didn't the patrolman deal with the situation differently? …".
I hope that nobody is blaming the homeowner or the policeman.
If I had a knock on my door at 11 PM and did not recognize the person, I would probably call the police, and, if I were a policeman answering such a call, I would probably also tell that person "… maybe it would be a good idea to go door to door at 11:00 in the morning instead of 23:00 at night …".

8. **Chris W.**
April 12, 2006

Pindare,

Thanks for pointing to that paper. Not only is its content of deep interest, but its style is wonderfully engaging and lucid—head and shoulders above the typical arXiv posting. Given its authorship, I guess that shouldn't be surprising.

9. **Tony Smith**
April 13, 2006

Pindare and Chris W. both commented here about the Conway and Kochen paper at quant-ph/0604079 in which Conway and Kochen say (at page 9):
"… quantum mechanics and general relativity have been mutually inconsistent for most of their joint lifetime, an inconsistency that heterotic string theory resolved … by changing the dimension of space-time! …".

Most of the Conway and Kochen paper deals with their Free Will Theorem: If an experimenter has Free Will, then so must the particles in the rest of the universe outside the experimenter.

My question is:
Does the Free Will Theorem have anything to do with heterotic string theory's extra (beyond 4) dimensions of space-time,
such as some high-dimensional connection between expermimenter and the rest of the universe that correllates the experimenter's Free Will with the Free will of the particles in the rest of the universe,
or
was the reference to heterotic string theory a gratuitous irrelevant remark ?

Since Conway and Kochen say that Bohm and GRW are OK if they allow particles outside the experimenter to also have Free Will, and since Free Will of such particles is something with which I am happy (it has long been an accepted part of many cultures, such as Taoism, etc), it seems to me that such forms of Bohm and GRW are all that you need, and that heterotic string theory is not necessary.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – My descriptions of what Conway and Kochen say are based on the following excerpts from their paper:
"… The Free Will Theorem …
If the choice of directions in which to perform spin 1 experiments is not a function of the information accessible to the experimenters, then the responses of the particles are equally not functions of the information accessible to them.

… According to Bohm, the evolution of a system is completely determined by certain real numbers (his "hidden variables"), whose initial values are not all known to us. … What we do know about these initial values may be roughly summed up by saying that they lie in a set … St at time t … as t increases, St steadily shrinks … because the particles have made free choices. …

Bohm's theory so exorcised … is consistent with our assertion that particles have free will. … The exorcised form of Bohm's theory … prov[es] … the consistency of quantum mechanics … with … the Free Will property of particles. …

our assertion that 'the particles make a free decision' is merely a shorthand form of the more precise statement that 'the Universe makes this free decision in the neighborhood of the particles.' …

… Ghirardi, Rimini and Weber have proposed a theory [GRW] that attempts
to explain the reduction of the state in quantum mechanics by an underlying
mechanism of stochastic 'hits.' … in order to make the GRW theory relativistically invariant … the hits … need … some freedom (to be precise … they must be at least semi-free) …

… fundamental particles are continually making their own decisions. No theory can predict exactly what these particles will do in the future for the very good reason that they may not yet have decided what this will be! Most of their decisions, of course, will not greatly affect things – we can describe them as mere ineffectual flutterings, which on a large scale almost cancel each other out, and so can be ignored. … The authors strongly believe, however, that

there is a way our brains prevent some of this cancellation, so allowing us to integrate what remains and producing our own free will. …”.

10. **woit**
    April 13, 2006

    Tony et. al.,

    This is getting way, way, way off topic….

11. **Belizean**
    April 14, 2006

    Back on Topic:

    I never met Serge Lang, but he taught me calculus when I read his texts back in junior high.

    Thank you, Serge. RIP.

12. **Stephanie Frank Singer**
    April 15, 2006

    Serge Lang and I coexisted at the Math Department at Yale for four years. One winter night I was hanging out at LOM (Leet Oliver Memorial Hall, a.k.a., the Land Of Math) with Carlos Tomei, whose postdoc office was adjacent to Lang's office. We could hear the typewriter banging away next door. Bang-b-bang bang bang, with an occasional shloook (carriage return). All of a sudden the typewriter is silent, and we hear Lang speaking into the phone, in his outrageous French accent (think Steve Martin in the Pink Panther): “It is cold in here!” Crash (receiver hits cradle)!

    A beat.

    Then, clank, clank, clank, on goes the heat.

    This story is funnier to people who have lived in Yale housing and battled with the folks at physical plant.

13. **Stephanie Frank Singer**

    On the subject of memorials:

    Anyone interested in reading two letters George Mackey wrote to a young mathematician will find them linked to my low-tech website.

14. **woit**
    April 17, 2006

    Thanks Stephanie,

    I'll add a link to the letters to the Mackey posting, and reopen the comment section there in case anyone wants to discuss.

Schroer Notes and Other Links

April 13, 2006
Categories: Uncategorized

Bert Schroer has sent me some notes comparing the Lagrangian path integral and algebraic approaches to quantum field theory, which others may also find interesting. I have a very different perspective than he does, but have gone through the experience of at one time believing that basically all there is to QFT is to choose an action functional and then apply straightforward techniques to evaluate the path integrals you get. Non-perturbatively, this works beautifully for Yang-Mills theory, but runs into serious problems in many other cases, and it becomes clear that the path integral method, for all its virtues, does hide some very real problems.

Update: Some more notes from Schroer on AQFT.

Some other unrelated links:

There's an extremely well-known story about the young Gauss, and it turns out that, as almost always with such stories, the truth of what actually happened is rather elusive. American Scientist has a wonderful article about this by Brian Hayes entitled Gauss's Day of Reckoning.

The AMS has announced a Leonard Eisenbud Prize for Mathematics and Physics. It will be awarded every three years for a work published in the preceding six years that brings the two fields closer together. The first award will be made in January 2008. The prize was established by David Eisenbud (currently director of MSRI) and his wife in honor of Eisenbud's father, who was a mathematical physicist.

While I was away the Museum of Natural History here in New York sponsored a debate on the Multiverse, entitled "Universe: One or Many?". For some reports on the debate, see here, here and here. The last of these is from local blogger "mighty dasmoo", who really, really, doesn't like Michio Kaku.

The EPP 2010 Panel will release its final report to the public at a press conference in Washington on April 26.

Update: New Scientist also has some quotes from the "Universe: One or Many?" debate:

Kaku, of the City University of New York, spoke at one point of the possibility of tunnelling into other universes through space-time foam, harnessing the power of negative energy. "Genesis happens all the time," he said. "Continuous genesis in an ocean of Nirvana, and the ocean is an 11-dimensional hyperspace."

As Kaku spoke, Krauss, of Case Western Reserve University in Cleveland, Ohio, looked as if he was about to have an aneurysm. He turned to Kaku. "If there are an infinite number of universes," he declared, "I can't imagine one in which I agree with what you just said."

Update: Another report on the debate is here.

   April 13, 2006

   Bert,

   Interesting read.

   What other quantum systems differ greatly between operator and functional integral treatments, besides the spinning top?

3. **Lubos Motl**
   April 13, 2006

   I've read Prof. Schroer's text against the path integrals and it makes no sense to me. It is probably not even wrong.

4. **MathPhys**
   April 13, 2006

   Kaku is phenomenal. I'm always surprised by how he gets invited to speak at events next to respectable people.

5. **Bert Schroer**
   April 13, 2006

   Answer to JC:
   The functional integral representation in its strict measure-theoretic setting is limited to standard quantum mechanical Hamiltonians (kinetic energy + V(q)).
   The formal Duistermaat-Heckmann aspect (which leads to the "Schulman paradox") certainly shows up for any movement of a particle on a group manifold. The model must be integrable.
   By the way, I am not against the functional integral approach, I only indicate its limitations. In fact even in QFT where the approach becomes "artistic" there is nothing wrong with using it. My only plea is that one should not forget that it is artistic in order not to loose an enigmatic piece of future progress.

6. **ObsessiveMathsFreak**
   April 13, 2006

   From what I've read about Gauss, I think it's entirely possible that he was given either a dozen or so numbers, or a sequence of that length, and he simply added them up in his head. No formulae required.

   The part about his summation "trick" may have simply been tacked on later, or rather, the story was tacked onto the trick to pique the interest of otherwise disinterested students!

Certainly, there are people alive today who could mentally add up quite large lists or sequences of numbers, quickly and accurately, with no roughwork. It's well within the bounds of possibility that Gauss was such a person.

Tales often grow in the telling, but it's important to stick to the facts as well.

7. **jb**
April 13, 2006

I don't find the Gauss story dubious at all. I found the trick for calculating 1+…+10 when I was six or seven (of course, I failed to rediscover it when I was asked 1+…+100 several years later), and if some fellow mathematician told me he got 1+…+100 when he was eight, I wouldn't be surprised. Even more so, I have no reason to doubt the Gauss story — he did many much more impressive things and was also a whiz with arithmetic. And of course it's ridiculous to think that if it really happened, there would be primary documents proving it.

8. **Joe Zhou**
April 14, 2006

I've no doubt that Gauss just simply saw the summation trick when he looked at the problem. I consider myself rather dumb, always being one of the slowest in class to do an integral or to come up with proofs. But even I was visited by occasional flashes of insight in childhood. An uncle told me when I was 11 or so about how Zu Chongzhi from the 5th centry found the volume of the sphere by subtracting a cone from the cynlinder. That night, I applied Zu's principle to found the volume for any figure of rotation, and used that generalization to find the center of mass for the half circle, without any inkling of calculus or trignometry. And I am not even smart, almost failing the entrance exams for middle school that same year. Such flashes must be fairly common to intelligent people working on challenging problems.

9. **nayagam**
April 14, 2006

Brian Hayes has written some wonderful articles in American Scientist .The article on Gauss is of course good, but I liked his article [The Spectrum of Riemannium](#) more.

10. **robert**
April 14, 2006

A feat of infant prodigeousness that rivals that of Gauss' summation of a finite number of terms of an arithmetic series is Dyson's summation of an infinite number of terms of a geometric series, which he did to alleviate the boredom when put down in is crib for a nap

http://plus.maths.org/issue26/features/dyson/index.html

And we have this tale from an unimpeachable source.

11. **Chris Oakley**
April 14, 2006

A feat of infant prodigeousness that rivals that of Gauss' summation of a finite number of terms of an arithmetic series is Dyson's summation of an infinite number of terms of a geometric series, which he did to alleviate the boredom when put down in is crib for a nap

Yes, but the Nobel prize was awarded for taking an infinite series, most of whose terms are infinite, and getting a finite result. Maybe Dyson is just as glad not to be one of them.

12. **Karthik**
April 14, 2006

I once listened to Michio Kaku's interview on the BBC. It was like a big fantasy novel.

Science is increasingly becoming like religion where the scientists (priests) interpret the Universe and God and the rest of the world just go by it.

13. **Chris Oakley**
April 14, 2006

Well, Karthik, for an antidote I suggest that you get a copy of [Peter's book](#). It's not out in the U.S. until September, but even so thus far 24 out of 27 people approve of my positive review. Oh, and Peter, my Swiss bank account is #0103242345 (UBS Zurich).

14. **Michael**
April 14, 2006

Peter, could it be that it is you, rather than the path integral approach to QFT, that is hiding some very real problems? The problems people have with path integrals seems to be inversely proportional to their scientific accomplishments.

15. **ObsessiveMathsFreak**
April 14, 2006

> Science is increasingly becoming like religion where the scientists (priests) interpret the Universe and God and the rest of the world just go by it.

It might seem that way when one looks at theoretical physics, but it is not the case for the majority of science. Applied fields of science, physics, chemistry, biology, etc, etc have made huge leaps in the last decade.

Look at how much the world has changed in even the last ten years. Mobile communications are commonplace, the internet is widely accessable, medicinal drugs continue to improve, we are gaining a better understanding of our histories through archeology and new research, we have mapped the globe down to the metre levels.

Science is having an impact on people's everyday lives, ironically at the same time that people feel science is becoming more and more distant from everyday life.

16. **JC**
April 14, 2006

Bert,

Are there any easy non-Euler-Lagrange ways to treat theories with Wigner spins above 2, besides the free particle cases not coupled to anything (ie. Fierz-Pauli equations)?

17. **Chris Oakley**
April 14, 2006

JC,

As far as I remember, higher spin inconsistencies arise because physical massless higher spin fields derive from gauge potentials in much the same way that F_{\mu\nu} derives from A_\mu for spin 1. The free field actions are invariant under gauge transformations in these potentials, something which either must be preserved when one introduces interactions, or generalised (e.g. Yang-Mills). This turns out to be impossible for s > 2 because one cannot write down a interaction that is gauge invariant for all the fields in the coupling (one is presumably not allowed to use the gauge-invariant field strengths here). If one is not using the action principle one would still require gauge-invariant couplings, so I do not see that one would be better off.

18. **Alejandro Rivero**
April 14, 2006

Feynman integral is just a dirac delta' to guarantee the extremality (say, the minimum) of the Lagrangian, but h-regulated. The point that quantum mechanics is the consequence of forbidding the h->0 limit in differential operations was guessed first by Pauli in 1923 (http://documents.cern.ch//archive/electronic/other/pauli_vol3//sommerfeld_0463-2.pdf) upon contemplation of landé j(j-1) formulae and this in turn inspires Matrix Mechanics.

19. **Tony Smith**
April 15, 2006

JC asked about high-spin particles, and Chris Oakley replied, mentioning that techniques like gauge invariance don't work for spin greater than 2.

Weinberg, in Volume I of his work The Quantum Theory of Fields (Cambridge 1995) at pages 243, 244, and 253 describes the high-spin situation in a bit more detail:
"… It should be mentioned that from time to time various difficulties have been reported in the field theory of particles with spin greater than or equal to 3/2. Generally, these are encountered in the study of the propagation of a higher spin field in the presence of c-number external field. Depending on the details of the theory, the difficulties encountered include non-causality, inconsistency, unphysical mass states, and violations of unitarity. …
… there are good reasons to believe that the problems with higher spin disappear if the interaction with external fields is sufficiently complicated. For one thing, there is no doubt
about the existence of higher-spin particles, including various stable nuclei and hadronic resonances. If there is any problem with higher spin, it can only be for 'point' particles, that is, those whose interactions with external fields are particularly simple. …
… both higher-dimensional 'Kaluza-Klein" theories and string theories provide examples of a charged massive particles of spin two interacting with a electromagnetic background field. …
… in order to construct a theory of massless particles of helicity +/- 2 … gravitons … that incorporates long-range interactions,it is necessary for it to have something like general covariance. As in the case of electromagnetic gauge invariance, this is achieved by coupling the field to a conserved 'current' theta ^ mu nu , now with two spacetime indices, satisfying d_mu theta ^ mu nu = 0. The only such conserved tensor is the energy-momentum tensor,
aside from possible total derivative terms that do not affect the long-range behavior of the force produced.
The fields of massless particles of spin j greater than or equal to 3 would have to couple to conserved tensors with three or more spacetime indices, but aside from total derivatives there are none, so high-spin massless particles cannot produce long-range forces. …".

I love the Lawrence Berkeley National Lab bubble photo of 'universes sprouting off' at http://www.world-science.net/exclusives/060330_multiversefrm.htm

My baby niece can blow lots of bubbles like that. So I wonder if Scientific American will do a feature about her model of the multiverse? 😉

21. **Bert Schroer**
April 15, 2006

Here is a summary answer to some questions concerning higer spin.
The important aspect of higher spin particles is neither the Lagrange setting not the equation of motion (E-L or not), but rather the formula which expresses pointlike covariant fields in terms of Wigner creation/annihilation operators (in momentum space!) and u-v interwiners (interwining the canonical unique m,s Wigner representation with the infinitely many covariant spinorial representations). Looking at such a formula one knows exactly in what physical Fock space this fields lives. Any such field can be used to define a polynomial interaction within the setting of causal perturbation theory (and if you have done this with one spinorial choice you can transform that interaction into any other choice of linear (in Wigner operators) field "coordinatization"). Fields of this type which in addition arise from field equations (i.e. the generic solution of the field equation obeys that formula with the intertwiners) are known for any spin e.g. the Bargmann-Wigner equations for (m,s) representations for m>0. The short distance behavior of the two-point function for such pointlike field becomes more singular with increasing spin. This can be overcome by not insisting in pointlike fields but allowing spacelike semiinfinite string-localization (not string theory!). In that case the intertwiner functions are more complicated and although only one physical Wigner spin enters, there are infinitely many spinorial representations (namely all which belong to the same physical spin) which enter (all this is contained in a paper which will appear soon in CMP, see also (math-ph/0511042). In terms of localized fields this amounts to a field which depends simultaneously on x and on a spacelike direction e (a point in de Sitter space of one dimension lower). In that case the field A(x,e) fulfills the causal localization of a string starting at x and going in e-direction to spacelike infinity. It fluctuates in both x and e and the e-fluctuation is the reason why the fluctuation in x can be milder than in the pointlike presentation of Wigner (m,s) particles. In fact the short distance behavior in x for this string-localized description does nit increase with spin! This makes it very interesting to look for a perturbation theory of string-like higher spin fields (work in progress). All these ideas are outside of Lagrangian quantization but inside the setting of modular localization. Even more fascinating is the modular localization approach for zero mass. I am very time pressed, but I will come back to this point (meanwhile you can have a look at the above reference where all these cases are treated in detail.)

22. **a philosophy student**

> …
> Science is having an impact on people's everyday lives, ironically at the same time that people feel science is becoming more and more distant from everyday

life.

There's a relative huge gap between science and applied science – *technology*. People see technology gradually evolving and by this are not amazed at new applications appearing, and excisting ones getting better, more sophisticated. Inherently technology is close to everyday life.

'Real' science, through time by its very nature probing deeper and deeper into the fabric of reality, has got involved with issues far away from everyday life. Nanotechnology, genetic manipulation an such still have an imaginable connection with future everyday life, but allready generate an awe feeling. Things as neuroscience and consciousness research, and multiverse theories even more. By claiming some deeper and fundamental knowledge, especially when bearing on excistence and human life, scientists, one can imagine, could evoke religious-like feelings, for this is what religion is all about.

23. **Bert Schroer**
April 16, 2006

In previous notes I explained the difference between (interpretive) autonomous and metaphoric arguments in an example taken from QFT. Perhaps another example of more immediate interest is the way how chiral QFT serves to solve some problems in higher dimensional massive QFT and how it enters as a basic structure in the construction recipes of strings which brings me back to the main theme of this Weblog.
In 4-dimensional QFT it is the holographic projection which recycles the original ambient spacetime indexing of quantum matter into a new indexing which associated to the causal horizon of the latter (the algebraic substrat is preserved but its spacetime indexing is radically changed). In the latter the original bulk matter appears as a transversely extended chiral matter (and in general the inversion will not be unique without additional information). The ambient quantum matter fluctuates (vacuum polarization) at the causal horizon of the ambient localization (half the lightfront in case of a wedge, the lower mantle of a double cone in case of a double cone localization) wheras the holograpic projection fluctuates only in lightray direction at the boundary of the lightray extension. If one's main interest is to study extensive quantities (energy, entropy) of the localized bulk (caused by vacuum polarizations at the boundary of the bulk) it is easier to calculate after the holographic projection instead of doing this directly with the bulk matter. What remains of the original bulk fluctuation is the vacuum polarization at the end of a lightlike interval. Some results can be found in hep-th/0511291. The role of chiral theories in the recipe for string construction is completely different. It is not appearing in form of a holographic projection but it is there from the beginning in form of a source space of a QFT whose "field-value space" (target space) is the arena of the quantum matter, except that it lacks the most important property of direct target quantum fluctuation. The only fluctation is that of chiral source theory (factorially) repeated 24 or 10 times (note that in the QFT holography the chiral theory is part of the spacetime-indexed original ambient matter). In this way deep and very interesting mathematics of modular forms is processed into metaphorical physics. It is more or less evident that a mathematical formalism whose physical interpretation is metaphorical instead of autonomous may activate a messianic expectation. It is therefore not surprising that in a recent article of a mathematician (hep-th/0601035) one finds the following remakable statement: "The rising number of string theorists is a good indicator of confidence that string theory (or, at least, the existence of supersymmetry) will be confirmed in accelerator experiments and in astronomical observations and that this can happen pretty soon". It is also not surprising that the foot-soldiers of such a metaphoric science become fundamentalistic. The academic version of cutting off the head of an infidel seems to renounce the hospitality to anybody whose critical remarks put some of the metaphors into question
(http://rivelles.blogspot.com/2006/03/ideology-sociology-and-psychology-of.html). This also shows plainly why John Horgan's terminology of calling the post string era of metaphoric physics "ironic science" does not fit this new reality. The foot soldiers of this new particle physics fundamentalism cannot be accused of any ironic attitude whatsoever.

Recently I sometimes asked myself whether Witten had any idea what strange monoculture his string theoretic creation would develop into. The only final logical step for a seemingly irrevocably metaphorical theory is that of Susskind and Polchinski and it would be interesting to know what holds Witten (and Gross) back from taking that ultimate anthropic step.

24. **JC**
April 16, 2006

Bert,

In principle, can the algebraic qft (aqft) framework derive an exact non-perturbative S-matrix solution for theories represented by, say:

– real scalar fields with a phi^4 quartic interaction in d=1+1 spacetime dimensions?
– a Thirring model with a four-Fermi interaction in d=1+1 spacetime dimensions?

(It would be impressive if this can be done easily in practice for other theories like phi^4 theory and Yang-Mills in d=3+1, or any number of spacetime dimensions).

At this point I don't know whether I should be impressed that aqft can derive exact S-matrix solutions for some special cases in d=1+1, corresponding to elastic scattering with no particle production.

In your paper hep-th/0003243, you show that theories in greater than 2 dimensions have a trivial S-matrix if tempered polarization-free generators (PFG) are used, and that theories in d=1+1 have no particle production if tempered PFG's are used. For a theory representing real scalar fields with a phi^4 quartic interaction in d=3+1, what special properties would the PFG's have to possess such that the S-Matrix is nontrivial and agrees with the ordinary perturbative qft results?

25. **Aaron Bergman**
April 16, 2006

If one produced a genuine anything for phi^4 in 3+1D without a cutoff, that would be worrisome. As I remember it, that theory has a Landau pole.

26. **Bert Schroer**
April 17, 2006

The simplicity of the family of theories which correspond to tempered vacuum-polarization-free generators of wedge-localized algebras is their algebraic Zamolodchikov-Faddeev algebra structure. The S-matrix appears simply as coefficients in that algebra. The double cone localized operators have already the full infinite vacuum polarization clouds (visible in the explicitly computed formfactors). The correlation functions are already extremely rich and complicated. Yes you should be impressed; no other approach has been able to achieve this. The massive Thirring model (Sine-Gordon) is among these models. But in general this approach does not start with Lagrangian names. It does not know what the name phi to the fourth power means because it is conceptually totally different and that name has no intrinsic meaning. Perturbation theory indicates that the latter has particle production and is not factorizing.
Outside factorizing theories wedge generators have a much more difficult structure and the aim would be to come to a perturbative understanding. This perturbation theory is expected to show the true frontier between sensible (alias renormalizable) and nonsensic theories. One expects that any theory which was renormalizable in the standard perturbation theory of pointlike Lagrangian field will also remain sensible in the new setting.

27. **Brett**
April 17, 2006

This discussion has raised an intriguing question in my mind. Normally, in QFT, there is an extremely unattractive division of how the fundamental parameters that describe the theory are introduced. Most free parameters are introduced in the Lagrangian, but that alone does not determine the physics, except in trivial cases. In sufficiently “nice” theories (e.g. anomaly-free gauge theories), the regulators that can be used are severely restricted, and those available all give equivalent results. (In contradistinction, in an anomalous gauge theory, there are generally no good regulators to use.) In this case, the regulator can be (almost) banished from the physics, and this is just perturbative renormalizability.

In phi^4 theory, much the same thing holds perturbatively, but nonperturbatively there’s a problem. It would be very interesting in AQFT gave a nonperturbative definition of this theory, with a cutoff, that did not separate the interaction and the regulator the way we ordinarily do. As a test of whether this kind of thing may be possible, I suggest looking for theories in 1+1 dimensions that look like the chiral Schwinger model, because that model is exactly soluble, but there is a regulator dependence in the final spectrum. If the regulator parameter could be encoded in the same way as the coupling in this theory, it would be quite interesting.

28. **Bert Schroer**
April 17, 2006

From a perturbative approach for wedge generators one does not expect anything new in case the models were renormalizable in the standard sense. But it could be that some of the models which one presently discards as nonrenormalizable may actually lead to perturbative expressions with a finite number of physical parameters. In any case these are presently pure speculations since such a “on-shell” perturbation theory has not been formulated and hence the approach based on modular localization remains limited to factorizing models.
I would like to return to the issue of functional integration since there seems to be a widespread misconception. Of course there are many quantum mechanical models for which the path integral representation has a mathematical meaning in terms of rigorous measure theory. However this does not mean that one can perform explicit analytic calculations. Take the hydrogen atom. Even though the functional representation makes sense it is not known how the important property of integrability (which makes the problem operator-solvable) is encoded in the integral. Since one knows the result from standard quantum mechanics one can of course add recipes to the functional integral which will lead to the known result; but this can hardly be called mathematical physics and is just a game of personal entertainment.
The fact is that besides interaction-free systems and camouflaged free systems (as the Schwinger model) there is no known case where you can base exact analytic calculations on functional integrals. Nevertheless the functional integral is useful for quasiclassical approximations and for perturbation theory and (as a result of its superficial geometric classical appearance) has a strong intuitive appeal.
In a previous remark I said that the functional integral in QFT is a bit deceiving because when you want to compute explicitly renormalized correlation functions the formal elegance of that functional expression on a piece of paper is of not of much use; you have to make your hands dirty and add a lot of additional wisdom and tricks which the elegant formula did at most “morally” (I used the word artistic) contain but not factually. The algebraic approach is more honest and more equilibrated. You list the properties you want (taking account of the singular nature of pointlike fields) and what you get at the end fulfills precisely your initial requirements. In the functional approach to QFT this is not quite so (as I previously explained).

29. **JC**
April 17, 2006

Bert,

(Silly question).

Is there a well defined “limit” in the aqft approach which reproduces the functional integral for a system like the Thirring model (for example)?

30. **Bert Schroer**
April 18, 2006

JC,
Not that I know. For the Euler-Lagrange equation of the Thirring model (massless or massive) the nonlinear term can be defined in terms of a Schwinger point-split limiting procedure. But a Lagrangian action is not really part of the quantum world (it is conceptually somewhere between classical and quantum) and it is unclear what such point-split formulation (related to operator product expansion) means in such a measure-theoretical classical setting.

31. **Robert**
April 18, 2006

I have only glanced over Schroer’s notes briefly, but there seems to be a point that in the algebraic setting (causal perturbation theory to be precise) one can do the perturbation at the algebraic level and only as a second step consider the representation theory in terms of states (i.e. linear, positive, normed functionals on the algebra of observables). Does Schroer claim this is not possible in the path integral setting? I always thought, the state (important especially in a curved background where you don’t have a prefered Minkowsky vacuum) is encoded in the path integral in the boundary conditions of the fields you integrate over. But as always, I may be wrong.

32. **JC**
April 18, 2006

Bert,

In the aqft framework, how exactly is the S-matrix a “purely” quantum object (as opposed to being between classical and quantum)? Do you mean that the aqft derived S-Matrix is the unique solution of a well defined inverse-scattering problem?

Are there any rigorous proofs which show that for a particular set of asymptotic scattering data (ie. incoming and outgoing particle states, crossing symmetries, number of spacetime dimensions, etc …), there exists a unique S-matrix in the aqft framework?

33. **Bert Schroer**
April 18, 2006

Robert,
functional integral representations require for mathematical reasons a Euclidean setting, but generic QFT in CST is totally outside a Osterwalder-Schrader setting. If it would not be outside then the state information would indeed be expected to reside in the boundary condition because this is the only freedom at one’s disposal.

34. **Bert Schroer**
April 19, 2006

JC,
it is only for factorizing models that the bootstrap construction of the S-matrix can be separated from QFT (which then can be constructed in a second step via the wedge generators). In the general case the S-matrix and the generators have to be constructed together in an iterative manner (as a scenario this was explained in m]one of my papers) but there are yet no concrete results. The reason why the S-matrix plays such an important role in nonperturbative construction is that in addition to its well-known role in scattering theory it determined the modular localization structure of wedge algebras (this is relatively new).
The inverse scattering problem for a given S-matrix with all the crossing and unitarity requirements has indeed a unique associated QFT if one assumes that formfactors fulfil the crossing property (this is true for factorizing models but it has not been derived in the generality one needs it from the principles of QFT).

35. **Alejandro Rivero**
May 5, 2006

For AQFT, I was very afraid that after the retiring of Haag it was going to be a dead field; Araki was active but very busy into politics of the IAMP sociery, and note that also Doplicher did a small jump to noncommutative spacetimes via his energy bkackholing relationship, so if he did not left the field, at least he put it in the backburner place. In Gottingen, Borchers did some continuity but very restricted to 1+1 field theory.

When student, one day I sneaked into Luruper Chausse theoretical library and sit in a small working table. There scattered on the table there were the manuscripts of all the papers Haag had received for editorial task in Comm Math Phys and similar journals; some assistent was surely ordering them for final archival.

In later years I have remembered this as a signal of exhaustion of the field too, to my own regret. I think a resuscitation will not be possible without (until?) reaching a depper understanding of the C* geometric work: non commutative manifolds, tangent groupoids, Hoft thingies, etc…

36. **Bert Schroer**
May 5, 2006

Alejandro Rivero,
The scientific situation is not quite as bleak.
There are new and very exciting ideas in the offing. If everything goes well we can hope for a second cataclysm (the first one was of course renormalized perturbation theory). As was the case already with renormalization theory, it will strengthen, deepen and significantly extend the old principles. The name "field" in QFT will more refer to its historical origin than to the new conceptual content.
The high mathematical and conceptual barriers you are mentioning are not necessarily an impediment. They maintain high standards and prevent that sociological effect which results if too many physicists are undergoing a bose-condensation along the lines of a monoculture. I am by no means elitist and anti-democratic but if too many researchers work on one problem this tends to create confusion and regress instead of progress just as you see if you follow the blogs on string theory in this weblog.
Mathematics is of course very important but is should never be allowed to run amok; the tuning between particle physics and mathematics is a very fine one and certainly I would be the last to plead for a return to a mathematical stone age in physics. Physical concepts should be always in the helm and the best situation is if they tell you what kind of mathematics is best for them.
Naturally if you work under such conditions there are very strong restrictions, not only from experiments but also (and this is particularly serious for theoreticians) with past concepts and principles. It is very far away from the "everything goes" maxime of string theory. This kind of conceptually-geared work needs more time and is certainly in a strong tension with the high impact index attributed to the fashionable subjects.
The question of whether there will be a future of particle physics which is worthy of its past depends presently very much on whether young intelligent, courageous and innovative young theoreticians in particle physics will find enough time to test their innovative ideas on past achievements or whether they will be "abgewickelt" (to borrow a German word which was very popular when the "Wessies" took over the academic institutions of the GDR) before they can accomplish this task and replaced by string theorists with a higher production efficiency.

The Jasons

April 15, 2006
Categories: Book Reviews, Uncategorized

One of the less well-known parts of the history of particle physics is the involvement of many prominent theorists in research (often classified) conducted for the U.S. military through an organization known as "Jason". My advisor at Princeton (Curt Callan) would disappear for a couple months each year to La Jolla and I remember hearing about Jason from various people back then. Unlike at Harvard, quite a few of the faculty at Princeton from those days were involved with Jason at one time or another (besides Callan these included Sam Treiman, Freeman Dyson, Roger Dashen, Val Fitch and Will Happer), and this showed itself in various ways, including an unusual degree of interest among Princeton physics professors in the question of how sound propagates in the ocean.

There's a new book out about the group, written by Ann Finkheimer and entitled [The Jasons: The Secret History of Science's Postwar Elite](). It's based on many interviews with Jasons, and tells the story of the group very much from their point of view.

Jason was founded in 1959, with funding from ARPA (now DARPA, Defense Advanced Research Projects Agency), and was nominally associated with IDA (Institute for Defense Analyses). It followed on various other attempts to set up theorists as consultants to the defense department, attempts whose organizers included Wheeler and Wigner. Charles Townes was largely responsible for starting Jason, but its first chairman was Murph Goldberger, and it was his wife who gave the group its name (based on Jason and the Argonauts, in search of the golden fleece). Murray Gell-Mann was a member of the initial steering committee.

Members of Jason gather each year for a summer session of working on various projects, some involving classified military research, some not. About half the reports they generate are unclassified. For a selection of these, and to get some idea of the sort of thing they work on, see here. In recent years the group has branched out to study many topics involving biology, and to include many non-physicists (mathematician Fields medalist Michael Freedman is rumored to have been a member).

In 2002 DARPA stopped funding Jason, in a fight over an attempt by DARPA to impose some new members on the group that they didn't want. This led to the group getting a new funding source: DDR&E, the umbrella for all defense research.

Over the years Jason has worked on many different topics, including anti-submarine warfare (thus the interest in how sound travels in the ocean), ballistic missile defense, adaptive optics and many, many others. It was most controversial during the Vietnam war, when as many as nine Jasons (including Sam Treiman and Steven Weinberg) resigned for a variety of reasons, from moral objections to the war to feelings that they were not doing anything effective.

The Finkbeiner book doesn't really do justice to the difficult moral issues involved in Jason's activities during the Vietnam War years. One early Jason report on Tactical Nuclear Weapons in Southeast Asia, by four authors including Freeman Dyson and Steven Weinberg, reached the rather obvious conclusion that the use of nuclear weapons in guerilla warfare wasn't a very good idea. It's not clear who if anyone at the Pentagon thought otherwise. For extensive background about this, see here.

Much of Jason's activity during the Vietnam War involved attempts to set up an electronic barrier to stop the North Vietnamese from infiltrating troops and supplies to the South. This was partly motivated by the fact that it had become clear to the military that bombing the North wasn't working, something that Jason knew, but was not revealed to the American people until the release of the Pentagon papers by Daniel Ellsberg. As part of the electronic barrier effort, Murray Gell-Mann spent time in the jungle in Panama testing out various pieces of equipment. For a very different perspective on the question of Jason and Vietnam from that of the Finkheimer book, see the 1972 article The Story of Jason from the web-site of Charlie Schwartz at Berkeley.

Many of Jason's most successful reports over the years have played the role of shooting down a bad idea (like nuclear weapons as a counter-insurgency tool). For a recent example, see the Hafnium bomb, which is the subject of a forthcoming book entitled Imaginary Weapons : A Journey Through the Pentagon's Scientific Underworld. It's unclear what Jason's current activities in classified military research consist of, but presumably counter-terrorism and how to fight insurgents in Iraq are two important topics. Despite the clear analogies with Vietnam, the war in Iraq has so far been a much less contentious issue in the U.S. One hopes that those physicists involved in helping the government pursue it will do better this time than the previous time around.

Update: There's a review of the book by John Horgan in this week's New York Times Book Review.

Update: For a right-wing ideologue review of the book, see the New York Sun, where the reviewer seems to believe the only problem with the Vietnam war was the "contemptible" people opposing it, "the ideologues on the left, who were busily dismantling the nation's colleges and universities at that time."

1. **Tony Smith**
   April 15, 2006

   With respect to DARPA's 2002 decision to stop funding Jason, a 13 May 2002 Mercury News article by Jim Puzzanghera at
   http://lists.jammed.com/ISN/2002/05/0090.html said in part:
   "… The dispute, according to members of Jason, stems from an attempt by the director of the Defense Advanced Research Projects Agency, known as DARPA, to force the traditionally self-selecting group to accept three members. Among the three are two executives from Silicon Valley, one from an Internet-related company and another from a computer firm, said one member of the group, who, like other Jason members, declined to name the individuals. The third person is an engineer from the Washington, D.C., area. The Jasons … said the three did not meet the group's rigid standards, which include having significant research accomplishments, being a tenured professor at a research university and being willing to commit to a lengthy annual summer research session. When the group refused to accept the three earlier this year, DARPA revoked its $1.5 million annual funding, Jason members said. …
   DARPA Director Tony Tether declined to comment on the dispute. Agency media officer Jan Walker … said the reason DARPA ended its financial support for the group was because Jason failed to adapt to the times. … Walker said … 'After the Cold War ended, a lot of the technology development moved toward information technology, and the Jasons chose not to lose their physics orientation to focus on DARPA's current needs.' …
   Steven Koonin … chair of … Jason['s] … steering committee … said … 'We still write reports
   that have equations in them. I don't think there's any other group that does that …' …".

   If Koonin's 2002 statement about equations is true, then I guess a Dark Age had, by 2002, already come to the USA.

2. **knotted string**
   April 15, 2006

   That report where they analyse the use of fallout radiation to form a 200-mile barrier to stop Vietcong attacks is a bit horrifying.

Hans Bethe was advocating clean nuclear weapons in March 1958, http://worf.eh.doe.gov/data/ihp1b/7374_.pdf page 9:

"The use of clean weapons in strategic situations may be indicated in order to protect the local population."

They detonated a 95% clean 5 megaton "Navajo" at Bikini Atoll on 11 July 1956 and then 9 megaton "Poplar" – after Bethe's positive report – on 12 July 1958. Low fallout data for "Navajo" shot: http://worf.eh.doe.gov/data/ihp1c/0881_a.pdf

There's a conflict between the scientific humanitarian approach and the military tactics of using napalm and agent orange in Vietnam. In Iraq they used depleted uranium shells. Is anybody interested in reducing the potential impact of weapons on civilians anymore?

3. **secret milkshake**
April 15, 2006

1. Clean thermonuclear weapon research was politicaly motivated. It was used as justification for founding the second lab (Livermore) that was competing with Los Alamos at the time. Livermore was sold on the premise of innovative designs and the clean hydrogen bomb was supposed to be one of them. In reality any megaton explosion produces a horrible falout.

It soon became obvious that it is difficult to miniaturise the clean thermonuclear bomb enough to fit on top of balistic or cruise missile. Clean bombs have the natural uranium (or low-enriched) uranium jacket replaced with lead. The rule of thumb is that they have about 50% yield and at least 150% weight of the similar design with the uranium jacket. The use of "clean" nukes in civil engineering (digging ports, re-vigorating exhausted natural gas fields) did not arrive and army did not like clean nukes anyway – for deterrent purpose, the produced falout is "added bonus'

2. The Weinberg-Dyson report against using nukes in Vietnam basicaly said "we would not achieve much by nuking the trail, the collateral damage (need to evacuate all civilians from the huge contaminated area) would be excessive and if someone gave a small nuke to Viet-Cong, our troops would be much more vulnerable to nuking than VC were to our nuking because we have large military bases and they do not."
It is not clear if Russians or Chinese would have given a nuke to Viet-Cong, in retrospect, so this last part of argument seems iffy.

4. **knotted string**
April 16, 2006

Thanks for clarifying the weight increase/ yield reduction issue with Bethe's project.

Why didn't Weinberg's electronic barrier work?

5. **Tony Smith**
April 16, 2006

As to Jason's "electronic barrier to stop the North Vietnamese from infiltrating troops and supplies to the South" and knotted string's question "Why didn't Weinberg's electronic barrier work?",
I can give an anecdotal explanation based on what I saw when I was at Ga Tech (superannuated grad student) during the Atlanta Olympics. The Olympic Village was in the center of Ga Tech. It was totally surrounded by a fence with electronic sensors with only a few well-guarded points of entry. The security force was USA Army Rangers, who were without exception very efficient, effective, courteous, and polite.
A friend of mine and I were walking near the fence (outside) and one of us inadvertently touched the fence. Within seconds there were overhead helicopters and armed ground troops. They saw that we had not realized that the fence (it looked like ordinary chain link) was an electronic sensor system, so they told us it was a sensor fence and please don't touch it again. We said OK, thanked them for their courtesy, and apologized for the inconvenience. They said, think nothing of it, we expected people might inadvertently touch it from time to time, and we have no problem dealing with that. What is driving us crazy is the squirrels.
IIRC, the Vietnam Barrier was never a single united fence (too much "border"), but electronic sensors were placed (often by air drop) on the "boundary". When a sensor went off, air strikes could be sent into the area. They killed a lot of tigers. (the Vietnam sensors sensed animals (including people) by such techniques as "smelling" urine, and mammal urine is mammal urine)

Tony Smith
http://www.valdostamuseum.org/hamsmith/

6. **knotted string**
April 16, 2006

Thanks, Tony. That gives me more respect for what Murray Gell-Mann was working in the Panama jungle.

7. **Lurker**
April 16, 2006

I've gone back and read old posts here to get my bearings. I find myself in Peter's camp as a string theory skeptic, but in Lubos's camp politically.

Knotted string, you said "In Iraq they used depleted uranium shells. Is anybody interested in reducing the potential impact of weapons on civilians anymore?"

No fighting force in history has gone to greater lengths to avoid civilian casualties than the coalition. They could have bombed Fallujah to rubble risking nary one soldier; for humanitarian reasons they went door to door.

Depleted uranium is cheap, hardly radioactive at all, makes great penetrators, and is deployed by armed forces all over the world, friend and foe alike. 18 countries manufacture DU penetrators. Tungsten, on the other hand, is impossible to cast and hard to machine, nonpyrophoric, and imported from China. Depleted uranium is an innocuous substance if you don't breath it or get shot with it. Do you have a better idea than DU? Send it to Rumsfeld.

The late Serge Lang was mentioned. The File is a great read. I corresponded with him about it in the late eighties, and hoped to meet him during a visit he made to Britain where I was at the time, but the scheduling didn't work out.

Best regards,

Lurker

8. **knotted string**
April 17, 2006

Thanks Lurker,

I know that DU is little more dangerous than lead bullets, and in that case there are other worries than long-term lead poisoning.

My cousin, in a British tank regiment, was concerned before his duty in Iraq that he was going to spend each day sitting beside radioactive DU shells. However, as you say it is 'hardly radioactive at all'. The U-238 half life is about the age of the earth. Decays get spread out over a long time so the decays per second – Becquerels – is the number of active atoms divided by the mean life (bigger than half life by a factor of 1/ln2 = 1.44).

I'd be concerned about breathing dusty air after a DU attack, of having a particle lodge in lung tissue and cause lung cancer. Is this risk trivial? Perhaps they should simply have a policy of cleaning up and burying DU hotspots under the topsoil after a war.

Serge Lang's File: McCarthyism from intellectuals at Harvard mentioned, on the Amazon book reviews page, sounds familiar…

9. **Carl Brannen**
April 17, 2006

If DU is such clean material, then how come the gov. is busily cooking up schemes to get rid of it safely?

http://web.ead.anl.gov/uranium/uses/repository/index.cfm
http://web.ead.anl.gov/uranium/faq/mgmt/faq25.cfm

Depleted Uranium is not classified as "low level radioactive waste" even though it is easily sufficiently radioactive to be classified that way. For this reason, US laws have to list it separately. For example:

"The Secretary, at the request of the generator, shall accept for disposal low-level radioactive waste, including depleted uranium if it were ultimately determined to be low-level radioactive waste,"
http://www.law.cornell.edu/uscode/html/uscode42/usc_sec_42_00002297—h011-.html

Pure DU would have radioactivity of 330 nCi/g (12 kBq/g):
http://www.physics.isu.edu/radinf/du.htm

But that figure is misleading because the decay products of U238 are also radioactive. Contrary to common sense, the maximum radioactivity emitted by a pile of recently purified DU peaks several thousand years after purification, not immediately afterwards. The peak radioactivity level is called the "secular equilibrium" level.

This level of radioactivity is actually quite high. For example:

"DOE Mixed Transuranic Waste (MTRU) is waste that has a hazardous component and radioactive elements heavier than Uranium. The radioactivity in the MTRU must be greater than 100 nCi/g and co-mingled with RCRA hazardous constituents."
http://www.epa.gov/radiation/mixed-waste/mw_pg3.htm

In disposing of this stuff by using it in the military, we are doing something that we will definitely be called to repudiate and possibly pay for.

Carl

10. **comentator**
April 17, 2006

Correction to Lurker; Fallujah is a city more o less three quarters the size of New York and even if they want, they could not bomb it to rubble, that could have been impractical and expensive. And they went door to door not for humanitarian reason but because there was no other way to go through a city that size.

11. **secret milkshake**
April 18, 2006

Well, they used white phosphorus there… (And that stuff is way nastier than napalm). Calling it "shake and bake".

12. **Ali Yegulalp**
April 18, 2006

Peter – I didn't realize you were one of Callan's students. What years were you at Princeton? I was there 1990-1995, also working with Curt. I spent a couple of summers in San Diego so I could keep meeting with Curt while he was busy being a Jason. I have to say it was kind of strange pedaling my rusty graudate student bicycle up to the big secuity barrier and telling the security guard over the intercom that Curt Callan was expecting me.

13. **Steve Myers**
April 18, 2006

Back to DARPA & JASON: beyond the tech stuff on electronic fences, etc. — doesn't anyone see anything wrong with these sciencetist – pentagon ties? How much of it amounts to being a dupe or selling your soul for grant money & being intimate with power?

14. **Steve Myers**
April 18, 2006

I just realized I coined a new word with the typo "sciencetist"

15. **sunderpeeche**
April 18, 2006

"…anything wrong with these sciencetist – pentagon ties?" … "selling your soul for grant money & being intimate with power?" I keep seeing statements like this. But if scientists like Oppenheimer had not served on the AEC, who would (help to) formulate nuclear policy after WW2? etc etc Yes, one gets intimate with power. That is a necessary consequence if one is to have a meaningful influence on policy. To be intimate with power for its own sake? I have no doubt that it happens. Probably much more so by non-scientists. And they are better qualified to advise on science/technology/military issues?

16. **woit**
April 18, 2006

Ali,

I was a grad student at Princeton quite a bit before your time: 79-84. Never got a free trip to San Diego. Actually, I heard from various people that later on, Curt was even more involved with Jason than he had been at the time I was a student.

17. **Belizean**
April 18, 2006

The standard joke about JASON is that it stood for July August September October November, because the task of writing up your summer research would invariably extend into the fall semester.

I was not a member, but I briefly worked for a defense contractor with whom they were cooperating. I remember spending a long time working through the torturous math in a JASON report by Roger Dashen concerning submarine wake generation, if I'm remembering correctly. I had to go down to La Jolla to present my own work. Got there, attended a Dashen talk. But, after hearing him, I was greatly relieved that my own presentation was cancelled by some scheduling problem.

18. **Tony Smith**
April 18, 2006

Steve Myers Says: "… Back to DARPA & JASON … doesn't anyone see anything wrong with these sciencetist – pentagon ties? How much of it amounts to being a dupe or selling your soul for grant money & being intimate with power? …".

An AIP web page at http://libserv.aip.org:81/ipac20/ipac.jsp?uri=full=3100001~!5052~!0&profile=newcustom-icos describes a 1987 oral history interview with Matthew Sands (an author of the Feynman Lectures) which description says in part:
"… Reasons for joining JASON; work on anti-submarine warfare, surface ship speed; … getting good data, counter-insurgency, Barrier Study (Robert McNamara), 1966; reasons for leaving JASON, 1969; its influential members; secrecy; relation of JASON work to academic physics work. …".

Does anybody here know what Sands's friend Feynman thought of Jason ?
Is it yet another issue on which Feynman and Gell-Mann had very sharp differences ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

19. **The Easter Bunny**
April 21, 2006

Another viewpoint,
"Thirteen of the nation's most prominent physicists have written a letter to President Bush, calling U.S. plans to reportedly use nuclear weapons against Iran "gravely irresponsible" and warning that such action would have "disastrous consequences for the security of the United States and the world."'
…includes Edward Witten, professor of physics, Institute for Advanced Study and Fields Medalist.
http://www.newswise.com/articles/view/519690/

20. **Pyracantha**
April 23, 2006

Have there ever been any women Jasons?

21. **Peter Woit**
April 23, 2006

Pyracantha,

I think that initially, back in the sixties, there were no women Jasons. More recently there have been some, one who is described in the book is Claire Max, now an astronomer at Santa Cruz.

Susskind Turns Down Templeton Prize

April 18, 2006
Categories: Uncategorized

OK, maybe they haven't offered it to him yet, but over at the Edge web-site, in a comment about John Horgan's recent piece about the Templeton Foundation, Susskind writes:

I don't understand the idea that a convergence between science and religion is taking place. I don't believe in any such convergence. Throwing huge amounts of money at scientists who claim to see such a convergence can only lead to a dangerous blurring of boundaries.

I hereby pledge to refuse any prize for advancing the so called convergence between science and religion.

I missed Susskind's recent public talk here in New York, about his book which the New York Academy of Sciences describes as "revolutionizing the field of physics". There is a podcast recorded just before his talk. He makes his usual points including claiming that the situation of the string theory anthropic landscape is similar to that of Darwin and the theory of evolution. He also claims that anyone who thinks it doesn't have experimental implications is wrong, pointing to Weinberg's "prediction" of the cosmological constant.

Comments

1. **anon**
   April 18, 2006

   Daddy, when I grow up, I want to be like you, the ultimate superhero: a physicist who collects payola from both from the Templeton and the Jason programs at the same time.

2. **Chris Oakley**
   April 18, 2006

   Following Susskind's noble example, I hereby relinquish any claim to the Olympic Gold Medal in Tobogganning for 2005, any claim to the Nobel Prize in Chemistry for 1902, for the Turner Prize in 1986, the Best Dressed IBM Employee for 2000 (mind you, I don't think I had much of a claim on that one anyway, and not just because I never worked for IBM), the Tour de France for 1980 and Miss Trinidad for 1972. All I ask in return is that Lubos Motl should give up any aspirations towards the Nobel Prize for Climate Change, if ever one is instituted.

3. **lmot**
   April 18, 2006

   I've always admired the Jasletons for advancing the convergence between religion and anti-submarine warfare.

4. **Kea**
   April 18, 2006

   Chris, I'm curious: why the date qualifications?

5. **Chris Oakley**
   April 18, 2006

   Chris, I'm curious: why the date qualifications?

   I *knew* that someone was going to read more into this comment than was intended. I suppose that that is the problem of this being a "scientific" forum (although Lubie might disagree about the fact).

6. **Jimbo**
   April 18, 2006

   Listening to Lenny's talk, he sez that Weinberg predicted the CC within an order of magnitude, via anthropic reasoning. Is that indeed the case ? Also, does anyone know if there exists a published derivation of the following relation (and by whom ?)

   Log (Mcc/Mn) = – 1/(alpha)^1/2 , where Mn = nucleon mass

   Thanx,
   Jimbo

7. **woit**
   April 18, 2006

   Jimbo,

   For extensive comments about Weinberg's "prediction" (which is the same "prediction" you get when you say you have no idea what causes the cosmological constant), see my recent posting about Polchinski's paper.

   Never seen the relation you give (and it's off-topic…)

8. **Alejandro Rivero**
   April 18, 2006

   Jimbo, as Mcc was thought to be 0, there are not a lot of logarithmic "predictions" yet. There is a good bunch of such kind (log and then fine structure constant) using M_planck against M_nucleon, at least as early as the 1960 and probably even more. It is offtopic here, but you can get a whole 11 pages thread at http://www.physicsforums.com/showthread.php?t=46055

9. **Alejandro Rivero**
   April 18, 2006

which is the same "prediction" you get when you say you have no idea …

But of course! Note that the anthropic principle is to ask for the existence of someone able to say "I have no idea".

10. **CapitalistImperialistPig**
April 18, 2006

Unlike you high-principled types, I intend to campaign vigorously for the Templeton Prize, based on my string theoretic proof of the existence of God, or, as I like to call him, *The Great Landscaper.*

11. **Sakura-chan**
April 19, 2006

The Susskind talking on that podcast is not the normal Susskind we know and love. I was stricken by his skepticism.

12. **Hech Baan**
April 19, 2006

1. I'm 100% behind Susskind's message. There is no boundary between science and theology. And religion shouldn't play any role in science. You are either a scientist or a theologist.

2. At the same time I don't think his book is revolutionising the field of physics.

3. When people make comments on the Anthropic principle my assumption is that they understand the topic they are talking about. To test my theory I ask the following question.

What would be your reaction if string/M-theory predicts only universes without live forms?

13. **Not a Nobel Laureate**
April 19, 2006

I developed a quantum mechanical "proof" of the existence the Holy Trinity years ago thereby inferring the existence of God.

1. The Holy Trinity can be understood as a superposition of QM eigenstates.

|Holy Trinity>

= alpha|Father>
+ beta|Son>
+ omega|Holy Ghost>

The Unitarians have previously shown that the inner product of the |Holy Trinity> state
with itself gives

alpha^2 + beta^2 + omega^2 = 1

where the eigenstates satisfy the usual orthonormality requirements.

2. The values of alpha, beta and omega in the above normalization may be empirically determined by checking the religious – historical records for the number of appearances of the Father, the Son and the Holy Ghost, respectively.

We will probably have to await further developments in understanding the Celestial Firmament of Holy String Theory a.k.a. Harp Theory or H-Theory to account for these values of alpha, beta and omega. However, leading quantum theological and quantum rabbinical researchers currently believe that the key lies in enumerating the 10^500 possible names of God.

3. When acted up by the Holy Roller Hamiltonian,
H_hro, a.k.a. the God Playing Dice with the Universe Operator, O_gpdu, the QM holy superposition state collapses / is projected into one of the
|Father>, |Son> or |Holy Ghost> eigenstates.
Ie.,

H_hro |Holy Trinity> = alpha|Father>

H_hro |Holy Trinity> = beta|Son>

H_hro |Holy Trinity> = omega|Holy Ghost>

QED

4. An outstanding quantum theological question is whether the H_rho is in fact Hermitian as has been postulated and are the eigenvalues thus positive definate, ie., without original negativity a.k.a. original sin, or not.

5. Many of the Faithful eagerly await the coming of the Second Quantization.

Now can I have my Templeton Prize . . . please.

14. **Jimbo**
April 19, 2006

Dear Not a Nobel Laureate,

Cracked me up…I would love to see Alan Alda do his best `Feynman', deliver that lecture w/a straight face & try not to split a gut laughing. I don't think it can be done ! Thanx for making my day.

Jim

15. **Thomas Larsson**
April 19, 2006

What would be your reaction if string/M-theory predicts only universes without live forms?

I would be most surprised if string/M-theory made **any** falsifiable prediction whatsoever, e.g. that sparticles **will** (not may) be detected at the LHC.

I would also be most surprised if Lubos Motl did not find yet another excuse to extend the deadline of his infamous experimental-discovery-of-susy-by-2006 bet, when sparticles have not been detected by the end of 2008. After all, the ultimate goal of string theory is to find ever more elaborate excuses why every string theory prediction disagrees with experiment.

16. **Hech Baan**
April 19, 2006

Dear Thomas Larsson,

Everyone knows that string/M-theory makes many predictions. The challenge is that we don't have enough data points to check them. So what do we do? Throw away the theory and try another one. We've decided to continue working on the theory to get more results. We assume that our theory is much more clever than we are therefore we will take its predictions very seriously regardless of our expectations and/or non-experts' opinion.

Now back to my question. You haven't answered it. I agree you will be surprised. But what would you do next? What would be your logical conclusion? Will it be?
A. String/M-theory is not even wrong so let's ignore anything it says.
B. String/M-theory therefore I don't exist.
C. String/M-theory says I don't exist, but I do therefore the theory is wrong.
D. Something else.

Hint: The question is linked to the Weinberg's prediction.

17. **Chris Oakley**
April 19, 2006

Hech Baan,

I would choose "A" and just hope that you were not the one marking the paper.

Not a Nobel Laureate,

I remember as a child being told that the Three were One and the One were Three and that that was a Mystery, but I could never see anything particularly mysterious about it. In fact, I would say that your explanation ties up the loose ends rather nicely, and would be happy to support your entry for the Templeton Prize if you want me to. As for my credentials, you will find my CV on my web site; to that I need only add that I was an altar boy at the local Catholic church from about 1967-1974 and a Governor of the local Catholic school (John F Kennedy – named after a famous Catholic philanderer) for about a year around 1986.

18. **Arun**
April 19, 2006

What energy scale does M/String Theory predict for supersymmetry to be effective?

19. **Thomas Larsson**
April 19, 2006

Everyone knows that string/M-theory makes many predictions.

This is of course a plain lie. Unless, of course, you take the predictions of supersymmetry, extra dimensions, and 496 gauge bosons seriously, in which case string theory has been disproven by experiments.

Let me quote Sheldon Glashow:

"It's called superstring theory and it is, so far as I can see, totally divorced from experiment or observation. If not totally divorced, pretty well divorced. They will deny that, these string theorists. They will say, "We predicted the existence of gravity." Well, I knew a lot about gravity before there were any string theorists, so I don't take that as a prediction."

But it is of course up to anyone to decide for him- or herself who is most credible: a Nobel laureate like Glashow or a liar like Hech Baan.

20. **woit**
April 19, 2006

Arun and Hech Baan,

M/String theory makes no prediction about the energy scale of supersymmetry breaking whatsover. It makes no predictions about anything, and anyone who starts going on about its predictions should be able to at least tell us what one of them is.

21. **Wolfgang**
April 19, 2006

Peter,

so what about Lubos' prediction that Lorentz invariance will hold at (arbitrarily) high energies ?

22. **woit**
April 19, 2006

Wolfgang,

Lubos has a highly idiosyncratic idea of what the English word "prediction" means. As for the one you mention, recall that most string theorists like to go on about how really understanding string theory will require a new way of thinking about what space is (and time too, probably). Dumping Minkowski space at short distances would also dump Lorentz invariance, it would seem to me.

Lorentz invariance at short distances is not exactly a distinctive prediction of string theory, and saying one's theory "predicts" some general principle shared by virtually all other theories is kind of silly. For instance, I could claim that "string theory predicts unitarity". Lorentz invariance at short distances is much more a distinctive feature of local QFT than of string theory, so it's not exactly a distinguishing prediction of string theory.

23. **Chris Oakley**
April 19, 2006

A footnote to the Lorentz invariance question: just because you can't deal with a scientific fact it doesn't mean that it is not true. Our understanding of QFT is based on an idea we inherited from quantum mechanics, which in turn was inherited from classical mechanics. This idea is that physics consists primarily of deriving the equations of motion of a given system. The configuration of a system in a constant-time hyperplane (the t=0 state) then is a boundary condition to which the equations of motion are applied. In a relativistic system, the equations of motion need to be covariant, but in addition one must be sure that *any* choice of spacelike hyperplane would work for providing the "t=0" configuration.

The notion of introducing an interaction into a quantum-mechanical system by an equation like

H = H_0 + V

seems so sweetly reasonable to most that they ignore the fact that H is the time component of a four-vector – a very non-relativistic construct. But something has to give when you try to make the theory relativistic, and sure enough, as Rudolf Haag showed in 1955, the only way in which this equation is applicable in this case is if V=0, in other words, when there are no interactions at all. This problem leads some to propose that Lorentz invariance is not correct, flying in the face of some of the most copious experimental evidence ever produced (bubble chamber data).

Chris Oakley wrote:

" . . . In fact, I would say that your explanation ties up the loose ends rather nicely, and would be happy to support your entry for the Templeton Prize if you want me to. . . "

You've just demonstrated why I've always been reluctant to put this "theory" into print – even in the Journal of Irreproducible Results. Someone might actually take it seriously, but then again, there are people who take string "theory" seriously so I guess it should come as no surprise.

When string theory can predict the spectrum of empirically observed particles and forces, as per the SM, then it will be worth paying attention to. Until then, it's just an interesting (at least to some) mathematical toy.

25. **Joao Leao**
April 19, 2006

Peter

As you well point out String Theorists have adopted the "novel" notion that, if they keep "predicting" what we already know, they may may somehow be exempted from having to predict something genuinely new and thus taking a risk on their exalted labors! It is one short step away from argueing that a universe fine-tuned enough to produce String Theorists must be highly contrained to exhibit the "physics" they portend to know!…

Now I, for one, understand why Susskind "predicts" he is a good candidate for the Templeton prize and rightly anticipates that will mean his enthronement as the Pope of the Megaverse (and Weiberg is his Prophet?). This would put one last kabosh on his claims to be doing science rather than some new religion of "constant landscaping".

26. **ksh95**
April 19, 2006

Chris Oakley said:

> the only way in which this equation is applicable in this case is if V=0, in other words, when there are no interactions at all

But nature almost always rearranges itself in such a way as to make V very small. Isn't this what Bogoliubov is all about?

Moreover, any residual interactions can show up as mass.

Change what you call a particle and change what you want to call that particle's mass and SR is preserved.

27. **Bert Schroer**
April 19, 2006

Chris Oakley,
as much as I usually agree with your points of view, I think what you said about relativistic QM and Haag is not correct as it stands. Relativistic QM by its very nature of lacking the vacuum polarization (which characterizes QFT) is a perfectly well-defined relativistic multiparticle theory, i.e. it fulfills all properties which you are able to formulate using the concept of Wigner particles (and not that of fields). It is called the theory of "direct particle interactions". The original idea is due to Fritz Coester (a good friend of Haag) and I have reviewed it in hep-th/0405105 (published in AOP).

28. **biophysicist**
April 19, 2006

Actually not a Nobel laureate you missed out on the fact that you can get the amplitudes exactly in your formulation. Since beta = alpha = omega ("I am the Alpha and the Omega", remember?), unitarity forces the amplitudes to all be 1/3.

Cheers!

29. **biophysicist**
April 19, 2006

err 1/sqrt(3). Whatever.

30. **Lord**
April 19, 2006

I don't understand the idea that a convergence between science and religion is taking place. I don't believe in any such convergence.

Religion informed by science would be a marked improvement over the current situation, and ethical considerations are certainly a valuable contribution to science.

31. **Eugene Stefanovich**
April 19, 2006

Bert Schroer wrote:

Exactly. Furthermore, using a unitary transformation (nucl-th/0102037) one can eliminate vacuum polarization terms from QFT and cast it into the form of "direct interaction" theory without losing its predictive power , i.e., the S-matrix remains the same. In this formulation, the Haag's theorem does not apply anymore. See physics/0504062.

32. **Not a Nobel Laureate**
April 19, 2006

biophysicist wrote

"Actually Not a Nobel laureate you missed out on the fact that you can get the amplitudes exactly in your formulation. Since beta = alpha = omega ("I am the Alpha and the Omega", remember?),"

Hint. Why do you think I choose the names of the variables I did 😉

It's a matter of some considerable debate amongst quantum theologists as to whether "Alpha and Omega" should be interpreted as alpha + omega. Also, the fact that Beta is not mentioned – is this a Divine Hint of a hidden variable theory or an extra dimension in the Celestial Firmament?

"unitarity forces the amplitudes to all be 1/3."

That would be 1/sqrt(3) as you corrected later, but the above quantum theological question stills awaits a definative ruling by the quantum theologists and quantum talmudists.

33. **Bert Schroer**
April 19, 2006

Eugene Stefanovich,
really very interesting. When I wrote my review I was not aware that this conceptionally correct phenomenological setting was known outside of nuclear physics. I do not know much about its practical usefulness, but its philosophical implication is quite interesting. Among other things it shows that Weinberg's statement that a relativistic theory which obeys the cluster factorization property must be a QFT is not correct. It is the (up to now) only successful physically consistent (macrocausal) nonlocal relativistic quantum theory I know. All other attempts especially those based on noncommutative modifications of QFT have not (yet?) been shown to be physically consistent (wrecking micro-causality usually also destroys macro-causality).

34. **Lubos Motl**
April 19, 2006

Peter: Of course that the Lorentz symmetry at the string scale is a prediction of string theory, much like unitarity, and it is not shared by any "competing" theory. For example, loop quantum gravity is neither Lorentz-symmetric nor unitary. This is why its proponents offer you long essays explaining that we don't really need unitarity, and they also offer you bizarre DSR (defective special relativity) predictions about the Lorentz symmetry violations etc. These predictions show how greatly predictive the theory is – this glory will last until the day when it's shown that this prediction is, of course, silly.

It is fair to say that string theory does predict that these effects are absent and unitarity is exact – and string theory is also the only theory of quantum gravity that makes this prediction. Concerning the word "prediction", Peter, I would also like to tell you and your crackpot fans (plus Wolfgang who is an extra higher category) that I not only know what it is in English, but I can also write it in the normal language: předpověď. 🙂

35. **Eugene Stefanovich**
April 19, 2006

To Bert Schroer:

Weinberg's statement is definitely not correct. In addition to the works of Coester and Polyzou mentioned in your review, there are other counterexamples worth mentioning:

1. non-local QFT: M. I. Shirokov, "On relativistic nonlocal quantum field theory", Int. J. Theor. Phys. 41 (2002), 1027

2. A beautiful series of papers by H. Kita in 1966-1973. The last paper in this series is "A realistic model of convergent quantum mechanics of interacting particles" Prog. Theor. Phys. 49 (1973), 1704 where you can pick up the other references if interested.

36. **Hech Baan**
April 19, 2006

Chris Oakley,

Wrong answer and I'm glad you are not contributing to science any more.

Thomas Larsson,

Any mathematically consistent theory makes many predictions. Sheldon Glashow is just saying that we don't have enough data points to verify the predictions. This is exactly the point I made.

Peter Woit,

String/M-theory predicts that we all consist of strings, including people who don't appreciate the theory.

37. **Simon**
April 19, 2006

Hech Baan: That last statement brings to mind a bumper sticker I saw once…
"Jesus loves you, even if you don't want him to"

At the moment string theory can only believed on faith… it is beautiful, has a lot of desired properties, but is not scientifically confirmed.

I found the bumper sticker offensive… I'm trying not to take your comment the same way!

38. **Hech Baan**
April 19, 2006

Simon,

I'm not saying that string/M-theory is confirmed. The theory could be correct or wrong. However, it's more than believe on faith and it does make predictions. But unfortunately we are not in a position to verify them yet.

The last statement is in line with what Nils Bohr said about his horseshoe on the wall: "Of course, I don´t believe in it! But I have been told it would help even if you don´t believe in it!"

There is no intention to offend anyone.

39. **woit**
April 19, 2006

Hech Baan,

I notice that you love to keep repeating that string theory makes predictions, but you can't actually come up with one. Either give us a legitimate scientific prediction that comes from string theory, or stop attacking others and repeating nonsense.

40. **Hech Baan**
April 19, 2006

Peter Woit,

The following are some legitimate scientific predictions: graviton, supersymmetry, extra dimensions, changes in the topology of spacetime.

41. **Not a Nobel Laureate**
April 20, 2006

Lubos Motl Says:

April 19th, 2006 at 6:33 pm

"Concerning the word "prediction", Peter, I would also like to tell you and your crackpot fans (plus Wolfgang who is an extra higher category) that I not only know what it is in English, but I can also write it in the normal language: předpověď."

From your postings, it strikes me that in an earlier time you probably would have been an equally vicious proponent of "Scientific Communism".

It's no accident. Both theories have equal merit in their claims of being scientific and "Scientific Communism" at least made predictions about the development of society which turned out to be wrong over time.

Previous fads such as hadronic string theory, Regge poles, S matrix and bootstrap models were blown away by experiment which in turn lead to better theories and predictions. String theory is apparently in no such danger, thus it's proponents can continue to hold strong opinions and mis-represent them as facts.

Unless 1) the LHC discovers something new; and 2) more economical means of particle acceleration are developed, the field will sink into obscurity or form the basis of a new religion.

42. **Not a Nobel Laureate**
April 20, 2006

On the other hand, every other field of physics that I can think of apprears to be enjoying remarkable experimental and theoretical progress.

43. **Chris Oakley**
April 20, 2006

Hech Baan's predictions of String Theory

Graviton: never observed
Supersymmetry: wrong
Extra dimensions: no evidence
Changes in the topology of spacetime: no reason to believe this

44. **where?**
April 20, 2006

about Baan's string predictions: how heavy are supersymmetric particles? How large are extra dimensions?

As far as I know, string 'predictions' have an uncertainty of about 16 orders of magnitude. A planet is about 16 orders of magnitude bigger than an atom. How can you do atomic physics if you cannot distinuigh an atom from a planet?

45. **knotted string**
April 20, 2006

I love string theory. It has enough branes behind it to cover all possibilities, so it's a safe bet. It's can't be disproved!

46. **Thomas Larsson**
April 20, 2006

Let me quote from subsection 1.6 of hep-th/0204131:

"The long-standing crisis of string theory is its complete failure to explain or predict any large distance physics. String theory cannot say anything definite about large distance physics. String theory is incapable of determining the dimension, geometry, particle spectrum and coupling constants of macroscopic spacetime. String theory cannot give any definite explanations of existing knowledge of the real world and cannot make any definite predictions. The reliability of string theory cannot be evaluated, much less established. String theory has no credibility as a candidate theory of physics."

It might be worth pointing out that Dan Friedan was one of the leading string theorists during the 1980s, founder of the string theory group at Rutgers and winner of the MacArthur "genius" grant. But then again, why would anyone care about his opinion, when the great authority Hech Baan proclaims that string theory makes many predictions? After all, Baan has succeeded (probably) in getting into grad school, and has published exactly zero papers in hep-th. (I found a W.A. Baan with ten e-prints in astro-ph, but that is probably another person).

Let me emphasize that it is nothing wrong if a speculative science makes no predictions in early stages. However, with 20,000+ man-years invested in string theory, it is hardly in an early stage, and the antropic nonsense shows that nobody seriously thinks that it is possible to change this situation. What I do loathe, however, is the ridiculous lie that string theory is predictive. This is a gross misrepresentation, verging on scientific fraud.

Incidentally, I met Friedan in a summer school on Iceland in 1990 (Friedan's wife is Icelandic, although she did her Ph.D. in Lars Brink's group in Göteborg). I travelled with a mathematician friend, who was very enthusiastic about Friedan's recent work, with Steve Shenker, on CFT on a Riemann surface. Friedan himself was quite subdued, however. He refered to his work as "very abstract", and it was clear that he didn't mean it in a positive sense. Soon after that Friedan disappeared from the literature for ten years, and we all know how that ended.

47. **woit**
April 20, 2006

Hech Baan,

None of those are legitimate scientific predictions that can be used to test string theory (even in principle).

Gravitons are what you generically expect in any quantized version of gravity, even if you could observe them, this wouldn't be any evidence for string theory.

Unbroken supersymmetry is experimentally ruled out, broken supersymmetry depends on an energy scale, and string theory tells you nothing about this, so it makes no predictions about supersymmetry at all.

String theory may or may not require 10 (or is it 11?) dimensions, depending on how you feel about non-critical strings. But it tells you virtually nothing about any of these dimensions, their sizes, shapes, etc. Their is no experimentally testable (even in principle) prediction about extra dimensions from string theory.

String theory does not tell you what the topology of space time is, much less how it will change.

Please stop repeating things you clearly don't understand, you're just adding to the noise level here.

48. **Christine Dantas**
April 20, 2006

Peter Woit wrote:

[String theory] makes no predictions about anything, and anyone who starts going on about its predictions should be able to at least tell us what one of them is.

I think I have quoted this here before, perhaps it would be frutifull to quote it again (gr-qc/0501053):

> String theory schemes in any dimensions always predict new fields which couple in different ways to the various matter sectors. As a result a large variety of effects are allowed by string theory, including effects leading to violation of Lorentz invariance, violation of the UFF and violation of the Universality of the Gravitational Redshift (UGR) is encountered. From the viewpoint of the phenomenologist a disappointing aspect of string theory is that it appears that it cannot be falsified on the basis of these effects. String theory may predict many new low-energy effects, but it can also be easily tuned to avoid all of them.

49. **Christine Dantas**
April 20, 2006

I did it again. I should be more careful to avoid typos. Sorry for the "frutifull" (–> fruitful).

50. **Zelah**
April 20, 2006

Let's get real guys. Everybody here agrees that QFT is the best theory of high energy physics we have!

And frankly nobody has any idea of how to unify QM and Gravity such that low energy physics could test the results.

Now regarding your question Hech Baan, I would reply D. The reason is that String Theory is clearly valid in some sense as a QFT!

Unfortunately, your linking Weinberg prediction of cc scale to your question depends apon your assumptions regarding how science works! Put it this way, there are many papers which predict various values for the CC!

An amateur mathematician.

51. **Who**
April 20, 2006

Christine, I often find your comments helpful but in this case I can not make sense of your quote from
http://arxiv.org/abs/gr-qc/0501053
the paper by Giovanni Amelino-Camelia et al.
The quote is not self-consistent. If a theory "can easily be tuned" to avoid making a prediction then it simply does NOT make the prediction.

The point of restricting scientific theories to ones which make testable predictions is that the theory must bet its life on a future observation or measurement so that it can be falsified and discarded.

the question one asks of a theorist is **what future observation, what specific result of a specific measurement, would make you give up your theory and change fields?**. If a string theorist can not answer that question then string theory does not make any predictions in the empirical science sense.

It is not like the "predictions" that people make at New Years which are more vague and informal, really just guesses. A scientific prediction STAKES THE THEORY.

As an astrophysicist, I am sure that you know this! So how do you interpret the passage you quoted from Amelino-Camelia? To me it is self-contradictory. What am I missing?

I suppose the quote could be taken as confirming what Peter said. Did you mean it as corroboration? I really am confused about what you are driving at, please be a little more explicit!
=================================

Zelah said "And frankly nobody has any idea of how to unify QM and Gravity such that low energy physics could test the results."

That is not correct Zelah. Many papers. Here is a recent one you can check out by Shahn Majid (noncommutative geometry, Cambridge)
http://arxiv.org/abs/hep-th/0604130
Algebraic approach to quantum gravity II: noncommutative spacetime
S. Majid
26 pages, 2 figures; book chapter to appear in D. Oriti, ed., Cambridge Univ. Press

"We provide a self-contained introduction to the quantum group approach to noncommutative geometry as the next-to-classical effective geometry that might be expected from any successful quantum gravity theory…"

Majid has something to say which is FALSIFIABLE, and it would seem rather interesting, about putting QM and spacetime geometry together.

People should stop applying the sloppy model of string theory indiscriminately to other QG fields, which ARE turning out to be predictive.

—quote Majid second paragraph page 2—
This is also the first noncommutative spacetime model with a genuine physical prediction[1],… The NASA GLAST satellite to be launched in 2007 may among other things be able to test this prediction through a statistical analysis of gamma-ray bursts even in the worst case that we might expect for the parameter …
—endquote—

Majid's idea is quite conceivably wrong, in which case measurements by the NASA satellite will refute the idea. Either way, win or lose, it's progress. (keep your fingers crossed that GLAST goes up as planned)

Please not to suggest that non-string QG theories fail to be testable at accessible energy (in this case it is Gammaray Burst energy)

52. **Erik**
April 20, 2006

I love string theory. It has enough branes behind it to cover all possibilities, so it's a safe bet. It's can't be disproved!
LOL! That convinced me, I'm joining the string theory pack! I can't loose!

53. **Hech Baan**
April 20, 2006

Peter Woit,

Graviton:
String/M-theory with gravitons incorporates the full structure of Einstein's theory. At the atomic level, it departs from Einstein's, which doesn't work quantum mechanically. The nature of the departure is unique to the string/M-theory. So, the prediction isn't just the existence of the gravitons but their unique properties.

Supersymmetry:
String/M-theory's prediction is that there should be supersymmetry. Supersymmetry predicts that for every elementary particle there is a superpartner particle. It makes detailed predictions about how superpartners will behave.

Extra dimensions:
String/M-theory predicts that there are extra dimensions with unique features. It doesn't tell you everything about extra dimensions' sizes, shapes, etc. as Einstein's theory doesn't about spacetime's. E.g. the topology of empty spacetime in Einstein's theory can be R^4, RxTor^3, R^2xTor^2, etc..?

Changes in the topology of spacetime:
Once again Einstein's theory doesn't tell what the topology of spacetime is either, but it tells you that whatever topology is it won't change. String/M-theory predicts that it will change in distinctive ways.

I'm going to ignore your last comment. It's offensive.

54. **woit**
April 20, 2006

String theory does not depart from GR "at the atomic level".
It does not predict unique, distinctive properties for gravitons.
It does not make detailed predictions about how superpartners will behave: it can't even predict their mass.
It does not predict "unique features" of extra dimensions, it is consistent with an infinite variety of different sorts of extra dimensions.

It does not tell you how topology will change.

Please stop repeating hype you have heard elsewhere. If you know of specific, scientific predictions from string theory that can in principle be checked, tell us what they are, don't just claim that they exist. Let me be specific: If you were given an accelerator capable of accelerating particles to Planck-scale energies, what would be the experimental signature that would show that string theory was true, such that if you didn't see it, you would know string theory was wrong?

55. **Christine Dantas**
April 20, 2006

Dear Who,

Amelino-Camelia et al. are indeed not being scientifically rigorous in their use of the verb 'predict' (at least in that passage), since they use it interchangeably with the term 'allow for'.

Thus, having acknowledged the fact that they are using the word "prediction" in the more ordinary, vague sense, the interpretation of that quote is as straightforward as it could be.

They are just mentioning that string theory can *accommodate* a plethora of new phenomena, and at the same time, that *accommodation is not a scientific prediction* (and I hope it will never be). Accommodation often presuposes that things can be adjusted, or brought to an adaptable state. One thing is to claim or conclude by whatever means that new phenomena could be expected. Another thing is to supply the quantitatively precise conditions at which these phenomena are supposed to be measured or observed.

In conclusion, what I really interpret from that passage on Amelino-Camelia et al.'s paper is a simple background message that string theory cannot be a theory after all (at least, not yet). Perhaps they could have said it differently, so as to avoid the understandable feeling that what they are saying is not self-consistent.

My present attitude towards string theory is that it is just an approach to quantum gravity (or to unification), but not a theory (yet). There are several worrisome things like the landscape (and all the anthropic issue) and the lack of predictability in string theory that makes me uncomfortable. So I often agree with what Peter Woit continuously write here. An of course I completely acknowledge that other approaches have their own serious problems as well. But that is another story.

Best regards,
Christine

56. **Hech Baan**
April 20, 2006

In the accelerator I will be colliding very high-energy particles. Occasionally a high-energy graviton will be produced that will move off into extra dimensions and disappears. It will look like a jet of high-energy particles and there would be nothing balancing the energy and momentum of that very high-energy jet.

57. **woit**
April 20, 2006

Accelerators produce all sorts of things that show up as missing energy, this has nothing to do with string theory. I think you're repeating the standard example of what would be evidence for a brane-world scenario. But string theory doesn't predict a brane-world scenario. In the most popular "string theory phenomenology" models, we don't live on a brane in higher dimensions, observable by energy escaping the brane. Instead the extra dimensions are planck scale. The signatures for this are different than the brane-world signatures and depend completely on the size and shape of the extra dimensions.

58. **no**
April 21, 2006

Baan, phenomenologists tried to compute collider signals of gravitons escaping in extra dimensions using the (non-renormalizable) Einstein gravity, because strings (and other quantum gravity models) failed to give concrete results.

Observing extra dimensions would be evidence for extra dimensions, not for strings.

59. **Juan R.**
April 21, 2006

Hech Baan wrote,

"What would be your reaction if string/M-theory predicts only universes without live forms?"

A more interesting questions is

"What would be string theorists reaction if string/M-theory predicts only universes without live forms?"

It is clear that many string theorists would claim that live forms are stupid 😉

You claim that string M-theory does many predictions but after you lack to cite even a single!

You said

"String/M-theory predicts that we all consist of strings, including people who don't appreciate the theory."

This reflect a complete misunderstanding of the concept of prediction. The string is not a prediction of string theory, it is one of axioms of the "theory". Moreover, even if i forget this point, your claim is wrong, because it is now know that string is not fundamental. That is reason of joke "string theory is now a theory without strings".

Another imprecision yours is that you lack to state that M-theory is not formulated (even Witten claims that nobody know M-theory is). It is difficult that an inexistent theory can do predictions. Another point is that the most *close* to M-theory has been formulated (M)atrix theory is not a theory of strings, it is a theory of pointlike objects: D0-branes.

The lesson is that initial string theory was so wrong that today nobody (including string theorists) believes on perturbative metric, nobody believes on 10D spacetimes, nobody believes on 2D extended objects as fundamental. The three were claimed to be correct a few years beyond…

Some comments on the rest.

String/M-theory with gravitons does not incorporates the full structure of Einstein's theory. The causal structure of string is wrong when compared with GR, and this is reason for a non-perturbative generalization of string theory. That generalization breaks basic axioms of string theory and this is reason nobody has formulated M-theory still.

Supersymmetry is not a String/M-theory's prediction. Supersimmetry is a need of the theory because internal difficulties. The problem you are ignoring is that String/M-theory needs supersymmetry at all levels as cure of internal inconsistencies and cannot offer a description of the world was non-supersimmetric. THat is we observe.

We may offer a non-supersimmetric model (the SM) and if in a future supersymmetry is found in laboratory then develop a more general theory with supersimmetry at high energies. String/M-theory introduces supersimmetry at all energies and none mechanism for which we can recover a non-supersimmetric description at low energies. That is reason that in 40 years none string theorist has been able to derive the SM.

In science, any new theory unable to explain known data is inefficient and if cannot derive previous theories at use then it is metaphysics.

Moreover, it is simply false that String/M-theory makes detailed predictions about how superpartners will behave.

String/M-theory does not predicts that there are extra dimensions with unique features. The history of number of dimensions in theoretical physics is a fascinating example:

4D, 5D, 26D, 10D, 11D, 12D? 4D?

In fact, there is people claimining a return to 4D string models.

It is interesting see you absolute claim on "prediction" of dimensions from string theory. What is a dimension in string theory?

Witten recognizes "On the other hand, we don't understand the theory too completely, and because of this fuzziness of spacetime, the very concept of spacetime and spacetime dimensions isn't precisely defined."

Juan R.

60. **Chris W.**
April 21, 2006

Hech Bann: *String/M-theory predicts that we all consist of strings, including people who don't appreciate the theory.*

This reminds me of something. In my late teens I read B. F. Skinner's *Beyond Freedom and Dignity*. In contemplating the all-encompassing scope of Skinnerian behaviorism, it occurred to me that the theory could be used to explain (and dismiss) the behavior of its critics.

I was secretly infatuated with this idea for about a year and a half, and then began to recover my senses. A few years later I began to study Karl Popper's writings and to consider his epistemological critique of Freudian psychology, and thereby began to truly understand the potentially pathological nature of "universal" explanations.

Of course, Hech Baan was just joking.

61. **Who**
April 21, 2006

Christine,
I agree with you on those issues.
(At first I did not understand the thrust of your quote.)
Thanks for clarifying.

Who

62. **Paul Valletta**
April 21, 2006

Surely Susskind can redeem himself once and for all? If he can get a Hydrogen and Oxygen molecule to bond in any dimension other than 3? If for instance he can theoretically proove that it is possible to combine these two elements, and thus produce water in the, say 5th dimension, then he can bring to an end the "Many Worlds", Parallel Universe's, and Anthropic issues to a concluding close?

And as a side line, he could start a factory that sells this 5th dimensional water and retire with a "nice little earner" !

The first step to the proof of "life" in other Universe's or Extra Dimensions, is to experimentally or Theoretically?.. Proove that "H2O" can be created in "other" dimensions.

Anthropically Susskind can argue that Water, and all our Elements of our periodic table have "leaked" from other dimensions into our, but somehow that does not seem to wash with me!

Lenny, fetch me a glass of water from any dimension other than 3-D, and I would gladly raise it as a toast to your good health and wealth!

63. **Paul Valletta**
April 21, 2006

Actually, I do not see Lenny opening a factory, it would be more to his stature that he opens a Baptising Water Spa?..I can see Peter Woit being first in line to this Anthropic Cleansing?

64. **knotted string**

Science Fantastic

April 20, 2006
Categories: Uncategorized

Michio Kaku has joined the Talk Radio Network, where he will have a new radio show called "Science Fantastic" that will appear on 90 radio stations around the country. Topics that will be covered include "black holes, higher dimensions, string theory, wormholes, search for extra-terrestial life, dark matter and dark energy, the future of space travel, genetic engineering, the aging process, the future of medicine, the human body shop, artificial intelligence, the future of computers and robots, as well as topics from science fiction."

The blurb at Talk Radio Network describes Kaku as "one of the world's leading experts in theoretical physics, and according to New York Magazine, one of the '100 Smartest People in New York.'" It goes on:

Dr. Kaku is the co-founder of string field theory, one of the main branches of string theory, the leading candidate for the unified field theory. Many in the scientific field call this "The new Copernican revolution."

Kaku's appearance on Talk Radio Network is rather remarkable, given that many of the other talk show hosts there are extremist purveyors of right-wing sewage like Michael Savage and Laura Ingraham. In the past, Kaku has been known for his left-wing politics, hosting a radio show entitled Explorations on New York lefty radio station WBAI, rebroadcast on other Pacifica stations such as KPFA in Berkeley.

Comments

1. **Not a Nobel Laureate**
   April 20, 2006

   I've always found it interesting that academic physicists tend to be doctrinaire leftists, while engineers tend to be far more conservative in their socio-political views.

   Is it because the main source of funding for academic physicists is the State?

2. **Not a Nobel Laureate**
   April 20, 2006

   "Science Fantastic" seems somewhat tangential to the topic of string theory and it's problems.

3. **Lurker**
   April 20, 2006

   Michael Savage is nuts, but right half the time. I've never heard Laura Ingraham say anything I disagree with but I seldom listen to her. I'm not apologizing for off-topic because you brought it up. 🙂

   BTW FIRST!!!1li!!

4. **Lurker**
   April 20, 2006

   third, whatever

5. **woit**
   April 20, 2006

   I know extremely few "doctrinaire leftist" academic physicists, and I don't think they're any more numerous than doctrinaire rightists in physics departments. Most academics I know are more liberal than the general US population, but with politics about average for a Western European country. On the whole, they tend to not be "doctrinaire", but think for themselves. There was a long tedious discussion about why this is over at Cosmic Variance, with one explanation being that academics are just smarter than the average American. But this is off-topic. this posting is about a new radio show, one of the main topics of which will be "the new Copernican revolution"….

6. **woit**
   April 20, 2006

   Please, I just don't want to know it if my readers are Michael Savage and Laura Ingraham fans, it will make me too depressed. No more about them, please, I've had a long day…

7. **Hech Baan**
   April 20, 2006

   String/M-theory isn't "the new Copernican revolution". It's not even a revolution. It's just our next logical step to understand the nature.

8. **fishfry**
   April 20, 2006

   As Lurker says, Savage is nuts but right half the time. He can be really hateful at times … other times he's surprisingly ahead of the curve.

   Peter, if you don't want to know your friends' politics … don't ask.

9. **Troublemaker**
   April 20, 2006

   Peter, if you don't want to know your friends' politics … don't ask.

   He didn't.

10. **Jimbo**
April 21, 2006

I know nothing of these right-wing nuts. I do know, that Michio Kaku, like Carl Sagan, has charisma to burn, and that in this country he is an intellectual beacon, in a sea of idiot worship. Lets hope he gets the word out, & fans the flames of curiosity about Nature's frontiers.

11. **Chris Oakley**
April 21, 2006

By the by, I am guessing that the title "Science Fantastic" derives from "Light Fantastic". The latter name was applied to a TV series about physics recently here in the UK, but it is based on a misunderstanding. The original was a poem (L'Allegro) by John Milton, apparently written in 1632, which contains the lines

> Haste thee, Nymph, and bring with thee
> Jest, and youthful Jollity,
> Quips and cranks and wanton wiles,
> Nods and becks and wreathed smiles
> Such as hang on Hebe's cheek,
> And love to live in dimple sleek;
> Sport that wrinkled Care derides,
> And Laughter holding both his sides.
> Come, and trip it, as you go,
> On the light fantastick toe;
> And in thy right hand lead with thee
> The mountain-nymph, sweet Liberty;
> And, if I give thee honour due,
> Mirth, admit me of thy crew,
> To live with her, and live with thee,
> In unreproved pleasures free

"Tripping" the "light fantastick toe" here means "dancing", "light" being used in the sense of "not heavy" and "fantastick" being used in the sense of "fanciful".

So the "light" has nothing to do with electromagnetic radiation.

12. **Simon**
April 21, 2006

The title of Kaku's show, 'science fantastic' is in reference to the Terry Pratchett book of 'the light fantasic'.
Kaku chose this because it is the sequal to 'the color of magic'.
This makes sense because Kaku is looking for a fantastic new science that will be a sequal to the color of magic (QCD). 🙂

13. **Chris Oakley**
April 21, 2006

OK – so Kaku is exonerated on one count. However he is guilty on the count of liking Terry Pratchett (or *Douglas Adams for the undiscerning* as I like to think of him).

14. **knotted string**
April 21, 2006

Because Kaku is the world's leading physicist, expert on string theory and also on biological stuff, I'm uneasy with the use of string theory in horror stories:
http://www.marklaflamme.com/

"The world's leading physicist, in a delirium of genius, attempts to use the science that has consumed his life to bring his 8-year-old daughter back from the dead. … With toys to entice, gravity to tug at unseen dimensions, and string theory to unravel the world's most ancient secret, a grieving father awaits the return of his child from a place eternally unreachable. The little girl that comes to him is a child no father could want."

15. **MathPhys**
April 21, 2006

The rise and rise of Michio Kaku never ceases to amaze me. I hope he does a good job on the radio talk show circuit. We need all the scientists that we can get on such circuits. I understand the public's fascination by black holes, extra dimensions, etc.

Popularizing science is a good thing. I thought Brian Greene did a very good job with his book on strings. I was always very pleased to see people reading it on commuter trains, etc. I also know of one teenager who read it and was very inspired by it.

I hope Kaku will be equally positively influential.

16. **knotted string**
April 21, 2006

MathPhys, I agree! I hope he interviews Lubos Motl. Also, Jacques Distler would be interesting. I hope Kaku interviews him:

'These are exciting times to be a theorist. It is fair to say that we really don't yet know what string theory is about, but we are learning.' – Jacques,
http://golem.ph.utexas.edu/~distler/

17. **sunderpeeche**
April 21, 2006

Good for Kaku. One doesn't have to agree with all that he says (for example he opposed the Cassini mission because it carried plutonium and needed a flyby of Earth for a gravity assist), but if he can get kids interested in science, then that's good. Not all of them will necessarily become string theorists, and perhaps one of them will really discover the Next Great Breakthrough.

18. **andy**
April 21, 2006

‘Science Fantastic’ sounds like it will cover the very same information that is covered on the ‘Art Bell Show’ (along with space aliens and bigfoot.)

19. **Who**
April 21, 2006

sunderpeeche
** but if he can get kids interested in science, then that’s good.**
my experience of young people whose imaginations have been infected by Kaku is that he does not get them interested in science,
he gets them interested in pseudoscience.

Kaku brand Gee Whiz may enrich the fantasy life of some but contribute to a public misconception of what science is and ultimately, I suspect, undermines legitimate scientists’ credibility. I do not believe that it adds to the ranks of young people who are actually motivated and able to do hard science.

One can ask in whose interest is it to degrade the integrity of the enterprise and promote public misunderstanding of what it’s about.
I believe a rightwing talk radio slot is consistent with what Kaku does.

20. **Mark LaFlamme**
April 21, 2006

Knotted String, you have nothing to worry about. No one will confuse my main character with Mr. Kaku. In fact, when I do interviews, I quickly admit that I’m nothing near an expert in quantum mechanics. I’m merely one of those laymen who are fascinated by the science. I advise those who ask me about it to read Kaku or Brian Greene. Presently, I’m reading Kaku’s “Einstein’s Cosmos,” which serves as a great biographical piece but also a smooth introduction into quantum theory for those without scientific backgrounds.
If it’s any consolation, this work of fiction has generated interest about string theory among groups who might never have given the science a second look.

21. **adam**
April 21, 2006

Whoa, wait a minute. Bill Nye is a populizer of science. Michio Kaku is a populizer of science fiction. Every time I hear him talk, my head spins with all of his promises of how string theory is going to solve world hunger.

22. **lmot**
April 21, 2006

I think that any young person with the intellectual gifts to contribute to physics, would likely be smart enough to see through Kaku’s act, and would conclude that if this charlatan is the public face of theoretical physics, then maybe there is something wrong with the discipline.

23. **Billy**
April 21, 2006

Looks like they’ve finally found experimental evidence to support string theory:
here

“Cosmologists claim to have found evidence that yet another fundamental constant of nature, called mu, may have changed over the last 12 billion years. If confirmed, the result could force some physicists to radically rethink their theories. It would also provide support for string theory, which predicts extra spatial dimensions.”

Has the successful PR of string theory had the consequence that you can
get some free press attention by claiming that your experiment provides
the missing proof of string theory? Will we hear
“Experimental support found for string theory!” more or less times than
we heard that Iraq supported Al Qaeda and was building nuclear
weapons?

24. **Nick**
April 21, 2006

Savage is not even wrong

25. **steve**
April 21, 2006

I first encountered Kaku when he was acting as an anti-nuclear-power nut (OK, activist). His shocking dishonesty about the risks of nuclear power and glib self-promotion pretty much made me figure that anything he wrote on physics could not be trusted by a layman like myself. I had him binned with Sternglass and that crowd. The Cassini farce simply confirmed this opinion. Is there some legitimate achievement of his that explains his stature?

26. **CapitalistImperialistPig**
April 21, 2006

Nick – Nope. Savage is wrong.

Michio Kaku certainly seems to have a lot of enemies! I liked his popular book on strings, though it wasn’t nearly as informative as Brian Greene’s books. I found his QFT book amusing to browse but impossible to learn much from. I’ve got his string books too, but there again I found the presentation hard to follow.

27. **MathPhys**
April 22, 2006

Kaku’s first physics book (first edition appeared in the mid 80’s) was strange. He talks about things that I believe that (in the mid 80’s) he didn’t understand. I believe I’m right because when I met him and talked to him at that time, and it was clear to me that he’s unfamiliar with the technical details.

His more recent physics book on strings is even stranger. It’s written as if he downloaded lots and lots of papers from the archive, then sat there summarizing them. There are hardly any explanations of any depth in these books.

On the other hand, I commend him for the effort. He surely covers a lot of ground, and the books can serve as a very starting point for learning these things. At least he tells you what’s in these papers.

I wouldn't have bought these books, if it weren't for the fact (implied in the acknowledgements) that Luis Alvarez-Gaume (someone I respect and trust) proof read them for mistakes.

I'm sure he's a very smart guy, but I don't think he has the time or the interest to put his nose to the grind and really learn the technical details of the topics he discusses in these books.

28. **Billy**
April 22, 2006

Michio Kaku is a fun guy. He's responsible for a significant chunk of the "technobabble" on Star Trek and he was a significant pre-Elegant Universe factor in the string theory PR campaign. His futurology science has been entertaining in recent years but is, like most science fiction, overly focussed on traditional ideas of technology rather than the biotechnology (and direct brain-computer interfaces) which will dominate 21st century technology.

29. **pl@nk**
April 22, 2006

"my experience of young people whose imaginations have been infected by Kaku is that he does not get them interested in science,
he gets them interested in pseudoscience."

Totally agree.
I've seen Kaku talk about many thing but never Science in general or Physics in particular.

30. **Peter Woit**
April 27, 2006

Please stop it with the personal attacks on Kaku, I've just deleted one. If you want to criticize his activities, or what he has to say, that's fine, but there's no need to go on like Lubos Motl.

Witten Geometric Langlands Talk and Paper

April 22, 2006
Categories: Langlands

I spent yesterday afternoon down in Princeton, and attended a talk by Witten at the Institute on his work relating gauge theory and the geometric Langlands program. He says that his paper with Kapustin is done, it's about 220 pages long, and will appear on the arXiv in Monday's listings. So Sunday night, this link to [hep-th/0604151](hep-th/0604151) should start working. He's also working on a book on the subject, where he would be the sole author.

At the start of talk, Witten noticed that many of the Institute's mathematicians were there, and warned them that they had come to the wrong talk, since it was one aimed at physicists. Pierre Deligne got up and left, but others, including Sarnak and Langlands himself, did stay for the whole thing, although I'm not sure how much they got out of it.

Witten began by giving an outline of the talk, emphasizing six main ideas that were crucial to what he wanted to explain. He also listed as number zero the idea of geometric Langlands itself, saying he would talk about it at the end if he had time (he didn't). The six main ideas were:

1. From a certain twisting of N=4 supersymmetric Yang-Mills one can construct a family of 4d TQFTs parametrized by a sphere. The twisting is the same sort that occurs in his original TQFT for Donaldson theory, in that case coming from N=2 supersymmetric Yang-Mills. The TQFTs he considers have an S-duality, part of a larger SL(2,Z) symmetry.

2. Compactifying the theory on a Riemann surface leads to topological sigma models, based on maps from the Riemann surface into the Hitchin moduli space M_H of stable Higgs bundles. The four dimensional S-duality corresponds here to a mirror symmetry of these topological sigma models.

3. Wilson and 't Hooft operators of the 4-d gauge theory act on the branes of the topological sigma models. Branes mapped in some sense to a multiple of themselves by these operators are called electric or magnetic "eigenbranes" respectively.

4. Electric eigenbranes correspond to representations of the fundamental group, this is one side of the geometric Langlands correspondence.

5. The 't Hooft operators of the gauge theory correspond to the Hecke operators of the geometric Langlands theory although these are now defined on the space of Higgs bundles, not G-bundles.

6. Using a certaing co-isotropic brane on M_H, magnetic eigenbranes give D-modules on the moduli space of bundles. The electric-magnetic duality coming from S-duality in the gauge theory relates electric and magnetic eigenbranes, giving the geometric Langlands duality between representations of the fundamental group of the Riemann surface in the Langlands dual group, and "Hecke eigensheaves" on the moduli space of G-bundles.

By the time he got to the 6th of these ideas, he was running out of time and things got very sketchy.

Witten made clear that this work doesn't directly give dramatic new physics or mathematics, but rather just explains some tantalizing relations between gauge theory and Langlands duality, ones that were first noticed in work of Goddard, Nuyts and Olive in 1976, and pointed out to him by Atiyah way back then. The geometric Langlands program is famous among mathematicians for its difficulty (I still have trouble getting my brain around the concept of a Hecke eigensheaf..), and for its tantalizing nature, bringing together a range of different mathematical ideas (many involving conformal field theory, although these seem to be different than what Witten is doing). The new relations between this subject and supersymmetric gauge theory and TQFTs that Witten has unearthed may very well lead to some very interesting new mathematical developments in the future. Undoubtedly it will take people a while to make their way through the new 220 page paper and absorb all that he and Kapustin have worked out since last summer.

Comments

   April 22, 2006

   Wow.

2. **MathPhys**
   April 22, 2006

   Wow, wow.

3. **ooh, a bandwagon**
   April 22, 2006

   Wow, wow, wow.

4. **ooh, a bandwagon**
   April 22, 2006

   Seriously though: is there any way to give a rough intuitive feel for what a Hecke eigensheaf is? My vague memory of a talk I heard once is that it's a way to define, given a particular curve on a given space, a sheaf on the moduli space of curves on the space? Is there a handwaving explanation of what it is and why we want it?

5. **Kea**
   April 22, 2006

   I have no idea, but I found this several-100-page definition by Beilinson and Drinfeld:

   http://www.math.uchicago.edu/~arinkin/langlands/hitchin/

   If we have to read these sorts of things as 'background' to the 200+ pages…well, I don't know how old you guys are…

6. **Kea**
   April 22, 2006

   The *first line* of section 1.1.1 reads: let Y be a smooth equidimensional algebraic stack over C.

7. **Tony Smith**
April 22, 2006

About the Witten/Kapustin paper at http://www.arxiv.org/abs/hep-th/0604151, Peter said:
"… The six main ideas were:
1. From a certain twisting of N=4 supersymmetric Yang-Mills one can construct a family of 4d TQFTs parametrized by a sphere. …".

Does that mean that the physics of the paper is no good if conventional 1-1 fermion-boson supersymmetry is no good?

Does that mean that the paper is likely to be interesting math but vacuous as to physics?

Could that explain "… Witten noticed that many of the Institute's mathematicians were there, and warned them that they had come to the wrong talk, since it was one aimed at physicists. Pierre Deligne got up and left …" ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – A quote from Burton Richter about such supersymmetry:
"… I would say that supersymmetry is a pure "social construct" with no supporting evidence despite many years of e□ort. It is okay to continue looking for supersymmetry as long as it doesn't seriously interfere with real work (top, Higgs, neutrinos, etc.). …".

8. **Kea**
April 22, 2006

Does that mean that the physics of the paper is no good if conventional 1-1 fermion-boson supersymmetry is no good?

Tony

Witten clearly knows perfectly well that 4d TFTs make much better physics than SUSY.

9. **Aaron Bergman**
April 23, 2006

There is little truly "new" physics in the paper. What it does is show how a fair chunk of the structures that show up in Geometric Langlands appear in compactifications of this particular twisted N=4 SYM theory. He also works out the details of the twistings, the D-branes, the Wilson and 't Hooft operators, the various moduli spaces, etc. What one hopes when one finds new connections between mathematics and physics is that each can inform the other. This is certainly not like SW theory where Witten revolutionized the study of the invariants of 4-manifolds, but hopefully this is a good beginning. Maybe we'll even learn a bit about gauge theory from all of this.

Some mathematicians got up and left, in all probability, because Witten was giving the talk for a physics audience. The language and backgrounds needed are often very different.

For Hecke operators, physics-wise they're very easy. In this theory, you've compactified the 4D theory on a Riemann surface cross the upper half plane. There is some boundary condition (ie, D-brane) on the boundary of the upper half plane. One can put an 't Hooft loop in the 4D theory located at a point on the Riemann surface and parallel to the boundary of the upper half plane. From far away, this looks like a different boundary condition, giving an operation on D-branes. The data of a point on the Riemann surface and a representation of the Langlands dual of the gauge group (which is associated to the 't Hooft loop just as a representation of the gauge group is associated to a Wilson loop) give a Hecke operators. This Hecke operators acts on the derived category just like the 't Hooft loop acts on D-branes which are objects in the derived category.

On the math side, I can't quite decipher my notes, but I do have something like this. I don't vouch for any of it. Given a vector bundle (all associated to a given G-principal bundle, maybe?) on a Riemann surface, we can pick a point and a subspace of the fiber at that point. We can then look at the space of sections that are restricted to live in that subspace at the chosen space. This is the space of sections of a new vector bundle (read 'coherent sheaf', perhaps). It turns out that the space of inequivalent operators has to do with pairs of vector bundles that are isomorphic on the complement of a point (making these, in a sense, local operators). With a little work, this gets related to a loop grassmanian and eventually a double coset space which turns out to be exactly the coweight lattice mod the Weyl group, ie, a representation of the Langlands dual group.

That probably doesn't help, does it.

10. **anon (previously "ooh, a bandwagon")**
April 23, 2006

Aaron, thanks for the physics definition of the Hecke operator; at least *that* formulation is easy to grasp. Unfortunately I don't quite see how to relate it to the math talk I once heard, or how to make sense of your math paragraph, but I suppose that's because of things like your "with a little work"…. 🙂

11. **?**
April 23, 2006

Are you sure you attended the talk for physicists?

Speaking seriously, why physicists not directly interested in mathematics of things like very-SUSY gauge theories should try to read that paper?

12. **Tony Smith**
April 23, 2006

If the "family of 4d TQFTs parametrized by a sphere"
is constructed from "N=4 supersymmetric Yang-Mills"
then
how do those "4d TFTs make much better physics than SUSY" ?
(Which Kea says is something that "Witten clearly knows perfectly well".)

Aren't those 4d TFTs plagued by the SUSY in the N=4 supersymmetric Yang-Mills from which they are constructed ?
If not, then where did the SUSY go ?

Are Witten/Kapustin saying that their 4d TFTs break the SUSY, and are they presenting this work as a physical mechanism of SUSY symmetry breaking ?

If the SUSY is physically wrong, and is not broken by their 4d TFTs, then wouldn't their model be unrealistic as a physics model ?

Of course, as in index theory, Donaldson theory, etc, SUSY can be very useful in mathematics, so again it seems to me that the paper is likely to be very interesting math, but vacuous as physics.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

13. **Peter Woit**
April 23, 2006

Tony,

The theories being studied here are not the sort of physical supersymmetric theories that some people believe are physically realistic. They are TQFTs derived from supersymmetric gauge theories, much like the TQFT used in Donaldson theory. Witten is not claiming they are relevant to the real world, just that they lead to interesting mathematics.

14. **Bert Schroer**
April 23, 2006

Peter,
the danger of such a talk to a physicists audience by a famous personality with a rich pre-Atiyah physics past is of course that all the problems of placing sophisticated mathematics on top of conceptually underdeveloped physical ideas will agrevate the present crisis. The interesting sociological aspect is that top mathematicians seemed to have lost some of their unqualified admiration with which they looked at the physicist's magic.

15. **Tony Smith**
April 23, 2006

Peter said "… Witten is not claiming …[the TQFTs in hep-th/0604051]… are relevant to the real world, just that they lead to interesting mathematics. …". I certainly agree with the claim of "interesting mathematics".

However, as to "the real world", look at the reaction of a very smart conventional superstring theorist, Aaron Bergman. He said:
"… There is little truly "new" physics in the paper. …
He [Witten] also works out the details of the twistings, the D-branes, the Wilson and 't Hooft operators, the various moduli spaces, etc. …
For Hecke operators, physics-wise they're very easy. … This Hecke operators acts on the derived category just like the 't Hooft loop acts on D-branes which are objects in the derived category. …
What one hopes when one finds new connections between mathematics and physics is that each can inform the other. …
Some mathematicians got up and left, in all probability, because Witten was giving the talk for a physics audience. The language and backgrounds needed are often very different. …".

It seems to me that Aaron Bergman, a physicist, is saying that hep-th/0604051 DOES contain what he considers to be physics (in fact, not even "new" physics, and so therefore stuff already well known to be physics),
and that he hopes that the math of hep-th/0604051 will be seen to be connected to physics (and therefore to the physical real world).

As Bert said, there is "… danger …[in]… such a talk to a physicists audience …",
particularly if it is so physics-oriented that Witten felt called upon to have "… warned … mathematicians … that they had come to the wrong talk …".

Again, please let me repeat that hep-th/0604051 (from what discussion I have seen about it) does seem to me to be likely to be very interesting mathematically, as was the use of SUSY in index theory, Donaldson theory, etc.

Why did the authors submit it to the physics archive hep-th instead of the math archive (and why did the Cornell arXiv moderators allow it to be placed in hep-th) ?
They could have submitted it to the math archive (since it is likely to be very good math) with a cross-listing to hep-th (since it uses some techniques and structures that are discussed in papers on hep-th).
However,
they submitted it to the physics archive hep-th which seems to me to indicate that the authors DO think of the paper as being physics, which implies describing physical reality – or has conventional superstring theory so distorted the definition of "physics" that description of physical reality is no longer part of it ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

16. **Bert Schroer**
April 23, 2006

Tony
thanks for your pertinent question. I do not see any scientific answer, again it seems to be sociological.

17. **Bert Schroer**
April 23, 2006

The moderation of hep-th/ which should be geared to particle theory is indeed highly biased.
Distler rejected a single cross listing in hep-th of my paper about the protagonist of QFT Pascual Jordan (I think it is important to know one's own history and my article contains some little known facts which have profoundly influenced my present research on advanced QFT). It is clear that he did not approve of the political introduction (the only reason why I sent it to physics/, and not to hep-th). His note of cross rejection reads:
Dr. Schroer,
Your paper does not appear to deal even indirectly with theoretical high
energy physics, and therefore seems inappropriate for cross-listing in hep-th.
We appreciate your cooperation.
arXiv moderation
(this was his answer to my letter: Dear arXiv-moderation,
I kindly ask you to rescind your decision against cross-listing my paper physics/0603095 in hep-th. My reason is that about 80% of the essay deals with the protagonist of QFT Pascual Jordan (including some new fact which I found through the study of his old Zeitschrift fuer Physik papers) and having only one cross listing cannot be

interpreted as any abuse of the cross-listing system.
with friendly regards
Bert Schroer)
I of course could have answered him that this is an updated small part of an extensive paper on Jordan which was not cross listed but rather posted some time ago on hep-th without any problem, but I got tired of this nonsense.

18. **Aaron Bergman**
April 23, 2006

Speaking seriously, why physicists not directly interested in mathematics of things like very-SUSY gauge theories should try to read that paper?

You probably shouldn't if you don't like this sort of thing.

I should say, BTW, that much of the point of this paper is that many things in the geometric Langlands program that seem like hopelessly abstruse math from the physics prespective (of course mathematicians feel otherwise) turn out to be natural objects in the physics, in fact, objects that we've known and loved for years.

19. **anonymous**
April 23, 2006

Tony writes:

"However, they submitted it to the physics archive hep-th which seems to me to indicate that the authors DO think of the paper as being physics, which implies describing physical reality"

I wouldn't say that. Theories with N > 1 SUSY or topological field theories have been considered "physics" for some time, and rightly so — they have much in common with things that describe physical reality, but they are easier to solve. That they are unrealistic does not mean they are not physics.

Think of it this way: the study of Newton's laws in the context of frictionless ramps and pulleys, which every student learns, is considered "physics", even though it's really just a dramatic oversimplification of reality. If you can't understand the dramatically simplified, solvable examples, good luck trying to understand the mechanics of real-world systems! TQFTs and N=2 SUSY QFTs and such things have an analogous relationship to the Standard Model.

20. **urs**
April 23, 2006

> Think of it this way: […]

Yup, that's why there is a "th" at the end of "hep-th", not a "ph".

21. **woit**
April 23, 2006

Bert,

I don't think what Witten is doing here will aggravate the present crisis, which I see as driven mainly by ideological attachment to the failed idea of string-based unification. There are problems with the way physicists approach the use of mathematics in their work, but I don't think these are the main reason for the current sad state of particle theory.

Actually the fact that this new work of Witten has little to do with string theory, but instead relates 4d gauge theory and interesting mathematics, seems to me rather encouraging. Perhaps it will cause people to move on from failed string theory projects to something more promising. It will be very interesting to see what effect this work has. The mathematics involved is rather difficult, and the QFT techniques are pretty intricate, so I'm not so sure how many people will be willing or able to follow Witten into research in this area. But then, nothing much else is going on.

Tony,

The use of QFT to do new things in math is very much on the boundary of the two subjects, and I don't see anything to be gained by saying it is "not physics", or "not math". It's both, potentially leading to both new insights about math and about QFT, and there's no reason for it not to be on hep-th. The problem with hep-th these days is not that it is too mathematical, it is that it's full of worthless work about completely obscure and pointless results supposedly related to string theory. Some of this is mathematically sophisticated, most of it isn't.

22. **Levi**
April 23, 2006

My reaction to Peter's post was similar to that in the first five comments on this thread. Does anybody want to make an estimate of how many people in the world will have both the expertise and the sustained interest to carefully read this paper when it appears? Is there anyone reading this comment who is planning to undertake the task?

I'm not making this comment to denigrate Witten's work on this subject. I'm genuinely curious about the number of people who are expert enough in both math and physics to work in this area.

23. **anonymous**
April 23, 2006

Levi wrote:

Does anybody want to make an estimate of how many people in the world will have both the expertise and the sustained interest to carefully read this paper when it appears? Is there anyone reading this comment who is planning to undertake the task?

I think a lot of people will read it, though maybe not so many will read it carefully and in detail. Aaron's comments make it pretty clear that the physics is nothing exceptionally weird; it should be comprehensible to many, many people. The technical details of current work in geometric Langlands seem much less approachable, at least from the perspective of a physicist, but Witten is coming at this from a physics perspective so I'm sure he will explain some of this in understandable language. Furthermore, he's an exceptionally clear expositor and his papers tend to be surprisingly readable even when they're rather technical.

24. **Levi**
April 23, 2006

Here's a link to a paper dicussing the relationship between Langlands and CFT, written for physicists, evidently.

http://www.arxiv.org/abs/hep-th/0512172

25. **?**
April 23, 2006

dear anonymous,

the analogy with friction forgets the fact that (so far) only one strongly coupled gauge interaction is relevant for physics: QCD. From a fundamental point of view, QCD is a successfully closed issue, despite the fact that doing computations around 1 GeV is hard. Since the s and c quark masses are around 1 GeV, it seems unlikely that QCD has some hidden mathematical simplicity: more likely brute-force lattice will continue to be the only way of getting physically relevant results.

26. **Aaron Bergman**
April 23, 2006

Actually the fact that this new work of Witten has little to do with string theory, but instead relates 4d gauge theory and interesting mathematics, seems to me rather encouraging.

The topological string is very important here, particularly with the identification of the compactified theory as an A- or B-model and the boundary condition technology that goes with that.

I don't know how many people will end up reading the thing, but I can tell you that it includes me for what it's worth. We had a semester long seminar on geometric Langlands and physics here at UT which definitely helps. That and having David Ben-Zvi around to answer questions on the math side.

27. **woit**
April 23, 2006

Aaron,

Does the "topological string" really come into this? As far as I can tell (not having yet read the 220 page paper…), what is involved are TQFTs based on a fixed Riemann surface or Riemann surface with boundary. This is 2d QFT, not string theory if you're not summing over genera.

28. **Aaron Bergman**
April 23, 2006

This is a semantic argument probably not worth having, but in their full glory, the Hecke operators act on derived categories and the like which correspond to the possible branes in the theory. Call that whatever you want; that's the physics.

29. **woit**
April 23, 2006

Personally, I'd call 2d QFT on a fixed 2d background "2d QFT", not string theory, even when there's a boundary. But, that's just me.

30. **anonymous**
April 23, 2006

"Personally, I'd call 2d QFT on a fixed 2d background "2d QFT", not string theory, even when there's a boundary. But, that's just me.

LOL! And then he goes on to say its a matter of semantics! What a ridiculous comment by Bergman. But, that's just me.

31. **Fine**
April 23, 2006

It is evident that most people have no clue whatsoever about the Langlands Program.Also, it is absurd that people are arguing whether the paper should be in hep-th. Has anyone beside Aaron have anything concrete to say? I look forward to see the analysis of the 220 page paper (not just what Witten said in the Simon's workshop)

32. **CapitalistImperialistPig**
April 23, 2006

Levi – thanks for the link, but you ask *Does anybody want to make an estimate of how many people in the world will have both the expertise and the sustained interest to carefully read this paper when it appears?*

Let me offer up the answer of Mathew 22:14 *Many are called, but few are chosen*

Saint John Chrysotom opined: *"Among thousands of people there are not a hundred who will arrive at their salvation, and I am not even certain of that number, so much perversity is there among the young and so much negligence among the old."*

The theological evidence makes it pretty clear that only Aaron and 99 others are likely to be among the saved.

…………(the old and negligent)

33. **Levi**
April 23, 2006

most recent anonymous,

From the introduction to the paper that I linked to above:

"In recent lectures E. Witten outlined a possible scenario of how the two dualities – the Langlands duality and the S-duality – could be related to each other. It is based on a dimensional reduction of a four-dimensional gauge theory to two dimensions and the analysis of what this reduction does to "D-branes". In particular, Witten argued that the t'Hooft operators of the four dimensional gauge theory recently introduced by A. Kapustin become, after the dimensional reduction, a Hecke "eigensheaf", an object of interest in the geometric Langlands correspondence."

So it really *is* a semantic argument.

34. **Bert Schroer**
April 23, 2006

Peter,
your view that the present crisis of particle physics is solely caused by a mental perversion called string theory does not hold water. It is simply not true that particle physics was healthy up to the day when sinister string theory appeared on the scene. Neither can one expect that the crisis in particle physics would evaporate suddenly if only the protagonists would see (and admit) that they are heading into the blue yonder where there will be no physical landing place.
Such paradigmatic changes in the delicate relation between the weight physical concepts in relation to sophisticated mathematical formalism do not happen out of a sudden, they rather announce their coming a long time before. The profound misunderstandings in the role of Euclideanization and that of the artistic role of the path integral (at one time in the not so distant path more than 90% of papers on gravity in the QFT setting were written in the euclidean Riemannian setting) were such warning signs.
Particle physics in particular in its local quantum physical setting has its own powerful autonomous conceptual structure and to make it jump over a ready made mathematical stick (or a more floppy string) like a dog does not have much of the chance. The first mathematician who saw that was of course von Neumann and his present day's followers are asking local quantum physics what kind of mathematical concepts it leads to. Differential geometry you can impose on functional integrals but not on the principles underlying QFT.
The point which Tony Smith made is absolutely crucial and your struggle against the aberrations of string theory will be futile if you do not recognize the root of problems and keep looking only at the symptoms.

35. **CapitalistImperialistPig**
April 23, 2006

Bert and Peter – Conceptual roadblocks are not exactly new in physics or any other science. In physics, these are usually surmounted with the help of new experiments. The *crisis in particle physics*, such as it is, is due to the fact that we have neither new data nor important unexplained experimental facts. I suspect that new breakthoughs may have to wait for new data – or at least for a theory that makes an accessible prediction.

36. **woit**
April 23, 2006

CIP (and Bert),

Sure, the fundamental problem is that physics is used to making progress by getting new clues from experiment and it hasn't gotten any in a long time. But, even with a lack of new experimental clues, theorists still can learn new things and slowly make progress, although it's a lot harder. To do this, I think they need to try many different things, since it is very unclear what is the right direction to go in. The kind of new algebraic thinking about the fundamentals of QFT that Bert advocates is one direction that should be pursued, I also think there are geometrical ideas motivated by path integrals that also deserve attention. The problem with the dominance of string ideology has been the way it has driven out the kind of other very different ideas that should be tried, of very different kinds.

37. **Kea**
April 23, 2006

The link works! Right. References first, hmmm: Gualtieri, Runkel et al on CFT, Hausel, plus all the obvious ones…dammit, I might have to try and read this…but I'm not expecting to get far in a hurry. 🙂

38. **Kea**
April 23, 2006

Peter previously mentioned the helpful article:

Mikhail Kapranov, *Analogies between the Langlands correspondence and topological quantum field theory*, in Functional Analysis on the Eve of the 21st Century, Vol. 1, Birkhauser, Boston, pp. 119-151.

39. **Who**
April 23, 2006

several comments here have discussed the general issue of crisis in physics, so I hope it will not be off topic to provide a link followup to Peter's post of 25 January "Die Physik steckt in der Krise"
http://www.math.columbia.edu/~woit/wordpress/?p=334

To some extent that post and comments thereto concerned Reiner Hedrich, who was funded by the German Science Foundation to study the situation in theoretical physics and was interviewed for the article in Die Zeit.

Hedrich posted this article on arXiv today
http://arxiv.org/abs/physics/0604171
String Theory – From Physics to Metaphysics

In the earlier chain of comments Andre Bresges gave a bit of background on Hedrich and the author, Max Rauner, of the article in Die Zeit
http://www.math.columbia.edu/~woit/wordpress/?p=334#comment-8199
and Eli Rabett provided this translation
http://rabett.blogspot.com/2006/01/lost-this-is-something-of-new.html

since the earlier coverage of Hedrich and his study of (at least confusion and misdirection, if not) crisis in theoretical physics was interesting, I thought some might wish to have a look at Hedrich's 30-page paper.

40. **Arun**
April 23, 2006

The line "Although multiverse scenarios and anthropic selection are not only motivated by string theory, but lead also to a possible explanation for the fine tuning of the universe, they are concepts which transcend the framework defined by the epistemological and methodological rules which conventionally form the basis of physics as an empirical science. " is so exceedingly polite 🙂

41. **Kea**
April 23, 2006

Witten on page 5: *A second major gap [in this paper] is that we do not shed light on the utility of two-dimensional CFT for the geometric Langlands' program*. Sigh.

42. **woit**
    April 23, 2006

    Kea,

    That's the strange thing about Witten's recent work: it seems to involve quite different uses of 2d QFT to get Langlands duality than the 2d CFT ideas that have motivated the mathematicians doing geometric Langlands (and that are discussed for instance in the Frenkel review article). Well, this means there is still a lot about this story which is not understood, which means there is still a lot to do…

43. **woit**
    April 23, 2006

    Who,

    Thanks for pointing that out. A quick read of it leaves me with the impression that he's avoiding just drawing the simplest conclusion from all the material about the problems of string theory that he has gathered: it's a wrong idea about unification and should be abandoned.

44. **Kea**
    April 23, 2006

    But they reference Runkel et al, and they seem to use Riemann (2D) surfaces like a skein theorist would, and take a look at Kapustin's [41] for motivation, and and and…

    Why don't they *even comment* on the utility of category theory here? Is it because it's all obvious to them?

45. **Kea**
    April 23, 2006

    Frankly, I'd rather be talking about geometric Langlands here…

    Thank you. Perhaps you could summarise some of your views of this paper so far.

46. **Aaron Bergman**
    April 24, 2006

    I'm waiting for the book :).

    Seriously, it's too long to completely absorb. Much of it is showing that things that intuitively ought to work really do so, like the particular twisting of N=4 SYM, the action of S-duality, and the details of the sigma model you get when compactifying. (On that point, it's much more readable to me than Vafa's work on the subject, but, then, I almost always find Vafa incomprehensible.) I like the sections on the action of the 't Hooft and Wilson operators. After various skims, it looks like the new math, if anywhere, is hiding in the book. I'm not sure what it leaves to say about the physics of this particular model, though. It's an impressive exegesis.

    What the paper does, I think, is bring Langlands to physicists. What I'm not sure it does is bring the physics to the mathematics. But that's not a criticism; it's probably too much to ask Witten to revolutionize every mathematical subject he thinks about, and we haven't even seen the book yet. As usual with when physics meets mathematics, it amazes me how many of the things that snow up in the physics had already been anticipated by the mathematicians. I guess they're smart, too.

    The good news (for me at least), is that it doesn't kill the project I've been thinking about with a few other people on the subject. You'd like it; it has categories in it.

47. **Kea**
    April 24, 2006

    🙂 Cheers

48. **Not a Nobel Laureate**
    April 24, 2006

    The discussion of the Witten paper reminds me of the bon mot about Schwinger.

    "Other people publish to show how to do it. Julian Schwinger publishes to show that only he can do it."

    Of course, the similarity is superficial. Schwinger's physics papers contained testable predictions – the Lamb shift, the gyromagnetic ratio, etc.

49. **Aaron Bergman**
    April 24, 2006

    The discussion of the Witten paper reminds me of the bon mot about Schwinger.

    "Other people publish to show how to do it. Julian Schwinger publishes to show that only he can do it."

    That's remarkably inapposite. Witten is one of the best expositors in the field.

50. **amanda**
    April 24, 2006

    "That's remarkably inapposite. Witten is one of the best expositors in the field."

    That's rather like saying that Jesus Christ was one of the most important characters in the New Testament. EW completely revolutionized the way papers are written. Which makes his current tedious divagations all the more painful. We are all waiting for him to show us the way forward, and this is what we get? I mean, does anyone really believe that this is going anywhere? A sad contrast to http://arxiv.org/abs/hep-th/0106109, let alone the 1998 papers…..

51. **dan**
    April 24, 2006

Has Witten made any reviews or comments or written any papers on background independent quantum gravity, esp LQG, spin foam, or CDT approaches? Has he shown any interest in these approaches?

52. **woit**
April 24, 2006

Dan,

No, and those topics have nothing to do with this posting.

53. **bigbigbig**
April 24, 2006

dear experts and crackpots,

about the 2d QFT or string theory argument, yeah, I think it's only fair to call it string theory once you couple the topological sigma model to 2d gravity.

54. **Tony Smith**
April 24, 2006

Here are four questions that came to mind after initially looking at the Kapustin-Witten paper. I apologize in advance for their simple-mindedness.

Kapustin and Witten say:
"… N = 2 super Yang-Mills theory can be twisted to make a quantum field theory realization of Donaldson theory …
Similarly, N = 4 super Yang-Mills theory can be twisted in three ways to make a topological field theory. Two of the twisted theories … are closely analogous to Donaldson theory … The third twist … turns out to be the twist relevant to the geometric Langlands program, and we will call it the GL twist. …
A hyper-Kahler manifold has … a family of complex structures parameterized by CP1, obtained by taking linear combinations of I, J, and K …[with]… quaternion relations … ".

Donaldson, in Bull. AMS 33 (January 1996) 45-70, said:
"… in the latter part of 1994 … the work of Witten and Seiberg … used … N = 2 supersymmetric Yang-Mills theory … The essential ingredient … is … a duality between electricity and magnetism proposed in 1977 by Olive and Montonen. …".

Question 1:
Is it fair to say that Seiberg-Witten Donaldson theory is based on complex (N=2 SYM) electricity-magnetism duality, and Kapustin-Witten Langlands theory is based on extending that duality to the quaternionic (N=4 SYM) case ?

Kapustin and Witten also say:
"… N = 4 super Yang-Mills is most easily constructed by dimensional reduction from ten dimensions. Ten dimensions is the maximum possible dimension for supersymmetric Yang-Mills theory … the metric of ten-dimensional Minkowski space R1,9 or Euclidean space R10 … have symmetry groups SO(1, 9) or SO(10) … To reduce to four dimensions, we simply take all fields to be independent of the coordinates x4, . . . , x9. The components AI , I = 0, . . . , 3 describe the four-dimensional gauge field … while the components AI , I at least 4, become four-dimensional scalar fields … the symmetry is really Spin(1, 9) reduced to Spin(1, 3) x Spin(6) (or Spin(10) reduced to Spin(4) x Spin(6)). The group Spin(6) is isomorphic to SU(4) and is known as the "R symmetry group" of the theory. We will call it SU(4)R. …".

Questions 2 and 3:
Isn't that SU(4)R the conformal group used by Jackiw and Rebbi in Phys. Rev. D 14 (1976) 517 entitled "Conformal properties of a Yang-Mills pseudoparticle" ?

Might it not be useful to extend the quaternionic approach of Kapustin and Witten to octonionic structures based on the approach of Grossman, Kephart, and Stasheff in Commun. Math. Phys. 96 (1984) 431-437, where they said: "… In the present paper we will study the properties of the last fundamental Hopf map (i.e. the Hopf fibration of hte 15-sphere …) in relation to solutions of pure eight dimensional Euclidean Yang-Mills field equations with gauge group Spin(8). … The solution is invariant under the action of Spin(9) … which is a subgroup of the Euclidean conformal group O(9,1) in eight dimensions. … Let us proceed in analogy with Jackiw-Rebbi …" ?

Question 4:
As to octonions, in math.RA/0105155 John Baez said: "… the canonical octonionic line bundle over OP1 generates Bott periodicity …".
What might be the role of Bott periodicity in an octonionic generalization of the Kapustin and Witten paper ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

55. **Aaron Bergman**
April 24, 2006

Is it fair to say that Seiberg-Witten Donaldson theory is based on complex (N=2 SYM) electricity-magnetism duality, and Kapustin-Witten Langlands theory is based on extending that duality to the quaternionic (N=4 SYM) case ?

Not really. The duality is most present in N=4 SYM. Seiberg-Witten theory is, in a sense, the residue of that duality in the N=2 case. When you do a topological twist of N=2 SYM, you get a theory that computes Donaldson invariants. Applying the Seiberg-Witten results on N=2 SYM to this twisted theory gives rise to Seiberg-Witten invariants of 4-manifolds. There are a number of different twists of N=4 SYM. The ones related to Donaldson invariants were investigated by Vafa and Witten. This is a different twist. Nonetheless, all of this is related to the S-duality of N=4 SYM.

I don't know what sense SU(4) is a conformal symmetry. The conformal symmetry in N=4 SYM in 3+1 D is PSU(2,2) ~= SO(4,2). The full symmetry supergroup is PSU(2,2|4). The SU(4) is the R symmetry, not the conformal symmetry.

I'm not sure the relevance of quaternions, much less octonions, to this whole thing. You can't add more supersymmetry to N=4 SYM, regardless, as that would entail particles with spin greater than one, and it wouldn't be a gauge theory any more.

56. **urs**
April 24, 2006

> all of this is related to the S-duality of N=4 SYM.

Which again is thought to come from the modular transformations of a torus on which you have compactified some 6D theory to 4-dimensions.

Do you know if the Langlands thing has a nice interpretation in these six dimensions?

57. **Aaron Bergman**
April 24, 2006

That's certainly a question that has occurred to many people. I can't remember if the relevant twist can be thought of as coming from six dimensions, however.

58. **Who**
April 24, 2006

In response to Dan's question *Has Witten made any reviews or comments or written any papers on background independent quantum gravity…?*
there is negative comment on the (Kodama) QG ground state employed by Lee Smolin and others. see this article:
http://arxiv.org/abs/gr-qc/0306083
A Note On The Chern-Simons And Kodama Wavefunctions
Edward Witten
Exerpt from abstract: "Yang-Mills theory in four dimensions formally admits an exact Chern-Simons wavefunction. … It is known to be unphysical … Similar properties can be expected for the analogous Kodama wavefunction of gravity."

Exerpt pages 1 and 2:
"…This is what we call the Chern-Simons state. It is far from being normalizable,..
The Chern-Simons wavefunction of Yang-Mills theory has an **even more surprising gravitational analog, commonly called the Kodama state [2]. Some authors have proposed the Kodama wavefunction as a starting point for understanding the real universe; for a review and references, see [3].** Our discussion here will make it clear how the Kodama state should be interpreted. For example, in the Fock space that one can build (see [3]) in expanding around the Kodama state, **gravitons of one helicity will have positive energy and those of the opposite helicity will have negative energy**.

—references—
…
[2] H. Kodama, "Holomorphic Wave Function Of The Universe," Phys. Rev. D42 (1990) 2548.
[3] L. Smolin, "Quantum Gravity With A Positive Cosmological Constant," hep-th/0209079.
…
——————
Lee Smolin just finished given a course to University of Waterloo students called Introduction to Quantum Gravity using the cited article as his main text. The course has 25 lectures, video is available online, and it goes thorough much of hep-th/0209079 section by section.

For a modern view of the LQG ground state
http://arxiv.org/abs/gr-qc/0604044
Graviton propagator in loop quantum gravity
Rovelli et al.
this cites Smolin on the Kodama ground state as reference [38] on page 17.
It is still not clear how generally Witten's apprehensions concerning the LQG ground state apply, if they do. For example see page 2 of the Rovelli et al paper:
"…The physical correctness of these theories has been questioned … two "bad" terms: an exponential with opposite sign,… and a dominant term … We show here that only the "good" term contributes to the propagator. The others are suppressed by the rapidly oscillating phase in the vacuum state that peaks the state on its correct extrinsic geometry. Thus, the physical state selects the "forward" propagating [33] component of the transition amplitude. This phenomenon was anticipated in [34]…"

====================
so I would amplify what Peter said, in reply to Dan.
YES Witten has published comment on LQG (in particular the notion that proposed LQG ground state might have forwards and backwards propagating gravitons—something addressed recently in a different context by Rovelli), however as Peter rightly points out this is NOT GERMANE TO THE POSTING.

59. **urs**
April 24, 2006

> I can't remember if the relevant twist can be thought of as coming from six dimensions, however.

At least in 6D there are candidate strings which one could hope would have a topological twist.

60. **urs**
April 24, 2006

Aaron,

if you ever feel like saying more about that autofunctor on the category of branes and how it comes from line operators in a fashion considered in FRS formalism (as remarked by Witten/Kapustin on p. 100), please don't hesitate. 🙂

(I will be awfully busy the next days. After that I might try to have a look at this.)

61. **Aaron Bergman**
April 24, 2006

Dunno much about FRS. Sorry. Guess you'll have to wait for the book.

62. **Tony Smith**
April 24, 2006

Aaron Bergman said that he doesn't "… know what sense SU(4) is a conformal symmetry. The conformal symmetry in N=4 SYM in 3+1 D is PSU(2,2) ~= SO(4,2). … The SU(4) is the R symmetry, not the conformal symmetry. …".

SU(4) is the Euclidean version of conformal symmetry, since SU(4) = Spin(6) = Euclidean version of the conformal group.
If you use nonEuclidean signature, the relevant conformal group is SU(2,2) = Spin(2,4).

As to their use of the Euclidean SU(4) = Spin(6) version of the conformal group, Kapustin and Witten say:
"… The twisted theory is a formal construction in the sense that twisting violates unitarity and only works in Euclidean signature. … To construct a twisted theory in Lorentz signature, we would have needed a suitable homomorphism Spin(1, 3) into Spin(6). Because of the compactness of Spin(6), a non-trivial homomorphism does not exist. If one replaces Spin(6) by Spin(1, 5) to work around this, the couplings to fermions will no longer be hermitian and the energy is no longer bounded from below. … however …

we split off the time direction and take M = R x W, where R parametrizes the time, W is a three-manifold, and
the metric on M is a product. Then time is not involved in the twisting, and the twisted theory makes sense with Lorentz or Euclidean signature and is unitary and physically sensible. …".

In other words, Kapustin and Witten transfer the signature complications from the conformal group to the manifold by continuing to use the Euclidean conformal group SU(4) = Spin(6) but changing the manifold from something like S4 (where time is on an equal footing) to something like S1 x S3 (where time is S1 and space is S3).

Aaron Bergman also says that he is "… I'm not sure the relevance of quaternions, much less octonions …".

Perhaps octonionic structure might be relevant to Loop Operators. Kapustin and Witten say:
"… What is really unusual about the four-dimensional TQFT's … compared to other theories with a superficially similar origin, is that they admit operators that are associated to oriented one-manifolds …
In gauge theory, the most elementary loop operator is the Wilson loop operator. ,,,
In our problem, the dual of a Wilson operator is an 't Hooft operator … ".

Since the imaginary octonions generate the 7-sphere S7, and since S7, although not a Lie algebra, is a Malcev algebra (having no Jacobi identity, but instead a Moufang identity) with naturally occurring Moufang loops, the ideas in the paper by Loginov at hep-th/0109206 might be useful. Loginov says:
"… the linear representations of analytic Moufang loops … are closely associated with the (anti-)self-dual Yang-Mills equations in R8. …".

April 24, 2006

The Euclidean version of the conformal group is SO(5,1). su(4) ~= su(6) is the compact form of the complexification of so(5,1). I'll leave the rest for someone else.

64. **Michael**
April 24, 2006

Peter,
you do know that SUSY gauge theories are intimately related, in many cases exactly equivalent, to certain string theory backgrounds, don't you? SUSY gauge theories "know" automatically about extra dimensions and many other things. If you can draw a reasonably clear line between SUSY gauge theories and string theory, do that and publish it. If not, you better stop claiming that the "new work of Witten has little to do with string theory".

65. **woit**
April 24, 2006

Michael,

Sure, the same theory Witten is twisting to get his TQFT (N=4 supersymmetric YM), is related to string theory on AdS space. But that plays zero role in the Kapustin/Witten paper. This may be the only paper in recent years involving N=4 supersymmetric YM that doesn't reference Maldacena's AdS/CFT paper.

Feel free to point out where in Witten's new work string theory plays an important role. Otherwise, stop making a fool of yourself.

66. **John Gonsowski**
April 24, 2006

"The Euclidean version of the conformal group is SO(5,1). su(4) ~= su(6) is the compact form of the complexification of so(5,1)."

My guess is that Tony is talking the Lie Algebra for the group and you are talking just the group and since Kapustin and Witten seem to be talking Lie Algebra, I'll vote for Tony's rendition even if you would have preferred Tony to be more precise. (I am of course biased and have plenty of trouble getting the general idea without worrying about things like signatures and the group vs. the algebra).

67. **Michael**
April 24, 2006

Peter,

string theory provides a geometric picture that is *equivalent* to the quantum dynamics of the SUSY gauge theory. Whether you talk about one or the other is a question of terminology.

Since you asked, let me give you two examples, which you missed because you either didn't read or didn't understand the paper. The first shows the importance of string theory to the present work, the second the importance of the present work to string theory.

(1) The massless open-string states of the canonical co-isotopic brane furnish the brane's endomorphism algebra. In perturbation theory, open strings form a sheaf of noncommutative algebras. These statements are at the heart of understanding the mathematical significance of eigenbranes. Rest assured that these facts would have remained obscure were it not for the authors' extensive experience with "physical" string theories.

(2) The Blau-Thomson construction of Wilson operators of TQFTs and their magnetic duals plays an important role in recent string theory research. References are given at the beginning of Section 6. The present work deepens our understanding of the construction.

68. **Aaron Bergman**
April 24, 2006

I'll vote for Tony's rendition

You're welcome to think whatever you want.

69. **woit**
April 24, 2006

Michael,

I don't doubt that the author's experience with string theory taught them many things that were useful in this work, and I also don't doubt that lots of facts about these kinds of TQFT are useful to to string theorists. But, neither of these makes string theory an important part of this work. By your logic, string theory is an important part of virtually anything anyone does these days in pure QFT, since it is likely they learned some facts about QFT by thinking about string theory, and it is likely that most anything about QFT will have some application to string theory somehow somewhere.

If you want to feel better about the failure of string theory by going on about how gauge theory and 2d TQFT is really string theory, no one's going to stop you, but it is kind of silly.

70. **anonymous**
April 24, 2006

By your logic, string theory is an important part of virtually anything anyone does these days in pure QFT

Peter sees the light! 😉

71. **Tony Smith**
April 24, 2006

It seems necessary for me to clarify terminology and notation.

Lorentz group = Spin(1,3) of Minkowski space

anti de Sitter group = Spin(2,3) = Sp(2) used in supergravity

Conformal group = Spin(2,4) = SU(2,2)
It is the group Spin(p+1,q+1) of which the Lorentz group Spin(p,q) = Spin(1,3) of Minkowski space is a subgroup.

I used the term Euclidean Conformal group in the sense that the 6-dim space over which the Spin group acts has Euclidean signature (0,6), so that in my terminology Euclidean Conformal group = Spin(6) = SU(4).

I think that in Aaron's terminology Euclidean Conformal group is taken to mean Spin(1,5) in the sense that it is the group Spin(p+1,q+1) of which the group Spin(p,q) = Spin(0,4) of Euclidean 4-space is a subgroup.

I hope that this clarifies the terminology I was using. Even if you prefer Aaron's terminology, and I think that it is fair for you to do so, the meaning of my comments should now be clear.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

72. **Kea**
April 25, 2006

Peter sees the light!

I must say, I agree with anonymous. Come on, Peter! Why not start calling yourself a String theorist? It's just a name. Then we could stop having these silly arguments.

73. **Chris Oakley**
April 25, 2006

I feel that I ought to now apply for a grant from the Templeton Foundation. Using what title, I wonder? Let me see: "0-dimensional, non-supersymmetric string theory in 3+1 dimensions".

No, too boring. They'll fall asleep as soon as they open the envelope. How about "Searching for God using 0-dimensional, non-supersymmetric strings in 3+1 dimensions?"

Better, but I still don't think that they'll go for it. I know! "Searching for remnants of the Primordial Sneezing by studying 0-dimensional, non-supersymmetric string theory in 3+1 dimensions". That *might* do it! Of course, I'll mention God if I have to.

74. **urs**
April 25, 2006

> Why not start calling yourself a String theorist?

I predict that in the future everybody will be a string theorist for 15 minutes.

More seriously, it seems to be true that string theory is like a large dictionary of field theories. Many subtle things about field theories find their explanation when regarding their embedding into string theory. In the case under discussion here, it is not only AdS/CFT. There is an embedding of 4D SYM into a 6D theory which is believed to explain the S-duality of the SYM. That 6D theory is some theory of strings on 5-branes. (I guess that's in the end the more relevant embedding for the Langlands program. But what do I know.)

Fields and strings are tightly interwoven. Many feel that this suggests that strings play a role in nature. This is often refered to as the "qualitative" agreement of string theory with observation. And it's true.

Quantitative agreement is a different issue, as readers of this blog might have heard somebody say before.

While it is only fair to admit the phenomenological problems of the idea of string unification, it is also only reasonable to acknowledge the usefulness of strings for understanding issues in field theory.

75. **Zelah**
April 25, 2006

Here is my piece regarding what Witten et al has wrought!

Whatever you think of Mr Witten's acheivements in regards to phyiscial predictions, as a leader of physics he is our Grothendieck.

Like Grothendieck, he did not actually reach the promised land, but revolutionised the way EVERYONE THOUGHT ABOUT MATH/PHYSICS.

Grothendieck showed mathematicians how to be CREATIVE yet rigourous! Witten is now showing physicists how to UNDERSTAND the world, without experimental data!

I think that Mr woit has constantly underestimated this problem of lack of expermental data for the high energy community since the 1980's. Mr Witten's brilliance was to create a physics program enlightened enough that some the worlds best minds like Maldecena and Brian Greene became physicists and not say molecular biologists!

Reading Mr Witten latest efforts are truely awe inspiring! Even thought I understand maybe 1% of what was going on, The way Witten illuminates areas of Mathematics I was always fascinated by in with such ease is magical to observe.

Finally, it is obvious to me that String Theory is changing everyone way of thinking regarding QFT! The reason for this is SUSY, which is natural from a Stringy point of view, but completely unmotivated from a QFT point of view! SUSY/Strings is allowing theorists to examine models which are intractable without these insights! Seiberg_Witten is unthinkable without these insights!

This is the point. How does one think about SUSY concepts starting from QFT? If you Mr Woit can generate INTERESTING theoretical physics models from pure QFT, please feel free to publish.

An amateur mathematician.

76. **Thomas Larsson**
April 25, 2006

This is the point. How does one think about SUSY concepts starting from QFT?

As something which for all practical purposes has already been disproven by experiments. We just wait for the LHC to be the last nail in the coffin 🙂

77. **Chris Oakley**
April 25, 2006

The position of supersymmetry as a physical phenomenon is summarised by the plight of the Black Knight here.

78. **Michael**
April 25, 2006

Peter,
Not much remains of your original statement. You admit that tools from string theory were important. You also admit that the results can be important in the further development of string theory. You know, and didn't debate, that there is an exact formal equivalence between the field theories at hand and certain string backgrounds.

Clearly, then, the "new work of Witten has little to do with string theory", right? Look, you are being pathetic once again.

"[…] string theory is an important part of virtually anything anyone does these days in pure QFT, since it is likely they learned some facts about QFT by thinking about string theory, and it is likely that most anything about QFT will have some application to string theory somehow somewhere"

You said that like a real prodigy. Of course, that is most likely exactly the point. Let me be clear about this. Absent SUSY, it is not clear what we can learn by realizing the field theory as a string background. The problem is the limit which we must eventually take to decouple the stringy modes and isolate the gauge dynamics. SUSY is the only thing that guarantees no phase transitions can occur in taking this limit. There are three ways out: either we learn that SUSY exists in nature, or we learn how to master the difficulty I mentioned, or both. Giving up? Only Peter Woit could suggest that…

79. **woit**
April 25, 2006

Michael,

Lots of tools developed by people doing string theory will get used in other non-string theory contexts. This doesn't turn non-string theory into string theory. Lots of tools developed by people doing non-string theory will get used in string theory. This doesn't turn non-string theory into string theory.

The fact that N=4 SYM has a string dual is of course interesting, but this doesn't explain the relation to geometric Langlands that Witten is investigating. If you know otherwise, write a paper about it and it will make your career.

80. **Kea**
April 25, 2006

Peter

It doesn't matter what you say! If it's interesting and has anything at all to do with graded algebras, well of course it *must be* String theory. You wouldn't have to be a real String theorist. You could be a "String theorist".

81. **Anon**
April 25, 2006

Yes Peter, don't you understand! If the paper has any Greek letters (translation for Michael to understand: "squiggly symbols") it has to be string theory. See, just like the argument Michael pointed out earlier, this makes your entire blog useless. Way to go Michael!

82. **Benni**
April 26, 2006

sometimes ago woit wrote commenting Douglas talk at solvay where he wrote about the nichtmare of stringhteory:

"under this circumstances, it is standard scientific practice, to acknoledge that [string theory] is a failed project and go on something else"

It will be interesting if Witten will continue to publish String papers or if he leaves the field.

83. **Chris Oakley**

April 26, 2006

It will be interesting if Witten will continue to publish String papers or if he leaves the field.

It looks as though EW has not been working on String theory in the proper sense in the last year or so anyway.

BTW, If the Superstring locomotive hits the buffers I do not think that EW can be blamed. He just does what interests him, and however much he would like to be called a physicist the fact is (in my book, at least) that he is a mathematician. Physics may provide the raw material, but what seems to trip his trigger is playing around with the ideas in a highly abstract way. I do not sense, and never have sensed an urgency in bringing any of this hyper-theoretical stuff to market.

No, the problem is the personality cult that has been built up around him, something he seems to be uncomfortable with himself, but has occurred because of the absence of any real individualism, originality or creative ability amongst the majority of theoretical high-energy physicists practising today.
I think that the psychology is just this: if someone is demonstrably better at something that oneself, then putting them on a pedestal is a way of dealing with one's inferiority.

84. **Moeen**
April 27, 2006

For anyone interested, it seems Edward Witten will be speaking about this topic again at the [Conference in Honor of the 60th Birthday of John Morgan](). An abstract for the talk is available [here]().

85. **woit**
April 27, 2006

Thanks Moeen,

I should have mentioned that Witten will be speaking about this to mathematicians here next Thursday at the John Morgan conference. There will also be quite a few other interesting talks here as part of that conference, and I'll try and write something about them here after the conference is over.

86. **Bert Schroer**
May 2, 2006

Chris,
if you want to evaluate a person's contribution to particle physics you must consider also older contributions. What you say about EW certainly does not take into account his pre-Atiyah contributions.
When physics meets mathematics on a profound level, success is not always guarantied. A story with a very happy end developped when Born had only the diagonal part of the p-q relation and looked for a mathematically talented young collaborator to understand the rest. He first asked Pauli who arrogantly rejected the offer with the warning that Born's mathematical inclination could spoil the immediate intuitive grasp of Heisenberg on the new mechanics (in other words: don't meddle with Heisenberg). He then asked Jordan who hardly went to any physics course (because the tended to be in the early morning hours) but who was helping Courant with some chapters of the famous Courant-Hilbert mathematical physics book. This story had a very happy end indeed; not only did Jordan compute the off-diagonal part, but he also contributed the first avatar (yet still somewhat confused) glimpse into QFT and in the subsequent 3-man paper the three (Born, Jordan and Heisenberg) harmonized perfectly together. In this case you did not have to wait for history to tell.

87. **Chris Oakley**
May 2, 2006

Bert,

Was it Dirac who said that that was a time when second-rate people could do first-rate work? None of the people you mention were second rate, but the same would not apply today. Nowadays, there are no obvious easy wins (not that I can see, anyway) and part of the problem is that some first-rate people have done second-rate work and been rewarded with Nobel prizes.
Anyway … as regards Ed Witten … I have the highest respect for him and although I am no expert I am reliably informed that his early work was outstanding. The problem is with his fan club. Physics research, like most frontier areas, needs a small number of independent thinkers, not these hundreds or thousands of sheep.

88. **Bert Schroer**
May 3, 2006

Chris
you said it. Instead of the great traditional schools which cultivated not only disputes between them but also encouraged criticism within, you now have these globalized monocultures with a guru at the helm. It is not that people are less intelligent but rather that the Zeitgeist of globalized capitalism prevents them from reaching their true potential. A particularly impressive illustrative example is Lubos Motl whos crap he writes about anything non stringy serves a useful sociological purpose. String theorists love him, because reading that stuff spares them the toil to seriously look at other things. It works both ways, because in this way he becomes promoted and being close to the hegemon the danger that he will ever be confronted with his past crap is virtually zero; it is a win-win situation in which only physics looses.

89. **Tony Smith**
May 3, 2006

Bert Schroer said "… Instead of the great traditional schools which cultivated not only disputes between them but also encouraged criticism within, you now have these globalized monocultures with a guru at the helm. …".

That is clearly (to me) true. A question is Why are things different now?

Take, for example, Sommerfeld, a student of Lindemann, who was a student of Felix Kelin.
Lindemann's students in addition to Sommerfeld included Hilbert and Minkowski.
Sommerfeld's students included Bethe, Heisenberg, Pauli, and Stueckelberg.

(List from [http://genealogy.math.ndsu.nodak.edu/html/id.phtml?id=31357]() and Silvan Schweber's book "QED and the Men Who Made It" (Princeton Un. Press 1994) which says at page 667: "… Stueckelberg … obtained his Ph.D. with Sommerfeld in 1927 …".)

Can you imagine a more independent group of brilliant minds ?

Although all of them go back to Felix Klein, and I am sure that they all respected Klein and his work, at no stage in the family tree Klein – Lindemann – Sommerfeld – Bethe, Pauli etc did ANYONE set themselves up as a "guru" to a herd of sheep.
Even though there was NO "guru", space does not permit listing the accomplishments of those people.

It is interesting to compare the math/genealogy of the current conventional superstring guru, Ed Witten:
Ed Witten studied under David Gross (another student of Gross was Frank Wilczek);
David Gross studied under Geoffrey Chew (Gross was Chew's only PhD student);
Geoffrey Chew studied under Enrico Fermi.

Look at their records. Fermi was brilliant.
Chew, with his S-matrix bootstrap program, became a guru shepherd with many sheep, only to see the program fail, being eclipsed by quarks and the Standard Model.
Gross and Wilczek published the details of asymptotic freedom more or less simultaneously with Politzer, but all of them had been anticipated by 't Hooft who had already announced at a meeting (but did not publish in detail) the key idea.
Witten (like Gross and Wilczek) has done some very interesting work, particularly math-oriented, but (like Chew) has become a guru with a herd of sheep, being the guru of superstring theory which (according to Distler et al hepph0604255) "… is constructed to produce an S-matrix with precisely these properties. … analyticity … unitarity … Lorentz invariance …", which is very reminiscent of the Chew bootstrap.

The difference between those groups that stands out to me is that
Klein – Lindemann – Sommerfeld – Bethe, Pauli etc were anchored in European culture,
while
Fermi – Chew – Gross – Witten were, since Fermi came to the USA, anchored in the USA.

You might extend the Klein – Lindemann – Sommerfeld – Bethe line to the USA with Bethe, and then you might claim Feynman (not a PhD student of Bethe, but certainly heavily influenced by contact with him at Cornell) for that line. However, I don't think that anyone would see Feynman as typical of USA physicists.

If you try to extend the Fermi – Chew – Gross – Witten line, you see that the most prominent protege of Witten is Harvard Professor Lubos Motl.

Is there really a cultural difference (European v. USA) that accounts for the guru-sheep phenomenon in today's high-energy theoretical physics ?

If not, then why the difference between the
Klein – Lindemann – Sommerfeld – Bethe, Pauli etc line
and the
Fermi – Chew – Gross – Witten line ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

90. **Bert Schroer**
May 3, 2006

Tony,
as a small footnote one should add the role of Kurt Symanzik in preparing the soil of asymptotic freedom discussion. He started the renaissance of perturbative short distance investigations in terms of parametric differential equations featuring coupling-dependent functions beta and gamma (Kallen-Symanzik equation). That signs in those functions are hugely important he illustrated in the pedagogical but unphysical model of a quadrilinear scalar selfcoupling with changed sign of the coupling term and it was immediately clear to Sid Coleman that all the physical sign of all standard couplings did not permit Symanzik's searched "holy grail" of short-distance weakening of interactions. Sid, who (in the best tradition of Pauli) was a brilliant art critic before his health failed, had a deep admiration for Symanzik and he popularized his program in the US. Parisi in Rome got attracted to it and after 't Hooft's thesis on renormalization of Yang-Mills couplings, Symanzik prodded 't Hooft to look also into that sign question. At a conference in Marseille 't Hooft finally told Symanzik that the model seemingly provided his looked for exception, but he did not announce this publically (probably because he wanted to cross check the nontrivial calculation).
It is interesting that Symanzik in later years on several occasions pointed out that since the asymptotic freedom calculation is done in the wrong phase (i.e. not with a parametric differential equation in terms of a physical mass parameter in the confined phase), the asymptotic freedom statement has the status of a consistency check and not of a structural theorem. In this repect the situation in certain two dimensional models (e.g. Gross-Neveu) is better.
With all appologies to Peter for having somewhat strolled away from his given theme.

91. **Bert Schroer**
May 3, 2006

Sorry for misspelling Callen's name

92. **Tony Smith**
May 3, 2006

Two additional details:

1 – Curt Callan (of the Callan-Symanzik equations) was Peter's advisor at Princeton; and

2 – Since Symanzik studied under Heisenberg at Goettingen, he might be considered part of the line
Klein – Lindemann – Sommerfeld – Bethe, Pauli, Heisenberg, etc

Tony Smith
http://www.valdostamuseum.org/hamsmith/

93. **Aaron Bergman**
May 3, 2006

I know I shouldn't respond to such silliness, but can you tell me *any* sense that Lubos is "the most prominent protege of Witten"? They've never even been at the same university. Witten also has had a number of students who, oustide this bizarre little internet bubble we all inhabit from time to time, are much more prominent than Lubos.

94. **Tony Smith**
May 4, 2006

Aaron Bergman says "… Witten … has had a number of students who … are much more prominent than Lubos. …".

According to http://genealogy.math.ndsu.nodak.edu/html/id.phtml?id=31293 Witten has two PhD descendants:

1 – Dror Bar-Natan (web page at http://www.math.toronto.edu/~drorbn/LOP.html) who has written many nice papers on knots, links, tangles, cobordism, etc., as well as some very interesting papers on Torah codes and equidistant letter sequences in War and Peace. I like his work very much, but to me it seems that his most important work is math and not physics.

2 – Scott Axelrod, who was at one time an Assistant Professor in the math department of MIT (resigned around 1998).Searching the arXiv in math and physics, I did not find any papers by him since 1995. More recently, he seems to be at IBM doing interesting work on speech recognition, natural language generation, etc. He has in the past done interesting physics and math work, but his current work, while also very interesting, does not seem to me to be physics.

As to the prominence of Lubos Motl, he is an Assistant Professor of Physics at Harvard University, and may be the best-known advocate of conventional superstring theory. Not only is his blog well-known, and allowed to do trackbacks with arXiv, but he is a founder and moderator of sci.physics.strings.
As to why I consider him to be a protege of Witten, Motl's web page at http://schwinger.harvard.edu/~motl/sf/arxiv-nytimes.html quotes a 2001 NY Times article as saying:
"… In 1996, when Mr. Motl was a 22-year- old undergraduate … at Charles University in Prague … Dr. Witten, perhaps the premier figure in string theory, astonished Mr. Motl by writing to congratulate him on his 1996 posting. Mr. Motl still refers to Dr. Witten, only half-jocularly, as "the flying god knowing everything." …".
It seems likely to me that Witten has supported Lubos Motl througout his career – moving to the USA – getting a PhD at Rutgers and now a Harvard Professorship.

Of course, there is a certain amount of subjectivity in choosing "the most prominent protege" of anyone.
I have stated my reasons for choosing Lubos Motl as the most promient protege of Ed Witten in the context of physics.
If I have any facts wrong, I am willing to stand corrected and reconsider.

Aaron is, of course, free to disagree and state his choice and give his reasons therefore.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

95. **Bert Schroer**
May 4, 2006

Tony.
Kurt Symanzik as well as Harry Lehmann and Wolfhart Zimmermann started their joint innovative work at Heisenberg's institute, but scientifically they were kind of revolutionary "young Turks" in fierce opposition to H. who at that time was working at another of those ill-fated TOEs (Weltformel) in the veil of a nonlinear spinor theory. Hence to count them into the same genealogy is only true in a superficial geographical sense. There was also a strong subconcious rejection (generation gap) of the older generation because they were blamed for the mess of the Third Reich. The few post-war physics innovators in Germany were youngsters who were forced from school directly into Hitler's army and spend a short time as POWs (Lehmann was a POW in North Afrika, Kurt Symanzik in Marseille and H.-J. Borchers in northern Germany); they were usually a bit older when they returned and started their studies and they were certainly very highly motivated. Rudolf Haag, whom I consider most original, was scientifically 100% selfmade. He went as a schoolboy to the UK to visit his older sister exactly on the eve of the war. During the war he was interned in a Canadian POW camp and that is where he started to become interested in physics. Although none of these people can be easily placed into a genealogy, they started a "school" in the sense of creating a common coherent stock of knowledge and scientific culture. Detlev Buchholz, Klaus Fredenhagen and several others (including myself) have been formed in that school and the very strong and original group of mathematical physicists at the University of Rome (all in the math. department, Sergio Doplicher, John Roberts, Danielle Guido and Roberto Longo) are either directly or indirectly also related to it.
But since the "market value" of such usually more long-range scientific investments in the new globalized physics scene (which determines economical survival) is not very high, you may very well wittness already the end of this genealogical line.

96. **Alejandro Rivero**
May 4, 2006

If you take this thread into genealogy, please let me remember that I moved my page to the wikipedia
http://en.wikipedia.org/wiki/Genealogy_of_Theoretical_Physicists
The condition to add branches in the main page is to keep at a reasonable distance of a prized (Nobel, Fields, etc) physicist, but other branches can be built in the talk page, as a provision for the future(?).

97. **Peter**
May 4, 2006

Tony,

The students of Witten you mention are just his students who were mathematicians. He has had quite a few physics Ph.D. students. One of the first was my fellow student at Princeton Jon Bagger, who is now at Johns Hopkins, and I think could be characterized as more of a phenomenologist.

I don't think it's at all fair to pin the blame for Lubos Motl on Witten. Undoubtedly Witten encouraged him when he was starting out, as he encouraged many people, but Lubos was not one of his students and never worked with him. I doubt that he approves of the kind of ranting that Lubos has made his trademark in recent years.

98. **Aaron Bergman**
May 4, 2006

Tony, that page is for mathematical "descendents" of Witten. His physicist students include Eva Silverstein, Shamit Kachru and Cumrun Vafa (IIRC). Lubos is also far from "the best-known advocate of conventional superstring theory." That would probably be Brian Greene and (god help us) Michio Kaku. So, what you're basing your statement on is a single e-mail. That's quite a stretch.

99. **JC**
May 4, 2006

Bert,

(slightly offtopic)

Besides Heisenberg, Jordan, Stark, etc …, what other physicists went through "denazification" after the war?

100. **Bert Schroer**
May 4, 2006

JC:
probably most of those (Jordan, Stark,…) who were not interned in Farm Hall (for some reason von Laue was also at Farm all, although he was not a member of the uranium club and he was even recollected as anti-Nazi by Einstein). But I am not sure about the extent of de-nazification. The physicists who where in Russian occupied East Germany like Manfred von Ardenne, probably did not go through that process. I have heard that Euler, the collaborator of Heisenberg, who was a communist, got so fed up with what he saw going on at the University of Leipzig that he volunteered for the airforce and died (he was shot down) soon after.

101. **Tony Smith**
May 4, 2006

Aaron and Peter, thanks for giving me more information. In light of it, I would revise my earlier statement from

"If you try to extend the Fermi – Chew – Gross – Witten line, you see that the most prominent protege of Witten is Harvard Professor Lubos Motl."

to

"If you try to extend the Fermi – Chew – Gross – Witten line, you see that the most prominent proteges of Witten are, as working physicists: Jon Bagger; Eva Silverstein; Shamit Kachru and Cumrun Vafa.
In the eye of the general public, the best-known advocates of Witten's conventional superstring theory are Brian Greene and Michio Kaku, but AFAIK neither of them come from the Fermi – Chew – Gross – Witten line, so that line cannot be credited (or blamed) for them.

Thanks very much for the additional information. Now I am a bit less ignorant than before. (Aaron might say that I still have a long way to go, and he might be right, but at least I am making some progress.)

Tony Smith
http://www.valdostamuseum.org/hamsmith/

102. **Tony Smith**
May 4, 2006

Bert Schroer said "… Kurt Symanzik as well as Harry Lehmann and Wolfhart Zimmermann started their joint innovative work at Heisenberg's institute, but scientifically they were kind of revolutionary "young Turks" in fierce opposition to [Heisenberg] who at that time was working at another of those ill-fated TOEs (Weltformel) in the veil of a nonlinear spinor theory. …".

Would it be fair to extend the Klein – Lindemann – Sommerfeld – Bethe, Pauli, Heisenberg, etc line
to LSZ through Pauli, who called them the "Feldverein" ?

As to Heisenberg's TOE (Weltformel), didn't Pauli disagree and withdraw, leaving the paper to be published by by Durr, Heisenberg, Mitter, Schlieder, and Yamazaki in Z. Naturforschg. 14a (1959) 441 ?
Does Durr continue to work on it ?

Tony Smith

May 4, 2006

Tony
(with Peter's permission), yes Pauli felt scientifically very close to the Feldverein. He certainly recommended Lehmann highly as a successor to Wilhelm Lenz. Pauli also felt a strong emotional attachment to the University of Hamburg where, at the recommendation of Sommerfeld (Lenz also came fro the Sommerfeld school) he got his first position as an assistant to Lenz (at the time when he had his epiphany about the exclusion principle while strolling along Rothenbaumchaussee). In Hamburg he also gave his last colloquium (about the neutrino). That's when I saw the great man the first and last time. He also made his peace with Jordan but only after pouring all his sarcasm on him for having cultivated that naive Nazi sympathy ("Jordan is in the possession of a pocket spectrometer which allows him to distinguish between a deep red (communism) and an intense brown (the Nazi color)") giving him the advice to care about his pension instead of meddling in politics.
Sorry, let's return again to the present where most of the interesting stories happen in the US.

104. **Alejandro Rivero**
May 5, 2006

I can understand Laue was included in Farm Hall if only for affinity. Anecdotically, note he is buried next to Otto Hahn (If I remember well, they are right to Planck family burial, while Hilbert is left about thirty or forty steps).

About Pauli, his Zurich lineage has produced Osterwalder and some other interesting researchers (eg some things from Albeverio or even from Frolich).

I think lineages are interesting because one has always a tendence to follow the research track of his advisor, so if the advisor is well centered on productive physics his descendents are more likely to be (instead of random wandering around mathphys "interesting" problems). This explains, in part, the clustering of Nobel prizes along lineages.

The Hype Goes On

April 23, 2006
Categories: This Week's Hype

Yet another example of the seemingly infinite supply of bogus "evidence for string theory" is a recent Slashdot posting about a claim to have measured a change in time of the proton/electron mass ratio. It is based on a New Scientist article that states:

If confirmed, the result could force some physicists to radically rethink their theories. It would also provide support for string theory, which predicts extra spatial dimensions.

The original PRL paper about this is here and it is free of anything about string theory. The string theory nonsense appears to come from the following press release, which says:

Standard physics does not have an explanation as to why M_p/m_e has this value, nor can it provide an explanation as to why it would vary. However, superstring and M-theories do provide qualitative explanations for the M_p/m_e value and also predict possible variations of the fundamental constants.

It's unclear where the author got this particular piece of incorrect string theory hype. Not from Lubos evidently, who says that according to string theory the proton/electron mass ratio is constant, unless it isn't.

Update: This particular piece of nonsensical string theory hype even makes it to USA Today:

Such changes to fundamental constants would lend support to modern-day versions of string theory, which has varying constants built into its basic equations. String theory holds that on the very smallest distance scales possible, strings or loops of energy vibrating at different frequencies are the components of sub-atomic particles. String theory has also been a hot topic in physics for decades among theorists looking for a better explanation than "that's just the way it is" of why fundamental constants have their fundamental values. So far, string theory has more critics than results, it should be noted.

Update: The hype even makes it into Nature which is normally better at avoiding this kind of nonsense:

But various versions of string theory suggest that extra dimensions occupied by a particle might affect properties such as its mass. Subtle changes in these dimensions could make physical constants vary slightly, explains Barrow. However, "there's absolutely no observational evidence to support this vast array of ideas," cautions Fabian. The paucity of hard evidence for string theory may be partly responsible for the upsurge in interest in variable constants, Barrow adds; results like Ubachs' could eventually provide a good way to assess the ideas. "I'm sure we'll see some theory papers about this," he says. "I might write one myself."

Comments

1. **knotted string**
   April 23, 2006

   I subscribe to New Scientist. It's useful and sometimes you see outraged letters about the articles it prints, in later issues.

   You quote the passage that has been in every new scientist article about stringy stuff for 20 years:

   'If confirmed, the result could force some physicists to radically rethink their theories. It would also provide support for string theory, which predicts extra spatial dimensions.'

   Journalists have a list of 7 things to remember in a story (who, where, when…) the most essential being WHY?

   Don't go trying to attack them for just doing their job, which is to report orthodoxy like strings. In order to do that, it has to invent some reason that seems plausible. Is that OK?

2. **Lubos Motl**
   April 23, 2006

   These journalists often seem to confuse "new physics" and "string theory". An evolving constant of the Standard Model would surely be new physics. At low energies, it could probably be described by some new light rolling scalar fields as long as the effects are local.

   Such a light rolling scalar field would not be incompatible with string theory. Various vacua of string theory give us lots of different scalars – sometimes scalars that are hard to get rid of. But being new physics that does not contradict string theory is something very different from being evidence for string theory.

   Peter humiliates my uncertainty about the question whether the SM parameters must be constant. I think that they are but I don't have a proof. Do you have a proof in either way? This question can clearly be answered only once we hav the full theory that includes these questions.

   I believe that they are constant because of two reasons: qualitative and quantitative ones. A qualitative reason is Occam's razor. A quantitative reason is that if there were some freedom for the parameters to vary, the expected change per 12 billion years would be larger than the tiny percentage that they measure. Explaining such a slow evolution would be a new hierarchy-like problem.

   But of course such new problems may exist. We have seen quite a few of them.

3. **Jimbo**
   April 23, 2006

   The reality of NS is, that altho they have GREAT artwork, and sexy hyped cover stories, they have consistently tended to exaggerate the veracity (if any) of scientific research at the frontiers.
   I could quote various examples, but the one that stands out in my mind is from 5 yrs ago, when NS did a story about a prof. from U.Conn who was working on a laser-based technique to create closed time-like curves in the laboratory, which would enable transport of subatomic particles forward/backward in time.
   Not only has the research delivered nothing, but its basis was refuted by theorists from the Tufts Cosmology Institute 3 yrs later. To read the article, tho, one came away with visions of the the Morlocks eating the Eloi….NS is great eye candy, but that's as far as it goes.

4. **CapitalistImperialistPig**
   April 23, 2006

Luboš – Is that really you? What you say is not only perceptive but balanced and polite. I particularly like your point about a new hierarchy problem – but it would be nice if some theory (string or otherwise) could sweep up all the hierarchy problems at once.

5. **MathPhys**
April 23, 2006

Lubos,

For a man who refuses to acknowledge its exitence on his own blog, you are surely a keen read of, and participant in discussions on this one.

6. **The Great Landscaper**
April 24, 2006

Notice that if the cosmological constant is small thanks to a fine tuning done once and for all (as happens e.g. in the landscape anthropic scenario) then this experimental result is wrong, because a variation of m_proton/m_electron would lead to a large unobserved variation in the cosmological constant.

Confirming this experimental result would kill the landscape anthropic interpretation. I do not know how Popper would classify something that can be disproved but cannot be proved.

7. **Chris Oakley**
April 24, 2006

Like CIP, it worries me to see a balanced, reasonable post here from Luboš. Is he going soft? The business I worked in for the majority of my working life (investment banking) works on the principle of Survival of the Fittest. Unfit (read non-profitable) genes are ruthlessly eliminated. Academia OTOH seems to work on the principle of eliminating the most interesting genes, leaving a slurry of talentless, inoffensive morons to keep the whole thing going. Does Luboš fear that if he does not keep his head down then he too might be eliminated, I wonder?

8. **knotted string**
April 24, 2006

Lubos has added two new 'political stickers' to his blog:

http://www.northamericanpatriot.com/provictory/

and

http://www.physics.harvard.edu/~motl/no-libs.html

"Say No to Political Correctness"

9. **Chris W.**
April 24, 2006

I do not know how Popper would classify something that can be disproved but cannot be proved.

> ..as a scientific theory that makes universal assertions, ie, almost any theory of substantial scientific interest. Popper made this abundantly clear in his writings.

His position was echoed many years ago by Robert Geroch, when he remarked that he couldn't imagine what a "proof" of a physical theory would look like. Furthermore, he said this in a book aimed at a general audience, *General Relativity from A to B*.

10. **Aaron Sheldon**
April 24, 2006

Um…Is our knowledge of red-shift nearly anywhere as reliable as our knowledge of labratory H2 absorbtion lines? Isn't it a bit like comparing apples to oranges?

I mean, we measure red-shift by assuming the relationship between spectral lines remains constant. But then we introduce an observation that says the relationship between spectral lines is not constant, then how are we to calibrate red-shift?

Something has to give, and I think it will require refining our understanding of red-shifts.

11. **Lubos Motl**
April 24, 2006

Dear Great Landscaper,

although what you write may sound controversial, I tend to agree with you that according to everything we know, a measurably evolving proton/electron mass ratio would imply a much more dramatic evolution of the vacuum energy (imagine that the masses of the light particles to the fourth power contribute) unless there exists some more robust cancellation mechanism that keeps vacuum energy tiny. Your point is pretty good, by the way.

Such an evolving ratio could indeed contradict the current landscape paradigm in which all moduli are stabilized throughout most of the cosmological evolution. It would also contradict my preconceptions about constants being constant, however, without claiming that it's too important. 🙂 I still hope that both the anthropic principle as well as the conjectured evolving constants will be superseded by future research.

Chris Oakley: when I read most of your texts, among which the review of the NER book is the softest one, my peace usually disappears. 😉

Best
Lubos

12. **George Japaridze**
April 24, 2006

Well, I can't help rememebering the paper published in Naturwissenschaften (1931, I think) by Hans Bethe and colleauges. Hope that people will find the story amusing. In that paper it is stated that at absolute zero electron is not completely frozen, but still moves on Bohr's orbit, i.e. according to Eddington, has 1/alpha degrees of freedom, alpha being the fine structure constant. Since there are protons also, the article said, we need to add the same amount of degrees of freedom, according to Dirac's Hole

Theory. In all, we have now 2/alpha degrees of freedom. Now, in order to reach absolute zero, we have to take away from our neutral system -(2/alpha – 1) degrees of freedom. Authors say, and I remember that very well – "We have subtracted 1 to not to account for a rotational degree of freedom" – real perl.
Therefore, authors state, the temperature for the absolute zero is -(2/alpha -1) (Unit-Centigrade). Plugging in -273, authors obtained for a fine structure constant the value alpha = 1/137 which as the stated, "is in the remarkable agreement with the data".

Naturwissenschaften did not get the hoax and actually published the article; Zommerfeld, Bethe's supervisor, was furious. For a little while.

Sometimes I wonder, are these discussions of time-space-orientation-number of dimensions dependence of fundamental constants (have no idea why electron's or proton's mass or fine structure constant are fundamental, better than any other mass or coupling) jokes like Bethe's, or people really believe in what they say? I mean, either we have experimental confirmation, or experimental discrepancy, or some other, fashion independent way to confirm or reject the statements made, or we don't call ourselves physicists any more.

Knowing virtually nothing about Strings and M-Theory (believe that I'm in majority here), and no personal offense to anyone, what I hear about "Landscape Theory of Everything etc" makes me think that the whole idea what physics is and what it's suppose to be is being redesigned.

Pretty sad. Well, at least Bethe & Company honestly admitted that their paper was joke and nothing else – they did not claim that the way of thinking/building up Physics must be changed. It was assumed as a common sense back then…

13. **MathPhys**
April 24, 2006

I remember the time (almost 10 years ago) when I looked up one of Mike Duff's review papers on dualities, dualities of dualities, branes inside branes, etc, etc.

It was the first time I looked up a stringy paper in almost as many years, and I wanted to catch up a bit. I distinctly remember seriously wondering if that's science fiction.

I thought the best words to describe what I was reading were the lyrics of a song that went like:

A circle in a spiral.
Like a wheel within a wheel.
Never ending or beginning.
On an ever spinning reel.

I actually now admire the baroque creativity and imagination of the author and his colleagues, but I also cannot say it's physics.

To me, these are very elaborate mathematical structures, which can be very pretty to look at. But (and I know I'm preaching to the converted) physics must, must make contact with some experiment.

Strings has moved too far from experiments.

14. **WebGuy**
April 25, 2006

Hey, for someone who has mastered physics, do me a favor:
Fix the frames alignment at the bottome of this layout… Sheesh.. 😉

15. **Alejandro Rivero**
April 25, 2006

bethe beck riezler. Yes, it should not have passed referral, even plain reading, because 273 is an arbitrary point and both celsius and absolute are arbitrary scales (the zero absolute is not arbitrary; to say that the frozen point of water is 273 is the arbitrary thing). I would suspect that the editor was in the joke or authorised it.

By the way, we have recently found the equation for the fine structure constant and it is 1/135.28. Sorry for all the guys betting for 1/137.00x

But wait, everyone knows that the inverse of fine structure constant is got using the
unix command **host** **http://www.cobleskill.edu**.

16. **Alejandro Rivero**
April 25, 2006

(That last host command is supposed to be executed in the terminal, not to click on it. Info on closest hosts will be appreciated, just for curiosity)

Now, I found that the paper of Bethe et al has been photo-scanned into a biography of Guido Back but in spanish, so english googlers could miss it. It is at
http://www.ciencia-hoy.retina.ar/hoy02/guido4.jpg
in page
http://www.ciencia-hoy.retina.ar/hoy02/guido2.htm

17. **Chris W.**
April 25, 2006

MathPhys,

Never mind the lack of contact with experiment. Strictly from a theoretical point of view a lot of this stuff is obtuse and ugly. However, it's a great playground for technical virtuosity and pedantic elaboration, for those who are happy to base a career on nothing but that.

18. **J.F. Moore**
April 25, 2006

Peter – sorry to be off topic, and if I missed the news, but could you clarify about when your book will be available? Today is the date that Amazon.com lists publisher availability in the US, but it doesn't appear to be so, alas…

19. **woit**
April 25, 2006

Last I heard publication date was June 1 in the UK, September in the U.S. If I get better information about this, I'll post it here.

20. **Lurker**
April 25, 2006

Hi **J.F. Moore**,

[Not Even Wrong : The Failure of String Theory & the Continuing Challenge to Unify the Laws of Physics (Hardcover)]

Notice the date:

Hardcover: 256 pages
Publisher: Jonathan Cape (**April 25, 2006**)
Language: English
ISBN: 0224076051

Today.

And availability: *Usually ships within 1 to 3 weeks*.

Best regards,

Lurker

21. **woit**
April 25, 2006

I think Amazon has the wrong information, and today is not the publication date. For one thing, I haven't seen any books yet myself….

22. **Anon**
April 25, 2006

Peter,

As publicity and giving an idea about the book, perhaps you could post small excerpts from the book over the next several weeks. That will give others an idea of the level of technical stuff plus content.

23. **J.F. Moore**
April 25, 2006

September! That's a long wait. Thanks for the information though.

Lurker – If you read my comment all the way through to my second sentence, you would have noticed that I already had that (apparently wrong) information. Thanks for the effort, though.

24. **Eli Rabett**
April 25, 2006

Minor point, but the Celcius scale is now defined by absolute zero and the triple point of water, which, at least for a chemist, is not so arbitrary.

25. **Toothpaste**
April 25, 2006

so like what does "compulsive reading Roger Penrose" mean?

26. **amanda**
April 26, 2006

Maybe this is only partially relevant to the topic 🙂 but it seems that arxiv trackbacks from The Reference Frame are no longer supported, see
http://arxiv.org/abs/hep-th/0604151

27. **Lubos Motl**
April 26, 2006

Dear Amanda,

I've never had any automatic trackbacks – it's not supported by blogspot.com. I am only submitting trackbacks manually when I say something that could be useful for the readers of the articles.

Best
LM

28. **woit**
April 26, 2006

I figured Lubos wasn't submitting a trackback in that case since the only substantive thing in his posting was a link to the discussion of the Witten paper over here, and I appear to still be banned from trackbacks to hep-th.

I actually have no idea what is going on with arXiv trackbacks these days, and based on previous experience, it's not clear that it's worth my time to inquire with them about it. A trackback to a posting about a paper (Schroer's) that was in the "physics", not "hep-th" category did appear, but no trackbacks to postings about papers on hep-th have appeared. Maybe moderators for other sections of the arXiv are not banning links to what I write, just Jacques Distler, who is still intent on enforcing a "no criticism of string theory policy", but who knows what is going on there…

29. **Lubos Motl**
April 26, 2006

Sorry, Peter, but the main substantive thing in my short article were links to my two previous articles about the Langlands duality. The second most important thing in the short article are comments of Xi Yin about the relative depth of the arithmetic and the geometric Langlands program, and attempts to embed the arithmetic program into a new version of string theory.

A link to a semi-relevant mostly crackpot discussion here was just a complement, and it would be a good idea for you not to overestimate your importance by two orders of magnitude.

30. **woit**
April 26, 2006

OK, Lubos, I'll continue to look forward to your highly insightful and well-informed discussion of the Langlands program.

31. **Lubos Motl**
April 26, 2006

Let me emphasize one more the critical difference in our understanding of the trackbacks.

I view the trackbacks as a potentially useful service for the readers of the arXiv.org articles who may find a fast summary of some relevant issues, including those that are not discussed in the articles. It may be particularly useful months or years after the articles are submitted and when the readers have already forgotten a large portion of these issues. Consequently, I am only submitting the trackbacks if I feel that there is something relevant in my texts that the readers may actively want to see.

On the other hand, you try to submit trackbacks whenever you write something nasty (i.e. all the time) that is safely irrelevant and uninteresting not only for the actual readers of the arXiv.org articles – but also for all other people with IQ above 90 for that matter. In other words, your goal of submitting the trackbacks is to confuse the readers and spread your and your crackpot fans' moronic propaganda and silliness.

And that makes a difference. 😉

32. **amanda**
April 26, 2006

Dear Lubos,
I was only joking 🙂 . I'm sure Jacques D would never dream of stopping your trackbacks.

33. **Lubos Motl**
April 27, 2006

Of course that he would. He tries to treat everyone in the same way, especially everyone who is not Jacques Distler himself :-), especially if this everyone sometimes irrirates Jacques as some of my postings surely do. 😉

34. **Plato**
April 27, 2006

Lubos Motl:*These journalists often seem to confuse "new physics" and "string theory". An evolving constant of the Standard Model would surely be new physics. At low energies, it could probably be described by some new light rolling scalar fields as long as the effects are local.*

I think Peter here has always stated that any derivation of string theory must arise from the current standard model, and your saying, that string theory does in fact extend from the standard model theoretically?

So any new physics would in essence arise from the standard model so too then it could be called string theory?

So considering IceCube, how would string theory apply?

35. **knotted string**
April 27, 2006

'confuse the readers and spread your and your crackpot fans' moronic propaganda and silliness'

Lubos,

(1) Peter and his readers are countering stringy propaganda.

(2) have you given up climate crackpottery yet?

(3) Can you predict if and when when Jacques Distler will cease to be 'subtly hostile' to questions about string theory from his own students, let alone Peter; see http://utphysguide.livejournal.com/3047.html

😉

36. **woit**
April 27, 2006

Amanda,

Don't know what happened, maybe Lubos decided to manually submit a trackback, maybe Jacques decided that Lubos was so insightful that he decided to add the trackback himself. Anyway, at this point there's exactly one trackback to the new Kapustin/Witten paper, pointing to the commentary by Lubos. There's none to the commentary here since Jacques evidently continues the ban on trackbacks to my blog from hep-th.

I realize this is petty, and one shouldn't take anonymous student evaluations very seriously since they're often off-the-wall, but the one linked to in the previous comment is pretty hilarious, it's from a student in Jacques's string theory class:

"Jacques Distler is quite possibly the worst physics professor I have ever had. He has the uncanny ability to make even the simplest concepts utterly incomprehensible. He is a true intellectual snob, and he treats most questions with open hostility. Unless you have a PhD in math and already know string theory, you will not learn anything from Distler. String theory is hard, but not as hard as Distler wants it to be."

37. **Chris Oakley**
April 28, 2006

This anonymous student should show more respect. I am sure that there are those who pay handsomely for the privilege of learning from the Flaming Spear in the String God's left hand.

38. **Benni**
April 28, 2006

When one reads the discussion there:
http://golem.ph.utexas.edu/~distler/blog/archives/000348.html
I think one cannot state distler as snob or attacking or unfriendly whatsoever.

I think that he tried really to discuss with Peter and ended his discussion with the words:

Your anti-string theory screeds have engendered a strong reaction in some quarters.
Personally, I find them simply boring. They are an uninspired rehashing of the same set of complaints voiced a decade and a half earlier http://arxiv.org/abs/physics/9403001, minus the wit and vigour of the original.
I sat down this evening and reread this entire comment thread. I have come to the conclusion that our discussion has degenerated quite far enough. If you want to discuss the physics issues involved, please feel free to respond, and I will be happy to lend whatever further insight I can. If, however, your interest is simply to post anti-String Theory diatribes, I would ask that you post them on your blog, rather than here.

I think, seeing the above discussion, one can say, that distler is far away from beiing unfriendly or aggressive.

and this was the beginning of "not even wrong"!

39. **Nigel**
April 28, 2006

Benni, I notice Jacques didn't delete your comments from his blog! I wonder why? 😉

Jacques was charming when he deleted my constructive and helpful suggestion on his blog and then gave a non-sensical reason over on Cosmic Variance!

See http://cosmicvariance.com/2006/03/03/crackpots-contrarians-and-the-free-market-of-ideas/#comment-15117

It is just as well I'm used to censorship and so I don't take a mere comment deletion as a personal insult

40. **Benni**
April 28, 2006

Nigel wrote
>Benni, I notice Jacques didn't delete your comments from his blog!

no! Jacques did not delete me. Instead, he put me into his killfile. No one with the username "Benni" can post comments on his blog anymore!

41. **Bert Schroer**
April 29, 2006

Benny,
I only know Distler in his role as a hep-th moderator, but my little experience casts serious doubts on his objectivity.
Several years ago I posted a paper about the protagogist of QFT QFT Pascual Jordan on hep-th (hep-th/0303241). He is (politically) a very controversial figure, but I found some really breathtaking connections of some of his (at that time unaccomplished) ideas to ongoing conceptual developments in QFT.
About a month ago I extracted a shorter version, updated it with new scientific remarks of interest to QFTs and posted it in physics (physics/0603095) since the context was a bit more political (which only led to a change of title and introduction). For this reason I found it more appropriated to post it in the physics and society part with the idea of making a cross listing (it was the only crossing, so there was no abuse of the cross listing system involved). Well, the moderator took it off with the argument that its content is not related to particle physics. This of course creates a grave inconsistency in the moderating system with the past decision where the content had its main listing in hep-th (and now it cannot even be cross listed).
I would like to point out that the moderators of an international archive cannot act as the prolonged arm of its government and reject cross listing paper because it addresses a problem which has political ramifications. It would be unimaginable to have an international server located in Europe which rejects cross listing papers from US contributers because in addition to the relevant content for particle physics there is something which the moderator does not like.
Benny, in this context it does not interest me whether Distler (as he is often painted in this weblog by others) is a foot soldier of string theory or not. At issue is that freedom and democracy which his government preaches everyday to others. His role is not that of a hegemonic nanny but that of an objective servant of a world community.
I should add that I also completely agree with Tony (see the Langlands… discussion) that the Witten-Kapustin paper is mathematical physics and should have appeared as a cross listing in hep-th. The reason why this is not done is sociological not scientific (e.g. the moderator may argue that most of the potential readers are customers of hep-th and at this late stage they may even get confused about the authors having changes their motivations).

42. **Benni**
April 29, 2006

physics/0603095 is not a borderline case. One can clearly state, that it has nothing to do with hep-th.

In my opinion, the moderation rules of the section "physics and society" should be more strict.
There maybe relevant and interesting studies, which investigate eg. social networks with physical methods.
But Arxiv should not be the place where one can express his political opinions or rantings. Only papers acceptable in scientific journals of an exact science should arrive at arxiv org. physics/0603095 is in my opinion not of a scientific value that is high enough.

43. **Bert Schroer**
April 29, 2006

Benny,
what about my first paper which was even posted on hep-th and not just cross listed? Was the monitor too lenient?

44. **Benni**
April 29, 2006

the first paper is in hep-th. Although I think it is more appropriate for physics.hist-ph where is the correct place for many similar papers. See
http://xxx.lanl.gov/list/physics.hist-ph/recent
I think your paper is at the wrong place.

BTW, I think the section physics.pop-ph should be either moderated or shut down!

45. **Who**
April 29, 2006

> that the Witten-Kapustin paper is mathematical physics and should have appeared as a cross listing in hep-th. The reason why this is not done is sociological not scientific (e.g. the moderator may argue that most of the potential readers are customers of hep-th and at this late stage they may even get confused about the authors having changes their motivations).

sounds interesting. perhaps you could spell that out more detail for those of us like myself benefitting from explicitness.

It sounds as if you are saying that the W-K paper, for example, is really math-ph, it is not high-energy particle theory. But the habitual readers of hep-th have become so accustomed to reading mathematics and believing it is particle physics that it would CONFUSE them if you abruptly tried to sort things out and apply the categories as defined. They might wonder "What's wrong, isn't Witten doing particle physics any more? Has he switched fields?" The hypothetical moderator doesn't want to confuse the customers, so he has a reason to classify papers incorrectly.

I suppose that is what you mean. It's a droll reflection on the situation that has developed.

46. **Aaron Bergman**
April 29, 2006

Bert, you're aware that Jacques is Canadian, right?

Speaking only for myself, the first paper has some physics content. The second has absolutely none. I can't discern any insconsistency here. The interests of a "world community" would hardly be served by allowing extended political argument on hep-th.

47. **Chris Oakley**
April 29, 2006

Bert,

Being typeset with TEX and having references at the end does not make something a scientific paper. physics/0603095 is more the sort of thing I would expect to see in the New York Times with a title like, "The folly of invading Iraq: a physicist's view"

48. **Bert Schroer**
April 29, 2006

To Who says,
yes you got it correctly, but there is something to be added. Another reason why hep-th is used for math-ph. communications is that this site is the best for reaching the majority of mathematicians. Most of them believe that hep-th is the direct source where they can get the fresh and mathematically raw data for new conjectures in their most original metaphorical unspoiled form, and in order to make it a genuine market place they also sometimes post their more refined versions there. In fact most of them believe that we particle physicists live in our best of all times. They don't realize that they are erecting their golden castles on our physical ruins.
My remark about reaching one's readers by maintaining certain traditions was not really a criticism. And to be honest, given the sociological situation as it is, I am not totally surprized that my sociological/historical article was not even permitted a cross listing (it was never intended to be posted in hep-th).
I was just thinking that the same argument of having one's readers at a certain site which is conceded to most contributers would also apply to me.
No Chris, the article is not suited for the NYT. I think it is of interest to my particle physics colleagues to know that the the protagonist of our area was a rightwing belligerent character (just like Motl). He believed in the Heraklitean tradition that a war once in a while is necessarry to keep up progress. What really did him in was that by the time the Nazis came to power he genuinly thought that the "new order" of the "new state" was the sociological counterpart of the quantum revolution he initiated together with Born and Heisenberg and all by his own (and against the rest of the world) he created QFT in its modern form (bypassing configuration space from the beginning).
I think it is interesting to know the main reason why after Einstein and Heisenberg one of the greatest physicists of the 20 century lost the chance to be proposed for a Nobel prize and became the "unsung hero of QFT". I wrote this article in the Einstein year and of course I was thinking that Jordan lost the Nobel prize because he was living (politically speaking) in the wrong time: if he could be time shifted to the presence he may not only have gotten the Nobel prize but may have joined the neocons and played an impotant role in justifying the present war. A great man but a rightwing nut, life is complicated.
Chris why do you think I should be prevented to indicate the existence of this article to my colleagues who never look into physics/?

49. **JC**
April 29, 2006

Bert,

(slightly offtopic)

During the Nazi era, were there any strong reasons as to why Heisenberg stayed in Germany? Was he ever threatened with expulsion to Dachau by the SS, for using relativity theory (classified as "jewish physics" by the Nazis)?

50. **Thomas Larsson**
April 29, 2006

JC, your question is answered in Todorov's Heisenberg biography, physics/0503235

51. **Who**
April 29, 2006

thanks Thomas, history and the life experience of major figures in a field are surely part of understanding it. I was happy to find the short biography of H. you pointed to readily available on the arxiv, and read it with interest.

Apropos nothing in particular, another biographical document available on arxiv, one I like very much, is a memoir by the late Asher Peres "I am the cat who walks by himself"
http://lanl.arxiv.org/abs/physics/0404085

memoirs and history such as this give the arxiv an extra dimension, and make it all the more remarkable as a web institution

52. **Chris Oakley**
April 30, 2006

Bert,

I am sorry, but I think that physics and politics should be kept separate. Although I personally would not object to a cross-listing of your article in hep-th I can at the same time understand why it was not included. I should add that Peter (who obviously, like yourself, has strongly-held political beliefs) does an excellent job of keeping this kind of thing out of this forum. To see what happens when one is unable to exercise this manner of self-control one need only take a look at Lubos's blog. However brilliant (?) his scientific insights, to many he is going to just be that nutty, right-wing Harvard physics professor.

53. **Bert Schroer**
April 30, 2006

To Who says
Most of my knowledge about Heisenberg's role in Nazi-Germany came from the Farm Hall report (the result of wiretapping on the interned members of the German Uranium club) and from a biography by Klaas Landsman. I think these sources were also used by Todorov. Somewhere it is mentioned that Heisenberg was in trouble when an SS-journal accused him of being a "white Jew". but on the other hand he became the boss of the German war related Uranium research group and was probably consideres by the allies a greater threat than Jordan. Besides a personal encounter of Jordan as a student my interest in his biography was greatly stimulated by an article of Engelbert Schuecking "Jordan, Pauli, Politics, Brecht, and a variable gravitational constant" which appeared in the October 1999 issue of Physics Today. Different from Heisenberg's relation to the Nazi's (he was never a party member) Jordan joined the party quite early (already in 1933) but despite his open Nazi sympathies (apart from anti-semitism) the Nazi's did not trust him sufficiently to consign him with any important war-related scientific task; in fact these sympathies were never reciprocated. After the war he took a pro-US position in the issue about nuclear weapons against a campaign supported by Born, Heisenberg and another 16 members of the German scientific establishment.
Coming back to the main issue, there seems to be a misunderstanding; I never intended to post my article in hep-th and I completely agree that it does not belong there, but I thought I could let the hep-th readers (most of my particle physics papers were posted there) know by crossing listing (there is unfortunately no other way) that there is such an article.
I still do not understand why there is a censorship against cross-listing (the policy is against an abuse in form of mutiple cross listings, but making one crossing is certainly within the policy). Why isn't there more transparency on this point?
Stories like that of Asher Perez are fascinating to people like me who are approximately from the same generation and therefore are deeply stamped by the tragedies of the 20 century (without Who says remark I would have never come across these interesting biographical notes). Assuming for the benefit of the argument that Asher's scientific articles would have been posted in hep-th, why would he be prevented to indicate the existence of a historical article concerning his own life by a cross listing to hep-th? Does the monitor worry about the hep-th consumer getting too much distracted?
A short side remark may put this point into sharper focus. One of the most interesting episode of my life was the way in which the historical figure of Olga Benario one day entered the 10 year lasting collaboration on particle physics with Jorge Andre Swieca from Brazil (and linked our otherwise disparate life lines in a completely unexpected way). It would be obvious why I am deeply disappointed with a recent Brazilian film "Olga" where this pivotal figure whose biography reflects the tragedy of the 20 century is used as a vehicle for telling a love story. As a particle physicist you want to make such reminiscences available at a place where you scientifically contributed for a significant part of your professional life and not at a place which your colleagues rarely visit. I thought that among other things this is the purpose of cross listing. As a lack of transparency in the application of this policies by the hep-th monitor I still do not know whether I would be permitted to do this.
Chris, did you really read my article to the end (Jordan&war)? Or were you to much offended by my introduction ("rant") and had to stop?

54. **island**
April 30, 2006

> I am sorry, but I think that physics and politics should be kept separate.

I think that's the most sane statement that's come out of science in about 20 years.

INSANITY
…we all know that in all matters of mere opinion that [every] man is insane–just as insane as we are…we know exactly where to put our finger upon his insanity: it is where his opinion differs from ours….All Democrats are insane, but not one of them knows it. None but the Republicans. All the Republicans are insane, but only the Democrats can perceive it. The rule is perfect: in all matters of opinion our adversaries are insane.
-sam clemens

55. **Bert Schroer**
April 30, 2006

Chris,
since our remarks were posted at the same time, let me come back to them. If you feel offended by my US policy criticism I can understand this and perhaps I overdid it. It is the kind of reaction of disappointed love which is especially strong with people you feel very close to (the most intense arguments are often within the same family). Of course I did not forget the pivotal US contribution to the liberation of Europe from the Nazis and facism.
I was a research associate at the University of Illinois (60-62), went for one year to Priceton (where I collaborated with Korkut Bardakci) and for the rest of the decade got an assitant professorship (later associate) at the University of Pittsburgh. This was the happiest time in my life and my memories of life in the US are 100% positive (one reason I stayed away in more recent times is that I do not want to spoil them). As somebody who run away from East Germany I once got into a weird situation when, during my two years as a research associate working with Haag I went with him to a summer school in Boulder/ Col. When one day there I bought a Time Magazine I found an article about two mathematicians (Bill Martin and Bernon Mitchell) who did some secret work for the NSA and fled via Havanna to the Soviet Union. I remembered Martin's name from having taken over his rented apartment and bought his used piano. But the photos at those times were very unclear and I thought there was a mix-up on my part. When I returned to Champaign-Urbana the CIA people were already waiting for me; they found the cheque with which I payed the piano in a Wahington safe. They suspected me to be involved and what really stunned me was that they knew incredible details of my life including the part in East Germany. It took me some days of thinking to resolve my surprize. When I went through West-Berlin by plane to West-Germany I had to go through a camp (Fallingbostel near Hamburg, a former internment or concentration camp). This lasted some weeks and during this time there were frequent interrogations by German authorities. These transcripts of those were passed to the CIA. After one month of meeting with the two agents in a bar in Champaign-Urbana (naturally them paying the beer) I finally succeeded to convince them that this was a weird coincidence. Decades later when I told this story to Ludwig Faddeev at a conference dinner he laughed at me and told me that both had applied for a job at the Steklov Institute in St. Petersburg; by that time they apparently had Russian wifes. It seems that communism succeded to converttwo gays (at least temporarily) into hetero-sexuals. While I was living in Champaign-Urbana I moved outside the campus and rented the souterrain of a house of a very conservative fundamentalist family. They observed every step of my life. They were worried about girl students visiting me but what got them really upset was my participation in the unitarian church where I sometimes went because they had interesting speakers (it was more like a social club and many of the speakers were from the civil rights

movement). When they reprimanded me as a refugee from eat East Germany for being sympathetic to communists I left and moved again on campus.
All these episodes added some spice to my life but they never dented my admiration of the US.
During the last years in high school in stalinist East Germany my school mate was Hellmut Karasek who became later a well-known journalist and literary critic. Our admiration for the American way of life was without limits. He left East Germany a couple of month after me. Contrary to my experience he had problems to enter the US after his studies in Tuebingen. (I think because he was a paying member of the FDJ during the last year of school). When the ripples of the Ms Carthy era finally vanished he went to tne US anf lived for a couple of month together with Billy Wilder in LA. With the material he collected he wrote a fabulous book, a kind of Billy Wilder biography. One of the most interesting interviews of Woody Allan (which appeared in Germany) were done by him.
It is true that my enthusiasm suffered some serious setbacks in more recent times, but this may yet turn out to be transitory.
The criticism of string theorists does not penetrate much, but your remarks Chris, really entered my skin. To be compared to somebody like Motl who uses photos of bombers with nuclear weapons and who can hardly await the "nuking" of Iran (it makes me vomint looking at this) really hurts. He certainly represents all the disagreeable sides of Pascual Jordan without having yet shown the innovative talent. One of the points of my essay was of course that in principle those two apparent extremes may come together.

56. **Chris Oakley**
April 30, 2006

Bert,

I finished your article just now. I still think that your article belongs in the NYT, but maybe with a title like "Physics and pre-emptive wars: the case of Pascual Jordan".

Off-topic, and we may be in comment-deletion territory but, what do you know about Kallen's work circa 1950, specifically "Formal integration of the equations of quantum theory in the Heisenberg representation", Arkiv för Fysik, bd. 2, #37, p.37 (1950)? I realise that you would have only been 17 at the time, but if you have any recollections I would be very interested to hear them. The work is referred to in his 1972 text book on QED.

Island,

The situation can be summed up as follows:
*Opinions are like ***-holes. Everyone has one.*

57. **Arun**
April 30, 2006

There is a letter in the NYTimes today, signed by Leonard Susskind, Freeman Dyson, David Gross and Walter Kohn, and 15 other members of the National Academy of Sciences – expressing concern about Guantanamo.

"Although this is not a scientific issue in the usual sense, we feel that to ignore it would be to abdicate our responsibility to the truth".

April 30, 2006

Bert,

(also slightly offtopic)

How much was physics (and science in general) affected by Marxist type ideologies during the East German communist era?

I remember stories from German colleagues during the mid 1990's mentioning that a number of academics at the Unter den Linden campus in Berlin (and other universities in the former East Germany), were dismissed shortly after German reunification. Many of the dismissed academics were allegedly people who specialized in things like Marxist economics, communist "political science", etc …

60. **Bert Schroer**
April 30, 2006

Chris,
o.k. I am more than happy to get away from the present political glitch (unlike the past one it has not yet solidified) back to particle physics. I also want to make my peace with Distler, but a bit more transparency in applying those cross listing rules would be very helpful. If it is the admixture of ongoing politics (he probably does not mean the solidified past politics which has became part of immutable history) this should be stated and then one knows in advance and can adjust formulations appropriately.
Of course I did not read Kallen's article at the time when it appeared, but I do remember his handbook article where he based the perturbation theory directly on the Heisenberg fields. This method had been later called the Yang-Feldman approach and for interactions in terms of polynomial pointlike free fields the result is the same although to go from the time-ordered to the retarded functions is a bit cumbersome. The Kallen approach is less popular because you have to cope with two different c-number two-point contractions. In the late 80s and 90 this approach was sucessfully revived (for certain problems) by Othmar Steinmann. In the recent noncommutative settings the Yang-Feldman approach seems to be the conceptually safest (you want to check that the asymptotic part called "incoming" really has the algebraic commutation structure of a free field which is highly questionable since the validity of cluster factorization and macro-causality is in doubt, people only looked at the unitartity problem but forget the macrocausality properties without which the theory does not allow a particle physics interpretation) I have reviewed this situation in AOP 319 (2005) 92. I think you find further useful literature in there and as far as I know nothing really new has appeared afterwards.
I noticed through a recent email exchange with Wally Greenberg that some authors really thought that noncommutative theories continued to be local. He tried to straighten them out on this. But if they did not read my article (where this was an important point), they probably will not look at his either. Maybe he succeeded because, he went to Finnland and had the chance to talk to them directly.
I am wondering what Peter thinks; instead of banging away at string theory we are using his weblog for other purposes.

61. **Chris Oakley**
April 30, 2006

Hi Bert,

Thanks for the clarification. I cannot understand why it is called the "Yang-Feldman" approach when all they do in their 1950 Phys. Rev. paper is to say (end of sect. 1A) "general rules can be formulated for writing down the various terms to any order in e but, for practical compuatations, they are usually more complicated than Feynman's rules". But where are these rules? Kallen actually derives them! I don't know if you've seen my work on the subject (linked to from my name above), but I was just using free fields as terms in an expansion rather than representing asymptotic states, much in the spirit of Kallen's earlier 1950 paper (Ark Fys, band 2, no. 19, p.187). It is indeed more cumbersome but has the advantage that (i) one can read off matrix elements directly and (ii) it can also be used for non-local field equations, and specifically ones that do not lead to nonsensical infinities.

So one could thereby develop a comprehensive QFT without infinities and without having to consider Superstringy abstractions.

(NB: The last sentence was added just to try to forestall deletion of this comment on the grounds of being off-topic).

62. **Bert Schroer**
April 30, 2006

As to the anti Guantanamo campaign: better late than never.
Let us be united on this matter. The present discrepancies on matters of particle physics are quite insignificant compared to taking care of our civilization which plays an essential role in modern science.
When I criticise ideas then even in those cases where I mention names (because they are inexorably related to some ideas) I never put the character and sincerity of persons into question and I think Leonard Susskind and David Gross know this. What they may not sense as much as I, Peter Woit and many others is that their influence down to the carries of present day students (in particular on their impact ratings, stipends etc) is so strong that in case the gigantic jump into the conceptual blue yonder (using Feynman's style of pointing to the speculative nature of frontiers) fails (only few jumps succeeded in the past, there is always a risk), we may end in a long period of a particle physics void (also the new exiting astrophysical problems require a profound understanding of particle physics). The reason may simply be that too much time was spent in the blue yonder so that the solid ground from which this journey started will be forgotten and after several generations can only be reconstituted by

doing “particle physics archeology”. The survival of the fittest in the sense of a hegemony material control is not a mechanism which should be applied to particle physics especially if a hegemon can change the rules of attributing weight to the ongoing research.
To JC:
life in eastern Germany at the height of Stalinism (starting from 1951 to the time of Chruschov) in high school was very tense because most us (including Karasek and me) came from the lower middle class (my father was a fiddler who stabelized his life by taking on a fixed job in the administration of the Solvay caustic soda production) and the tension between home and school (with two type teachers, the old ones to whom you could be somewhat confidential and the new who we generally did not trust). We had a Russian teacher from Kazachstan named Olga Benkenstein and we played terrible pranks to her just out of frustration and sensing that she was weak, not because we disliked her. If Karasek and I ever would have found the chance for a later appology, we would have done this; youngsters can be very cruel (already in those days).
Concerning the treatment of the “Ossies” by the “Wessies” at the universities (example the Humboldt university) it was like other situations of sudden changes with part of society becoming powerless: this is a time of settling scores, personal denunciations people loosing their jobs etc. (not so different from what happened during the military dictatorship in Brazil during the 60s).
Chris,
I think you are right, the main contribution of Yang-Feldman beyond Kallen is to bring the equation of motion into the Yang-Feldman integral form (where the zero order in fields appear explicitly), but I do not have a reliable recollection. If I remember more (or find the handbook article in the cbpf Rio de Janeiro library which is probably the best in Brazil, I will let you know. The proper formulation of causal perturbation theory does not lead to infinities because the distributional character of fields is taken into account. The problem is that in so called nonrenormalizable theories the known setting does not tell you to intrinsically separate out a finite parametric submanifold (finite number of coupling parameters). This refers only to the standard way of doing perturbations, and not to future other implementations. Brunetti and Fredenhagen recently gave convoncing arguments that by using their new local covariance formulation they can recover background independence (and perhaps develop an background independent concept of a graviton). Mund and I test presently our concept of massless higher helicity string localized fields which as a result of their simultaneous fluctuation both in Minkowski and de Sitter space (the space of spacelike string directions) have much milder fluctuations in Minkowski space. The new conceptual problem is to implement interactions for string-localized fields. Only if these results turn out to be negative you can say with more confidence that there unlike gauge theory there exists no finite parametric submanifold for helicity=2. Then it would make sense to say that QFT cannot incorporate perturbative gravity. String theorists tend to premature apodictive statements because they confuse their carricature of QFT with its autonomous content.

63. **island**
April 30, 2006

> […] the National Academy of Sciences – expressing concern about Guantanamo

I think that it’s the implied endorcement that’s insanely dangerous.

64. **Bert Schroer**
April 30, 2006

retarded answer to a question of JC:
high school physics was not at all influenced by Stalinism. Biology was a different story. Scharlatans like Lyssenkow and Mitschurin had to be given a central role in biology classes. This was often done by teachers against their own better knowledge. I remember a funny phrase of my biology teacher whose halfhearted attitude in teaching such things ended in bloopers like this: “what the wheat was going through within half a year after disseminations on the fields, Mitschurin did in two weeks in a shelter”. This referred to a process called “jarowisation” in which the wheat grains where sprincled with icy water to make them more resistent against the cold so that one can grow wheat also in colder northern zones.
There was indeed a lot of injustice done against some of my colleagues who were physics professors at east german universities. For example Arnim Uhlmann who was a professor in Leipzig was retires against his will and only reveived a fraction of the retirement pension of a professor in the West. He was a deputy of the peoples chamber but nobody came up with any complaints of any personal sufferings from any action by Uhlmann. It is my conviction that everybody has the right to make his living and his carrier even in a dictatorial situation as long as he does not make life miserable for others. Compromises are allowed, see Brecht’s famous play about the life of Galilei.

65. **Bert Schroer**
May 1, 2006

Chris,
I am only using this weblog since I was unable to find your electronic address; the content of this remark is not of general interest to the participants of this weblog.
Kallen did go into some perturbation theoretical details (as you said) whereas Yang-Feldman did look at details. But even Kallen did not provide the computational “guns” (even though his first name was “Gunnar”) to do the n-th order. I think that doing perturbation theory directly in terms of Wightman functions (this is what Steinmann allegedly did) is equivalent to the Kallen-Yang-Feldman setting. Actually the proof of equivalence with the time-ordering approach is technically and conceptually quite involved. In a completely watertight form it is probably contained in the University of Hamburg project of a mathematical physics formulation of all aspects of perturbation theory (Fredenhagen, Brunetti, Duetsch….)
I met Gunnar Kallen only once; he looked very young for his age. As a student I probably was more afraid of his temper (“Gunner”) than others. He was extremely bright&fast and had the temper of Pauli (and my adviser Harry Lehmann, who however was very soft and helpful if it came to students). On several occasions he got into heated discussions with Julian Schwinger.
For some reasons he reminded me of the main character in Robert Musil’s “The Confusions of Young Torless”.
He was an amateur pilot and died in a crash when he was flying together with his wife in a Cessna (she survived). The weather on that day was excellent and he was an experienced pilot. There was the rumor that got extremely depressed when his wife was diagnosed with terminal cancer, i.e. he that he comitted suicide because he lost the will to survive his wife.

66. **Chris Oakley**
May 1, 2006

Hi Bert,

My e-mail is coakley@cgoakley.demon.co.uk. Yes, I had read the story of Kallen’s untimely death. Obviously a great loss to theoretical physics.

You probably saw that I got into fairly heated discussions with the referees over my papers between 1986 and 1987. All probably completely pointless; I suspect that a lot of the aggravation could have been avoided if either the referees or myself had been better aware of the work done by Kallen et al in the late 40’s/early 50s. Of course, I would be very interested to hear about any material that could possibly be relevant.

The basic idea, though, seems to have been all but extinguished in the literature. The Stueckelberg connection I only found out through this web log, for which, thank-you Danny Lunsford (and Peter for providing the forum) … the Kallen work I discovered only through an internet search. He does mention it in his QED text book, but – I don’t ever recall ever studying this, at least not before last week.

67. **woit**
May 1, 2006

Been away for a long weekend, mostly away from the internet. Now back and will write about some new things soon. You’re all forgiven for the off-topic comments since many of them were quite interesting….

68. **Who**
May 1, 2006

damn! why didn't I get in there during the break from supervision? I could have been talking all weekend about Smolin's idea of cosmo natural selection determining the fundamental constants so as to maximize black hole abundance. what a wasted opportunity!

69. **woit**
May 1, 2006

Who,

Even from a very slow and hard to use dial-up connection, I might have done what I could to put a stop to those…

70. **SomeBody**

In http://www.math.columbia.edu/~woit/wordpress/?p=380#comment-10196 Bert Schroer says

"[…] somebody like Motl who uses photos of bombers with nuclear weapons and
who can hardly await the "nuking" of Iran (it makes me vomint looking at this)"

Pardon me, but where did Motl do any of this? His blog post on the possibility of a nuclear strike on Iran

http://motls.blogspot.com/2006/04/readying-massive-nuclear-strike-on.html

looks nothing like your description of it. Did I miss something?

Dan Freed on Twisted K-theory and the Verlinde Algebra

April 26, 2006
Categories: Uncategorized

Dan Freed recently gave the Andrejewski Lectures at the Max Planck Institute for Mathematics in the Sciences in Leipzig, and has put the slides from his first lecture [on-line](). These give a beautiful overview of his work with Hopkins and Teleman relating loop group representations and equivariant K-theory, and explain one aspect of the relation to topological quantum field theory. His second and third lectures aren't available on-line. The second was supposed to cover the way they use Dirac operators, which is explained in their papers. The third lecture was evidently about the relation to Chern-Simons, which isn't in their papers so far, and which I'd be quite curious to know more about.

This fall, Dan will be giving a graduate course on Loop Groups and Algebraic Topology, which should be quite interesting.

Comments

1. **Dick Thompson**
   April 26, 2006

   I have a question/suggestion. Everything these days seems to involve twisting, and apparently there are different kinds of twists (e.g. Witten's new paper has a different kind of twist from his previous ones). Could we get a general intro to the twisting concept? Are twists the new representations?

2. **Peter Woit**
   April 26, 2006

   Dick,

   Sorry, but I don't immediately see any connection between the two kinds of twisting. Maybe there is one if you think about it the right way though…

3. **M.**
   April 27, 2006

   Amusing to see you have a new pet project. As it happens, the subject at hand (namely G/G WZW models) was explored and left by string theorists more than 10 years ago. The main statements mathematicians are making have long been known. See old papers by string theorists for the spectrum of the Dirac/BRST operator, the relation with the fusion rules, and the relation to Chern-Simons on S^1, amongst many other things.

4. **woit**
   April 27, 2006

   M.,

   It's not a new pet project, it's an old pet project, see http://www.arxiv.org/abs/hep-th/0206135

   Besides my own speculations about the significance of Freed-Hopkins-Teleman for physics (which have nothing to do with string theory), there's a huge amount of interesting new ideas in their papers that are not in the string theory literature.

   As much as I admire mathematical work of this high quality, as a physicist I have a different completely autonomous access to the problems connected with the Verlinde algebra. For me the issue is related to an extension of the Nelson-Symanzik duality in the new context of chiral QFT (i.e. in the context of a more involved spin-statistics connection due to the appearance of braid group statistics). This is a kind of symmetry which is particularily interesting for 2-dim. QFT at a finite temperature. It is almost trivial if you are allowed to represent your QFT in terms of Feynman-Kac representation, it is just the symmetry between space and Euclidean time in a temperature state. A more general and rigorous setting of N-S duality can be found in a recent paper (C. Gerard and C. Jaekel, mat-ph/0403048). This is of course related to the issue of Euclideanization (B.S. hep-th/0603118), one of the most subtle issues in QFT (unfortunately it has been banalized beyond recognition, for critical remarks in this direction see K-H. Rehren, hep-th/0411086) which in the standard context is inexorably linked with the names Osterwalder Schrader (and also Symanzik, Nelson and Guerra).
   But in the chiral context with braid group statistics it takes on a completely new form and the relevant Euclideanization is that of the modular localization approach (B.S. hep-th/0504206 (published in AOP) and hep-th/0603118). It uses the amazing power of the modular theory of operator algebras (adjusted to the localization concepts of AQFT) and reproduces among other things the Verlinde relation as a special case of an extended concept of temperature duality (a kind of self-duality in which the Euclideanization leads to a QFT which is of the same noncommutative kind as the original one, which the old Nelson-Symanzik duality within the O-S Euclideanization setting cannot provide) of a full thermal theory (and not just of the zero-point (partition) function). The conformal symmetry of the underlying QFT permits to make a complex extension of temperature to the tau parameter. The two field theories live (in the sense of physical localization) on circles, the connecting torus is nothing else than the old connecting Bargman-Hall-Wightman analyticity region (albeit in a more sophisticated veil) which has no direct operator interpretation. Since the charge transportation around the circle mixes the charge superselection sectors (F-R-S, Rev. Math. Phys., Special Issue, (1992) 113), the Euclideanization involves the statistics character matrix S defined by Rehren. Although in all concrete model calculations Rehren's S turned out to be the same as Verlinde's S, the derivation by modular Euclideanization provides the missing structural argument why they are always the same.
   My remarks could be misinterpreted as lamenting about recognition of work I have been involved with, but this would be much too superficial; what makes me really sad is that tremendous schism which caused young particle physicists to have lost their own rich conceptual past and which presently could be of help to do the fruitfull kind of mathematical physics with physics at the helm of moderation; but what I see is that physicists take their ideas and orders from mathematicians, the less agreeable aspect of the otherwise positive legacy of the Atiyah-Witten era.
