> A bizarre coincidence is that on Monday, October 5, just a week before Guralnik, Hagen, and Kibble's paper was received by the editor of *Physical Review Letters* in New York, and hence around the time that it would have been submitted to the journal, Peter Higgs gave a seminar about his mechanism at Imperial College. Neither Guralnik nor Kibble has any memory of this, and extensive correspondence between us has failed to shed light on this.

If the Higgs particle does show up at the LHC and the Nobel committee starts debating who should get the prize, this may become relevant. Another thing that I learned from Close that argues for Higgs in this context is that he was the first (in 1966) to write down a model ~~with Yukawas giving masses to the fermions~~ .

Close knows especially well the British cast of characters in this story, and one issue he devotes attention to is the unusual story of J. C. Ward's eventful career and the question of why Ward and Kibble weren't the ones to come up with the Weinberg-Salam model. Ward and Salam had worked on unified electroweak theory, minus the Higgs, and Kibble was very much involved in the Higgs story. One of the factors at play according to Close's account was Ward's rather paranoid nature, which made him unwilling to share ideas.

Another Nobel-related part of the book that will likely be controversial is the discussion of Salam's case for sharing the Nobel with Weinberg and Glashow. This topic recently was raised by Norman Dombey in a preprint on the arXiv (discussed a bit here), which refers to Close's book. Close gives a detailed description of Salam's activities around the time he was supposedly doing the Nobel Prize winning work, raising the possibility that he may not have had the right idea independently of Weinberg. One thing that is clear about this particular story though is that no one involved, including Weinberg and Salam, understood the significance of the Weinberg-Salam model at the time.

An argument might be made that the book has quite a lot of "inside baseball", about who exactly did what, and what people's relative cases for recognition might be. If you really detest this sort of thing and want nothing but the physics, maybe you should stick to The Second Creation. But, if like me, you're fascinated by this history and want to learn something new about it, go out and get a copy soon.

Update: I should make it clear that what I wrote here about Salam is my own interpretation of the story, not that of Close. He explains that Salam learned about the Higgs mechanism from Kibble, and had a unified electroweak theory with Ward, so it makes perfect sense that he would come up with Weinberg-Salam, independently of Weinberg, and he was lecturing about something. Still, the lack of any written record of exactly what Salam had pre-Weinberg makes one wonder…

Update: For the first-hand case that Salam did lecture on the Weinberg-Salam model pre-Weinberg (which is also described in Close's book) here's this from Robert Delbourgo:

> Dear Peter
>
> There have been murmurs on your blog-site, following Dombey's article I think, which cast doubt on Salam's worthiness for the prize. I wish to refute the innuendos and aspersions which are circulating.
>
> I was indeed present at the talks given by Salam on SSB for weak interactions where the famous model was described. Paul Matthews also attended, but being Oct that year, Tom Kibble was away on sabbatical at Rochester. I am prepared to take an oath on that.
>
> It was more than one lecture, but I cannot remember whether it was two or three talks which he gave as it quite long ago. Then I went to the library and spotted Weinberg's paper, newly arrived, and pointed it out to Salam and urged him to write up his own independent discovery ASAP. Matthews also encouraged him to do so and the first opportunity was the Nobel Symposium. That is the long and short of it.
>
> I hope that ends the the rumours and controversy!!!
>
> Bob Delbourgo

   I've read that Einstein considered The Einstein-Maxwell-Dirac System ~1930. Do you know who first considered The Einstein-Yang-Mills-Dirac System?

2. **Charles**

November 22, 2011

Like Dombey, Frank Close takes liberties with memories and diaries in several areas from a quick scan of this book and footnotes.

For example, the IC seminar by Peter Higgs that you note may have taken place but not in October 1964. Not possible GHK would have skipped this as they were all there at this time – Kibble is particular would recall this. A person named Ray Streater organized the seminar at IC and he is unable to confirm the date of the session. This likely took place in 1965 – Hagen would have been back to Rochester by then but Guralnick and Kibble were still at IC.

Just one example, where Close should be more careful with the facts – or at least how they are represented.

3. **William Tell**
November 23, 2011

"Knowing the history of a subject has always seemed to me an integral part of really understanding it, so I'd argue that anyone who wants to really understand modern particle physics should spend some time with a book like this."
You mean to say that extraterrestrial scientists will never really understand the SM physics?

4. **Peter Woit**
November 23, 2011

Charles,

The information about Higgs' talk is from Higgs's diary, which Close has access to. Close notes in a postscript to the book that he found memories of the period sometimes in conflict with the written record, which is much more reliable. He encourages anyone with evidence that conflicts with what he has written to contact him.

5. **Peter Woit**
November 23, 2011

William Tell,

Extraterrestrials will have their own history of how they found the Standard Model (or something like it…), and use that history to better understand it. They would undoubtedly benefit from access to our history, just as we would learn a lot if we knew theirs. If you can get ahold of an extraterrestrial history of how they developed their Standard Model, I for one really, really want to read it.

6. **Vladimir Kalitvianski**
November 23, 2011

There is a video-interview of Murray Gell-Mann about it. It is worth watching episodes 150-152, I think. http://www.webofstories.com/play/52253?o=MS

7. **Bernhard**
November 23, 2011

Vladimir,

This was very interesting.

Off-topic: By accident I saw also Gell-Mann´s comment on string theory. I knew he was sympathetic but when you hear him saying that Glashow "helped to spread the entirely wrong idea that superstring theory can never be tested" one really feels like asking him what is his exact idea on how to do that…

http://www.webofstories.com/play/52254?o=R

8. **Peter Woit**
November 23, 2011

Bernhard,

Gell-Mann's comments about Ward and Salam are quite interesting and relevant to the book. As for string theory, the video is from almost 15 years ago, at a time when enthusiasm was much higher. He may by now be more sympathetic to Glashow's point of view. Enough about string theory though, a topic mercifully irrelevant to the book.

9. **Bernhard**
November 23, 2011

Sorry Peter, I couldn't resist. But back to the point what I am a bit uncomfortable is that it seems these late accusations of Salam not being responsible for Salam-Weinberg is the fact that Salam is not here to respond these attacks. If this video is really from 15 years, than is from the time Salam died. I wonder if people confronted Salam with this when he had a chance to fight back.

10. **Peter Woit**
November 23, 2011

Bernhard,

The video says it is from 1997, Salam died in 1996. So, yes, he couldn't respond to Gell-Mann.

Close explains in his book that people's recollections of this era often diverge significantly from the written evidence he turned up. Although Salam and many others are not around, Salam's papers are and I'm sure he kept whatever could document his case for a piece of Weinberg-Salam. Evidently the Nobel committee was convinced by what was sent to them, and at some point (50 years after the prize?) the nomination materials become public I think. Dombey and Close both had access to the nomination from Matthews, written by Salam. This one is a case for the historians of the future to work on, but my impression is that Close gives a fair account of the evidence he turned up, and he doesn't seem to have an ax to grind here.

11. **Avattoir**
November 23, 2011

Can I just say, Peter, as someone who's a professional with a number of academic degrees but quite limited capacities in math and interest but only incidental exposure to physics, the earlier post you link to her on the subject of who might the Nobel prize go to if the Higgs were to be found was the most fun one I've found here in the year I've been visiting; and it and this one too finally got me off my duff to order your book.

So much for the fanboy part – but, though it's an imposition that doesn't actually demand a response, I wonder if you've read Louisa Gilder's book on Entanglement, and if so what your thoughts are.

12. **Peter Woit**
November 23, 2011

Avattoir,

Thanks, I hope you'll enjoy my book. If you liked the kind of thing I was writing about the Higgs mechanism history, there's a lot more of that in Close's book.

I haven't read the Gilder book, although probably should have. It looks good, with an historical take on the subject that would be interesting. My interest in interpretational issues in quantum mechanics though is somewhat limited, and life is just too short to read everything one would like to.

13. **Charles**
November 24, 2011

Happy Thanksgiving.

Source is understood but likely not correct from place or topic which is unfortunate for the story and the book. More broadly, this footnote that you highlighted struck me as odd/interesting and seems to have a similar tone to Dombey's article on Salam. In two papers in the last few years, Guralnik has stated how he learned of the other PRL submissions (and PA) when submitting the document for publication.

http://arxiv.org/abs/0907.3466

http://arxiv.org/abs/1110.2253

As these links point out, after seeing pre-prints at IC of Higgs and Brout/Englert, GHK famously referenced them and also referred to a theory that was "partially solved" by BE and H (as you pointed out in related blog they did not reference Anderson). So again, I was just confused by what Close was getting at with this footnote.

I have not completed the book but the other oddity is the selection of other "facts" and "contributions" that Close brings forward on this clearly charged topic of the "Higgs" mechanism. Some initial thoughts include…

1) Again, for the footnote on page 388….is Close and Higgs trying to imply PH gave GHK the idea and in a matter of two days they wrote a paper that was considerably more complete than PH or BE – improving the concept by showing both the degrees of freedom and explicitly how the Goldstone theorem is avoided? Guralnik was working on topic with Gilbert back in Cambridge, MA in 1962 and 1963 and published an earlier paper (Phys. Rev. Lett. 13, 295 (1964)) which has the basis of the GHK approach to the mechanism (submission date precedes the others) so that is a hard case to make (if he is trying to put that implicitly in the reader's head).

2) The 1966 PH paper that FC puts great stock in, writes down some terms that contribute to higher order corrections to the leading approximation given in the PRL papers. This is fairly trivial and represents little new insight or any surprise to anyone who does quantum field theory. Not completely sure Close's background or understanding on these points. Prior to this '66 PH paper, there was a similar contribution by GG who gave a talk in 1965 containing detail beyond that contained in any of the PRL submissions (see http://arxiv.org/abs/1107.4592v1).

3) Similarly, the follow-up paper by TK (Phys Rev 155, 1554 (1967)) is considered by most (even TK) to be a minor extension to the 1964 GHK paper and FC puts a lot of weight in that contribution also – more than the larger physics community.

4) When discussing the naming of the mechanism and Nobel politics he does not mention t'Hooft and his role. In their Nobel winning paper, t'Hooft and Veltman reference all three PRL papers and even refer to the mechanism as the "Higgs-Kibble mechanism" (http://igitur-archive.library.uu.nl/phys/2005-0622-155148/13877.pdf). Since winning the Nobel, t'Hooft has removed credit from the GHK team and pushed hard for a BEH award…and I am sure written letters to the Swedish Academy. As I have posted here before, t'Hooft feels many Europeans have been ignored for Nobel Prizes and sees the "Higgs" story as an opportunity to partially fix past snubs.

So as I read a footnote that seems to be false, it was odd that important items from this story that can be more easily verified by papers and lectures were omitted. It is difficult to deal in half-truths on this topic. Not being able to get the organizer (Streater) of the seminar at IC to confirm the date or clarify the point of the footnote leads me to believe it was somewhat careless (at best) or intentionally false (at worst) in order to help PH's or someone else's case in this "game of credit". FC may have felt he lost the personal side if he relied more on the papers but these two extremes could have probably been better combined better for this topic. Again, the similar in tone (as you said:" curmudgeon") to Dombey and Salam is notable.

Will circle back after I complete book and do more research .

Again, Happy Thanksgiving

14. **O Zapata**
November 25, 2011

Dear William Tell,

Peter's opinion coincides with that of Aristotle; don't forget, the most important physicist for almost two millennia:

"If you would understand anything, observe its beginning and its development."
Aristotle

This was valid for the physics of the Presocratics as it is today to understand the fundamental issues behind modern theoretical physics ("what if there is no Higgs?").
Another quote, more controversial, this time by a modern particle physicist:

"Finally, learn something about the history of science,or at a minimum the history of your own branch of science. The least important reason for this is that the history may actually be of some use to you in your own scientific work. For instance, now and then scientists are hampered by believing one of the oversimplified models of science that have been proposed by philosophers from Francis Bacon to Thomas Kuhn and Karl Popper. The best antidote to the philosophy of science is a knowledge of the history of science."
Weinberg.

Best.

15. **teeth**
November 25, 2011

Another quote from Aristotle worth remembering, to gauge the measure of his wisdom: “Women have more teeth than men because they talk more.”

16. **iwanna prize**
November 27, 2011

Scornful of the award of the Dannie Heineman Prize for Mathematical Physics to seven people, leaving out Anderson?

The web page of the DH Prize says no such thing
http://www.aip.org/history/acap/institutions/heineman.jsp

Wiki even tells the 2012 winner to be Jona-Lasinio
http://en.wikipedia.org/wiki/Dannie_Heineman_Prize_for_Mathematical_Physics

Perhaps Anderson is scornful of the J J Sakurai Prize for Theoretical Particle Physics.
The award in 2010 was to six people (not seven samurai), but no Anderson in any case.
And the 2012 prizewinners are listed by Wiki
http://en.wikipedia.org/wiki/Sakurai_Prize

Anderson is being hypocritical. He wants a piece of a prize for theoretical particle physics? Anderson has long opposed HEP in toto. Anderson wrote a NY Times op-ed article opposing the SSC. Anderson may have written a book review of NEW, but I have heard Anderson lecture before, and what he would really like is NEHEP.

17. **spin**
November 27, 2011

Hey “iwanna prize”:

Like it or not, it was a condensed-matter theorist who first figured out the now so-called “Higgs” mechanism. Who says that he cannot win a prize for theoretical particle physics. He’s probably smarter than most of them.

I can’t help thinking that if the high-energy people gave Anderson his due credit at that time, maybe later on he would not so oppose the SSC and everything related.

18. **Peter Woit**
November 27, 2011

iwanna prize,

Thanks for the corrections re Anderson’s non-prize, he has this wrong in his book, but it’s clear he’s referring to the Sakurai prize.

19. **prizewinning**
November 27, 2011

Awarding prizes is a very subjective thing. Many if not most prize awards are controversial. The memory of the award of the Nobel Prize to Kobayashi and Maskawa and omitting Cabibbo is probably still fresh in people’s minds. And this was not even cross-disciplinary HEP/condensed matter. Any award of a prize for the “Higgs” (choose any other name you like) mechanism, and/or discovery, will almost certainly be heavily criticized. BTW Anderson already won the Dannie Heineman prize in 1975.

http://www.nndb.com/people/911/000099614/

However, it was the DH prize awarded by the Gottingen Academy of Science. It is awarded every two years and is a sister prize to the APS award, which is the Dannie Heineman Prize for Mathematical Physics. As the web page also states “Since winning his Nobel honors, Anderson has used his public platform to speak out against the “Star Wars” military missile program, and against federal funding for a proposed $8B superconducting supercollider in Texas.” It is a matter of record that Anderson was one of the most prominent condensed matter physicists who thought that termination of the SSC would cause the $8B to flow into funding for condensed matter physics. The truth is that after the SSC was terminated, there were across-the-board cuts in many areas of science funding. Basically, “if the HEP community can absorb an $8B loss to their program, then you can also absorb a sacrifice of $1B (or whatever) to your program”.

As for Salam, the whole discussion seems silly. The award of the Nobel to Salam did not deprive anyone else. Awarding the prize to Salam did not detract from the merits of Weinberg. Murray Gell-Mann put in a good word for Glashow, and Glashow deserves his share of the prize, too.

20. **J**
November 27, 2011

A side note to Charles’s comment about t’Hooft’s role in the Higgs crediting:

indeed, I recently attended a public lecture by t’Hooft on particle physics and standard model (for the general public). The ppt page on the Higgs mechnism listed only three names, i.e. Higgs, and Brout-Englert.

21. **anonymous**
December 3, 2011

Related link from National Post highlighting the Nobel Prize issues and The Infinity Puzzle book by Frank Close discussed here.

http://news.nationalpost.com/2011/12/03/large-hadron-collider-the-god-particle-six-creators-one-nobel-prize/

22. **Anonyrat**
December 7, 2011

One possible lesson from Frank Close’s narration is that the ideas that prove to be correct are often born with no seeming connection with experimental reality – it can take decades for that to happen.

Another possible lesson from the same book is that those ideas languish in minor modest obscurity and are not hyped, until their day comes, when they do connect up to reality.

If string theory is as successful some day as Glashow-Weinberg-Salam-ABEGHHK'tH etc, presumably it will be because they stop making TV programs about it.

The Ultimate Guide to the Multiverse

November 28, 2011
Categories: Multiverse Mania

Yet another cover story about the Multiverse can be found this week at *New Scientist*, which calls it The Ultimate Guide to the Multiverse. As just one more in a long line of such stories over the last decade, a trend that shows no signs of slowing down, one can be pretty sure that this is not yet the "ultimate" one, nor even the penultimate one.

The content is the usual: absolutely zero skepticism about the idea, and lots of outrageous hype from the usual suspects (Bousso, Tegmark, Susskind, etc.) We're told that scientists are now performing tests of the idea, even at the LHC. The LHC test has been a great success: Laura Mersini-Houghton used the multiverse to predict that the LHC would not see supersymmetry, and that prediction has worked out very well so far. There's a companion editorial Neutrinos and multiverses: a new cosmology beckons, which tells us that the multiverse is now orthodoxy, backed by "almost everything in modern physics":

> The widest crack of all concerns a theory once considered outlandish but now reluctantly accepted as the orthodoxy. Almost everything in modern physics, from standard cosmology and quantum mechanics to string theory, points to the existence of multiple universes – maybe 10^{500} of them, maybe an infinite number.
>
> If our universe is just one of many, that solves the "fine-tuning" problem at a stroke: we find ourselves in a universe whose laws are compatible with life because it couldn't be any other way. And that would just be the start of a multiverse-fuelled knowledge revolution…
>
> These are exciting, possibly epoch-making, times.

This past week also saw the premiere of the Multiverse episode of Brian Greene's *Fabric of the Cosmos* series on PBS. It's more or less an hour-long infomercial for the Multiverse, with the argument against it pretty much restricted to some short grumpy comments by David Gross about how he didn't like it. Brian's pro-multiverse argument was that many new advances in physics are all pointing to a multiverse, and he showed support for the idea as resting on a three-legged structure. One of the legs was string theory, and I've described elsewhere recently how circular reasoning makes this one very shaky.

The multiverse propaganda machine has now been going full-blast for more than eight years, since at least 2003 or so, and I'm beginning to wonder "what's next?". Once your ideas about theoretical physics reach the point of having a theory that says nothing at all, there's no way to take this any farther. You can debate the "measure problem" endlessly in academic journals, but the cover stories about how you have revolutionized physics can only go on so long before they reach their natural end of shelf-life. This has gone on longer than I'd ever have guessed, but surely it has to end sooner or later, and I have no idea what rough beast will slouch onto future covers of *New Scientist* and episodes of Nova a few years down the road.

Comments

1. **Quantumburrito**
   November 28, 2011

   I don't think the multiverse will end any time soon since people will always be suckers for fairy tales.

2. **Peter Woit**
   November 28, 2011

   Quantumburrito,

   Yes, but even most children get bored if you keep telling them the same fairy tale every night, and sooner or later start demanding a new one.

3. **Chris Oakley**
   November 28, 2011

   It could be that Susskind, et al have been told the answers to the "ultimate questions" by a race of hyper-advanced aliens, but have also been told to keep it quiet or risk being annihilated. String theory, 11 dimensions, multiverses and all the other B.S. is just their way of throwing the rest of mankind off the scent.

4. **grant davis**
   November 28, 2011

   Well, as long as Ed Witten and all the best and brightest at the Institute for Advanced Study pursue and exalt the untestable String Theory, instead of speaking out against it, expect the multiverse mania to continue.

5. **Giotis**
   November 28, 2011

   Inflation is now part of Standard model of Cosmology (supported by an increasing corpus of evidence) and almost all models of inflation predict eternal inflation and thus the multiverse. Thus the multiverse stands on solid theoretical ground regardless if String theory is correct or not. String theory though gave a boost to the multiverse idea because String theorists are the dominant group of the top American Universities and these Universities more or less determine what is orthodoxy and what is not. So indeed in the last decade we had a paradigm shift.

6. **Beelzebud**
   November 28, 2011

   I started watching that Nova episode, and turned it off before it was over. When he starts going on about how there is an exact copy of himself in an alternate universe, it just made the whole thing too silly to even take seriously.

   I'm open to the idea of "pocket universes", etc, but even if that's the case I don't see how anyone could draw the conclusion that they have copies of themselves in multiple universes. Is there some mathematics they are using to make this guess, because the show is so light on technical details I felt like a toddler he was talking to? Please tell me that these conclusion are arrived at based on something tangible. I just don't see why the universe would be making exact copies of human beings, or anything else for that matter.

   It's not hard to see why physics hasn't gone anywhere in 20 years, after watching part of that episode. I'm not even sure if he talked about one thing that can be verified with observation or experiment. He might as well be trying to prove that the bible is true.

7. **aa**
November 28, 2011

almost all models of fairys include leperchauns.

8. **Aidyan**
November 28, 2011

I’m not particularly in love with multiverse theories, tend more to be an agnostic. However, as far as I could see from some papers there are ideas to test the hypothesis and something has been already done (see e.g. http://arxiv.org/abs/1012.1995). So far data seem to dismiss it, but I wouldn’t say that the theory is (or will forever) be impossible to test.

9. **Peter Woit**
November 28, 2011

Aidyan,

I wrote extensively about that heavily-hyped “test” of the multiverse here

http://www.math.columbia.edu/~woit/wordpress/?p=3879

10. **the aethereal multiverse**
November 28, 2011

Omitting the internet and blogs etc., the aether theory was taken very seriously (hyped?) by distinguished physicists at the turn of the 19-20th centuries. Sir Joseph Larmor, the Lucasian Professor of Mathematics who preceded Dirac, wrote a monograph “Aether and Matter” in 1900
http://books.google.com/books/about/Aether_and_matter.html?id=jvZImrMMUcIC

But in 1905 Einstein came along and offered an alternative explanation of the observed phenomena, viz. the (Special) Theory Of Relativity, which did not require the aether hypothesis for the propagation of electromagnetic waves. And as events proved, the theory of relativity could do a better job of explaining things than could the aether theory. The aether theory did not go away of its own accord. It went away only when something better came along. Furthermore the aether theory was never explicitly disproved. It was simply abandoned. But Larmor was not a fool; he is remembered today for Larmor precession, if nothing else.

So today the multiverse is hyped, and there is tv and the internet etc. The multiverse is taken seriously by talented minds. It is also disbelieved by talented minds. But the ultimate arbiter will be the advent of an alternative theory, which can do a better job of explaining observed phenomena. Until that happens, the multiverse will not go away.

11. **grant davis**
November 28, 2011

dear aethereal multiverse,

but the multiverse explains nothing and cannot be tested. thus some other theory cannot out-perform it in the realm of explaining nothing and untestability, unless it is also not science.

there is no need, as you argue, to disprove non-science with science. simply put, the multiverse is not science. we do not need any additional science to somehow displace non-science. rather, the non-science of the multiverse ought be outed and then ignored because scientists are supposed to be moral, rational, logical, honest creatures.

🙂

12. **Peter Woit**
November 28, 2011

the aethereal multiverse,

I think there is a real danger that the people pushing the multiverse will be successful at what they’re trying to accomplish: getting people to give up on conventional scientific standards, and turning this into the new orthodoxy. One motivation for this is to avoid admitting the failure of string theory unification. If they’re successful, young people who enter the field will be taught that there’s no alternative to string theory unification, the problem has been solved by showing that it is inherently impossible to do better. As this becomes more and more entrenched the path for someone looking to do something better (and better than pseudo-science is not much..) becomes harder and harder. This is not like the beginning of the last century when there were a lot of experimental hints pointing in promising directions.

Interestingly, despite his dedication to string theory, David Gross is someone who clearly finds this too high a price to pay, at least so far. The disturbing trend I see is more and more physicists who should know better falling into line here.

But this is an argument about what the scientific orthodoxy will be. It may very well end up being the string theory multiverse. If so though, there are only so many years that science magazines can keep putting it on the cover as a new revolutionary idea. At some point there will have to be something new for the cover, and I’m wondering what it will be.

13. **Nathalie**
November 28, 2011

Dear aethereal multiverse,

I can’t resist adding to your statement “Larmor was not a fool …” that moreover Larmor had Lorentz transformations before Lorentz and some physicists in Leiden, including Lorentz himself, knew that.

14. **Beelzebud**
November 28, 2011

the aethereal multiverse,

“So today the multiverse is hyped, and there is tv and the internet etc. The multiverse is taken seriously by talented minds. It is also disbelieved by talented minds. But the ultimate arbiter will be the advent of an alternative theory, which can do a better job of explaining observed phenomena. Until that happens, the multiverse will not go away.”

What observed phenomena does a multiverse hypothesis describe? Honest question. I'm by no means an expert.

15. **bcs**
November 28, 2011

It seems many distinguished theorists committed themselves to the multiverse idea. Some are willing to bet their house or dog's life on it, some are only willing to bet his friend's house and dog's life. Whether they really believe it, or just try to find something to go beyond standard model… I don't know.

It is well known that some high-energy theorists consider condensed-matter physics probably not much better than chemistry, economics, or biology. There has been a long list of such people: Dirac (implicitly), Gell-mann, Pomeranchuk, etc. Of course, I myself don't think so.

However, at this particular juncture, I consider myself lucky that I can still do physics research the old honest way, guided by the experiments.

16. **Bernhard**
November 28, 2011

This was very depressing, as usual. I hope this will go away, I simply can´t believe HEP (and cosmology) are taking this course, we are risking going from respectful fundamental science to the laughable part of physics (if we already didn't), a new astrology.

My hope is that the at some point people will just stop funding this thing or at least to fund only exceptional cases. To make this mainstream is absurd. Pointless speculation after speculation, hype after hype these guys just won´t stop. At least it is clear the purpose they serve: show business and nothing at all to do with science or the truth. Makes me sick.

17. **Giotis**
November 28, 2011

Beelzebud

It explains the observed value of the cosmological constant and in general why the universe seems fine tuned for life.

There is no other explanation for that at the moment (and according to many there will never be one). The alternative is to believe in God…

18. **the aethereal multiverse**
November 28, 2011

Beelzebud – "What observed phenomena does a multiverse hypothesis describe?" None that I know of. The aether theory of 19C also failed to explain any observed phenomena. All attempts to detect the aether wind failed. (The Lorentz-Fitzgerald length contraction was born as an attempt to reconcile the null result of the Michelson-Morley experiment.) And yet the aether theory remained the orthodoxy.

grant davis – "… because scientists are supposed to be moral, rational, logical, honest creatures." That is the (Platonic?) ideal, which is clearly not happening, on a large scale. A lot of it has to do with lining one's pocket with salaries.

PW really hits the nail on the head (or punches the head on the nose, if you prefer) – "This is not like the beginning of the last century when there were a lot of experimental hints pointing in promising directions." They key is *experimental hints*. That is the really lacking ingredient in these modern times. And that leads to the danger of a change (or corruption) of the scientific orthodoxy. But all of that will only change for the better when new data (BSM) comes along, and an alternative theory which can do a better job of explaining it.

19. **DB**
November 28, 2011

Until prominent physicists step into the limelight to ridicule and debunk these charlatans the situation will only deteriorate. The likes of Greene, Kaku et al. have free reign because they encounter precious little pushback from professionals of far greater eminence than they.
There seems to be a culture of omerta, where one does not speak out against one's "colleagues" in public. Dirty linen is to be washed only in private. The fear seems to be that such arguments aired in public would damage physics funding generally by creating the impression that physics was wracked by disagreement and division.
From this perspective it seems that allowing the likes of Greene to peddle their nonsense is viewed as the lesser of two evils.

20. **a**
November 28, 2011

The problem is not the hype.
The problem is that this anthropic stuff could be true.

We should at least try to get some physics out of it, see e.g.

http://arxiv.org/abs/1111.2551
"Anthropic solution to the magnetic muon anomaly: the charged see-saw"

21. **Bernhard**
November 28, 2011

a,

This paper assumes that "the only scalar existing at the weak scale is the Higgs" and that the explanation for this lies in anthropic reasoning.

Even if I were to swallow the assumption for the sake of seeing what phenomenology comes out of it I absolutely not accept that the "explanation" for this should in any way be anthropic related.

22. **Aidyan**
November 28, 2011

Didn't they tell us that the atomistic hypothesis is mere metaphysics since we won't never have a microscope showing us atoms? (E. Mach) Who said that we will never be able to know the star's chemistry because they are too far away? (A. Comte) And what about that famous guy who told us that he "never frames hypothesis" but now we know from his manuscripts that he did so continuously? I think that history has shown how rejecting too quickly a theory only on the assumption that it will never be testable or because too speculative (here multiverses) is not reasonable.

23. **Peter Woit**
November 28, 2011

Aidyan,

I don't think you can argue away multiverse arguments trivially as in "we'll never observe other universes", but if you look carefully at the multiverse arguments being made (see for instance the link I gave you earlier) you find that they are very weak, full of holes, and outrageously overhyped. Before going to magazines and TV to claim a new scientific orthodoxy, multiverse advocates should have something more solid than "it's not impossible that someday we might somehow figure out how to get evidence for this, even though things don't look promising right now", which is where they are today.

24. **Aidyan**
November 28, 2011

Peter, ok this sounds better… 😉 As to the motives which stand behind the "outrageously overhyped" arguments I tend to subscribe to what Smolin describes in the (much less discussed and taken into consideration) last chapter of his book "the trouble with physics". Just an excerpt (you certainly already know, but also for others):

"Put simply, the physics community is structured in such a way that large research programs that promote themselves aggressively have an advantage over smaller programs that make more cautious claims. Therefore, young academic scientists [note: S. Feeney is a PhD student] have the best chance of succeeding if they impress older scientists with technically sweet solutions to long-standing problems posed by dominant research programs. To do the opposite – to think deeply and independently and try to formulate one's own ideas – is a poor strategy for success. Physics thus finds itself unable to solve its key problems. It is time to reverse course – to encourage small, risky new research programs and discourage the entrenched approaches. We ought to be giving the advantage to the Einsteins – people who think for themselves and ignore the established ideas of powerful senior scientists."

Sorry, if I advertise another book… 😉 But in my opinion he got to the root of the problem, which is not scientific but political/ideologic/sociologic. As long as the (unwritten) rules on which the academic system is based will not change it will remain a pious illusion that these things can change either.

25. **Peter Woit**
November 28, 2011

Aidyan,

What Smolin wrote applies well to the string theory story, but the multiverse one is much stranger. The multiverse remains quite unpopular among physics departments, with only a small number likely to hire someone working in this area (and lots of NSF panels likely to refuse to fund multiverse grant proposals). It seems to me that what is happening is that multiverse proponents are trying to do what string theorists used to accuse me of doing: going to the press and TV to try and win an argument they have lost with their colleagues. If they can get the public sphere to believe that this is now "scientific orthodoxy", they may break down the unwillingness of physics departments to put up with this kind of pseudo-science. I suspect this isn't going to work, that young multiversers will find that this is no way to get a permanent job. But, we'll see, the campaign continues, with multiverse mania still dominating the media, and only David Gross willing to try and do battle on those grounds.

26. **pravda**
November 28, 2011

Look at the situation from the other point of view ~ what's in it for anyone (including David Gross) to do battle with the multiversers? (or string theorists, or anyone else promoting hype …) Probably they just open themselves to a heap of abuse, and receive no real reward from "the establishment". How many physics departments (or govt labs ~ Fermilab? CERN?) encourage their staff to make public statements against "people who promote hype"? "Standing up for scientific merit" isn't exactly rewarded. Lots of people grumble about the hype, but to speak out is to label oneself as a troublemaker.

27. **Puzzled**
November 28, 2011

The "multiverse" PR campaign puzzles me, for a much simpler reason than most of the issues raised here… the issue is "what problem does it resolve?" I can't see any problem for which "multiverse" provides an "aha" moment. Most truly powerful scientific or mathematical ideas create that sense of "now I get it" when something truly paradoxical suddenly makes sense.

Maybe I misssed something in my 60 years of mathematical and scientific life that requires a multiverse (and/or the "anthropic" principles that beguile the media) to resolve. Otherwise, it's another "just so" story – plausible, entertaining, and just clever enough to impress the rubes.

While it's kind of sad that these things sell books and get grants, science is really not defined by the well-funded and most visible. Intellectual integrity ultimately defines science for those who do science. The best and worst part of science is that anyone can say they are a scientist, but in the end, the "aha" is the only real measure of science. (not the "coolness factor" and the folks that go to the best parties).

28. **Einstein's Bastard Son**
November 29, 2011

String theory first started to enter the public consciousness in the mid 80s. Your book and Smolin's weren't published until 2006. So I'm guessing that this new multiuniverse craze might last at least 20 years.

29. **Einstein's Bastard Son**
November 29, 2011

*multiverse

30. **Bobito**
November 29, 2011

The "multiverse" is basically a religious argument.

"God" is also a hypothesis that "explains" the observed character of the universe. Lack of explanatory power is not the reason that "God" is a bad answer to questions about the nature of the universe. Rather, it is a bad answer because such an explanation provides nothing, in operational terms, that was not available before.

The "multiverse" as explained by many is not so different from "God".

31. **John**
November 29, 2011

It is important to point the differences between the different kinds of multiverse, for example in this blog I have not seen a clear position respect to the work of David Deutsch on the quantum multiverse, Deutsch have two long books (one publish this year) and many papers on this subject but strangely there is not yet a post about this, I think this is a strange gap in the multiverse mania series. I think Deutsch ideas have not been consider seriously yet, mainly because ideas that include the word multiverse are rejected even before being considered, maybe would be useful to use constructions as strings-multiverse, inflation-multiverse, quantum multiverse to be more clear.

32. **Guillaume**
November 29, 2011

Yes, I'd be interested to hear what Peter thinks of Deutsch's quantum multiverse too. I've already suggested that a while ago.

Having skimmed through his latest book, my own opinion on that particular topic is that his version of the quantum multiverse requires an *uncountable infinity* of universes, and that's just unphysical.

I could say a lot more about his book, which contains some interesting stuff and a lot of outrageous crap, especially when he ventures out of pure science into the real of human affaires.

33. **besnard**
November 29, 2011

I find this multiverse bashing a bit sad. As Peter sais in response to Aydan, multiverse arguments are not trivially wrong. Generally speaking, a theory is not unscientific because it sounds crazy to some people. In fact, a single infinite universe already contains the same strange things as the multiverse. One has to remember also that most, if not all, physical theories make claims about entities that cannot be observed.

Finally, I agree that the claim "there is a multiverse" is by itself impossible to disprove. But the situation is entirely different if a theory predicts A, B, C, and D : "there is a multiverse", and A, B, C are usual falsifiable predictions. If it turns out that A, B, C are observed, then you have to believe in D until someone comes up with a better theory that explains A, B, C but does not imply D. The problem with multiverse hype is that there is at the moment no such a solid theory which happens to predict a multiverse (although I think a case could be made for eternal inflation).

This is why I think critics should concentrate on the theories, and not on the multiverse idea per se.

34. **Peter Woit**
November 29, 2011

John and Guillaume,

The "multiverse" of various interpretations of QM is a completely different issue than the string theory landscape pseudo-science one. In the QM case, you may be able to perfectly sensibly talk about a "multiverse", but you can also describe exactly the same theory and same physics without invoking "other universes". Because of this I confess to a distinct lack of interest in this kind of debate over interpretation of QM, it seems to me to just avoid the interesting issues in favor of empty arguments over language. So, I haven't read Deutsch's books and so don't have anything to say about them. I did read a recent New Yorker profile of him and wrote a bit about it here:

http://www.math.columbia.edu/~woit/wordpress/?p=3656

My reaction there was that his argument that the existence of a quantum computer meant you had to have a multiverse didn't make sense to me. This is still true, but, again, my main problem is that I'm not convinced it's a non-empty issue worth thinking much about.

35. **SteveB**
November 29, 2011

One aspect of this problem is the economic one. There seem to be more new books being published than new, interesting and testable ideas. When a popular, well spoken physicist writes a new book they make the circuit of the radio shows (Fresh Aire, Science Friday, etc.), also the magazines, and eventually Nova TV. All of these need popularity to survive. Popularity is dependent on the public's "gee whiz" factor — and in my opinion — more important than Science, truth, or usefulness.

I found Greene's Nova series to be totally lame, with no real content, but just cute. unnecessary CGI . What a waste of 4 hours of potential science programming. New scientist is producing more and more of these silly articles and they are always highlighted on the cover. Almost every week! What a waste! (We have heard from a NS contributor here before, maybe she will provide some inside info about what the heck is going on there.)

Give me some dinosaurs or underwater archaeology anyday. I'd like some TV shows on new astronomical observations, on solid-state physics, on the electrical grid.

These just don't have the popularity for the American public who do believe fairy tales and vote for advowed anti-science candidates.

Sad times….

36. **Beelzebud**
November 29, 2011

Giotis,

That sounds an awful lot like just trading one myth for another one that you prefer more.

37. **Trevor Turton**
November 29, 2011

Lots of good, strong comment here. Is the take-home message Multiverse == astrology 2?
This is of course a math forum debating some deep physics questions, and one could be forgiven for thinking that the math guys are just sour because they haven't been made an offer by the physics funding machine.

38. **Joel Rice**
November 29, 2011

The trouble with the LHC is that it has not put a nice juicy Discrepancy on the table, like a Lamb Shift to cast doubt on Dirac, so there would be a real problem to work on. It is curious that they want to speculate about multiverses rather than why muons exist.

39. **why muons exist**
November 29, 2011

Joel Rice – Thanksgiving is over, but at Christmas dinner I suggest you engage the family in a discussion "why are there multiple families of leptons?" Don't blame anyone but yourself if you are dunked in a pot of boiling oil.

Trevor Turton – "… one could be forgiven for thinking that the math guys are just sour because they haven't been made an offer by the physics funding machine." The vaunted "physics funding machine" is regularly starving for money, so if the math guys are sour, I can only imagine they receive negative funding.

40. **Puzzled**
November 29, 2011

Just a quick comment… afaik "epicycle" models of planetary orbits were never proven "wrong", per se. In fact, it's a small exercise in Fourier analysis to develop a "sum of complex exponentials" (e.g. circular orbits) that would approximate any ellipse to any degree of accuracy you want. That ellipses are simpler solutions to a differential equation formulated according the invers-square gravitation than sums of complex exponentials is nice for planetary orbit calculations.

But one could also use the Fourier decomposition as a more general way to solve a much larger class of theories about gravitation (including some problems in GR). So maybe there are two "aha" ideas here: Fourier analysis, which is a truly great idea (and more or less the same as epicycles) and Kepler's Laws, which is a truly great idea about observed physical reality. But one could keep epicycles and still have Newton's Law… and you still need a version of "epicycles" calledFourier analysis to do good solutions to large classes of differential equations.

Which is the "truth"? There is no "law of the excluded middle" here… both are simultaneously likely to be true. I'd suggest forgetting about truth, and focus on what a theory gives us as ways of knowing. There multiverses and string theory both are pretty barren deserts.
Falsifiability is not enough, nor is

41. **Coin**
November 29, 2011

Bernhard: "the only scalar existing at the weak scale is the Higgs"

It would be awfully interesting to compile a list of anthropic-reasoning arguments whose conclusions are, or sometime after being made turn out to be, in conflict with experiment. It seems like you should be able to find plenty of anthropic arguments which are structurally as sound as the ones multiverse advocates commonly cite, but produce factually incorrect results…

TAM: "'This is not like the beginning of the last century when there were a lot of experimental hints pointing in promising directions.' They key is *experimental hints*. That is the really lacking ingredient in these modern times."

You know, this is an oft-repeated thing, and I understand what you and Peter mean by it, but I don't really feel like it's *true* and it seems to get less and less true all the time. It seems like we keep stumbling over all kinds of fascinating experimental hints all over the place, but it's not convenient or doesn't come in the form physicists know how to easily consume it (ie a scattering diagram) so we scratch our heads and go "huh, that's funny, well let's see what the LHC finds". Dark energy is the biggest, most burningly difficult to ignore example here. Colliders might not have found any new particles in decades, but astronomy *has* (my understanding is that the bullet cluster observation can only be explained by the existence of a WIMP-like particle). Every time we poke at neutrinos we find more strange things about them– the OPERA result is probably BS, but "how fast do neutrinos move and what is their rest mass?" seems like an incredibly tantalizing question which no one seemed very interested in until the OPERA BS result threatened Einstein. And in areas I don't understand so well we seem to be learning more about inflation all the time, UHECRs are a thing, quantum computers are coming online…

And a lot of these "hinty" areas of physics, it seems to me we could be pushing a LOT harder than we are, there are whole experimental avenues that could be full of even stranger things but which we're just not really exploring. In particular look at all the astrophysics probes that have been cancelled since 2006 (Google "beyond Einstein program", it's sad) climaxing with LISA finally biting the bullet just a few months ago– astronomy has been one of the most productive sources of new experimental physics data in the last ten, fifteen years but there seems to be very little interest in or pressure toward funding astrophysics.

I'm not sure I'm qualified to make a statement like thus, but– I really feel like it's possible someone a hundred years from now could look at this period and see not a period devoid of experimental hints, but a period when we were awash in hints we just didn't understand what to do with and leads it didn't occur to us to explore.

42. **Peter Woit**
November 29, 2011

All,

A reminder: this isn't a general physics discussion forum, there are good reasons why I refuse to moderate such a thing. The topic might be kind of dumb and tedious, but if what you want to write about is something else, please restrain yourself…

43. **archytas**
November 29, 2011

Peter,

I read Deutsch's "Fabric of Reality" (not to be confused with "Fabric of the Cosmos"). As I recall, one of his main arguments for the many worlds interpretation of qm had to do with a photo's behavior in a Mach–Zehnder interferometer. He argued that the photon was interfering with itself in another universe. I am probably not doing it justice without an exact quote. I only mention this, because I know there was more to his argument than just the computational power of a quantum computer.

It was an interesting read, but one cannot help but be bothered by the ontological cost the MWI, which is infinite by my estimate.

44. **Bernhard**
November 30, 2011

Coin,

The problem with these kind of arguments is that they are never unique and cannot be made to disprove the theory. You can, as you said, come up with hypothesis with verifiable consequences and claim they each one of them is anthropic inspired. But what's the point? What is happening is clearly that only one part of the argument is really being tested. If a multiverse could be tested by simply saying "if anthropic reasoning is right than there must be a single Higgs scalar and the consequences are A, B and C. If not, the multiverse idea must be abandoned", than I'm all for it. But that is clearly not what's happening. If this supposed anthropic argument fails, you just come up with another one, if fails, with another one and so for. Eventually I can see someone making the correct assumption but I doubt there is any reason to believe it would be correct because of anthropic reasoning, even if one can trivially find a connection with it.

45. **Sascha Vongehr**
November 30, 2011

You may like to consider that many worlds and multiverses are much much older than those guys you apparently do not like.
More hype for the multiverse “fary tale” right here:
http://www.science20.com/alpha_meme/modest_agnostics_expect_multiverse_and_hold_many_worlds_true-85038

46. **Joel Rice**
November 30, 2011

What bothers me about the sorts of things Brian Greene says is the implication that there is no particular necessity that the universe we observe be this way, other than being in a Bang where the fine tuning goes our way – as if that is the only reasonable way to look at fine tuning. Where is the necessity of having a particular kind of collection of particles? If that structure of matter is determined by some algebra then all universes ought to be equivalent – the necessity of this universe having electrons is the same necessity in any universe. It is a structural thing rather than a matter of coupling constants. Of course, if particles are stringy then one has a lot more flexibility – the question is whether there is too much flexibility. I always wonder if we are not skipping over algebraically elementary stuff when we are trying to explain physically elementary stuff. Things might be fine tuned for reasons that have nothing to do with coupling constants – if algebra determines what associates with what, and coupling is just a phenomenological device for description. The Multiverse says you do not get the big picture from looking at this universe. Is that an algebraically reasonable thing to assert ? It seems to follow from their assumptions. One might say we don’t see supersymmetry because of the multiverse, but I am more comfortable saying we don’t see it because it isn’t there.

47. **dane**
December 3, 2011

thanks for sharing this! im gonna bookmark your site!!

48. **lun**
December 5, 2011

One of the “usual suspects” is currently giving a talk in Columbia,essentially about this paper
While being skeptic,I have to admit this IS kind of thought-provoking, and he does have a kind of a non-trivial post-diction (he calls it a prediction). If it was really true that one can relate the cosmological constant “coincidence” to the (in principle calculable) number of states in the landscape,it would be something approaching a phenomenology.

49. **anonymous**
December 7, 2011

The big revelation next week will not be a discovery or signal claim or anything close to it. Only an elimination of an energy range for the boson.

More Higgs Non-News

November 30, 2011
Categories: Experimental HEP News

The latest Higgs non-news is that there is news about when there will be news. The Scientific Policy Committee at CERN will meet on December 12 and 13, with the agenda for December 13 featuring a 15 min presentation by the CERN Director-General on "CERN plans for communications on the Higgs boson search at the LHC" in the morning. This will be followed in the afternoon by a public event including half-hour updates on the SM Higgs searches from each of the experiments, and a "joint public discussion" about what it all means.

Before the LHC I tended to be 50/50 on the odds for a SM Higgs vs. no SM Higgs. As data has come out during the past year, and rumors have arrived in recent months, my take on these odds has gone back and forth. First it looked like maybe there was a 140 GeV Higgs, then not. Then I was hearing that nothing was being seen by either experiment, followed by rumors about something being seen by one, but not the other, making a SM Higgs start to look unlikely. Lately though, I'm starting to hear that maybe both experiments are seeing something in the Higgs to gamma-gamma channel. Is it at the same mass? What's the statistical significance if you combine the results? Looks like we'll hear about this on December 13 (unless someone leaks the news to a blogger first…).

For now, I'm back to 50/50. According to the latest Higgs coverage in the New York Times, back in 2005 Frank Wilczek was willing to give 10/1 odds in favor of the Higgs (although he wants a SUSY version), at least if the stakes were in Nobel chocolate coins.

Update: This month's Physics World has a long article by Matthew Chalmers (not available free online I think, see here) about the search for SUSY. In includes details about David Gross's SUSY bet (with Ken Lane):

> SUSY is "alive and well" according to the Nobel-prize-winning physicist David Gross of the Kavli Institute for Theoretical Physics in Santa Barbara, who helped to create quantum chromodynamics – the theory of the strong
> force. "People shouldn't pay too much attention to the bounds now because it's signals that matter," he told Physics World. "When will I give up on SUSY? I have a serious bet with Ken Lane that it will be found after 50
> inverse femtobarns ," he says.

The LHC won't accumulate that amount of data until quite a while after it comes back up at or near design energy in 2014. So, it looks like Gross won't have to pay off his gambling debts until 2015 or so.

Comments

1. **chris**
   December 1, 2011

   begging for rumors, eh? well, I'm dying to hear them, too of course.

2. **Frank Quednau**
   December 1, 2011

   I've been looking for a betting shop where you can bet on the Higgs boson being found within a period of x or not, but couldn't find one. Anyone knows?

3. **Peter Woit**
   December 1, 2011

   Frank,

   If such a thing exists, one obvious problem is insider trading. There are 6000 or so physicists with some sort of access to internal CMS/ATLAS data, smaller groups with more detailed access to the latest analyses of data, and these people all have friends…

4. **Philip Gibbs**
   December 1, 2011

   From the title is looks like we now have news of a date when they will give us news about how the news will be communicated when they have it. If it helps, an anonymous commenter at viXra says CMS and ATLAS will each give 30 minute talks about new Higgs results after the council meeting, but I don't see that on indico yet and it is not certian that they will be public even if they really happen

5. **a**
   December 1, 2011

   ATLAS and CMS do not speak among themselves, and experimentalists at CERN are very strict. So, the people that already know what ATLAS and CMS will announce are theorists working away from CERN.

6. **Philip Gibbs**
   December 1, 2011

   The seminars are real and public, http://indico.cern.ch/conferenceDisplay.py?confId=164890

7. **aa**
   December 1, 2011

   intrade has several higgs markets
   observed before dec 31 is currently 17%

8. **Blendletan**
   December 1, 2011

   If you are interested in betting on Higgs, http://www.intrade.com/v4/markets/?searchQuery=higgs

The odds being given are kinda strange if you ask me, btw…

9. **Chris Oakley**
December 1, 2011

Thanks, aa and Blendletan for the link to intrade. I just signed up and sold 29 x December 2011 Higgs. This cannot be called insider trading as I left HEP in July 1987 (I would have happily put the same trade on then, BTW). It is not irreligious either as, in my humble one, calling it the "God" particle is one of the stupidest things ever.

10. **DB**
December 1, 2011

Tomasso Dorigo believes that the hints of a Higgs at 119 GeV (+/- 2) as seen last summer by CMS , of which he is a member, will be vindicated in due course. He offered me 3/1 but while I may be sceptical, those odds were not good enough to bet against.
Initially, ATLAS didn't see these hints, but there have been discussions between both groups and it may be that after some adjustments to their processing they now also see something.
In any case, it would be unreasonable, given that the LHC is poorly positioned to find a low mass Higgs, to expect an early decisive conclusion.
But if ATLAS is now seeing something similar, and if the additional data since the summer conferences show even a slight improvement on the initial signal, then this would be compatible with the sort of evolving discovery pattern one might expect from the LHC in the low mass regime.
An early result could be provided by the Tevatron data – which has better resolution in the gamma-gamma channel – concerning a 95% exclusion of Higgs. The Tevatron dataset will never be able to confirm a Higgs to 5 sigma, but it can exclude one @95%. But all's quiet on that Western front. A couple of months ago some at CERN tried to argue that a 95% exclusion on the Higgs would not be enough, but they failed to explain why the LEP2 exclusions below 114 GeV, which were also only 95%, would not then also need to be revisited. But this distraction seems to have taken a backseat for now.

11. **Thomas Larsson**
December 1, 2011

Exactly what does "Observation of the Higgs Boson Particle" mean at intrade? 5-sigma? Published? Announced at some conference? Announced by whom? (ok, probably a spokes-person for atlas or cms).

I'm willing to bet against 5-sigma by Dec 31, 2011.

12. **SD**
December 1, 2011

@ Thomas Larsson: from the rules tab in
http://www.intrade.com/v4/markets/contract/?contractId=700241

"Clarification (Jan 5th 2009): for the Higgs Boson particle to be "observed" there must be a "five sigma discovery" of the particle."

There are 126 shares at $0.5/share (where $10 ($0) means (no) discovery): I think you are not the only one willing to bet against it. 😉

13. **Chris Oakley**
December 1, 2011

SD,

It is trading at $1.60 now, so if you "sell" then you get $1.60 if it is not found, but have to pay out $8.40 if it is; reverse these if you choose to buy. The inferred probability of finding the Higgs before 2012 is therefore 16%.

14. **ohwilleke**
December 2, 2011

The kind of disclosure format that is in the works sounds more like an exclusion than a find.

15. **Frank Quednau**
December 2, 2011

well, thanks for the link to the "intrade" platform, didn't know that one yet 🙂

16. **SD**
December 2, 2011

Chris,

If you want to sell (buy) the price is $0.5 ($1.59), so the average probability is 10.5%. The spread reflects the uncertainty of this prediction, as quantified by "the market". In practice if you want to make money by betting against the Higgs being discovered by 2011, you would earn $1 for every $20 that you invest (but I think that there are also rather large commissions, so you might actually get no money at all). So I think that, though I'm 99% sure of no 2011 Higgs discovery, I'll keep that money in my wallet, ready to pay (part of) a nice dinner.

17. **Kent Traverson**
December 2, 2011

In 1997, when the SETI Institute was conducting a scan of the sky for any alien signals, a strange one was detected. While the staff quietly tried to figure out what it might be, one of the workers there ran to call his girlfriend that they may have found The Signal. She spread the news from there and in a matter of mere hours the rumor grew exponentially.

The signal turned out to be from a satellite of terrestrial origin. But the moral of the story is, humans are a bunch of big gossips, so you should be getting your Higgs rumor news in no time. And you will share, won't you?

18. **Eric**
December 2, 2011

“So, it looks like Gross won’t have to pay off his gambling debts until 2015 or so.”

Well, if the Higgs mass turns out to be 119 GeV or so as rumors suggest, then I think that Gross will most likely be winning his bets. This is exactly the mass range predicted by the MSSM.

19. **Peter Woit**
December 2, 2011

Eric,

Since 119 GeV is exactly the mass predicted by the MSSM, I guess if the latest rumors about a 125-126 GeV Higgs turn out to be right, that’s it for the MSSM, no?

20. **Vince**
December 2, 2011

Eric said “This is exactly the mass range predicted by the MSSM.” The key words are “mass range”, not “119 GeV is exactly the mass predicted by the MSSM.”

21. **Eric**
December 2, 2011

Peter,

As Vince points out, I did not say that the MSSM predicts exactly 119 GeV for the Higgs mass, but rather that this is in the range predicted in the MSSM. This range is essentially less than 130 GeV down to 114 GeV, including the LEP limit. A 125 GeV Higgs would also favor SUSY.

22. **Peter Woit**
December 2, 2011

Eric,

I see, the “exact” prediction of the MSSM is that the Higgs has a mass not already ruled out by experiment…

23. **Eric**
December 2, 2011

Peter,

The upper limit on the Higgs mass (130-135 GeV) in the MSSM has been known for a long time, and it is no accident that the remaining viable mass range for the Higgs is consistent with this. If the observed Higgs mass is within this range, which may very well be the case, then this implies that superpartners will be observed. So the point I am making here is not that SUSY predicts the exact mass of the Higgs, but that observation of the Higgs in the mass range preferred by SUSY implies that low-energy SUSY exists and will be observed at the LHC.

24. **Anonyrat**
December 2, 2011

UK Telegraph coverage of the Higgs search:
http://www.telegraph.co.uk/science/large-hadron-collider/8928575/Search-for-God-Particle-is-nearly-over-as-CERN-prepares-to-announce-findings.html

25. **Mitchell Porter**
December 3, 2011

Eric said

“The upper limit on the Higgs mass (130-135 GeV) in the MSSM has been known for a long time, and it is no accident that the remaining viable mass range for the Higgs is consistent with this.”

In what sense is it *not* an accident? Isn’t “the remaining viable mass range” a result of LHC search strategies, not of theory?

26. **Martin**
December 3, 2011

> Before the LHC I tended to be 50/50 on the odds for a SM Higgs vs. no SM Higgs. As data has come out during the past year, and rumors have arrived in recent months, my take on these odds has gone back and forth.

Hi Peter,
I have always thought you were a SUSY sceptic. Now you seem to be positioning yourself as undecided. Or does “no SM Higgs” mean no Higgs at all rather than a SUSY Higgs instead?
Cheers,
Martin

27. **Peter Woit**
December 3, 2011

Martin,

There I meant no Higgs at all (i.e. no elementary scalar field playing the role of the Higgs). I’m still a SUSY skeptic, even if there is a Higgs at 125 GeV…

28. **crandles**

Re: Betting at intrade

What would you like to see in the way of scientific betting?

Intrade wrote

https://www.intrade.com/forum/
"What would be the time span involved in this market? Mid-2012, end of 2012?
How would the existence of Dark Matter be confirmed? What criteria would you suggest?

We haven't had a great record with scientific markets in the past, but if we have a short-medium term markets (no longer than a year out) that will generate interest and trading volume we'd consider it. "

Maybe they need scientists to ensure questions are well posed.
Is it too late for: Confirmation of detection of WIMP in Earth based laboratory?
Does confirmation mean peer reviewed paper published?

I don't think intrades fees at $5 per month regardless of number of contract traded is much, but bank charges for conversion to US$ and transfer to Ireland and then back again mean it is probably not worth looking for a certain 5% return before fees unless you are going to leave the money there for other opportunities. For that you may need or want more scientific contracts. So suggesting more contracts when intrade asks might make sense.

A 125-126 GeV Higgs?

December 2, 2011
Categories: Experimental HEP News, Favorite Old Posts

Some more detail on Higgs rumors I've been hearing recently. Evidently the latest ATLAS data shows an excess in the gamma-gamma channel around 126 GeV, of the size expected if the Higgs is there, and CMS is also seeing an excess (2 sigma?) around 125 GeV in the same channel. I haven't heard anything about confirmation of this in other channels. Independently, someone has posted a [similar rumor at viXra log](), and Philip Gibbs is writing about it [here](). This looks to be still not a conclusive Higgs signal, but the closest thing yet. More details may or may not emerge before the public talks on December 13.

Update: Latest rumor is that the significance of the ATLAS gamma gamma bump is almost 3 sigma.

Update: This morning's rumors are a 3.5 sigma 126 GeV excess at ATLAS in the ATLAS-only combination, and 2.5 sigma at 124 GeV for CMS. Heuer's message to all CERN personnel says the December 13 announcements will be "significant progress in the search for the Higgs boson, but not enough to make any conclusive statement on the existence or non-existence of the Higgs." Presumably they're waiting for 5 sigma before claiming conclusive proof.

Comments

1. **Jester**
   December 2, 2011

   That would be weird, given that in the summer dataset both ATLAS and CMS had a deficit in gamma-gamma around 125 GeV…

2. **Mark**
   December 2, 2011

   According to Motl, this is very close to Kane's favorite value 127 GeV !

3. **Amos**
   December 2, 2011

   Has to be close to *someone's* favorite value.

   Gibbs says "at this mass the standard model has problems with vacuum stability that are likely to require supersymmetry or something similar to stabilize."

   Can someone explain that?

4. **Marc Sher**
   December 2, 2011

   Amos—if the Higgs mass is 125 GeV, then the quartic self-coupling of the Higgs, which (like all couplings) changes as the energy scale changes, will become negative at an energy scale well below the Planck or unification scale. That means the vacuum becomes unstable. Supersymmetry would cure this, and so would many other theories. Since the energy scale at which the self-coupling goes negative is well above the reach of accelerators, it is possible that whatever new physics solves the problem can't be seen in accelerators. Of course, we all hope that the new physics is at the TeV scale.

5. **Cliff**
   December 2, 2011

   Gordon Kanes work has been really interesting to me even before the rumors of a 125-127 GeV Higgs… So this result has me a little bit excited.

   You can confirm from his presentation here that 127 GeV is indeed the preferred value (see the conclusions page of the slide):
   http://conferencing.uwex.edu/conferences/stringpheno2011/documents/kane.pdf

   I actually downloaded this a while ago, so I can confirm that he didnt just make a different pdf for each possible mass haha

6. **anonymous**
   December 2, 2011

   Take a look at this one: The Standard Model (SM) plus gravity could be valid up to arbitrarily high energies. Supposing that this is indeed the case and assuming that there are no intermediate energy scales between the Fermi and Planck scales we address the question of whether the mass of the Higgs boson m_H can be predicted.
   http://arxiv.org/abs/0912.0208

7. **Henry Bolden**
   December 2, 2011

   Wired magazine has an article about impending Higgs news (or non-news):

   http://www.wired.com/wiredscience/2011/12/higgs-lhc-anticipated/

   Disclaimer: No Brian Greene has been harmed in the making of this message.

8. **Paolo Valtancoli**
   December 3, 2011

   I remember that an indian guy applied the four colour theorem to the SM finding that the best value for Higgs mass is (2 M_W + M_Z) / 2, i.e. a 125 GeV Higgs mass!

9. **Frank**
   December 3, 2011

   Doesn't the primary decay of a 4th quark family b' quark also involve a photon? Then a b'-b'bar would produce gamma-gamma signal also, confusing the interpretation until a complete analysis determines the spin of the original particle.

10. **Peter Woit**
December 3, 2011

Frank,

In principle lots of things could produce a gamma-gamma signal. But remember that the SM Higgs predicts exactly the width and size of such a signal, and my understanding is that this is consistent with what the experiments are seeing.

11. **Bernhard**
December 3, 2011

Width ans size may be and of course since it is consistent it will be tempting to interpret the signal as a SM Higgs, but until its spin is measured, which will take a lot of data, even this consistency can be put into question.

12. **Peter Orland**
December 3, 2011

Hi Marc Sher (who I used to know at Santa Cruz many years ago),

Though the basic thrust of your argument is right (i.e. that scalar fields are problematic at high energies), it is not true that the quartic Higgs coupling becomes negative. I am pretty sure you are thinking about Landau's pole.

I hope Peter W. will indulge my discussing the technical issues, so to avoid causing too much trouble, I'll be brief. He may permit my comment because they directly concern the Higgs mechanism.

Landau's formula for the effective coupling is only good for small couplings. It breaks down at high energies, where it predicts the sign change. The pole/sign change is fictitious.

The real problem is that if the coupling at high energy (say with a Planck-scale cut-off) is not fine-tuned to some enormous value, the coupling at the TeV scale is nearly zero. This can checked by the renormalization group in 4-epsilon dimensions, by 1/n-expansions and by numerical simulations. It is also strongly indicated by some rigorous results about triviality, but these don't quite work in four dimensions. There is no change in the sign of the coupling.

Some field-theory books present the Landau pole as gospel, even though it is completely unphysical. The real problem is triviality/fine-tuning.

13. **emile**
December 3, 2011

Bernard,

How long it takes depends on the mass of the Higgs (assuming it exists). With a WW signal, the spin can be checked without that more data IF there is a Higgs and that the mass is not too far from 130. In the case of WW->lnln analyses, both experiments use a delta(phi) cut between the two leptons which assumes a spin 0 particle decaying to two vectors. That distribution can be measured too. If there is a Higgs and if the mass is in the 115-120 range, then it would be a lot harder and would indeed take a lot more time.

14. **anon**
December 3, 2011

What I heard: CMS's 119GeV peak in gammagamma is still strong, but another at 124GeV appears.

15. **Thomas**
December 3, 2011

Peter O:

I believe Marc does mean what he wrote (Higgs self coupling goes negative). This is due to the contribution from Yukawa couplings (primarily the top), which will drive the Higgs coupling negative if m_top/m_H is too large. This is known as the vacuum stability bound (and it has been checked in lattice calculations).

16. **Peter Orland**
December 3, 2011

Thomas,

This is something I should know about. Thanks, I'll look into it.

17. **Younghun Park**
December 4, 2011

Peter and everyone
If the signal remains at 3~4 sigma level until 6th 1212, what will CERN conclude?
They will conclude that Higgs exists or not?
If the level of the signal doesn't come up to 5 sigma, what will happen?

18. **Younghun Park**
December 4, 2011

I'm sorry. 6th 1212 -> june 2012 or december 2012

19. **Amos**
December 4, 2011

Peter:

Thomas' comment was enough to locate this article : http://arxiv.org/abs/hep-ph/9307342v1 which seems to sum it up.

20. **Marc Sher**
December 4, 2011

Peter–Thomas and Amos are correct, although the reference Amos gives is quite outdated–the papers of Quiros and others are more updated with the proper top quark mass (http://arxiv.org/abs/hep-ph/9703412 is a good summary). It has nothing to do with the Landau pole. The quartic coupling goes "negative" above some scale, or if you wish to not think about negative couplings, solve the RGE for the Higgs potential and there will be an instability at high scales. But frankly, since few people believe it's just the SM up to huge energy scales, it doesn't matter that much.

21. **Jeff M**
December 4, 2011

Pardon me for asking, but aren't 124 GeV and 126 GeV miles apart? I mean even physicists wouldn't claim to have found a particle with a mass of "about 125GeV," would they? Is someone expecting one or the other of these numbers to move a percent or two when more data comes in? I don't see how you could possibly combine these results to claim you have found something, if anything it would indicate exactly the opposite.

22. **Cesar Laia**
December 4, 2011

I guess the peaks come out as distributions centered at 124GeV and 126GeV. So if you combine both experiments we get a larger and broader peak with a 125GeV mean value.

23. **Jeff M**
December 4, 2011

@Cesar,

Yes, I'm sure that is the case, and I'm sure the statisticians have ways of combining that sort of data, but I have issues with that even in more "normal" cases like population sampling. Guess it's just that I'm a mathematician, and I just don't trust statistics about things like this, too much flexibility with your assumptions. Could just be that I never liked the SM, elegant as it is, too many parameters…

24. **Peter Woit**
December 4, 2011

Jeff,

You can look up the expected width of the bump, I think it's very roughly 2 GeV or so. Remember, right now the bumps are near the limit of statistical significance, not something well-resolved where you can precisely locate a peak. The numbers being quoted are also not as precise as possible. It could very well be that the ATLAS peak is near 125.5, the CMS one near 124.5. So, the small discrepancy in mass value is probably not significant.

Yonghun Park,

As you accumulate better statistics, if there's a Higgs there, the statistical significance should increase. If there's nothing there, it should decrease. Both statements are probabilistic, but with very high probability if substantially more data is accumulated.

25. **anonomous**
December 4, 2011

Are there other channels besides the WW signal to verify the results or is this the only data that will verify the Higgs existence? What does the Tevatron data say about this channel? How much more data collection (and how long) is required going into 2012 to get to the 5-sigma level?

26. **SpearMarktheSecond**
December 5, 2011

I think the natural width of a Standard Model Higgs at M_h=125 MeV or so is only… 5 MeV.

http://www-library.desy.de/preparch/desy/proc/proc02-02/Proceedings/pl.1a/haber_pr.pdf

I think detector resolution broadens that observed full width to maybe 3-4 GeV, or a sigma of about 1.5 GeV.

http://hal.in2p3.fr/docs/00/36/46/31/PDF/LAPP-EXP-2008-09.pdf

27. **SpearMarktheSecond**
December 5, 2011

Whoops M_h=125 GeV.

28. **Jack Lothian**
December 5, 2011

Being both a statistician & former physist 124 & 126 could be the same point – depends how many points were measured in the empirical distributions, how smeared out the empirical peaks are in the two distributions & the standard deviation of the underlying distributions. I am sure somebody has figured this out at CERN. It is such an obvious point that I suspect that they are checking this point closely.

29. **The show must go on**
December 6, 2011

STRING/M SUSY theory PREDICTS the HIGGS mass to be 126 ± 2 GeV
http://arxiv.org/pdf/1112.1059
in full agreement with the fully correct rumors.

By the way, can I post the main plots that will be presented on Dec 13?

30. **Mark**
    December 6, 2011

    @The show must go on, in case you did not know, Kane had made this exact point about the Higgs mass, including the plot, a while ago. See the corresponding post on Motl's blog.

31. **Bernhard**
    December 6, 2011

    The only prediction that was confirmed up to now is that whatever one finds at the LHC is is of course a prediction of string theory, despite the fact that is this very thread people pointed out to other articles (e.g. Shaposhnikov and Wetterich) that make a even more accurate prediction regarding the Higgs mass (I'm not saying the model is correct) and very importantly in 2009. Kane's article was sent on Monday December 5 when the whole world already heard the rumors, really, what kind of "prediction" is that? It may be that Kane wrote about it before, but THIS specific article cannot be used as a serious prediction. Best case scenario is a postdiction.

32. **Eduardo**
    December 6, 2011

    It is interesting to note that from global analysis of low energy data~(electroweak data, with high statistics but very low energy),
    e.g., In Fig 1 of arXiv:1110.5807 [hep-ph]~(and references therein) , always appears an small "bump" between 120-130
    (there is a shark peak between 115-120, but that is due the Lep2 constrains).
    The bumps coming from global data analysis have different meaning~(They are not so crazy as the colliders or any Single experiment. It remains for years and are very difficult to wash away)

33. **brazilian**
    December 6, 2011

    Hello guyz, I'm not a scientist, I just like reading about science, and I don't know if it's my english that is really bad (I'm brazilian), but I can't until now undertand the implications of string theory and SUSY in the search for the higgs boson, can someone help me? I was reading about it, some blogs, comments, etc, and I got some understandings…

    What I did understand is that string theory (M theory included) predicts SUSY, but if SUSY is not found, that's OK, string theory can survive without it, correct? Then, I read that SUSY predicts some particles to be found at LHC, but if you don't find, that's OK, because it can be hiding somewhere else, I got it right? Then, about the higgs mass, if what I understood is correct, SUSY accept a really good range for it's mass, but if the higgs is about 125GeV, even if it minimize the need for SUSY to explain somethings, that would be a prediction from SUSY, if you find it in some other areas, you'll need SUSY to stabilize the system, and if you don't find it at all, then you need SUSY again!

    That's correct? I mean, or my english is really bad or SUSY is such a lank theory that can answer just about everything and cannot be proven wrong, that's really weird.

34. **Ronan**
    December 6, 2011

    Here is @iansample 's blog entry from today's Guardian in the UK

    http://www.guardian.co.uk/science/blog/2011/dec/06/is-higgs-boson-real

    It includes some reactions from Glashow, Wilczek, Randall, Veltman, t'Hooft ….etc

35. **Peter Woit**
    December 6, 2011

    brazilian,

    String theory has nothing at all to say about the Higgs, it makes no prediction about this at all. So, discussion of the pros and cons of string theory is off-topic here.

    The show must go on,

    You certainly can send me copies, and I'll summarize for our readers.

36. **Predictor**
    December 6, 2011

    It's interesting that somebody compared the Kane "prediction" with the "prediction" of Shaposhnikov et al. They're are pretty much on the same footing: pure wishful thinking.
    I mean, it's OK to play that kind of game, but you shouldn't call that a prediction. In the case of Kane, because of the huge amount of implicit or explicit assumptions. In the case of Shaposhnikov et al, because of the lack of any theory behind the whole construction.

37. **Jeff McGowan**
    December 6, 2011

    I just love it when I get people on a *physics* blog trying to teach me elementary mathematics 🙂 My issue about 124 vs 126 GeV is my surprise that the HEP peaks are wide enough to allow something like that, combined with my mathematicians inherent mistrust of things like the assumptions that go into statistical calculations like combining peaks. Actually, I'm kind of curious, for things like particle signatures, what are the theoretical rationales for what distribution you expect to see?

38. **Peter Woit**
    December 6, 2011

    Readers of other blogs who wonder about some disturbing material about me they might see there should refer to

    http://www.math.columbia.edu/~woit/wordpress/?p=4127

    and ignore it.

39. **Bernhard**
    December 6, 2011

Peter,

off-topic: will you comment on this paper: http://arxiv.org/abs/1112.0788 at some point?

40. **Coin**
December 6, 2011

So if there is a 3.5 sigma at 126 GeV with the current ATLAS analysis, and a 2.5 sigma at 124 GeV for the current CMS analysis, then when the combined analysis of both ATLAS and CMS is done next year which has been mentioned here previously– if the signals are real, what sigma would one estimate the combined analysis could probably get up to with this existing data? (Is this even a sensible question?)

41. **Peter Woit**
December 6, 2011

Bernhard,

Traveling today, will probably write something about that tomorrow.

Coin,

Philip Gibbs is the expert on this….

42. **JollyJoker**
December 6, 2011

Coin, about 4.3 sigma.

43. **David Ewan Kahana**
December 7, 2011

Interesting rumours, indeed, and I am confident
the Higgs will be found in the range 122-132 GeV, having
predicted its mass together with the top quark mass
in a composite model, before either top or Higgs were
detected. But I'ld point out there were similar rumours
of an excess in the b anti-b channel indicating a Higgs
in the range of 130-140 GeV just a couple of months back
(personal communication from W. Marciano). It was a similar
deal, a couple of sigma each in CMS and Atlas, which added
to a bit more than 3 sigma. It went away of course.

My last look at the 2 gamma data, with about
half of the total data set analysed showed points above
and below the theoretical continuum, and no
sign of a bump whatever. The SM Higgs width at this
mass is so small that I don't even remember the number
but I believe it's on the order of 1 MeV. So in this case
the width of any bump in the 2 gamma mass spectrum
will be determined by detector resolution, on the order
of 5 GeV. There was an extra factor of two available
in the integrated flux not analysed at that time, but
that only gives 40% better resolution of any bump
at 125GeV. So I can't believe this will be conclusive.

A SM Higgs this light just escapes the vacuum
stability and metastibility (due to finite temperature
effects in the early universe) if new physics only
appears near the Planck scale.

So it's premature for Kane and the supersymmetricians
to be rejoicing, I think. They should rather be worrying
about the absence of supersymmetry at 95% confidence
level, below about 1 TeV. Exciting times!

about 50%

44. **Jozef Šima**
December 7, 2011

The Higgs mass (125 GeV) was calculated, along with other parameters of the Universe, based on the model of Expansive Nondecelerative Universe, see our paper J. Šima, M. Súkeník, Nondecelerative Cosmology – Background and Outcomes, published in Pacific Journal of Science and Technology 12(1), 214-236 (2011) and included references.

45. **David Ewan Kahana**
December 7, 2011

I suppose it's only polite to leave references that can be checked, when one claims to have predicted something, so here are links to my various predictions of the top and Higgs masses.

I seem to remember that the major uncertainties at the time these predictions
were made was the value of the strong coupling at the Z mass. And we were using one loop beta functions for the evolution. But no theorists I talked to at the time believed in a top mass as a high as 160 GeV.

Standard-model bosons as composite particles

Phys. Rev. D 43, 2361–2368 (1991)
http://prd.aps.org/abstract/PRD/v43/i7/p2361_1

Prediction: Higgs ~140 GeV, Top ~ 160 GeV

Preprint (1993):
(Top and Higgs Masses in Dynamical Symmetry Breaking
http://arxiv.org/abs/hep-ph/9312316)
Prediction: Higgs ~ 125 GeV, Top 175 GeV

Publication:
http://prd.aps.org/abstract/PRD/v52/i5/p3065_1
Prediction: Top~180(185) GeV and Higgs ~130(135) GeV.

46. **pfogle@tiscali.co.uk**
December 7, 2011

sorry if this is a well known fact, but how correlated would the errors from Atlas and CMS be? Presumably there are shared system errors?

thanks.

47. **democrito**
December 7, 2011

Hi Pfogle,

the uncertainties of the two experiments are mainly statistical at this stage, and completely independent. There is, in truth, some strange common choice for background shape parameterizations (both experiments are using Bernstein polynomials for the background in their H->gamma gamma searches, which is odd at the very least, since the choice is not particularly bright), but most of the stuff is completely orthogonal. In particular, backgrounds in the gamma-gamma are data-driven, so no MC dependence is there.

48. **David Summers**
December 7, 2011

Well I guess now that I'm out of academia, I can comment without stepping on anyones toes – as I've had not direct contact with experimenters working in the field in 10 years!

Anyway the photon-photon channel is interesting, because only spin 0 particles can decay into two photons. So if a bump is seen in the photon photon mass – then it must be some kind of spin 0 particle, e.g. the Higgs.

So its just how big is the bump over the photon photon background. Alass don't have the code I once had, so can't do some simple calcuations of the various cross sections. Nice thing is though that for signals like this the significance of results builds quickly. So its at 3 sd now – give it another 6 months or so (or rather the next run), and it should be a very significant signal then.

Interesting though to hear about my PhD subject coming back to life …

49. **David Summers**
December 8, 2011

Oh yes – what I also should have said, is whats interesting about this channel is it only demonstrates a higgs in the electro-weak channel; e.g. responsible for mass of the W and Z; but non necessarily responsible for generating quark masses.

To establish the latter they would need to look for the b bbar branching ratio of the Higgs, and that will be a very messy signal down at 125GeV – probably can't be seen in all the muck.

So does make it an interesting time for high energy physics …

50. **Suzie**
December 8, 2011

Sorry to contradict you, David. How do you think the Higgs is being produced in the first place?

51. **Sascha Vongehr**
December 9, 2011

Hope you don't mind my extensively quoting from your blog here:
http://www.science20.com/alpha_meme/light_higgs_discovered_and_about_destroy_universe-85357

52. **Yatima**
December 11, 2011

Sascha Vongehr writes

December 11, 2011

Tuesday will be mostly a confirmation that there is enough data to narrow search to the 115 to 130 range with some hints of a signal (likely around 125). These hints will be less than 3 sigma.

55. **David Summers**
December 13, 2011

Suzie,

Only just check back here – taking my mind back 15 years to when this was fresh …

Higgs of about this mass at pp colliders are mainly produced by a pair of W or Z bremed of quarks in the t channel – these then merge to form the Higgs. So this is sensitive to WWH and ZZH couplings.

There is also a contribution from gluon fusion, via a top loop. That is sensitive to H t tbar coupling, and so mass generation for quarks. From what I recall though at these masses its t channel vector boson fusion which dominates – my memory though could be wrong, so I'd be happy to be contradicted ….

David.

String and M-theory: answering the critics

December 7, 2011
Categories: This Week's Hype

Mike Duff has a new preprint out, a contribution to the forthcoming *Foundations of Physics* special issue on "Forty Years of String Theory" entitled [String and M-theory: answering the critics](). Much of it is the usual case string theorists are trying to make these days, but it also includes vigorous ad hominem attacks on Lee Smolin and me (I'm described as having an "unerring gift for inaccuracy", and we're compared to people who campaign against vaccination "in the face of mainstream scientific opinion"). One section consists of a rather strange 3-page rant about Garrett Lisi's work and the attention it has gotten, a topic that has just about nothing to do with string theory.

Duff explains that his motivation for answering the critics is that we have been successful on the public relations front, supposedly responsible for the British EPSRC "office rejecting" without peer review grant proposals on string theory. I know nothing of this, but I think it's clear to everyone that the perception of string theory among physicists has changed, and not for the better, over the past decade. One dramatic way to see this is to notice that at this point, US physics departments have essentially stopped hiring string theorists for permanent appointments (i.e. at the tenure-track level).

String theorists have a problem not just with the public, but with their colleagues. The main reason for this is not Smolin or me, but the failure of the string theory research program. Duff's take on whether the landscape is pseudo-science is that string theory can't even tell whether there is a landscape, and he is "doubtful whether the kind of issues we are considering here will be resolved any time soon." On the question of the time scale for possible progress, he invokes the two millennia it took to get from Democritus in 400 BC to quantum theory early last century. His list of greatest achievements of string theory in recent years has just two items: applications to fluid mechanics and his own work on entanglement in quantum information theory. Given this, it's hard to see why he's surprised the EPSRC is cutting back on support for string theory.

While Duff has detailed complaints about exactly what Smolin wrote in *The Trouble With Physics*, he mentions my book without saying anything about what is in it (one suspects his policy of how to deal with it is that of Clifford Johnson and some other string theorists: refuse to read it). He does have some specific complaints about material from my blog:

- According to Duff:

> he wrongly credits me with having told author Ian McEwan about the Bagger-Lambert-Gustavsson model in M-theory, which he then proceeds to criticise.

This is based on a [book review]() about Ian McEwan's novel *Solar*, where I wrote about M-theory references in the book that "McEwan seems to have gotten this from Mike Duff, who is thanked in the acknowledgments". Since Duff is an expert on these topics and the only particle theorist thanked, this was an obvious guess, worded as such. In this review I wasn't criticising M-theory, just noting an interesting occurrence of it in popular culture. My only criticism was of McEwan, for the minor anachronism of a topic from 2007 showing up in a book set in 2000. In a segment from the novel that I quoted, one character is expressing opinions about M-theory research which you could call critical, but this material was written by the novelist, not by me (and I'm still wondering where McEwan would have gotten this from, other than from Duff).

- In two cases, Duff claims that I misrepresented his words on the blog. Both are cases where I wrote the blog entry based on information from someone who had heard him talk, since I didn't have access to his words themselves when I first wrote the blog entry. In general I try to be very careful about what I quote, making sure it is accurate and in context. In these cases, what was reported here was clearly labeled as someone else's impression of his talk, and Duff has some reason to be annoyed at not being quoted accurately, although it wasn't me doing it.

The first case was a posting about the [debate in 2007 between Duff and Smolin]() (see also [Clifford Johnson's blog](), which includes comments from Smolin), where one attendee [described]() the scene following Smolin's talk as:

> Smolin sat down. Duff stood up. It got nasty.
>
> The trouble with physics, Duff began, is with people like Smolin.

The transcript actually shows:

> Good evening everyone. The trouble with physics, Ladies and Gentlemen, is that there is not one Lee Smolin but two.

followed by an extensive description of Smolin as deceptive and two-faced, saying completely different things at the debate and in his book. From the transcript, I'd describe the "Duff stood up. It got nasty" part as completely accurate, the "The trouble with physics, Duff began, is with people like Smolin" much less so.

- The second case has to do with a [posting]() about a recent BBC program on superluminal neutrinos, where Duff discussed string theory explanations for this. Based on two e-mails people had sent me who had watched the program, I wrote that it "evidently featured trademark hype from string theorist Mike Duff about how string theory could explain this." The first commenter, who had also seen the program wrote in "I watched this tonight and can confirm that it did include stringy hype." Duff complains that

> I said that, although superluminal travel is in principle possible in the "braneworld" picture of string theory, in my opinion this was NOT the explanation for the claims

It still seems to me that going on a TV program to claim string theory as a possible explanation for this kind of experimental result can accurately be described as "hype", even if, since no one believes the experimental result, you express the opinion that string theory isn't the right explanation in this case.

Duff is much less interested in the virtues of accuracy when he describes my words. I guess I've joined Smolin on his list of targets because of what I've had to say on the blog (see [here](), [here]() and [here]()) concerning his publicity campaign claiming a "prediction of string theory" about qubits (recall that he thinks this is one of the two main advances in string theory of this decade). He claims that "falsifiability of string theory is the single issue of Peter Woit's 'single-issue protest group'", and that my argument about the qubit business "may be summarised as (1)It's wrong (2)It's trivial (3)Mathematicians thought of it first." One can read the postings and decide for oneself, but I'd summarise the argument quite differently: Duff has nothing that can possibly be described as a "prediction of string theory" and it's misleading hype to issue press releases claiming otherwise. The experimentally testable "prediction" is that "four qubits can be entangled in 31 different ways", but if experimentalists make measurements of four qubits that show something different, one can be sure that the headlines will not be "string theory shown to be wrong in a lab".

Duff's article contains an appendix about this, in the form of a "FAQ", where he explains that he approved the text of the press release headlined "Researchers discover how to conduct first test of 'untestable' string theory" which is misleading hype by any standard. Initially someone who was successfully misled in the Imperial media team added the subtitle "New study suggests researchers can now test the 'theory of everything'", which was later removed. Duff claims that Shelly Glashow, Edward Witten and Jim Gates told journalists that they didn't agree with this because of the "theory of everything" subtitle, implying that otherwise they were fine with the "first test of 'untestable' string theory" business (except for Gates noting that in any case this is just supergravity, not string theory). It would be interesting to hear from the three of them if they're really on-board with this "first test of 'untestable' string theory".

What Duff and some other string theorists don't seem to understand is that this sort of "answering the critics" is exactly what has gone a long way to creating the situation at the EPSRC that he is worried about. Unfortunately it has damaged not just the credibility of string theory, but of mathematically sophisticated work on particle theory in general. According to Duff

Just recently, in fact, EPSRC completely abolished its Mathematical Physics portfolio.

Update: Matin Durrani at Physics World (also a target of Duff's ire) has a blog entry about this here.

Update: Lee Smolin sent me the following comments on the Duff article:

> Maybe it would help if I provide some context for the debate Mike Duff took part in with Nancy Cartwright and myself in London in 2007. The occasion for the debate was the publication of my book TTWP in the UK and the reason for the debate was that I had insisted that, as the point of the book was to explore the role of disagreement and competing research programs in science, the best way to illustrate it was to have a debate. String theory was discussed in the book as a case study illustrating the issues and so it seemed appropriate to have a debate with a string theorist. I also insisted that in each of these debates a philosopher of science would be included to highlight the fact that the main themes of the book were longstanding issues in philosophy of science, having to do with how consensus forms within a scientific community on issues on which there is initially wide disagreement.
>
> There were two such debates in the UK, the other was at Oxford with Philip Candelas and Simon Saunders. That went very well, as Philip gave a strong defence of string theory that stayed focused on the scientific issues.
>
> Duff's construction of two me's is, so far as I can tell, a debating tactic to avoid addressing the key issues my book raises. He starts with
>
> "Who can dispute that the ultimate goal of a scientific theory is to make experimentally testable predictions? Who will challenge the need to keep an open mind and listen to unorthodox views? Who can disagree with the assertion that our current understanding is only partial and that the ultimate truth has yet to be uncovered? What Lee Smolin said in the London debate was so uncontroversial that, had I confined my response to these remarks, the evening would have would have fizzled out in a bland exchange of truisms."
>
> Indeed the constant theme of my book is the development of those "truisms." What Duff does not explore is that in spite of the agreement there may be over these "truisms", they have strong consequences for the evaluation of research programs in fundamental physics. Apparently we disagree about the implications for string theory. What Duff could have done is acknowledged these disagreements and explored the reasons for them. Instead he claims to attack my book, but it is striking that he does so, not by criticizing the text I actually wrote-but by attacking first the publicity blurb on the cover and then responses from journalists. As I have stated many times, the material on the cover was neither my text nor my choice and is more strongly worded than anything in the actual book. I hope it is obvious also that you cannot attack a book by pointing out inaccuracies in reviews.
>
> When he finally does get around to quoting from the book, he makes a few good points mixed in with distortions gotten by quoting out of context. Had he stuck to the good points he had we could have had a useful debate that would have shown the audience the role of disagreement among scientists faced with difficult questions. Had he done that, there would have been no need to construct a fiction of two me's. I am happy to leave it to readers of my book to judge whether its text is or isn't completely consistent with the "truisms" he asserts we agree about.
>
> There is one aspect of Duff's rant which deserves correction, which is his attack on me related to Garrett Lisi. What Duff says is, "So when Lee Smolin described him as the next Einstein, the publicity juggernaut moved into overdrive". There are several untruths in this short sentence.
>
> First, this refers to a Discover article of March 2008 which says, "With Smolin's aid, DISCOVER has scoured the landscape and found six top candidates who show intriguing signs of that Einsteinian spark" of whom Lisi is one. This was, so far as I recall, based on a phone call with an editor at Discover following a piece I had written for Physics Today on the challenges faced by those who do high risk-high payoff research. I think anyone who looks up the full list of six will see that the editors were aiming to illustrate a wide range of approaches to fundamental research, of which Lisi is at one pole. And as they make clear-the choice of the list was theirs and not mine.
>
> Furthermore, the media attention on Lisi had begun and peaked already in November of 2007, sparked by a New Scientist article, following immediately the posting of his article on arxiv.org. And while there was a very exaggerated media response-which I and others did our best to advise against-there was no "publicity juggernaut" ie no attempts by Lisi or anyone to seek publicity for him, no press releases, no publicist, no calls to journalists except to strongly advise the story was premature. I told everyone who asked not to write a story on Lisi because the preprint had just been uploaded and there had not been time for experts to evaluate it. Indeed, New Scientist had quoted me very much out of context, ignoring emails I sent them advising them not to write a story on Lisi's paper before the experts could evaluate it. So the reality was the opposite of the impression created by Duff's sentence.
>
> None of this is new, none of it is said for the first time. It is depressing to revisit these debates from five years ago. Most of us have moved on. At least I have, as readers of my next books, as well as the article I was invited to write for the same special issue, will, I hope, see.

Update: The following is Garrett Lisi's response to the Duff article. I should note that I'm not complaining about Duff's listing of my titles. If you want to make up your mind who is right based on titles, Duff's your man in this argument.

> Michael Duff's article is full of deceptive half-truths. To attack the commentary on Lee's book, while avoiding Lee's actual arguments, is just one example of this fundamentally dishonest tactic. A similar example is his reference to Peter as "Computer Administrator and Senior Lecturer in Discipline," as if Peter was not also a very knowledgable mathematical physicist. Duff then launches an attack on my work, once again focusing on a large volume of commentary by others rather than on my actual arguments. Also, Duff refers only to my first paper, saying it's never been peer-reviewed and published, avoiding the fact that I've since published papers on the theory, including "An Explicit Embedding of Gravity and the Standard Model in E8."
>
> Scouring Duff's rhetoric, baseless statements, and ad hominem attacks in search of some factual argument supporting his attack on my work, I can find only this:
>
> "Nature (and the standard model of particle physics) has three chiral families of quarks and leptons. 'Chiral' means they distinguish between left and right, as they must to account for such asymmetry in the weak nuclear force. But as rigourously proved by Jacques Distler and Skip Garibaldi, Lisi's construction permits only one non-chiral family."
>
> This is, once again, a misleading half-truth, avoiding the fact that a chiral family of quarks and leptons can be part of a non-chiral representation space, as is the case in E8. I cannot credit Duff alone for this deception, as its source is Jacques Distler — a master of the half-truth — but I can blame Duff for supporting it.
>
> For anyone who actually cares about the state of E8 theory, I would recommend my recent papers. Apparently Duff considers the work sufficiently threatening to the string program that he needs to attack it in this dishonest manner. If string theory models are as twisted and misleading as the statements in Michael Duff's paper, it's no wonder they're dying.

Comments

1. **Ms Quote**
   December 7, 2011

   I suggest you delete the last quote "According to Duff … EPSRC completely abolished its Mathematical Physics portfolio." This is a ripe candidate for misquotes later on.

Find out from someone in the EPSRC (if possible) to confirm this (and then cite them). Mathematical physics is a big discipline. It is unlikely to be cancelled in toto.

2. **Peter Woit**
December 7, 2011

Anyone who gets to the bottom of that post is likely to realize that "According to Duff" indicates high probability of inaccuracy in whatever follows. I'm guessing his claim does have some sort of relation to reality, presumably to this issue (in which case this is not just about mathematical physics, but mathematics in general)

http://www.dpmms.cam.ac.uk/~bt219/epsrc.html

or more specifically to this statement from EPSRC

http://www.cms.ac.uk/summaries/EPSRCreply.pdf

If any readers know more about this and can point to authoritative information, I'll add an update about this to the posting.

and

http://arxiv.org/abs/1108.1540

4. **Peter Woit**
December 7, 2011

Frank,

Not really. Life is too short to pay much attention to claims about string cosmology. From what I remember there were plenty of claims made 10-20 years ago about how string theory explained 3 space dimensions.

5. **LHB Jr**
December 7, 2011

In the paper, he says that Smolin called Lisi "the next Einstein." He fails to point out that Ed Witten is mentioned as a candidate for "the next Einstein" in the very same article, along with 4 other people with diverse backgrounds and viewpoints.

Seems to me that calling somebody "the next Einstein," and naming somebody, along with a handful of others, as a possible candidate for being "the next Einstein" are two different things.

6. **Clara**
December 8, 2011

Peter,

Duff's paper is so full of vague phrases and so empty of physics that to a casual reader it sounds like the rant of a typical unemployed who is jealous that other people have a job.

40 years without results is a track record that no theory in physics has ever achieved, especially with so many and so smart people.

Why are these people so obsessed to ride a dead horse? The obsession is barely understandable. There seems to be some religious drive behind it. You speak to many string theorists. Why are they doing this? What collective vision drives this considerable boy's network into the wrong direction?

7. **Bee**
December 8, 2011

First I was thinking how awful this thing got published in a journal I previously considered to have a pretty good reputation, probably entirely without peer review. Now I'm thinking, this will make an interesting piece for the history of science 100 years from now. I'm sure future students will have something to laugh about that one.

8. **felix**
December 8, 2011

It's incorrect to attribute the lack of job positions for mathematical physics to the influence of string theory. With or without string theory, mathematical physics is always a niche. For example, there is this beautiful research field of integrable models in statistical mechanics, started by people such as Onsager and Baxter. In addition to its obvious relevance to physics, it has connections with a wide range of mathematics including quantum groups, graph theory, topological quantum field theory, elliptic curves and so on. However, if you do a PhD in such a field, your chance of landing a job is even slimmer than a string theorist in this post-string hiring environment.

In fact, string theory *is* serious mathematical physics, as long as you ignore the ultra-speculative part such as the multiverse. There are too many examples, one of which is the AdS/CFT correspondence. People can argue about how precisely real systems can be approximated by AdS/CFT, but if you take a mathematical physicist's point of view and don't insist on immediate physical applicability, AdS/CFT is definitely one of the most striking achievements in modern mathematical physics.

By any reasonable standard, string theory has only *created* jobs opportunities for people pursuing mathematical physics, a field that's often overlooked by funding agencies. The real sad part is that you have to rely on hype about Theory of Everything to get funding for mathematical physics. Just look at what we have got into after string theorists were no longer getting many job positions. The jobs are now going to "phenomenologists" who are never tired of writing a 10,000th paper on MSSM or inventing a new variant of a new model for dark matter every day. This is a group of people whose vision and whose standard of work, overall speaking, are infinitely worse than string theorists.

9. **Crackpotl**
December 8, 2011

I can remember good old pre-Woit/Smolin days, when 100% of popular articles on string theory were fawning and uncritical. And then Woit/Smolin started their vicious smear campaign, the result of which is that 90% of popular articles are fawning and uncritical of string theory, and 10% voice skepticism to varying degrees.

10. **piscator**
December 8, 2011

The comments on EPSRC are off-base, there was a much bigger issue with EPSRC than simply a narrow restriction on not funding string theory or mathematical physics. In its forthcoming (now current?) fellowships round, EPSRC at one point announced that the they would only consider mathematics applicants doing applied probability (I think that was it). That is number theory, combinatorics, analysis, algebraic geometry etc (and yes mathematical physics) – if you were a young postdoctoral/junior faculty mathematician doing any of these areas, you were de facto ineligible for funding.

Unsurprisingly this caused a major rumpus between the research council that funds mathematics and the UK mathematics community. I haven't followed it all, and I don't know to what extent this policy was bad communication and to what extent a not-so-secret desire to fund only 'practical' areas. I think if you dig around on Tim Gowers' blog you can find the details.

11. **piscator**
December 8, 2011

In particular try this

12. **Nigel**
December 8, 2011

The Horizon "faster than light" BBC2 Horizon program used a political trick (maybe due to BBC editing, not necessarily completely controlled by Duff) of Duff first hyping superstring theory for ages using a loaf of bread to illustrate how a neutrino might take a short cut and arrive faster than light, and then at the end including a brief statement by Duff that he a rigorous scientist and wasn't hyping anything.

Horizon on BBC2 did the same trick using Sir Paul Nurse earlier this year in a different documentary which tried to lynch James Delingpole for asking questions in a different science. The trick is used by politicians over here. You first give a long subjective argument full of one-sided biased hype, then just when everyone is brainwashed, bored and changed channels, you inject a brief disclaimer to look objective.

It's the two-way bet used extensively by politicians, lawyers and the media here. Whatever happens, you claim credit. If you're right, you're right. If your hype is wrong, you highlight the brief disclaimer as "proof of rigorous objectivity".

Duff should stick to mathematical physics or defending non-mainstream ideas, not overhyped groupthink religion (disclaimer: this is just a suggestion, not a threat).

13. **Bobito**
December 8, 2011

Whatever one thinks of Lisi's preprint, no article considering him a potential Einstein (whatever that means) should be taken seriously, as such a claim is not well-founded in anything he has written and distributed publicly.

14. **Carl**
December 8, 2011

First they ignore you, then they ridicule you, then they fight you, then you win.

15. **Carl**
December 8, 2011

@Clara: One possible explanation is our old friend cognitive dissonance. When someone has sunk their career and their reputation, and in some cases the careers of their graduate students, into a field of study that increasingly looks to be petering out, that person is likely to do everything in their power to avoid acknowledging the reality.

Or as Hans Christian Andersen might have put it, when a child shouts out that the emperor has no clothes, it's a lot easier to have the child tossed into a dungeon than to admit that you've been parading around naked in public.

16. **Mike**
December 8, 2011

Here is a link to Gordan Kane's (and others) new paper talking about a predilection for the Higgs derived, it is said, from String Theory:

http://arxiv.org/abs/arXiv:1112.1059

I was curious whether you thought this was significant, or whether you thought that it could simply be a function of "backing into" the mass. By that I mean, noting the chatter about the potential predicted Higgs in the 124 to 126 range, and then, given String Theory's notorious "flexibility", choosing specific constraints and inputs that arriving at the projected Higgs mass?

17. **Joel Rice**
December 8, 2011

I've been reading Schweber's "QED and the men who made it." What a contrast to the speculation going on these days.

18. **Peter Woit**
December 8, 2011

Mike,

That's another topic to be addressed another day. Surely we're going to see in coming days/months a long list of claims by people that their model predicts the right Higgs mass, whatever it is. Kane has been promoting a long sequence of susy/string theory models over the years that supposedly make "predictions", evolving to fit whatever the latest data shows. If the Higgs really is at 125 GeV, it's right in the middle of a range that for 10 years or more has been by far the most likely one (from LEP and precision electroweak constraints). Everyone making "predictions" has concentrated on finding models with a Higgs in this range.

Anyway, this is off-topic. In Duff's favor, unlike Kane he admits that string theory isn't now able to make real predictions about the Higgs mass.

19. **Pheelios**
December 8, 2011

I am PhD student in conformal field (just finishing) in a UK mathematics department, I heard about the ESPRC cutting funding to string theory months ago from my supervisor who is worried about the funding implications it will have for him. The reason I gathered for the cuts was because prominent pure mathematicians in or related to the ESPRC hated string theory and thought the idea of a string theorist being let anywhere near a mathematics student was unacceptable. Personally I don't see why string theory shouldn't be funded from the pure mathematics budget, the only real benefits that either discipline confer to the average taxpayer is the mental training they give to their undergraduate and graduate students who then go on to apply it in the real world. As long as the level of teaching coming from a string theorist is the same as the level of teaching from a pure mathematician I don't see why the average taxpayer should be too concerned about the level of rigour that either discipline applies to it's own highly esoteric and detached research schemes.

20. **Peter Woit**
December 8, 2011

Pheelios,

I don't know what's going on in the UK, but my impression is that in the US, while many physics departments have become unhappy with string theory and are not hiring in that area, the situation in math departments hasn't changed much. Mathematicians have always had some interest in the math coming out of string theory, and are unconcerned about whether it works as a theory of everything. However, for a math department to hire someone, they need to be convinced that what they are doing has interesting mathematical implications, and most string theory work doesn't meet that standard.

21. **Bob Levine**
December 8, 2011

@Pheelios,

Do you actually find it plausible that objections from a few 'prominent pure mathematicians' would have so much influence with the ESPRC, when we've just been given a huge body of evidence (available in the links provided in this thread) that ESPRC has ignored virtually the entire mathematics research community in the course of gutting their fellowship programs so that only statistics and applied probability theory candidates are eligible for funding? Just about everyone who is anyone in the British mathematics community has signed one or another strong protests to the ESPRC about this radical new approach to setting funding priorities. It's quite clear that what ESPRC intends to support exclusively are branches of mathematics which are perceived as having immediately industrial applicability, with support eliminated *across the board* for highly theoretical foundational research. This policy shift seems more than sufficient to explain whatever defunding of work in string theory has gone on, quite apart from ST's failed track record.

Interestingly, one of the chief complaints in the mathematicians' response to the ESPRC fellowship cuts is that decisions at the agency are being made by people with no expertise whatever in the field; indeed, Delby seems to think that this is a *good* thing. It seems highly unlikely, given the the culture of the agency, that guidance from pure mathematicians on *any* point of policy would be taken seriously. So it might serve you well to dig a little deeper into the information you've received on this point before accepting it uncritically.

22. **Curious Wavefunction**
December 8, 2011

One dramatic way to see this is to notice that at this point, US physics departments have essentially stopped hiring string theorists for permanent appointments (i.e. at the tenure-track level).

Yes, but couldn't this also be because of the bad job market in which *nobody* is really getting hired? I guess my question is, if they are not hiring string theorists, who *are* they hiring then?

23. **chris**
December 8, 2011

LHC phenomenologists.

24. **Peter Woit**
December 8, 2011

Curious Wavefunction,

Hiring is definitely down across the board, but physics departments are still hiring theorists, just mostly phenomenologists. Dark matter or LHC phenomenology is popular. See

http://www.physics.utoronto.ca/~poppitz/Jobs94-08.pdf

and

http://particle.physics.ucdavis.edu/rumor/doku.php

for data.

25. **Marcus**
December 8, 2011

Chris, you might want to check that. What you say (LHC phenom'sts) doesn't accurately represent what I see here:
http://particle.physics.ucdavis.edu/rumor/doku.php?id=archive:2011

I see one offer to a string theorist (Baylor U. offer to Antonino Flachi) and a total of 10 offers marked "accepted" with two others apparently undecided because not marked "declined".

So 12 outstanding offers in HEP-theory as a whole. When I looked down the list I remember seeing quite a few cosmology/astrophysics people. You might want to make your own count. It seemed to me that these people were doing varied and interesting research, which could not all be lumped into "LHC phenomenology."
I'd actually be very interested to know how you or a knowledgeable HEP-theorist would sort the list of 12 out. We might learn something we didn't automatically expect by looking at how North American physics departments are behaving.

As a comparison, if you look back at the three-year period 1999-2001 the annual rate of firsttime HEP-theory faculty hires was about 18 per year, of which string

represented about 9 per year—essentially half of first-time faculty hires in US and Canada. The change from 9/18 down to 1/10 or 1/12 is remarkable—makes me wonder if there is something wrong with the statistics. But I am relying on what a HEP theorist at U Toronto has posted here:
http://www.physics.utoronto.ca/~poppitz/Jobs94-08
You can see his reservations and caveats by visiting his site and form your own impression. (I have a pretty high opinion, but check it out.)

26. **jg**
December 8, 2011

Mathematical Physics is still funded by the STFC (Science and Technology Facilities Council), funding for Standard Model and Beyond the Standard Model physics are 2nd and 3rd highest funded on the current list (~£84 million), Theory has another £19 million awarded

I think 2012 will be tough year financially for the UK, it'll be amazing if the Olympics break even. Come 2013, with better financial prospects and maybe LHC inspired promotion for particle physics the funding agencies may get generous again

27. **JC**
December 8, 2011

felix,

I guess one of the problems with string theory research is that its supporters make far too much claims about the real world physics based on a bunch of speculative ideas sugared with sophisticated mathematics.

I very much agree with what Phil Anderson said in his review about Peter's book:
"One may particularly cavil at the high level of hype around string theory, to the point of monopolising popular attention, and that the gigadollars of a number of philanthropists, as well as numerous physics department employment slots, are being farmed out to what is really an esoteric branch of algebraic geometry."

28. **strong field physicist**
December 8, 2011

Yes, its all very well to attack the sociology of physics and physicists – as if physicists can stop being people or as if the mechanism Lakatos described long ago is some new found foe to smite, and its another to allow your name to be put to a complete debasing of perfectly respectable physicists like M Duffy.

The thing is that you cant abstract your attempts to "correct" physics and physicists from the real life world of funding priorities we live in. We all know that that politicians prefer to fund banker bonuses and war machines (otherwise the politicians are quickly out of a job) than Science. So perhaps you could temper your sword so that it also strikes against the enemies of Science as well as the practioners of it

29. **Pechorin**
December 8, 2011

Peter, would you be willing to publicly debate Duff? I think the entire physics community would get a kick out watching you two beat up on each other. It might be educational, too.

30. **abbyyorker**
December 8, 2011

Well, Duff does make some good points. It's not all rubbish.

31. **Peter Woit**
December 8, 2011

Pechorin,

I don't see the point of trying to argue about scientific issues with someone who engages in ad hominem attacks, so, no, unless someone wants to pay me a huge sum of the money.

I have done public debates with string theorists in the past (one example was with Jim Gates in Florida a few years ago). People who attend such debates expecting fireworks tend to be very disappointed. Most string theorists and I actually disagree about far less than people think.

32. **Garrett**
December 8, 2011

Wow, if string theorists are that worried about me, they must be in even worse trouble than I thought.

33. **José Figueroa-O'Farrill**
December 9, 2011

There are some imprecisions in the comments, which I would like to clear up. I work in the UK and know the situtation fairly well.

The situation with the EPSRC and mathematical physics transcends String Theory. It so happens that the UK has a healthy hep-th community, many of whom work in stringy related topics and hence this decision does affect the stringy community in the UK, but it affects others as well.

It should be mentioned that the hep-th community in the UK is to be found both in Physics and Maths departments. This traditional blurring between mathematics and physics has been one of the main features in UK science; think Newton, Maxwell, Dirac,… This makes the EPSRC decision not to fund mathematical physics even harder to explain. The EPSRC has decided to stop funding mathematical physics, but will still fund Mathematics proposals inspired by Physics. In other words, it will not fund a research proposal about the use of Mathematics (however sophisticated) to solve a Physics problem (and Physics, for the EPSRC, includes the formal end of hep-th as well), but it will fund a proposal where ideas from Physics are used to solve a mathematical problem. The distinction is crucial and it amounts to EPSRC not viewing Mathematical Physics as part of Mathematics, contradicting centuries of UK scientific tradition. To be sure, annecdotal evidence suggests that there are mathematicians who agree with this decision of the EPSRC, but equally there are many who do not.

The situtation with STFC is that they have traditionally funded particle physics and in the absence of additional funding, they will not expand its remit to include mathematical physics per se.

It is naive to think that the fault for this lies in the string theory research community, just as it is naive to think that the fault lies in its detractors. It's a complex situation. EPSRC has re-invented its role from funders of research to sponsors of research. In other words, they wish to play an active role in deciding what research gets funded, a role which until recently was played by the scientists themselves.

34. **Shantanu**
December 9, 2011

Peter or others,
someone should ask him about his reponse to other critics of string theory such as Krauss, Woodard, T'hooft, and many others.
shantanu

35. **aa**
December 9, 2011

also this blog already seems like as public a debate as you can get

36. **Peter Woit**
December 9, 2011

Thanks José,

That's really a shame. As someone who thinks that the area in between math and physics is an exceptionally fruitful one, I was always pleased to notice that in Britain there seemed to be more overlap between the subjects than elsewhere, with people working on physics applications of mathematics often in math departments. A decision to try and reverse this in favor or enforcing rigid disciplinary boundaries is quite unfortunate.

37. **Peter Woit**
December 9, 2011

I've added to the posting a response to Duff's article from Lee Smolin.

38. **Henry Bolden**
December 9, 2011

More about the Mike Duff controversy in the article by Matin Durrani:

"String theorist sparks a spat"

http://physicsworld.com/blog/2011/12/string_theorist_sparks_a_spat.html

Disclaimer: No Brian Greene or Lisa Randall has been harmed in the making of this message.

39. **Anonyrat**
December 9, 2011

A future Frank Close writing the history of these times will have access to Duff's preprint. But will the material on this blog still be available thirty years from now?

40. **Peter Woit**
December 9, 2011

Anonyrat,

An interesting question, which amusingly enough I was discussing with Frank Close himself earlier this week (I was in the Bay Area at the same time as him and we met up). Perhaps some standard way of archiving blogs will emerge.

41. **Anonyrat**
December 10, 2011

Given that Columbia IAS has already lost a fairly widely cited published-online conference paper from 2002 – the webmaster searched, but sent me her regrets – I'm really concerned about the potential loss of information.

42. **Bernhard**
December 10, 2011

Peter,

perhaps you could make a selection of articles with potential historical interest in a book that you can either distribute in pdf in this blog or even find an interested publisher.

43. **John Duffield**
December 10, 2011

I see that Lee Smolin is on the editorial board of Foundations of Physics:

http://www.springer.com/physics/history+%26+philosophical+foundations+of+physics/journal/10701?detailsPage=editorialBoard

44. **james**
December 11, 2011

Duff does make a good point about how theres a dearth of any progress in quantum gravity, not just the popular theory. String theory is most definitely barking up the wrong tree, but, when it comes to uncovering the deeper mathematical model of the universe, who isnt these days. Anything new come out of LQG recently? Fundamental physics research thats destined to be wrong isnt neccesarily pointless. Maybe by barking up the wrong tree theyll tear down a branch. Who knows. It gives people something to do while we wait around for the next 1 in a 100 years einstein to pop out. Like Duff, I don't really get the String hostility in this way. Is it really a battle over funding and prestige? It seems to me the next einstein wont need too much by funding. He'll probably uncover the inexorable symmetry underlying the universe in a patent office with a pen paper.

45. **Aidyan**

December 11, 2011

There is nothing wrong in working on a theory that might turn out to be wrong. That's history of science. When you don't know what the truth is the only way is just to give a chance to this or that approach, theory or speculation. I've done this too for some time with so called non-extensive thermodynamics, and don't regret it. But sooner or later you have to admit (especially to your self) that, if after decades and generations of physicists the concrete results are still lacking, then you are probably going in the wrong direction and that you must move to something else. String theorists have to be blamed, not for the theory in itself, but for their decade long insistence on something to the exclusion of almost everything else and with great waste of human resources. Duff"s comparison of the development of string theory with the history of Laplace's black hole theory or Democritus' atomism is fallacious. The latter were relatively simple ideas subsequently forgotten for centuries with nobody working on it, the former is a theory on which hundreds, if not thousands, of physicists have worked now on for decades without tangible results. If strings will succeed nevertheless that would be a unique historical case. My own rule of thumb for considering a theory worth of attention is to set a limit of a dozen, max 15 years, for it to proof itself to be at least partially true. Otherwise it is time to close down the puppet show and fold up the makeshift stage.

46. **Albert Z**
December 11, 2011

James says: "It seems to me the next einstein wont need too much by funding. He'll probably uncover the inexorable symmetry underlying the universe in a patent office with a pen paper."

Perhaps he already has, but will anybody listen to a new paradigm that is radically different from prevailing assumptions?

If everyone thinks they know the "one true path" to unification, will anybody consider an untried route identitied by a "nobody"?

47. **harryb**
December 11, 2011

Following up a few of the references in the main piece and responses, I note the summary quote (lifted directly from the article "Stringscape" in PhysicsWorld Sep 2007, by Matthew Chalmers) by Ed Witten:

"There is an incredible amount that is understood,
an unfathomable number of details. I can't think
of any simple way of summarizing this that
will help your readers."

This reminds me of the UK comedy act Armstrong & Miller Physics Special (see youtube) where the professor refuses to attempt to simplify his new take on string theory. The sketch was supposed to be ironic, but Onion-like, it seems parody is only a few paces of absurd realities.

I think Peter's site here is a refreshing skeptical zone in the arcane world of modern physics. If String Theory is indeed fundamentally correct, then its should have no problem with educated questioning.

To the interested layman, Witten's words are quite concerning – it's as if to say there comes a point where those not fully involved in the deep details of string theory need no further explanation, but to take it on trust that a rarefied few (male) experts can handle it: the meaning of everything, the basis of the universe.

The parallels are too blunt to spell out.

In any event, questioning string theory or quantum loop gravity or whatever is the basis of normal science surely? I re-read Feynman's Value of Science essay (1955) where he ends it with the plea: "to teach how doubt is not to be feared but welcomed and discussed"

If only.

Still, I think this site helps keep that spirit alive and well thank goodness.

48. **Albert Z**
December 11, 2011

Nature, with the help of prudently skeptical experimentalists, keeps theoretical pipe dreams from wandering off too far into the swamp of pseudo-science. In the long run (and sometimes the very long run), that is.

49. **John Merryman**
December 11, 2011

Interesting comments on the nature of progress and skepticism. It seems, just like nature, we need to keep building out those large, unwieldy, unstable structures in order for them to collapse and see what hard little nuggets of content remain. On the other hand, maybe those large gaseous fields are every bit as natural as the little bits of mass into which they collapse. Lots of heat and some light are generated.

50. **Jon Lennox**
December 11, 2011

Anonyrat / Peter: The archive.org Wayback Machine archives of this site are pretty thorough (with the usual caveat that they run about six months behind).

For long-term storage, that's a single (organizational) point of failure, though.

51. **Chris Austin**
December 11, 2011

@ harryb,

I was surprised and disappointed by that unfortunate quote from Ed Witten; perhaps he had his mind on something else at the time, like Paul Dirac in that wonderful interview that Peter linked to recently.

Here's a one-page article from Witten's IAS website, where he does a better job of explaining why superstring theory is interesting.

52. **Peter Woit**
December 11, 2011

I've added as an update a response from Garrett Lisi to Duff's article.

53. **Dan Burgess**
December 12, 2011

Apparently even Google's a critic. A search for 'Not Even Wrong' brings up this result for Google books:
Not even wrong: the failure of … – Peter Woit

That's tough 🙂

54. **harryb**
December 12, 2011

@Chris Austin

Thanks for the link – agree it is a lot more accessible / humble on string theory's strengths / limitations. Leaves little room for any other line of thought though, with the suggestion that should any emerge, they will be reshaped as just a yet undiscovered element of string theory. But clear article.

I'm reminded again of Feynman's comment when asked if he had to leave one sentence behind to aid other civilisations: he noted it would need to be "Everything is made of atoms".

I guess Witten would rejoin "Everything is made of strings". Would this help or hinder these hapless civilisations I wonder.

55. **Hendrik**
December 12, 2011

Maybe not too far off-topic, is a piece by John Horgan in Scientific American, how in physics sometimes cranks are indistinguishable from experts. Based on a book by Margaret Wertheim, link is here. Of course strings are mentioned.

56. **Peter Woit**
December 12, 2011

Hendrik,

I ordered a copy of the book a few days ago, should arrive tomorrow, then review to follow shortly.

57. **Shantanu**
December 17, 2011

Peter or anyone else, does anyone know if smolin and Duff actually went for a drink or dinner after the debate?

58. **Dan**
December 26, 2011

Dear Peter,

even though, I might agree with what you say in some points of your article. The response you published from Lisi really needs a comment. Lisi makes comments about half-truths when he's the first one using them.

Lisi mentions the fact that his peer reviewed paper (in a conference proceedings) wasn't mentioned by Duff, but Lisi fails to say that this paper doesn't say that he succeeds in the unifications, it just provides an embedding for the "one family" standard model, something already present in Distler's paper.

About it, also, Lisi wants to make the readers thing that it's possible to include a chiral generation in a non-chiral representation. This is almost outrageous. Everybody knows that this sentence either makes no sense, or it states the obvious. Distler and Garibaldi's point isn't that the one generation isn't possible, they say that "because of the presence of an antigeneration, that generation will never be chiral". But, most importantly, they prove that three generations are impossible to get out of E8. And Lisi doesn't have any answer to this. Of course.

About Lisi's work being threatening to string theory, let's just have a laugh. What Duff is clearly upset at certainly isn't Lisi's theory, he's upset at who still doesn't clearly state that Lisi's was an interesting attempt, but the theory has so many holes and it's so incomplete that there isn't really a reason to give him so much resonance in the news. And when they prove his mistakes (he wrote several "wrong" statements, both physically and mathematically), then the press forgets and they don't give reasonable updates.

59. **Peter Woit**
December 26, 2011

Dan,

About Lisi vs. Distler/Garibaldi, I think both sides have had a chance to make their case, people can make up their own minds about this. The bottom line I think is that there are problems with Garrett's unification proposal, just like there are problems with all unification proposals out there. He's pursuing his and may someday overcome them, others may find some inspiration in what he has done for their own ideas. If you don't think his proposal can go anywhere, work on something else. It's not like there's a problem with the field being dominated by work on his ideas, crowding out others.

As to the complaint from string theorists that Garrett got too much positive media attention, and Duff's belief that this is such a big problem for string theory that he had to devote several pages to it of his short article defending string theory, try the following thought experiment. Imagine that Garrett's ideas fit into the string theory program, that he had some unification proposal he was pushing involving string theory (with similar problems to all the string theory unification proposals). The media would have found it just as attractive to write about the surfing outsider physicist with his revolutionary ideas about how to make string theory work. Do you really think Distler or Duff would have mustered the same outrage and gone on an anti-Lisi campaign? Would Duff have devoted pages of his article to the Lisi problem?

What's funny about both Duff and Distler is that they clearly have no problem with outrageous, dishonest media hype. They have both had their universities issue absurd press releases about their own work supposedly "testing string theory", when they had nothing remotely approaching such a thing, see

http://www.math.columbia.edu/~woit/wordpress/?p=510

and

http://www.math.columbia.edu/~woit/wordpress/?p=3127

It’s only when a string theory critic gets media attention that they get completely bent out of shape.

60. **Dan**
December 26, 2011

Peter, thanks for your answer.

I think you missed my point. Lisi “himself” says clearly that his theory isn’t currently able to reproduce the standard model, with one, two or three generations. He has no particle masses and doesn’t have the correct quantum numbers. This is clear to everybody who understands the physics. But Lisi’s answer here and in popular magazine is deceptive because he doesn’t always present this statement clearly.

There is a big different between the Pati Salam model, say, or other unifications models that are not complete, but that can at least explain the standard model, and Lisi’s model, that cannot even explain why the electron has a different mass than a muon. Or even if he can actually have a muon (second generation problem).

That is a huge incompleteness, much much bigger than not being able to prove, for example, whether or not N=8 supergravity is finite.

In general, forgetting about string theorists, there isn’t a hate towards E8, which is in fact used in many fields. The annoyance is towards some interviews or presentation of facts, that don’t say clearly that in Lisi’s theory: still we don’t know how to actually get this fermionic degrees of freedom (the unconventional BRST isn’t ever defined), still we don’t have a way to get chiral fermions in the one generation case (there is only a comment about it), still there is no way to get the three generations (not a real word about it, that says something mathematically meaningful), still we don’t have a proper symmetry breaking mechanism, still we don’t know if really the Coleman-Mandula theorem is valid or not in those limits, still we don’t know why it would be a finite theory… And I could keep going. Of course everybody is welcome to work on the theory they want. And the good thing about nature is that it doesn’t care about what theory we like. Eventually the right theory will become evident. What matters though, is to be honest with the readers, especially the ones who can’t understand most things we are saying. And to them we owe the truth, which is that Lisi’s model is not more wrong or less wrong than a million other models, but also that it is way way far from being a complete theory, given that it doesn’t even reproduce all the known results of the standard model, which most other “good” attempts to theories of everything instead can reproduce. This difference is important.

The other point that I was making wasn’t supportive of Distler, Duff or Motl or anyone else. I was just saying that Duff was upset because what I said above isn’t stated clearly enough. And the press makes it look like Lisi’s theory is as probably and as developed as lots of actually “working” theories (in the sense of at least reproducing known results and producing some predictions). Which is obviously not the case. Duff certainly isn’t upset or scared that Lisi’s theory will be creating problems to string theory, certainly not at this premature definition of the theory, does is just slightly more than some numerological correspondance between Lie groups and quantum numbers.

Think of a theory like the one that Nima Arkani-Hamed is working on. Do you think it is as developed as Lisi’s. Less worth? More worth? Do they have the same media attention? Do they deserve that compared to each other?

I’m not even saying anything bad about Lisi or his research. I’m just saying that the theory is in such a preliminary state that calling it theory of everything is almost a joke. Maybe, an work in progress, stil incomplete, attempt towards a theory of everything could have been better. Especially when people present it to the main public that isn’t capable of distinguishing between theories.

61. **Peter Woit**
December 26, 2011

Dan,

I just disagree with you about why Duff is upset. He has shown conclusively that he has no problem with misleading hype appearing in the media or making untrue statements himself when it’s part of a campaign that aligns with his interests. The idea that his problem with Lisi is just that he’s offended by inaccuracy in the media is not plausible.

62. **Dan**
December 26, 2011

OK, I understand your point of view. But again, I wasn’t supporting Duff’s point. I was just saying that the literal interpretation was about that. Then everybody is free to have their own interpretations. But it was misleading of Lisi to present his words in a deceptive way and changing the literal meaning of them. Which is always the problem with every statement that Lisi makes. He rarely talks any physics or math but very often gives deceptive and misleading answers. That’s all.

And even if Duff is wrong, or hypocritical and all that. What the media do with Lisi isn’t something to be proud of. It damages good physics. Maybe also Duff does, but it’s not with one bad thing that we cancel another bad thing.

Thanks for offering this space of confrontation.

63. **Peter Woit**
December 26, 2011

Dan,

My perception is different. Lisi’s public claims about his ideas seem to have about the average accuracy level you expect from someone enthusiastic about his own research. On the scale of the Distler and Duff press releases, not to mention the average popular book about string theory, he’s a stickler for accuracy. And, while the damage done by string theory hype to particle theory is huge and on-going, I just don’t see any significant damage from the media Lisi coverage.

I’m not sure what work of Arkani-Hamed’s you’re referring to, and quite possibly I don’t know what he’s up to most recently. But whatever it is, I’m sure it will get quite a lot of attention from other theorists, and media attention if it pans out. If he quits his job at the IAS, moves to Hawaii and takes up surfing, he’ll do much better on the media front.

64. **Dan**
December 26, 2011

Ok, let’s ignore for a second string theory. I believe myself that it has made its damages. I don’t even like string theory, and for a while we all know all the jobs where there. Similar thing with supersymmetry. We aren’t finding it, and still we will have to deal with some fine tuning problems to solve if the Higgs is confirmed at 125 GeV. Also, is it really a Higgs? Is it elementary? Is it composite? How does it couples, in case, with gravity and so on… all questions to answer. Fortunately at least in particle physics we will be busy enough with this.

But about Lisi, allow me to strongly disagree. I studied very carefully both Distler’s paper and all Lisi’s papers. And even if it’s true that he’s very excited about his theory it seems to me that he's not even trying to have progress in it, just to defend it for the status he's got in the media.

What did Lisi really publish about his E8 stuff after the first paper? His paper with the explicit matrix representation doesn't add anything to the initial structure. The result was even not only compatible, but in agreement with Distler and Garibaldi's paper. His paper with Smolin and Speziale is barely related to the unification part but there is no E8 and the fermions (his main innovation in the other theory) are treated in a completely different way. Has he published any mathematical work on the unconventional BRST theory that he said he wants to use? Has he published any results about whether or not he's safe from the extensions of Coleman-Mandula theorem? Has he found any way to get rid of the non-chirality and at least have a one generation standard model? Has he said anything specific about how he wants to recover the three generations out of fields with the wrong quantum numbers? Has he given any important math about this stuff in the last few years? Has he studied whether or not his theory is anomaly free, finite, renormalizable… etc? The paper with Smolin and Speziale certainly is not exhaustive about the topic.

So, at the end, why does he give lots of interviews saying that Distler and Garibaldi made unnecessary assumptions in proving his theory wrong, but never actually says why those assumptions are wrong, what they are, and how he thinks of actually progress?

To me this doesn't seem a very accurate. He seems, although, very lucid about responding to these questions without really giving an answer. So we, physicists, know that he gave no answer, while the general audience believes he gave a valid answer. I don't find this very encouraging…

Thanks!

Higgs Predictions and Results

December 12, 2011
Categories: Experimental HEP News

Tomorrow at 14:00 CET CERN will start to unveil the results of this year's LHC Higgs search, see here. Jester has just posted details consistent with what I've been hearing for the past couple weeks, although his numbers are slightly different. The big news is that both experiments are seeing something that looks exactly like a Standard Model Higgs in the Higgs -> gamma-gamma channel around 125 GeV. Some details about this signal:

- I've heard that ATLAS sees this with significance a bit less than 3 sigma, 3.5 if you combine results from other channels. To take into account the look-elsewhere effect, the significance of seeing such a fluctuation anywhere in the range studied is 2.2 sigma. Jester has

> The combined significance is around 3 sigma, the precise number depending on statistical methods used, in particular on how one includes the look-elsewhere-effect.

- What makes this something to take very seriously is that CMS is also seeing much the same thing in the gamma-gamma channel around the same mass. I've heard their significance is 2.5 sigma. Jester has

> All in all, the significance at 125 GeV in CMS is only around 2 sigma.

- Another channel that might start to have some sensitivity to a Higgs of this mass is the "golden channel", where you look for 4 leptons reconstructed as coming from 2 Z's. Here Jester says that ATLAS has three events near 125 GeV, contributing to the higher significance in the combined result. CMS also sees an excess involving three events, but they see this in the range 117-121 GeV, which should be too low to come from a 125 GeV Higgs. They also see a 2.1 sigma bump in ~~gamma-gamma~~ their combination at 119 GeV .

In this business, for each experiment a 2 sigma bump is not worth taking seriously, around 3 sigma is where it gets serious (and 5 sigma is the conventional standard to claim a discovery, they're definitely not there yet). But a 3 sigma bump from one experiment and a 2.5 sigma bump from the other, at the same place, is serious evidence indeed. It is still quite conceivable though that this kind of signal could disappear with more data (for this we'll have to wait until mid-2012). I think Jester has it about right:

> There is a good chance we're finally looking at the real thing, I'd say 50% based on the data alone and 80% adding our sincere convictions that Higgs must really be in that mass range.

One thing that can be predicted with certainty is a flood of papers from theorists claiming that their favorite model predicts this particular Higgs mass. Something to keep in mind when evaluating such claims is that for more than ten years we have known from LEP that the Higgs mass is above 114 GeV, and from precision electroweak measurements that it can't be too much above that value. Preliminary data early this summer showed some indications of a signal around 140 GeV (leading some to claim this as vindication of the multiverse, see here). By the end of the summer this was gone, with the combined CMS+ATLAS data excluding a Higgs down to 140 GeV or so at 95% confidence level, around 130 at 90% (tomorrow's data should have each experiment excluding down to 130 GeV at 95%, with a Philip Gibbs combination result sure to follow soon). Rumors of the gamma-gamma signal at 125 GeV have been circulating for at least the past two weeks.

We'll soon move from rumors to results, and I'll add anything new or different we hear tomorrow to this posting. Surely there will be a press release and a lot of versions of the results coming out of CERN, covered by the media and many bloggers. For some good recent blog postings explaining what to look for tomorrow, see Matt Strassler and Tommaso Dorigo.

Update: One correction. Besides the 124-125 bump in gamma-gamma, there's another bump in the CMS combination at low mass, around 119 GeV, but this is due just to the "golden channel" excess there, they see nothing there in gamma-gamma.

Comments

1. **petergreat**
   December 12, 2011

   I read that a SUSY Higgs can be indistinguishable from a SM Higgs, at least during the initial stage of discovery. Is the same true for composite Higgs models?

2. **Bob S**
   December 12, 2011

   http://news.cnet.com/8301-11386_3-57341543-76/has-higgs-been-discovered-rumors-of-watershed-news-build/

   Nice props for "blogger" Peter Woit. Heck, the article even states string theory is "contraversial"

This Week's Hype

December 12, 2011
Categories: This Week's Hype

The announcement at CERN tomorrow of a likely-looking signal for a 125 GeV mass Standard Model Higgs will probably unleash a flood of hype from theorists claiming this as evidence for their favorite Beyond the Standard Model scenario. One obvious problem with any such claim is that the CERN results correspond well so far to the Standard Model with no additions whatsoever, so spinning them as providing support for things like supersymmetry and string theory will require some work.

For the last decade we have known that the Higgs mass is above 114 GeV (from LEP) and unlikely to be very much higher than that (from precision electroweak results). This summer's LHC results disfavored masses above about 130 GeV, so for the last few months we've known that if the Standard Model Higgs is there, it should be between 114 and about 130 GeV. For a couple weeks news has been circulating widely from ATLAS and CMS that they are both seeing something around 125 GeV.

First out of the gate in the hype derby is Gordy Kane, who is quoted by Davide Castelvecchi at Scientific American claiming that string theory predicts the Higgs mass to be between 122 and 129 GeV:

> "If it's in that range it's an incredible success for connecting string theory to the real world," Kane says. He says he is confident that the upcoming LHC announcements, if they pan out as predicted, will constitute evidence for string theory. "I don't think my wife will let us bet our house, but I'll come close," he says.

It's unclear exactly what he's willing to bet the house on. If it's just that the Higgs is in that range, this might have something to do with the plots from the experiments widely circulating privately the last few days. In a remarkable coincidence, after more than 25 years of unsuccessfully trying to extract a definite experimental prediction from string theory, Kane and collaborators were able to achieve the holy grail of the subject (a prediction of the one unknown parameter in the SM, the Higgs mass) just a week before the CERN announcement. They submitted their paper to the arXiv the evening of Monday December 5, a few days after rumors of a 125 GeV Higgs were posted on blogs Friday December 2.

The paper deals with a "prediction" you get based on a host of assumptions about which particular class of string theory compactifications to look at. The main result is that in this particular class of models, you can relate the Higgs mass to the parameter tan(β) that occurs in SUSY extensions of the SM. As you increase tan(β) from around 2, the Higgs mass lies in a band, increasing from 105 GeV and a maximum of about 129 GeV:

> We will demonstrate that, with some broad and mild assumptions motivated by cosmological constraints, generic compactified string/M -theories with stabilized moduli and low-scale supersymmetry imply a Standard Model-like single Higgs boson with a mass 105 GeV < M_h < 129 GeV if the matter and gauge spectrum surviving below the compactification scale is that of the MSSM, as seen from Figure 1. For an extended gauge and/or matter spectrum, there can be additional contributions to M_h.

This conclusion and Figure 1 correspond closely to what is in the slides of Kane's talk at String Phenomenology 2011 this past August. The plot of Higgs masses as a function of tan(β) is there, giving a range of 108 GeV to 127 GeV. There is an intriguing comment on the conclusion slide:

> Single light Higgs boson, mass about 127 GeV unless gauge group extended.

I can't tell where the number 127 came from. Since 127 GeV is the top limit in the figure, and the wording "unless gauge group extended" is used, one guess would be that Kane meant that 127 GeV was the upper bound on the Higgs mass in this class of models.

There's nothing in Kane's August talk about a 122-129 GeV range for the Higgs mass, but in the December 5 paper it appears explicitly three times:

- In the abstract there's:

> When the matter and gauge content below the compactification scale is that of the MSSM, it is possible to make precise predictions. In this case, we predict that there will be a single Standard Model-like Higgs boson with a calculable mass 105 GeV < M_h < 129 GeV depending on tan β (the ratio of the Higgs vevs in the MSSM). For tan β > 7, the prediction is : 122 GeV < M_h < 129 GeV.

I don't see where the tan β > 7 comes from, presumably it's in one of their other papers.

- In the introductory paragraph there's:

> Furthermore, in G2-MSSM models we find that the range of possible Higgs masses is apparently much smaller, 122 GeV < M_h <129 GeV.

- G2-MSSM models are mentioned only briefly again in the paper, at the third occurrence of this particular mass range:

> For instance, in G2-MSSM models arising from M theory, Witten's solution to the doublet-triplet splitting problem results in μ being suppressed by about an order of magnitude. Hence, in these vacua, the Higgs mass sits in the range 122 GeV < M_h < 129 GeV.

Kane has chosen Lubos Motl's blog as the place to guest post and promote this string theory "prediction", concluding there:

> If generic compactified string theories with stabilized moduli correctly predict there is effectively a single Higgs boson and correctly predict its mass, it will be a huge success for the main directions of particle physics beyond the Standard Model, for supersymmetry and for string theory, both of which are crucial for the prediction. It will be a huge success for LHC and the accelerator physicists and experimenters who made the collider and the detectors and the analysis work. It will put us firmly on the path to understanding our own string vacuum, and toward the ultimate underlying theory. The value of the Higgs boson mass not only confirms the approach that predicts it, remarkably depending on its numerical value it may allow an approximate measurement of tan β, the μ parameter, the squark and gravitino masses, that the gauge group and matter content of the theory below the string scale is that of the MSSM, and that light (TeV scale) gluinos and dark matter are likely.

I don't quite see how finding a SM Higgs at 125 GeV is going to give all these different numbers and pieces of information. Kane claims that these string theory predictions also predict gluinos visible at the LHC within months from now:

> Then the gluino should be detected at LHC, and because of the heavy scalars the gluino decays are different from the ones usually discussed, being dominantly to third family quarks, top and bottom quarks. I won't explain that here because of space and time; we can return to it as the gluinos are being detected in coming months. They have not yet been systematically searched for.

In addition, there's a dark matter prediction that should be tested in "1-2 years".

If I were Kane, I wouldn't bet my house (or go to the press claiming the 125 GeV Higgs as a "huge success" for string theory) just yet. Assuming he's right, within months the gluinos will be there, and his ticket to Stockholm will be assured.

Update: My prediction in the first paragraph is coming true faster than I thought. In tonight's hep-ph listings one finds:

http://arxiv.org/abs/1112.2415 (m_H= 127 +/- 5 GeV)

http://arxiv.org/abs/1112.2462 (m_H < 128 GeV)

http://arxiv.org/abs/1112.2659 (m_H =126 +/- 3.5 GeV)

http://arxiv.org/abs/1112.2696 (m_H > 120 GeV)

There are going to be a lot of these…

Update: Over at a Nature live chat, Kane is giving the public some interesting explanations:

"for a higgs to be meaningful it must be part of a supersymmetric theory, so the superpartners should be found. The form it takes implies that gluinos should be found with masses around a TeV, maybe less, by summer, and decaying mainly into topquarks and bottom quarks."

"Recently we have published string theory calculations that imply the higgs boson mass is 125 GeV so if it is there are strong implications for connecting string theory to the real world, and for what the higgs discovery implies. we did that before the data."

"string theories are now well enough understood to predict higgs physics"

There will be another live chat involving Kane tomorrow, this one at Science magazine.

Update: Just took a look at the Science chat. Kane seems to have completely lost touch with reality, somehow deciding that the two experiments have reached the 5 sigma level needed to claim a discovery. As far as I know, he's the only one in the world to think this.

> Gordy Kane:
> YES. an experimenter from one experiment can't say that, but theorists see that two different experiments both saw a signal at about the same mass, and also saw additional channels, so it's a discovery!
>
> …
>
> Gordy Kane:
> The 5 sigma is a criteria people have chosen. i think as soon as the data are combined from two detectors, which is entirely legitimate, then the signal will indeed be over 5 sigma.

The following claims make about the same amount of sense as the discovery one:

> Comment From Tom
> Does the existence of a 125 Gev Higgs give any support to supersymmetry?
>
> Gordy Kane:
> Yes. first, for a long time it has been known that the lightest higgs boson of supersymmetry should be lighter than about 135 GeV (actually closer to 140 GeV but people make assumptions), so this is consistent. Then the supersymmetric string theories as i mentioned do predict the 125 number and it is a supersymmetric lightest higgs boson.

Update: The hype goes on, with a column today at Nature.

Comments

1. **glukanos**
   December 12, 2011

   Well, Kane did at least make a definitive statement (even if in a blog post, not a journal paper) about BSM particles, viz. gluinos will be produced at LHC and discovered in a few months. (The timescale will of course depend on the LHC operating schedule, a few months could easily become more than a year.) But, anyway, you have your definitive string theory/MSSM prediction of BSM. Consider it a Christmas present from Kane to you.

2. **Peter Woit**
   December 12, 2011

   glukanos,

   From his comments at the blog, the problem isn't not enough data, but the experiments not having done the right analyses (they were wasting their time looking for "unmotivated sugra"). He seems to think that they are now doing the right analyses, thus the "months" rather than "years" estimate. Presumably he's hoping for a Christmas present…

3. **Mark**
   December 12, 2011

   Since I've looked into the G2-MSSM scenario, it is probably worth mentioning that after moduli stabilization and SUSY breaking, the G2-MSSM scenario of Kane et al contains only *four* GUT-scale input parameters so it will be relatively easy to rule it out.

4. **Eric**
   December 12, 2011

   I think it's worth pointing out once again that the Standard Model with such a low-mass Higgs isn't really stable. This implies new physics to provide the stabilization, and supersymmetry is the best motivated option for this new physics. Furthermore, the Higgs mass has an upper bound in the MSSM of around 130 GeV. So, it is likely that supersymmetry will eventually be observed at the LHC. Then, models such as Kane's can then really be put to the test.

5. **Mark**
   December 12, 2011

Also, in contrast to the flux compactifications such as the KKLT scenario where one has no good reason to expect low-scale SUSY and has to fine-tune the tree-level flux superpotential to 15 orders of magnitude to get TeV scale SUSY, the non-perturbative M-theory vacua that result in the G2-MSSM scenario generate low SUSY breaking scale dynamically via the mechanism of dimensional transmutation (strong gauge dynamics).

6. **emile**
December 12, 2011

Eric, speaking of the SM being unstable, can you comment on this?
http://arxiv.org/pdf/1112.2150

7. **Anonyrat**
December 12, 2011

emile, remarkable if true!

8. **younghun park**
December 12, 2011

We must not trust the signal which amounts to the 2~3 sigma.
That signal may disappear in the next analyzing the remained data.

I don't understand why CERN will announce as it is the real signal.
Why?
I doubt if we trust the result of experiment done in CERN.

We must not believe any result until that proves true

9. **Urk**
December 12, 2011

I am no fan of this site, but I will say two things:

A) Kane knows less string theory than an unborn baby (less, because he knows many things that are not demonstrably true).

B) String theory is in no state to predict the Higgs mass. This is simply impossible, at this time, given whats known about the theory.

Don't take my word for it. If you're anywhere near a top 10 physics department, ask your local string theorist. Other issues (AdS/QCD? AdS/CMT? The controversial "Landscape"?) will bring nuanced responses, with uncertainty from good theorists. Not one will say string theory can now, in any reasonable sense of the word, "predict" the Higgs mass. They may say "random particular model X has N light Higgses!". This is very very different.

10. **Albert Z**
December 12, 2011

It is very disconcerting to see certain regulars at this blog acting as if the forthcoming LHC data unquestionably heralds the advent of the putative Standard Model Higgs boson. It seems close to proseletizing in the eyes of one who has a more skeptical view of the heuristic foundations of particle physics.

This wishful thinking: seeing only the positive "hints"; ignoring the various contradictions and uncertainties; downplaying the very shaky "predictability" issues, etc., seems uncomfortably close to the behavior of string/brane theorists who you rail against?

Troubling contradiction? Or am I too much of scientific skeptic? Or perhaps just too dim to receive the wisdom accessible to the fully initiated and sufficiently refined?

Albert Z

11. **pfogle@tiscali.co.uk**
December 13, 2011

from a layman… surely Kane is not 'predicting' M_h, but rather it sounds like using the phenomena to tune ST parameters, and show that MSSM is 'capable' of producing a credible explanation. It's the gluino mass that's the prediction here, and I'll await that result with bated breath!

12. **Urk**
December 13, 2011

I'll await the data with bated breath. Kane is making a strong argument for mandatory retirement with his statements.

13. **Z**
December 13, 2011

What a curious state of affairs we have in physics, where a "3 sigma" detection significance is taken by physicists to mean not a 99.9% confidence that the Higgs has been found, but something far lower. There are amusing statements on many blogs along the lines of "there's a 50% chance these 3-sigma results will hold up". Do people really not trust the analysis and fear systematics of the data from these large collaborations? Why doesn't 3-sigma mean 3-sigma?

I know HE astronomers that would be ecstatic about 3 sigma detections of pulsations or some such phenomena in their data.

14. **Phil**
December 13, 2011

In my experience, high energy astrophysicists are *frequently* ecstatic about their 3 sigma "discoveries", some of which indeed last long enough to appear in Nature 🙂 I'm more amazed the LHC folks understand their systematics as well as they do, and I'll forgive them a sigma one way or the other.

15. **Daniel**
December 13, 2011

Z: It doesnt mean "there is a 99.9% chance this is the Higgs" it means "if this was just random data the chance against this being nothing 99.9%".

Which sounds interesting until you think if you look at 1000 things you will have a 50% chance of getting a 3 sigma result. Im not sure how they take into account the look elsewhere effect with this analysis however.

There is no need to be impatient, if its real, its not going anywhere 🙂

16. **Bernhard**
December 13, 2011

String theory is really an amazing theory. It is capable of predicting the Higgs mass almost fours days after the result is publicly known, what a triumph.

Seriously, I wonder if Kane is being deliberately scientific dishonest with this Higgs story or just forgot what predictive and explanatory power of a theory is.

On the other hand if he keeps the some standards for the possible non-observation of gluinos in the next moths and announce he now thinks the whole string idea is likely wrong, this would make me satisfied.

17. **John Duffield**
December 13, 2011

I took careful note of Albert's comments, and I've been paying attention to recent developments. Sorry, but it doesn't feel as if it's just the BSM guys unleashing a flood of hype here.

18. **Breaking rumors**
December 13, 2011

The rumor is that after re-calibrations the CMS and ATLAS peaks do not coincide

19. **Bernhard**
December 13, 2011

Breaking rumors,

oh no! That would be so bad for string theory, I hope you're wrong.

20. **Albert Z**
December 13, 2011

The explanation is as follows.

In astrophysics, a 3 sigma result usually is vindicated by more data.

In particle physics, a 3 sigma event often-as-not "disappears".

See the difference?

Albert Z

21. **Mithras**
December 13, 2011

@younghun park:

I've actually had someone, on another site, tell me that "Well, yes. 3 sigma data has disappeared in further analysis, but never when there's been a theory there to predict it".

Being a layman at all this (I read physics for pleasure – you can back away slowly, I won't be offended), I didn't have a good citation to refute that at hand; the only thing I could think of (and haven't used yet) was solar neutrinos, where there was 3+ sigma of evidence that "we've got something wrong here", although that's likely not the way to word it.

Any thoughts?

22. **Quantumburrito**
December 13, 2011

I fear that the overzealous will go out of their way and swamp all media communication to convince an ignorant public that the Higgs now provides a new reason why string theory deserves all the support it can get. You may have to write a sequel to "Not Even Wrong".

23. **Cliff**
December 13, 2011

Whatever someone thinks of Kane's work, it is demonstrably not true that he adjusted his predictions in any significant way as a result of the links. Nice job muddying that up though.

Is it really so hard to identify the logic favoring a large tan-beta from his august presentation? Its because the gravitino mass naturally wants to be close to that of the lightest the moduli, which must be heavier than around 25 TeV due to the cosmological constraints. So the 127 GeV mass is favored because thats where it stabilizes for large tan-beta. So its a real prediction.

You didn't mention the reasons that G2 models were well-motivated in the first place, which is that they can naturally generate an ~electroweak mass scale while stabilizing moduli.

But I understand theorists aren't allowed to use any data or logic besides "string theory is true" according to the exchange we had over at cosmic variance a while ago.

24. **Peter Woit**
December 13, 2011

Cliff,

I don't see what you're complaining about in what I wrote. I wrote that I didn't understand exactly where the 127 came from. If you're telling me that the prediction of these theories is large tan(beta), and that as a result the prediction Kane is making for the Higgs mass is 127 GeV, that's fine, but it's not what he's saying in the paper. For the first calculation of the Higgs mass directly from string theory, solving the biggest problem of the subject, it would be a good idea if he explained more clearly what exactly he is doing.

As for the exchange at Cosmic Variance, I have no idea what you're talking about. I don't know who you are, or whether you're talking about an exchange over there weeks, months, or many years ago.

25. **Mark**
December 13, 2011

@Cliff, actually, you have it kind of backwards with regard to the gravitino mass, the constraint on the gravitino mass M_{3/2} less than O(10-100) TeV in these vacua does not come from cosmology but instead it comes from setting the tree-level vacuum energy to be small. Then, when they compute the moduli masses they find that the masses of the lightest moduli turn out to be close to the gravitino mass but less than twice the gravitino mass (the moduli cannot decay into the gravitinos by the kinematics). Then they note that this mass range is perfectly consistent with cosmology since the moduli are heavy enough to decay before BBN but the relic density must be non-thermal, etc, etc. What Kane is doing now is trying to extrapolate this result obtained for the non-perturbative G2 vacua to a "generic" string vacuum but I and many others don't think that his reasoning is justified because there are well known counterexamples where scalars can be much lighter than the gravitino. However, what I would definitely agree on with Kane is that moduli stabilization in a generic vacuum combined with cosmological constraints greatly disfavors low scale gauge mediation scenarios.

26. **Mark**
December 13, 2011

Well, I actually just reread what Kane said in the paper and on Motl's blog and the comments there and I guess I agree that in generic string vacua SUSY breaking is not sequestered, which translates into squarks and sleptons being as heavy as the gravitino. The known counterexample I had in mind was the KKLT scenario, where strong warping results in sequestering and light scalars and I admit that it is indeed kind of non-generic.

27. **chris**
December 14, 2011

Eric,

125 is right at the vacuum stability edge. if that turns out to be m_H, then there is work for a generation of lattice gauge theory to figure out whether the new physics scale in this scenario can be as high as m_planck.

but even if it might turn out to not be ok all the way up, the SM new physics scale will be well above 10^10GeV, maybe at about the GUT scale. so while there may be aesthetic reasons for low energy susy (fine tuning et al), there is no need. or, in other words, if m_H~125GeV and nothing else is found at the LHC, then any new collider below GUT scale energies will be a gamble: there is no strong reason to believe that it will find anything new.

28. **Eric**
December 14, 2011

Hi Chris,

Yes, I agree with you that a Higgs mass around 125 GeV is right on the borderline between being stable and unstable. Clearly, we'll need more data before the picture becomes completely clear.

29. **Mark**
December 14, 2011

First of all, I think that Kane is grossly exaggerating what he and his collaborators have demonstrated. String theory at this stage can not make a firm prediction about the Higgs mass and I think that he is doing a great disservice to the community by this type of hype. That said, there is definitely something in their work that's very intriguing and I'd like to highlight a few points below.

I think that it would be fair to say that string vacua that can be described in terms of N=1 D=4 supergravity with a low scale of SUSY breaking *generically* contain heavy sfermions and trilinear couplings but light gauginos (KKLT with warped sequestering is a non-generic counterexample). In addition, the masses of the lightest moduli are *generically* of the order the gravitino mass. These statementes would not be controversial among string theorists who know about moduli stabilization. On top of that, cosmological constraints imply that the moduli must be very heavy >O(10-100) TeV to preserve the success of the BBN. When you combine all of the above you may conclude that in such vacua even with low scale SUSY the lightest sfermions must be very heavy. What that means for the lightest Higgs in the context of the MSSM is that its mass will receive large radiative corrections mainly due to the heavy stop and will get pushed into the range above 120 GeV but below 130 GeV. Now, the exact value does, of course, depend on tan beta. With regard to tan beta being O(10) I'd recommend reading this paper: http://arxiv.org/abs/1105.3765 . Basically, tan beta ~ O(10) is needed to reduce the so-called little hierarchy problem when the scalars and trilinears are heavy, as can be seen from eq. 6 in that paper. So, the value of 127 GeV seems rather natural is such a scenario. Kane's optimism about the gluino presumably stems from the same considerations, namely, in eq. 2, there is a quantity denoted as R(t), that depends on M3 (related to the gluino mass) as you can see in the expression in the paragraph below eq. 2. So, the relatively light gluino is needed if one wants to keep the little hierarchy problem under control.
So I think that this is all definitely very interesting and in my mind compelling.

As for the G2-MSSM, this is definitely the simplest model of moduli stabilization out there – a strongly coupled hidden sector (SQCD with a single family of vector like matter) dynamically generates a non-perturbative potential that stabilizes all the moduli and generates a hierarchically small scale (there are no fluxes, no warping, no antibranes). And these guys did it for the most general Kahler potential compatible with G2 holonomy with an arbitrary number of moduli, found closed expressions for the moduli and derived soft terms in the MSSM largangian!

30. **Allan Rosenberg**
December 16, 2011

Peter,

Yes, the "prediction" business appears disingenuous (and your post is one of the best I've read, which is saying a lot). But, in all fairness to Kane, there's nothing wrong with a paper that identifies a subset of string theoretical models that accords with an experimental result or publishing it first. Just think of the vast swath of the multiverse and the numerous false vacua we can rule ourselves out of if we can identify a Higgs boson.

Wouldn't you be impressed if string theorists were able to present at least one vacuum that resolves assymptotically to general relativity and the standard model? I don't claim that string "theory" will get there, but isn't constraining the "theory" using experimental results the best way out of the "string theory proves everything" hysteria?

31. **Bernhard**
December 16, 2011

Kane´s campaign still at full speed:

http://www.nature.com/news/particle-physics-is-at-a-turning-point-1.9675

32. **Peter Woit**
December 16, 2011

Thanks Bernhard,

At least someone seems to have told him that there's no way this is 5 sigma…

I like how he claims that he published his "significantly more precise prediction" "just days before the CERN data were reported", without mentioning that it was four days after the CERN numbers were accurately reported on this blog and others.

Allan,

I just don't see that the new Higgs result (if confirmed) does anything much to constrain string theory vacua. You still can get almost anything you want. After claiming that the 125 GeV Higgs shows his string theory arguments are right, he does go on to claim that this implies gluinos showing up in the data any day now, definitely by summer. When there are no gluinos next summer though, he's just going to move on to other "string theory inspired" models. He has been engaging in this kind of nonsense for more than 25 years (see e.g his "String theory is testable, even supertestable" in Physics Today, back in 1997), with nobody calling him on it, no reason for him to believe they'll start now.

33. **Allan Rosenberg**
December 16, 2011

Ah, I didn't put Kane's name together with that article. I see your point. Perhaps the best way to do string theory would be to publish papers in entangled pairs–for every prediction a lab makes, it should publish another paper predicting the exact opposite. That way they can accumulate a string (sorry) of predictions well in advance of the rumors.

34. **Mark**
December 16, 2011

So, I was looking at slide 24 (gluino production cross section vs gluino mass) in Gordy's stringpheno 2011 talk:
http://conferencing.uwex.edu/conferences/stringpheno2011/documents/kane.pdf
and I'm not sure if the LHC will actually collect enough data by the summer to really test for gluinos. Let's say they collect 10fb^-1. From the plot, if the gluino mass is at, say 900 GeV, the production Xsection is 10 fb, which gives 100 events. However, taking into account the detector efficiency (at most few % according to the slide) is it realistic to expect some signal?

Today's Higgs Results

December 13, 2011
Categories: Experimental HEP News

The discussion after the talks is going on at CERN now, and the results that were presented agree well with what was posted here over the past week or so. This looks a lot like a Higgs near 125 GeV. Hiccups in the streaming make it difficult to impossible to follow the discussion. Caught Heuer at the end urging caution: "intriguing hints". This looks to me like a lot more than "intriguing hints": it's about what you would expect if a Higgs was there at 125 GeV, highly unlikely to see if there is no Higgs there.

The ATLAS results are here

Higgs to gamma gamma: 2.8 sigma bump at 126 GeV

Higgs to ZZ to 4l: 2.1 sigma (3 events near 125 GeV)

Higgs to WW to l nu l nu: Data not fully analyzed, 1.4 sigma excess at 126 GeV

Combination: 3.6 sigma excess at 126 GeV.

The CMS results are here

Higgs to gamma gamma: 2.34 sigma bump at 123.5 GeV.

Higgs to ZZ to 4l: 2 events seen near 126 GeV (expect .5 background)

Combination: 2.4 sigma excess at 124 GeV.

I see Tommaso Dorigo is posting a detailed analysis here under the title "Firm Evidence of a Higgs Boson at Last!". He's likely to be the best source around for a discussion of the details.

Update: Go to the blog of Philip Gibbs now to take a look at his (highly unofficial) plots of the combined ATLAS+CMS+Tevatron results on the Higgs. You might also want to check out Matt Strassler's blog entry about this, which wins the award for being downbeat ("Inconclusive, As Expected"). For some reason he is incensed by Tommaso Dorigo's "Firm Evidence".

Comments

1. **anon**
   December 13, 2011

   Though still too early to say, congratulations to Prof. Peter Higgs!

2. **Albert Z**
   December 13, 2011

   I would not be surprised in the least if the wheels fell off this latest Greatest Bump Hope within weeks.

   Then again, I am much less skeptical of a Higgs boson than the ad hoc "WIMPs", since the standard model, while quite heuristic, at least has considerable empirical support.

   Albert Z

3. **Foster Boondoggle**
   December 13, 2011

   What's the SM width of a 125 GeV higgs?

4. **Douglas Natelson**
   December 13, 2011

   I find your response interesting, Peter. Matt Strassler seems considerably more cautious, based in part on look-elsewhere concerns and whether the CMS number (123-ish) is compatible w/ the Atlas number (126-ish). As someone with no dog in this hunt, it'll be fun to see how this plays out, and particularly the media reaction in the short term.

5. **Peter Woit**
   December 13, 2011

   Foster Boondoggle,

   See this comment

   http://www.math.columbia.edu/~woit/wordpress/?p=4212&cpage=1#comment-101006

   The SM width is very narrow, so the observed width is due to the resolution of the detectors. Commenter thinks 3-4 GeV. The compatibility of the two gamma-gamma signals is a very interesting issue I'd love to see a detailed analysis of, much more relevant than the "look-elsewhere" effect you need to worry about if you only had data from one experiment. My impression is that, at this level of statistics, taken together they're reasonably compatible with a 125 GeV SM Higgs (and seriously incompatible with nothing being there at all…)

   Doug,

   Just as you can accurately describe the same glass as "half-full" or "half-empty", you can accurately describe this as "inconclusive" or "firm evidence". No one is claiming that this yet reaches the conventional 5 sigma level for claiming a discovery. An accurate description of the situation would be that the data shown is, given the statistics, consistent with a 125 GeV SM Higgs. It is fairly seriously inconsistent with the no Higgs hypothesis. More expertise in statistics than I have would be required to properly quantify the relative probability of these two hypotheses, perhaps that's something that will get done publicly soon.

6. **Trulo**
December 13, 2011

> the standard model, while quite heuristic, at least has considerable empirical support.

Albert, in this context "considerable empirical support" is the mother of all understatements.

7. **Roger**
December 13, 2011

I assume that you are preparing to write a rebuttal when Kane publishes an article about how this result confirms string theory.

8. **Peter Woit**
December 13, 2011

Roger,

Already done (on both sides), see the previous posting:

http://www.math.columbia.edu/~woit/wordpress/?p=4262

9. **VP**
December 13, 2011

Anyone have any comments on the fact that the ATLAS bump is 126-ish and the
CMS exclusion lower limit at 127 GeV?

10. **Peter Woit**
December 13, 2011

VP,

Other than that they're consistent?

What I'd really be interested in seeing is some attempt to sensibly combine the two gamma-gamma datasets. Would the result have a bump statistically consistent in width and size with the SM Higgs? As far as I know the answer is yes, but I'd love to know for sure.

11. **anon**
December 13, 2011

What's the implication for possible funding of ILC?

12. **Richard**
December 13, 2011

The significance of this announcement is that it is insignificant.
The press conference was almost certainly called to defend against funding cuts that are likely in a time of austerity and Euro-stress. The HEP community has gotten quite sophisticated at PR. Big physics needs big money. With the French under pressure to cut spending, the LHC folks need some smoke and mirrors to keep the Euros flowing.

Call me when you get to five sigma.

13. **Low Math, Meekly Interacting**
December 13, 2011

Assuming this is the prelude to a firm discovery, and the mass is just about what the result indicates, anyone care to comment on the potential for probing new physics at the LHC? I've seen some rather pessimistic assessments, i.e. this might be the harbinger of a desert all the way up to the GUT scale. A reasonable conclusion?

14. **Peter Woit**
December 13, 2011

anon, Low Math, Meekly Interacting

Knowing the Higgs mass means one can calculate exactly how well it could be studied by an ILC with different design parameters. If the LHC finds the Higgs is really there and behaves just like the SM says, and finds no other new physics, the case for not only the ILC, but any other expensive energy-frontier collider is going to be hard to make.

In that scenario, there's a real danger that what we saw today was the crowning achievement of this kind of experimentation, with prospects for the future rather dismal. For that reason, I and many others would have been a lot more excited if what we heard was that a SM Higgs was excluded or nearly excluded over the low mass region.

The LHC really needs to find SOMETHING that disagrees with the SM, or there will be trouble ahead…

15. **H125**
December 13, 2011

I feel the Irish Times newspaper gave us the most balanced headline for this 'discovery'

'God particle' may or may not exist.

That headline seems to summarise the situation for me.

Irish Times

16. **Michael Schmitt**
December 13, 2011

Hi Peter,

it is a bit too early to voice disappointment that this is “only” a SM-like Higgs boson. After all, we do not have discovery of anything yet. Secondly, we do not know whether it is a Higgs boson – does it have spin zero, can we show it couples according to mass by measuring some relative branching ratios, and is the production cross section the SM one? I agree whole heartedly that we need to break the SM (I have been hoping to do that for nearly 20 years now!) but perhaps we could wait and see what we have here – if anything at all. 😉

Michael

17. **Anon**
December 13, 2011

@H125, while it may be balanced, I find the terminology “god particle” simply detestable and misleading to the public as to what Physics is all about. As Laplace famously said: “Je n’avais pas besoin de cette hypothese-la.”

18. **Allan**
December 14, 2011

The date element of the link appears to have changed. The new, improved permalink is now:
[Higgs Boson Live Blog: Analysis of the CERN announcement]
Also (for now) is available from the main page.

A certain kind of statistician might ask “what is the largest bump reversal one would expect in a search of this nature?” The false alarm expectation might have been 3 sigmas, though the variance in this kind of meta statistic is often ludicrously high. In any case, I wasn’t all that impressed by the argument on one of the blogs that we’ve already seen an anomaly nearly as big. That could be normal on the path to discovery.

19. **Peter Woit**
December 14, 2011

Allan,

Thanks, fixed the link.

20. **ESB**
December 14, 2011

“The LHC really needs to find SOMETHING that disagrees with the SM, or there will be trouble ahead…”

Excuse me Peter, but if the LHC simply confirms the SM, what phenomena through which experiments, in your opinion, should the next generation of particle colliders study ?

This is a question which any proponent of higher energy colliders beyond the LHC can be expected to address.

21. **Samuel Prime**
December 14, 2011

I don’t have the time to read those papers to get an answer to this, but do I understand that the evidence so far obtained points to the SM Higgs and/or to a muti-Higgs scenario (where one can have as many as 5 Higgs particles)? (Or perhaps I’m uninformed about the number of Higgs in the Standard Model.)

Secondly, is the evidence supportive or consistent with non-SM Higgs?

22. **David Summers**
December 14, 2011

Michael,

Re a Higgs being spin zero.

if we see a resonance in the photon-photon channel, then we have the indication that some object is decaying to two photons.

Now there is a theorem (is it Yangs theorem – I forget) that only spin 2 or spin 0 particles can decay to two photons – its impossible for spin 1 to do this.

So if a resonance is decaying into two photons, is probably spin 0 (e.g. a higgs) – or something totally unknown (spin 2).

David.

23. **Bernhard**
December 14, 2011

Does anyone know if the seminar was recorded and posted somewhere? The transmission was so crappy I gave up in the middle and would be nice to see it wihout the hiccups.

24. **Anon**
December 14, 2011

Bernhard, isn’t it ironic? It’s the 21st century, and though we still don’t have flying cars, we are quite possibly on the verge of finding the Anderson-Higgs. Yet we cannot manage to broadcast a intelligible public announcement of this magnitude, which 20 years ago might have been done perfectly well by TV signal.

25. **tulpoeid**
December 14, 2011

The phrase “inconclusive, as expected” is not “downbeat”; it’s a very objective description of the results and of what >95% of cern experimentalists think right now (95 is a subjective but rather well-informed number).
Honestly, if lhc shut down *today*, would you be completely honest with yourself in believing that higgs is there? What’s with the hurry people? Find something else to play with for a few more months and then everything will be fine.

26. **Peter Woit**
December 14, 2011

tulpoeid,

I think “inconclusive, as expected” would have been a good headline for this past summer’s Higgs results. The latest results deserve something different and better.

27. **Peter Woit**
December 14, 2011

Samuel Prime,

The evidence presented is still not sufficient to claim discovery of a SM Higgs, although it is consistent with such a thing. It’s also consistent with all sorts of other possible Higgs sectors, especially if they’re not that different than a 125 GeV SM Higgs.

I’d summarize by saying that until now the experiments were just seeing random haze, but the latest results show something emerging from the haze, in exactly the way you’d expect if there were a 125 GeV SM Higgs. However, this is still a ways from being completely sure there’s something there, a long ways from seeing exactly what it is and whether it matches closely with what the SM says it should look like.

28. **VP**
December 14, 2011

If you look at Philip Gibbs’ “unofficial” combined exclusion plots for both November and December, you see that the 95% CL line (black line) is consistently at the upper edge of the two standard deviation band for the mass range of 115-170 or so GeV. To me it says that there is something at low masses (backgrounds?) we don’t understand. Yes, I know, different channels have different backgrounds but still, there is something funny. Wouldn’t this significantly dilute the statistical significance of any bump/excess? Wouldn’t that explain a higher likelihood of excess events in several channels?
http://blog.vixra.org/2011/12/13/the-higgs-boson-live-from-cern

29. **mp**
December 14, 2011

I am confused as to why everyone is hoping for physics beyond the SM. Why isn’t it good enough for the LHC to confirm the SM?

Is this purely a funding argument?
A, more fun, argument?

30. **Peter Woit**
December 14, 2011

VP,

I don’t think one can take seriously 1-2 sigma size deviations from expectations. Having systematic problems of this size in the understanding of backgrounds wouldn’t be unusual at all. That’s why you don’t start talking about “evidence” until you get to 3 sigma.

mp,

There’s a list (fairly short) of ways in which the SM is unsatisfactory. To my mind the most important one is that it’s incomplete: there’s a list of questions you would expect a fundamental theory to answer which it doesn’t (e.g. what determines the different values of the masses and mixing angles of elementary particles?). People who chose to work in HEP are rarely doing it for the money, more likely because they want to know the answer to such questions. Having an experimental result inconsistent with the SM would help a lot to give a hint as to where to look for an improvement of the SM. Without this, you can consistently take the attitude that the SM, incomplete though it may be, is the end of the story. The multiverse is often used to try and provide an intellectual underpinning for this, but, looking at the history of our increasing understanding of fundamental physics, I don’t see a good reason to believe that this pattern of progress has to stop here.

31. **Damasceno**
December 14, 2011

From a live chat in Nature.com happening now.

4:22 Gordon Kane: Recently we have published string theory calculations that imply the higgs boson mass is 125 GeV so if it is there are strong implications for connecting string theory to the real world, and for what the higgs discovery implies. we did that before the data.

Any surprise in the comment?

32. **Peter Woit**
December 14, 2011

Damasceno,

The Kane hype is just completely outrageous. I wrote about the source of it in the previous posting

http://www.math.columbia.edu/~woit/wordpress/?p=4262

and just added his comments from the Nature chat as an update.

33. **Peter Woit**
December 14, 2011

By the way, Science magazine tomorrow is running a similar live chat, this one with Rob Roser and Kane, see http://news.sciencemag.org/sciencenow/2011/12/live-chat-the-higgs-boson-at-las.html?ref=hp

34. **mp**
December 14, 2011

Well obvious I didn't mean "let's stop doing science because we confirmed the SM".

There are all kinds of unknowns in the SM that need to be figured out. In fact I believe there are decades worth of work ahead of us and strengthening our understanding of the SM and filling in the gaps sounds like pretty serious work.

I get that it would be more rewarding to find the next revolution for some physicists however not at all costs (I am talking to you string, multiverse, SUSY etc). I believe there should be a healthy balance between speculative and experimental science.

35. **jdm**
December 14, 2011

Peter,

First, thanks for making your reactions available. They're quite helpful in clarifying the implications for those of us who aren't in the loop.

Now, a nitpick: I don't believe mp was implying that high energy physicists are "in it for the money," but rather that the large-scale governmental/inter-governmental support that keeps very-high-energy physics chugging along would be seriously imperiled by a result that has long been touted as the missing piece in an almost complete theory (which appears to be the essence of your reply to anon, Low Math, and Meekly Interacting). This would seem to me to be a powerful and legitimate motivation for wanting to see the SM fail, and one not at all incompatible with equally legitimate intellectual factors you listed.

Presuming (however prematurely) that an SM Higgs is what CMS and ATLAS are seeing, that funding question would seem to me to loom large over physicists reactions to the results. I would even argue that the proximity of such funding questions probably has a chilling effect on the reception of "standard" results, which might otherwise generate the same kind of excitement the top quark did, despite some dissatisfaction with the SM as it stands.

-jdm

36. **Samuel Prime**
December 14, 2011

Thanks for your response, Peter.

37. **Peter Woit**
December 14, 2011

jdm,

Actually my impression is that things are the other way around. The people who run CERN (and have to be very concerned about their funding if they want to stay in business) have been worrying about not finding a Higgs. The worry is that the public and government officials deciding on funding would think: "these guys have been saying for years that they're spending all this money to find the Higgs, now it turns out they can't find it. Why should we give them any more money?" Once there's 5 sigma significance for a Higgs, I'm sure CERN will be appropriately and justifiably crowing about the discovery. Partly because they want the money sources to think of them as a success worthy of future support, but also because, well, they are a success and deserve to be proud such an achievement.

38. **jdm**
December 14, 2011

Peter,

Interesting. Thanks for that insight. Within the CERN context that makes a lot of sense. I'd still be surprised though if others, particularly in the United States, didn't look upon a no strings attached Standard Model result as reason to worry over the prospect of securing future funding, especially in the longer term. At any rate, it will be interesting to watch those dynamics as the play out.

-jdm

39. **Z**
December 14, 2011

There are still plenty of mysteries in HEP, like the anomalous magnetic moment of the muon, neutrino oscillations, dark matter, QCD in general…
The LHC will probably be funded for the next 15 years, if not longer. The ILC may be superseded by a muon collider design for the future, since a muon collider may be cheaper with existing infrastructure.

If nothing mysterious is found with the decades-long LHC run in the GeV/TeV sector, HE astrophysics may benefit since Chrenkov telescopes and space telescopes routinely see remnants of particles with energies several orders of magnitude higher than the LHC produces – and thus, they would be the only hope for seeing something beyond the SM. An grand-observatory class X-ray telescope studying neutron stars could also highly constraint QCD equations of state.

40. **VP**
December 14, 2011

Peter,
"I don't think one can take seriously 1-2 sigma size deviations….."

Perhaps I didn't make myself clear enough. My point is that if I consistently measure something at 2 standard deviations above the "no Higgs" hypothesis , then an one SD fluctuation would appear as a 3 SD effect. As appears in Gibbs' plots the measurements of both experiments for the mass range ~115-170 GeV are consistently 2 or so SD above the "no Higgs" hypothesis.

41. **Peter Woit**
December 14, 2011

VP,

In my reading of the plot, I don't see "consistently 2 sigma" excess, maybe 1-1.5 sigma. In any case, it looks to me like whatever is locally happening around 125 GeV is 1-2 sigma above other fluctuations and systematic effects. So, 68-95% chance it's real. I like Jester's rough guess of 80% (which takes into account the sort of thing this is: looking for something we have reason to expect to be there, not something that shouldn't be there). One thing that definitely is true is that this is not a genuine 3 sigma effect, in the sense of a 99.7% sure-thing.

42. **Anonyrat**
December 15, 2011

Brian Greene has an op-ed in the New York Times about the Higgs.
http://www.nytimes.com/2011/12/15/opinion/waiting-for-the-higgs-particle.html

43. **tulpoeid**
December 15, 2011

' ' I think "inconclusive, as expected" would have been a good headline for this past summer's Higgs results. The latest results deserve something different and better. ' '

Why?

They are (i) not perfectly understood yet, and they are (ii) consistent with both assumptions. Moreover, this was expected and well calclulated given the current integrated luminosity.
Also, have you said the same about all previous 3-sigma hep results? Would you mind writing a post with the history of all 3-sigma results past?
God, I'm really glad cern people are proving to be better than the crowd commenting on blogs these days and they are staying unaffected for the biggest part (the management might not be the best example of what I'm talking about at the moment). I think you are exhibiting a very uncharacteristic case of string-theorist-like way of thinking during this last week.

44. **Paolo Valtancoli**
December 15, 2011

In my opinion the standard model is valid up the grand unification scale! In any case since the four colour theorem proved to be useful to derive the right Higgs mass, one should extract all its consequences for the MSSM model…

45. **Bernhard**
December 15, 2011

tulpoeid,

the CERN people, here and include both analysis leaders + teams are very excited about this. See http://www.nature.com/news/live-qa-the-hunt-for-the-higgs-1.9642

Murray says: " We have no proof, but I polled 10 tof the leaders of the ATLAS search and my wife last night if they thought we had found it and they ALL said yes. But that is not proof, it could be over-excitement."

Got the picture? Nobody is claiming a discovery but the feeling of optimism among the experimental folks that this result will hold up is very high. They might be wrong and acknowledge that, but "inconclusive as expected" does not even begin to draw the correct picture of what people REALLY THINK about this result. That Strassler wants to be cautious that's fine, but again what a downbeat title.

46. **vmarko**
December 15, 2011

I remember seeing the CMS result in the H->4l channel to have observed 13 events, as opposed to the expected 9.5 at that peak. Is there any clear data published about the total **count** of excess events observed by CMS and ATLAS?

I mean, the luminosity of 5 inverse fb basically means they have produced 10^{14} or so collisions (essentially a very large number). Out of all that, they have filtered out only a **dozen** of events, and found 13 instead of expected 9 (in that channel). I guess that the total number of events (all channels summed) does not go above 100 or so. How much can you trust the statistics of that?

I could flip a coin 20 times, and get 13 tails plus 7 heads, instead of 10 plus 10. Does that mean that I am seeing some real signal about the coin fairness?

I believe that people could have a better intuition about how much to trust that 3.5 sigma result, if they knew the **actual number of observed events**, rather than looking at a fancy graph with a "peak that goes above the green and yellow strips". Is this data available anywhere on the net in a clear easy-to-read form?

Best, 🙂
Marko

47. **Peter Woit**
December 15, 2011

Marko,

You're just talking about 1 channel and 1 experiment. The interesting thing here is that there are 3 channels/experiment, no one giving much of a signal on its own, but they are all showing something. In the ZZ -> 4l channel, what's important is that you're seeing several events close to 125 GeV, with expected background at that energy very low.

48. **anonyrat**
December 15, 2011

Sorry, looks like comments on the old thread are closed, so posting it here. Part II of Norman Dombey's series on Abdus Salam is on arxiv.org.
http://arxiv.org/abs/1112.2266
"Abdus Salam: A Reappraisal. Part II Salam's Part in the Pakistani Nuclear Weapon Programme"

Abstract: Salam's biographies claim that he was opposed to Pakistan's nuclear weapon programme. This is somewhat strange given that he was the senior Science Advisor to the Pakistan government for at least some of the period between 1972 when the programme was initiated and 1998 when a successful nuclear weapon test was carried out. I look at the evidence for his participation in the programme.

49. **Peter Woit**
December 15, 2011

I realized I didn't respond to the question about numbers of events. Look at the CMS and ATLAS papers for each channel. For ZZ -> 4l they plot number of events vs energy, with the number of events in each bin 0, 1, or 2, expecting to see o in each bin. For gamma-gamma, they also give a plot of number of events vs energy, here the numbers in each bin are large (several 100/ GeV) and what you are looking for is a bump in the distribution.

50. **Bernhard**
December 16, 2011

Outrageous hype from M. Kaku at the Wall Street Journal:

"So far, one of the leading candidates to explain dark matter is string theory, which claims that all the subatomic particles of the Standard Model are just vibrations of a tiny string, or rubber band. "

http://online.wsj.com/article/SB10001424052970204026804577098382660789136.html

Apparently, Kaku already made a complete symbiosis of SUSY with string theory.

51. **Anand**
December 16, 2011

Looks like they will find the "Higgs.

Let the politics Nobel begin – by all three groups. First opportunity will be this weekend for Englert to work Nobel Committee member Lars Brink. Past performances were great on this topic.

http://cgc.physics.miami.edu/Miami2011.html

52. **Z**
December 16, 2011

If the Higgs is going to be confirmed, this is also good opportunity for the Nobel Foundation to change the archaic rules limiting the prize to three people before next year's prize. Even on the theory side, more than three people (including Peter Higgs) deserve the prize.

Perhaps, if selecting between an arbitrary number of people is too distasteful, awkward, or against the constitution/charter, the committee could also simply give the prize to the "CMS Collaboration" and the "Atlas Collaboration", letting those groups decide on how to split the prize money inside them. If corporations being people is good enough for the Supreme Court of the US, surely a scientific collaboration is a good enough person?

53. **simona**
December 16, 2011

Figures 1 and 2 in the ATLAS note show even a greater excess at ~102 GeV; however this mass range is left out in the statistical analysis in Figures 7 and 8 where the range begins at 110GeV. Any ideas on that?

54. **Peter Woit**
December 16, 2011

simona,

I don't know, but there likely is some innocuous reason, known to the ATLAS people. It's also possible they don't know, but figuring it out has been a relatively low priority. Whatever it is, LEP has ruled out the possibility that it's the Higgs, so ignoring it in these notes makes sense. The results presented this week in any case aren't the final analysis of this data, but whatever they could get done by the deadline of being ready to present on this date.

55. **Chris Austin**
December 17, 2011

LEP excluded the Standard Model Higgs below 114 GeV, but apparently more complicated Higgs sectors can still have some Higgs bosons with mass below 114 GeV, and be consistent with LEP. See for example [0811.3537](0811.3537).

56. **Chris Austin**
December 17, 2011

Jester wrote a great post on how a lighter Higgs could have escaped discovery at LEP.

The fact that ATLAS don't discuss the narrow excess at about 101 GeV in Figs 1, 2, and 5 (top right) of their Dec 11 note might simply be because the title is, "Search for the *Standard Model* Higgs boson". Although if you allow for the slightly shorter error bars at around 126 GeV, and that the excess there is in 2 neighbouring data points, the excess at about 126 GeV is perhaps a bit bigger than that at about 101 GeV.

57. **pah**
December 17, 2011

Chris Austin,

I see only a single-bin fluctuation, totally insignificant. It's debatable if there's a significant excess at 125 GeV, but what you're seeing at 101 GeV is nothing.

58. **Chris Austin**
December 18, 2011

In my second comment I should have said "more significant" rather than "bigger". I agree that the excess at 101 GeV is not significant.

59. **Ric - ½ g tr(Ric) = 8πT**
December 30, 2011

I think, after this is settled a discovery, we should focus on why the mass is so close to the half of the VEV (246 GeV). My thoughts is that the coupling constant is as that, yet anomalies and RG corrections drive it up to ~125 GeV.

Physics on the Fringe: Smoke Rings, Circlons and Alternative Theories of Everything

December 16, 2011
Categories: Book Reviews

There's a new very thought-provoking book out from Margaret Wertheim, entitled Physics on the Fringe: Smoke Rings, Circlons and Alternative Theories of Everything. Much of the book is the beautifully told story of "outsider" physicist Jim Carter, who has spent much of his life developing an alternative fundamental physics theory based on objects he calls "circlons".

I have to confess that, while respecting the impetus that leads people to develop such theories, I have essentially zero sympathy for this kind of thing as science. As Wertheim explains

> In Jim's theory of the universe, *everything* is mechanical; like INCOBO , the world he imagines is made up of simple mechanically interlocking parts. As with his engine, none of the parts are complicated and you don't need much mathematics to understand how it works…
>
> One way to think about what Jim Carter is doing is that he insists on a universe he can comprehend. As with the old Chryslers and Cadillacs that grace his front yard, Jim demands a cosmos he can figure out for himself.

One way in which I'm very different than Jim Carter is that I've never been one for insisting on ideas that I can figure out for myself. I'm grateful for and fascinated by the fact that there's a huge amount of knowledge about the universe out there discovered over centuries by a collaboration of a long list of brilliant people, and many places to try and learn about it. This kind of learning is a joy, and not being willing to engage with and try and appreciate the accumulated wisdom of the human race to me makes no sense. When I got to the point of learning about quantum theory, it became clear to me that this was something of great power and beauty, carrying the lesson that at a fundamental level the world is very different than the mechanical picture we derive from our human-scale intuitions. At the same time, fundamental physics and mathematics are deeply intertwined, with the deepest ideas in mathematics showing up when one tries to understand the deepest questions about physics.

The basic problem with efforts like Carter's is that the tools and ideas he is using just aren't powerful enough. There's no way they can be used to understand the universe (and test one's understanding by calculating from theory and comparing to experiment) with anything like the power of the Standard Model or general relativity. Anyone who wants to do better than the Standard Model or GR has to come up with equally powerful ideas. It seems unlikely that this can be done by any means other than understanding well the ideas behind these theories, as well as their weaknesses, as a starting point to look for something new.

Wertheim discusses a range of other failed and "outsider" ideas about physics. She sees an analog of Carter's vision in the the 19th century work of prominent scientists like Tait and Thomson, who studied smoke rings as a phenomenon that might model physics at the atomic scale. More recently, Steven Wolfram's *A New Kind of Science* featured claims that conventional fundamental physics could be replaced with ideas about cellular automata. Wolfram is a MacArthur winner, and Ph.D. in particle theory, so it's not by credentials alone that one can identify "outsiders" barking up an unpromising tree.

Remarkably, Wertheim explains that her motivation for writing the book came from attending a 2003 conference on string cosmology at the Santa Barbara KITP. This was at the beginning of the "string theory anthropic multiverse" madness which has afflicted the field since that time. In 1998 she had attended with Carter an annual meeting of the NPA (National Philosophy Alliance), a group of "outsider" physicists, and she was shocked to find the KITP hosting something that seemed not obviously different:

> That string cosmology conference I attended was by far the most surreal physics event I have been to, more bizarre than any NPA event for the very reason that this was not a fringe affair but a star-studded proceeding involving some of the most famous names in science…
>
> After two days, I couldn't decide if the atmosphere was more like a children's birthday party or the Mad Hatter's tea party – in either case, everyone was high…
>
> … the attitude among the string cosmologists seemed to be that anything that wasn't logically disallowed *must be out there somewhere*. Even things that weren't allowed couldn't be ruled out, because you never knew when the laws of nature might be bent or overruled. This wasn't student fantasizing in some late night beer-fueled frenzy, it was the leaders of theoretical physics speaking at one of the most prestigious university campuses in the world.

Besides the difference in credentials, there is an important difference between most recent mainstream theoretical work, even when in multiverse madness mode, and that of the "outsiders" of the NPA. Mainstream theorists recognize that they need to be compatible with the SM and GR. What they are doing is working within a conjectural extension (call it "M-theory") of the SM and GR, claiming to preserve the successes of those theories. In principle, working this way should provide a very tight constraint on what you can do. The problem though is that one doesn't know exactly what "M-theory" is. All one has is a list of conjectured characteristics, and these seem to be weak enough to allow a vast array of "vacua", of such complexity as to effectively remove much in the way of constraints on what you can observe at low energy. Since the conference Wertheim attended in 2003, there have been huge efforts made to extract some non-trivial implications out of this "landscape" scenario, with no success. In practice things have in many cases degenerated to the level of "outsider" physics: anything goes, and one ends up with a group of people making ambitious claims about their wonderful theory, with no conceivable way for such claims to be tested or backed up.

All in all, I think this is an important book, one which raises in an interesting way fundamental issues about how people think about and conduct research into fundamental theoretical physics. We're at an unusual point in the history of the subject, one where the foundations of how this kind of science has traditionally been done are being questioned. Wertheim's contribution to this questioning is worth paying attention to.

For some other recent reviews, see John Horgan here, and Michael Shermer here.

Comments

1. **J. Caleb Wherry**
   December 16, 2011

   When you say "…I have essentially zero sympathy for this kind of thing as science" are you talking specifically about Carter's work or do you mean this more generally? For instance, do you have the same feelings towards Penrose's Twister Theory? I would not consider Penrose (and others) "outsiders" as Carter is but am just curious if your statement encompassed people (and theories) such as Penrose. Thanks!

2. **Peter Woit**
   December 16, 2011

   J. Caleb Wherry,

   As I try and explain in the next paragraph, my lack of sympathy is for the idea of new foundations of physics built out of simple mechanical ideas, requiring little mathematics or anything beyond everyday intuition to comprehend. Penrose's twistors are very different.

3. **Anonymous**
December 16, 2011

I used to be very much in favor of alternative theories to physics. I still am, but after studying physics I only endorse the efforts of folks that are at least trying to maintain some consistency with what we already know. But it really gets me when people try the angle of trying to take the math out of physics. It reminds me of Sarah Palin trying to say we need a regular person in the white house and not a politician. I think it would be great if everyone could understand all the intricate details of physics, but the lazy approach or the idea that we can "dumb down" physics is completely absurd.

I have people tell me that sacred geometry leads to a theory of everything with almost no math. But these sorts of things are far from rigorous. So again, I understand science is driven by many alternate approaches, but like you said, there are some avenues that are just silly to go down.

4. **anon**
December 17, 2011

The crackpots who disregard mathematics are easy to identify. But on the other hand, there are crackpots who know much more sophisticated math than most physicists. This category even includes some professional mathematicians who stray into physics. Their problem is that they think whatever beautiful math must lead to promising theory in fundamental physics, with total ignorance of phenomenology and experiments.

5. **Bee**
December 17, 2011

I think the issue has two causes. First, there is an ever widening gap between what's going on in modern theoretical physics and what the average person has learned. Second, the average person has no clue how large that gap really is. So there is the occasional know-it-all who believes he has solved all problems without even understanding what the problems are to begin with. I believe this is supported by an abundance of terribly dumbed-down popular science books that leave the reader with the justified feeling like they can do better, without providing a guide how to, or without at least saying it's dumbed-down.

I have no clue what that particular string cosmology conference is she is talking about, but I suspect her impression is partly fed by her own lack of knowledge. I am not very fond of all the bubble-stuff, but some aspects of string cosmology are actually quite interesting, esp when it comes to CMB polarization. I am hoping we'll be able to sort out some models in the next years, and that will be a good thing.

6. **Paulibus**
December 17, 2011

Peter : you're quite right; Margaret Wertheim's book is thought provoking, especially for those frustrated by the sterility of lots of today's theoretical physics. Your first quote is particularly apt:

…what Jim Carter (her special crackpot) is doing is (insisting) on a universe he can comprehend. As with the old Chryslers and Cadillacs that grace his front yard, Jim demands a cosmos he can figure out for himself.

That's just what string theorists seem to have been (collectively) doing for the last forty years or so. They accepted Einstein's optimistic aphorism about the surprising comprehensibility (for us) of the universe. It's been brave of them, but sadly they've not had the restraining benefit of making confirmed predictions to keep them on the rails.

Perhaps, though, they've taught us (as Margaret Wertheim seems to be suggesting) that such optimism may just be anthro'centric hubris — like Einstein's happy thought, so well justified in that case by his geometrical description of gravity. But here in the 21st Century biologists and paleoantologists have pretty well confirmed for us Darwin's opinion, namely that the world is packed with us and our animal cousins, all quite similarly driven by quite similar DNA. Some, like my cat and the vervet monkeys in my trees, (probably) lack the capacity for understanding the universe fully. Perhaps we are also so limited, despite our wonderful discovery/invention of the Platonic world/language of mathematics.

Thanks for reviewing this book.

7. **Christian Takacs**
December 17, 2011

It's simply scandalous that anyone should try return physics to the understanding of the mechanical underpinnings of how the universe functions, instead of the far superior methodology of faith in anthropic principals, imaginary multiverses, virtual messenger photons, Higgs Bosons (31 flavors don't cha know!!), renormalization of infinite answers from finite quantities, and logical paradoxes loaded high with contradictions galore lined up like added features in a car salesman's pitch. After all, EVERYONE knows that all REAL understanding has ALWAYS come from the established academic elite, not common inventors, astronomy buffs, bicycle mechanics and patent clerks who presumed to try something without the blessing and peer review of their betters. Please for the love of truth, put the Hubris away Peter. From the debates that have gone on in your own site, it is quite apparent to even the lowly layman that esoteric theoretical mathematics have run rampant, wild, and free for decades… and made a hash of comprehending physics as anything other than verbose numerical onanism, or science fiction. Take your pick. Either way, someone is coming to change things . That someone is not going to be coming from inside your august academic ranks, or speak in the buzz words and tongues preferred by the HEP mathematical priesthood… that much is painfully obvious.

8. **Dave**
December 17, 2011

@Christian
We are on the verge of discovering a particle which allow us to confirm the correctness of a theory explaining how a unified force is observed as two separate forces. This is quite a feat of theoretical and experimental physics and is truly Nobel prize winning. Along the way it will also the falsification (or confirmation of the correctness) of a number of models of symmetry breaking. All of this came from the particle physics mainstream. How does that fit into your worldview ?

Also, how do you know the next big thing will come from outside of the pp mainstream ? You write that this is "painfully obvious" – can you share your soothsaying secrets and lay down the chain of logic which allows you to make such a declaratory statement devoid of uncertainty ?

9. **james**
December 17, 2011

Great review. I think in between the outsider crackpots and the fading string theorists there's reason to be optimistic. A new generation can start fresh. I dont think the foundations of science will change. String theory failed to predict the physical constants of our universe, la la la, so string theorists give up with the possibility of multiverses with a wide array of constants. Kind of embarassing, but understandable. They can work on this stuff in their later years.. Fresh minds come out of school. There'll be more people working on a consistent mathematical theory that has the standard model and its 40+ parameters as a unique prediction.

10. **Bobito**
December 17, 2011

The basic failure of the best, most imaginative physics crackpots is to forget that physics is an empirical science, and that what does not explain observed phenomena in a way useful for later building instruments and devices is really quite useless, and, moreover, not physics.

The psychological failure that leads to this is often related to a deeply entrenched arrogance. It is simply impossible that one person can reproduce the cumulative efforts of the hardest working, most imaginative scientists over several centuries.

11. **Yatima**
December 17, 2011

@Takacs

You write sarcastically: "all REAL understanding has ALWAYS come from the established academic elite, not common inventors, astronomy buffs, bicycle mechanics and patent clerks"

Please remind yourself of the fact that the fêted "patent clerk" had a prior good grounding in / knack for mathematical physics and could base his understanding on the previous work of Maxwell, Hertz, Lorentz and Poincaré (with the equations already fully formed) as well as the experiments of Michelson and Morley and "just" had to look at the ideas in a new way. And even then, Minkovsky had to come in to clean up the formalism. The next step (1915) came after the use of *more* amazing math combined with persistency and hard work over 10 years.

"That someone is not going to be coming from inside your august academic ranks, or speak in the buzz words and tongues preferred by the HEP mathematical priesthood… that much is painfully obvious."

The Chinese Cookie you will open today says "You are wrong". Now go and start working on Group Theory.

12. **Danny Black**
December 17, 2011

Yatima,

one should also remember that special relativity was not really a major contribution as it was "in the air", if Einstein hadn't come up with it someone else would have. As you pointed out Lorenz – from the "established elite" – had already come up with the key transforms and Poincare was close to establishing the same facts. Einstein essentially let the equations speak for themselves.

By the time Einstein DID come up with something original and unexpected – General Relativity – he was well established.

I am struggling to think of a major maths or physics breakthrough that was made by some "crank" outside the "academic elite" in the last 200 years, especially as one can argue the term "academic elite" only really gathered force in the late 19th century.

13. **Peter Woit**
December 17, 2011

Bee,

Wertheim has a physics degree and some experience among physicists. The string cosmology conference was in 2003 at the KITP, probably one of the first conference dominated by "the landscape", so at the height of enthusiasm for that idea. More recent conferences on the topic might have struck Wertheim differently, with the landscape proponents having eight years of going nowhere making for a lot less enthusiasm.

14. **Joel Rice**
December 17, 2011

There may be a lot of dumbed down popularized stuff out there, but there is also Veltman's book, not to mention Feynman's QED . If these folks want to see what they are really up against they should be reading Schweber's QED and the men who made it, and contemplating what it was like when Dirac was pestering Feynman with "but is it unitary" ! It is unconscionable to have the bad books driving out the good.

15. **Giotis**
December 17, 2011

"Even things that weren't allowed couldn't be ruled out, because you never knew when the laws of nature might be bent or overruled."

This isn't true. The fundamental principles of nature cannot be bent or overruled in the multiverse picture.

No String theorist or cosmologist could have made such assertion. Obviously the author hasn't the slightest idea about String theory or Cosmology. Her reaction is the naive reaction of an outsider.

16. **Jack Lothian**
December 17, 2011

Giotis,

Outsider-insider?? Just what do these terms mean. If she has a physics degree, she has to be in the top fractional percent of people who might be capable of understanding this type of complex math/physics. Are you saying only string-theory practitioners can understand this stuff and everyone else is a dilettante and incapable of offering valid criticism?
Her comment: "Even things that weren't allowed couldn't be ruled out, because you never knew when the laws of nature might be bent or overruled." May be a bit over-the-top & phrased in a way that I am sure no true believer would phrase it but the comment is a not an unreasonable précis of many comments that I have read here.

17. **Peter Woit**
December 17, 2011

Giotis,

If you interpret "Laws of Nature = Lagrangian of SM + GR", what she is saying here makes perfect sense.

About this time, possibly in reaction to the same conference, David Gross in his conference talks started quoting Churchill's words during the Nazi bombardment of London ("never, never…. give up!") as a call to arms to particle theorists to resist multiverse madness. It wasn't only "outsiders" who were appalled by this…

18. **Giotis**
December 17, 2011

Peter,

When we talk about laws of nature we mean the fundamental principles. Fundamental laws are the principles of QM for example and these you can't bend.

The content of SM is a derived concept, not a fundamental law/principle.

Regarding GR, the low energy limit of String theory is just supergravity which fully respects GR as an effective description of Gravity.

The author (due to ignorance I believe) gives the false impression that everything goes in the multiverse. This isn't true. There are fundamental physical laws which must be respected and deep physical principles you can't bend.

Jack Lothian,

"Are you saying only string-theory practitioners can understand this stuff and everyone else is a dilettante and incapable of offering valid criticism?"

No, but of course you must have studied the theory at least in some depth to have an opinion. This could take months or years depending on your background. The author obviously hasn't done that and a Physics degree doesn't mean anything in that respect.

19. **D R Lunsford**
December 17, 2011

Peter wrote (beautifully)

"One way in which I'm very different than Jim Carter is that I've never been one for insisting on ideas that I can figure out for myself. I'm grateful for and fascinated by the fact that there's a huge amount of knowledge about the universe out there discovered over centuries by a collaboration of a long list of brilliant people, and many places to try and learn about it. This kind of learning is a joy, and not being willing to engage with and try and appreciate the accumulated wisdom of the human race to me makes no sense. "

Yes that's about the entire matter right there -it's really a cultural matter. As long as the culture is respected, you can stand up for whatever you want to – but you have to make some effort to take in what has been done before. If you don't at least try that, then you don't get a ticket to enter the contest.

And what's really frustrating, is to see that culture threatened by unphysical ideas, and there's not much you can do to change it. At some point you lose patience and become Christopher Hitchens.

-drl

20. **Marco Masi**
December 17, 2011

Woit says: "When I got to the point of learning about quantum theory, it became clear to me that this was something of great power and beauty, carrying the lesson that at a fundamental level the world is very different than the mechanical picture we derive from our human-scale intuitions."

And this is the main reason I don't believe in string theory. A world which is too 'classical', intuitive, and made of 'objects' like strings or membranes, D-branes, etc. which please homo sapiens' belief system and his human-scale perceptual mind made of forms in space and time, but which is far from the very different story QM is trying to tell us. What we know about is a micro-world where forces are exchanged indeterminstically, showing up as particles and yet behaving like waves, in a nonlocal context where things appear entangled in space (and possibly also in time), etc. Where is there any place left for 'objects' like vibrating strings having tension and extension, or sharp N-dim curled up spacetime manifolds? There is nothing like that 'down there', neither more no less than there are colors, tastes or smells. These are only our anthropocentric reifications. And unfortunately this is what most 'outsiders' have in common with those who they claim to challenge with their 'new' theory when they think in terms of 'circlons' type of stuff.

So, what about going back to basics? But we have been told "shut up and calculate". In fact it worked for some time egregiously and that gave us the SM. String theorists where encouraged by this and now want to 'save the appearances' at all costs. But epicycles and defernts did that for a long time too, and yet turned out to be the wrong worldview nevertheless. I would not be surprised to see history condemning string theorists as the new Aristotelians.

21. **Giotis**
December 17, 2011

I forgot to respond about David Gross,

Gross reacted this way for completely different reasons. He never said that the theoretical structure/reasoning which leads to the Multiverse picture is crazy or unfounded. He just believes that is too early to make such claims since the theory is not mature enough to assert that the landscape is indeed its definitive prediction.

22. **LHB Jr**
December 17, 2011

Outsiders can be useful in breaking GroupThink. One excellent example of this is Yuri Knorozov. He was a pioneer in deciphering Mayan script. He lived in the Soviet Union, isolated from Western educational institutions, and brought a fresh (and ultimately correct) view of how to read Mayan script.

Interestingly enough, he did this when progress in decipherment had stagnated.

Given the vast democratization of information resources provided by the Internet, I don't see why a particularly clever person, with relatively modest training compared to today's elite, couldn't spark an insight that leads to a major advance in theoretical physics. Maybe it will require an outsider. As Yuri's Wikipedia page says:

He(Yuri) was perhaps shielded to some extent from the ramifications of peer disputation, since his position and standing at the institute was not adversely influenced by criticism from Western academics.

23. **Peter Orland**
December 17, 2011

Giotis,

You say the standard model is a “derived concept”, but the rules of quantum mechanics are “fundamental”. By that standard, all Lagrangians are derived concepts (if I understand your meaning).

I have seen similar arguments before by landscape advocates, trying to say that the standard model is not a theory of nature, hence we have to something more “fundamental”. This is philosophy, not physics. Furthermore, it is not good philosophy.

The principles of quantum mechanics aren’t very useful as form. They require content. I don’t care whether the content meets somene’s standard of fundamental.

This wordplay distinguishing “derived concepts” from “fundamental laws” ones is not meaningful. There is no physics without the former, such as a force law or a Lagrangian. By itself, the latter is hot air.

24. **anonomous**
December 17, 2011

If somebody found a way to find more symmetry in the SM with fewer equations that reduces the number of free parameters, then that should be considered a breakthrough. This is not the same as dumbing down the math, but simplifying it to within a greater symmetry of known results. Of course the new model would have to match all known experimental results and predict new ones – but clearly the current path between GR and the SM is not working, so we need to try something new.

25. **Peter Woit**
December 17, 2011

Giotis,

I don’t think Gross (or Churchill) was saying that “it’s too early” to give up. They were both saying “Never, Never, Never, etc. give up”, which is kind of different. It would be interesting to ask Gross what he would do in the event that string/M-theory is completely understood, but shown to have so many vacua of such complexity that you could never predict anything. I suspect he’d say that one should still not give up, but look for an alternate, better theory that was predictive. But, you’d have to ask him…

26. **Daniel L. Burnstein**
December 17, 2011

There is no reason why the likes of Fermat, Ramanujan, Faraday or Pascal not to exist today.

I know the common belief is that science is now a collective effort,. Yet there’s also no example of revolutions of science that have not been brought upon by individuals who thought outside the box, and often outside institutions. There is a reason for that. The kind of synthesis of knowledge and intellectual leaps required can only be done within the individual mind.

27. **Hendrik**
December 18, 2011

Thank you Peter, that’s a great review.

The fascination with outsider science springs maybe from the fact that we all have a bit of the outsider scientist in us,- after all, to solve a problem with substance requires thinking outside of the box. (Of course there are degrees of how far out an outsider is.)
According to Kuhn, scientific revolutions originate with the outsiders (the “seers” of Lee Smolin?), so it is good to have them around.

But perhaps the new element illustrated with string theory, is that an outsider theory can become mainstream, not by surpassing the experimental & predictive successes of its predecessors, but by sociological forces alone. Maybe an example that an outsider theory can be detrimental to science. An indication that the mechanisms of science (or physics) may be in disrepair.
–

28. **Robert D. French**
December 18, 2011

Carl Sagan addressed this in an episode of Cosmos. There was a psychiatrist who tried to introduce a crackpot theory for the creation of the solar system. His hypothesis was pretty easy to dispute, but he was censored by mainstream scientists. Sagan’s point was that we don’t know where the next big insight will come from, so we shouldn’t reject ideas out of hand just because they don’t meet a certain aesthetic. He also said that the suppression of ideas has no place in science.

29. **G Alex**
December 18, 2011

Yes, everybody officially welcomes ‘outsiders’. If you ask academics if they appreciate free thinking and original ideas everyone will tell you “of course I do, I even encourage it”. But that’s easier said than done and truth is different. The present academic system on the contrary accurately rejects from the outset those who dare to come up with their own research project based on unconventional ideas, especially if it does not fit with their ideological background. I found many of these then complaining that their students, despite being brilliant and well versed in the subject, for some reason they can’t understand, lack nevertheless of novel insights. But that’s no wonder… And when I hear about how ‘suppression of ideas has no place in science’ I can only lough about it. If not suppressed they are certainly discouraged to say the least. It is something intrinsic and deeply ingraved in our academic mindset itself.

30. **Bob Levine**
December 18, 2011

I’m afraid that some of the commenters here are forgetting a basic principle of scientific innovation: at *some* point, the novel approach must account at least equally well for the full range of facts as the conventional approach(es) it seeks to replace. People who complain about the rejection-out-of-hand of new or highly unorthodox hypotheses (or, at a more fundamental level, theories) should ask themselves if those hypotheses have come anywhere close to duplicating the predictive/retrodictive successes of the current ‘mainstream’ treatments, whatever they happen to be. That’s what the notion ‘burden of proof’ is all about. As far as I can tell, having *that* engraved in the ‘academic mindset’ is the reason why progress in science occurs is even possible.

31. **G Alex**
December 18, 2011

Yes precisely, at *some* point. But how can something get at that point if it is rejected out-of-hand? While the ‘mainstream’ approaches are frequently seen to be allowed to go far beyond that point, even if they failed in producing testable results.

32. **Fabien Besnard**
December 18, 2011

I think that the important, and difficult thing to do, is to distinguish between people with very unorthodox ideas (call them "outsiders" if you want, but they might also be found in academia), and crackpots (they can sometimes be found in academia too). Some have insisted here on the point that new ideas must always be compatible with known facts : this is certainly true but it is sometimes a difficult thing to judge (a striking example here is string theory). So it can't be taken against a new idea that it does not fit at once with all the known phenomema, since it might be a very long process to derive these phenomena from a theory. It is even possible that a incomplete, but in the end right, theory be for some time in violent disagreement with observation (think of the heliocentric theory which was unable to explain why we are not flung in outer space by the rotation of the Earth until Galileo came with a new theory of motion).
Perhaps a demarcation line could be found between reactionnary ideas and ideas which are only unorthodox, even wild, speculations.
Crackpots often tend to hold reactionnary ideas. By this I mean that they want to go back to an outdated world view : whatever the next revolution in physics will be, it will certainly not be to go back to some incarnation of Newtonian mechanics.

33. **skeptical**
December 18, 2011

People here seem to be suggesting that professional physicists should carefully consider every idea thrown at them in blog comments or on websites. Obviously, if they were to do this they would not have time to do anything else. The unfortunate fact is that the vast, vast majority of ideas from outside academia are nonsense (some ideas from inside academia are also nonsense, of course). I know it was true in the past that plucky outsiders with a different viewpoint could make a big impact, but that is simply not possible today. To see how to go beyond our current best theories you absolutely must be well-versed in them, and that is well-nigh impossible if you're not a professional. It's a pity that this is the case, but there you are.

34. **Mark Bennet**
December 18, 2011

Answering skeptical: there is a tension between being so inducted into the current model that you can't think differently, and knowing enough about the current model that you are confident/foolish/bold (same thing?) in thinking differently.

If a different model from the current one is required – think relativity or quantum mechanics -v- what went before – the person who makes the next great advance will have to be versed in the right material which is radically different from the Standard Model. They will inevitably also have to know why the Standard Model is so compelling over the range of physical experiment for which it "works" – so will need to have that aspect tied up: and that will no longer be possible for an amateur observer like me: probably.

35. **anonymous**
December 18, 2011

What happens is that the constant rejection of all ideas that seem crazy (like Plate Tectonics, which very slowly gained acceptance even though it had quite a bit of evidence), slows down growth in the field and creates a very disheartened attitude from the public, some of whom think about becoming scientists and then wonder if they can handle the bureaucracy. Slow and careful, but not so slow and careful that the field dies an early death.

36. **Bob Levine**
December 18, 2011

"What happens is that the constant rejection of all ideas that seem crazy (like Plate Tectonics, which very slowly gained acceptance even though it had quite a bit of evidence), slows down growth in the field and creates a very disheartened attitude from the public, some of whom think about becoming scientists and then wonder if they can handle the bureaucracy. Slow and careful, but not so slow and careful that the field dies an early death."

Wait a second. Plate tectonics was rejected at first, then became increasingly favored as paleontological and stratigraphic evidence accumulated, and is now the fundamental framework of geology. And geology is a thriving scientific field. How does the example plate tectonics serve to counter the claim that if an idea is robust, and succeeds in motivating a variety of independent lines of evidence, it *will* survive in the face of severe scrutiny? Isn't plate tectonics in fact a poster child for the vitality of ideas that really *are* correct, and for the position that the bar needs to be set high enough that only such ideas survive, and then only after proving themselves on multiple empirical fronts?

And are you really suggesting that people don't go into science because they're discouraged by the fact that very high standards of explanatory and descriptive adequacy must be met before being accepted into the body of scientific knowledge?

37. **G Alex**
December 19, 2011

Fabien, and skeptical I'm not talking about crackpots or people who self-learned outside the academia but of professionals and students inside of it. I have seen several trying to advance novel ideas and research lines but saw it rejected, not on the basis of being 'crackpotish', but because they did not fit with the selecting committee/supervisor agenda and ideological approaches on how to solve a problem or on what is "interesting" and what is not. Those students and researchers who have original ideas but are not that good in politics and in pleasing the hierarchy (and perhaps are the shy introvert guy), even don't dare to come up with something which is not strictly in line with the mainstream paradigm. Because after some attempts of having done so they learn quickly how it will end. And this state of affairs became even worse in the last two decades or so also in fields traditionally open to free thinking and which underwent a centralization based on the ideal of the 'big science' where reserach is conceived as in an assembly line and has to obey the diktats of few 'science top managers' (who in turn are also heavily dependent from the diktats of outside fundings). It is a matter of culture, it is the idea of how to conceive and organize research and education which has gone astray. In this climate the new Einstein for sure will soon leave or even never grow up.

38. **Casey Leedom**
December 19, 2011

People keep bringing up Einstein as an example of an "outsider who actually came up with something new." Hogwash. Einstein built his ideas on the evidence and the ideas of all who had come before him. If he had existed 200 years earlier he might have been bright enough to have come up with some revolutionary idea about mechanics. But he wouldn't have come up with Special- and then later General-Relativity. He needed the input of Maxwell and a whole host of others to build his ideas upon. People who wander off the beaten path and come up with something new are the ones who _do_ pay attention to the work that's gone before them and then find new insights from that information.

39. **Bobito**
December 19, 2011

There is a strong psychological tendency to celebrate the outsider, or the supposed outside (to label Einstein a "patent clerk" and try to portray him as an outsider is to exhibit a complete ignorance of the circumstances of his education and employment – he was highly educated in the classical sense and conversant with the relevant literature). The typical profile of the successful physicist is more like that of Chandrasekhar than that of Ramanujan – child of intellectuals, nephew of Raman, and supremely educated in the classics of both the east and west, in physics and outside of it too.

40. **Proudmemberofthecult**
December 19, 2011

Why apply the 'outsider' label only to string cosmologists? There's more communities like this out there. AdS/CMT is heading this way. Loop quantum gravity is here already…

41. **Robert Plant**
December 19, 2011

With regard to Carter's work – I can only add: In my thoughts I have seen, rings of smoke through the trees – and the voices of those who stand looking.

42. **srp**
December 19, 2011

One must distinguish between theoretical and empirical "crackpots." Arp was the consummate insider until his inconvenient observations and interpretations got him tossed from mainstream astronomy. Frank and the late Sigwarth paid a huge professional price for their empirical work. Krisch seems to have come through by soft-peddling (judging from his U.Mich bio page) the importance of his anomalous findings, but neither do I sense any groundswell by theorists to either show that those findings can be accommodated in the SM or to use them to go beyond it.

Read Benford's entertaining novel Timescape for an insider account of how professionals feel about discovering revolutionary empirical facts. Hint: Their initial impulse is often to try to bury them to avoid trouble. I bet there was a strong faction that wanted to do that on the recent superluminal neutrino claim, and I tip my hat to the team for releasing the controversial findings.

43. **emile**
December 19, 2011

When circlon theory can get the first 10 digits of the gyromagnetic ratio of the electron right, I promise I will then pay attention.

44. **Coin**
December 19, 2011

Giotis: "This isn't true. The fundamental principles of nature cannot be bent or overruled in the multiverse picture."

It seems to me like you can't really say this because there is more than one choice of multiverse. Certainly in a Tegmarkian multiverse (MUH!) "everything goes". How do we meaningfully determine whether we are in the Tegmarkian everything-goes multiverse, or in the constrained m-theory multiverse, or maybe even a non-string chaotic-inflation multiverse (which is also constrained but in a potentially different way from in m-theory)?

And even if we pick the m-theory multiverse– can you really tell me that there is exactly one way to *formulate* the m-theory multiverse such that string multiversers would all agree on which physical ideas are fixed and which vary between different points in the multiverse?

Once you've decided to start walling off physical principles as chance whims of the multiverse, I don't really see what principle we have to guide us as to when to *stop*. Why *not* go full Tegmark and suggest the "fundamental principles" of the m-theory multiverse (like QM) are just due to local multiverse conditions as well?

45. **anonomous**
December 19, 2011

Bob,

Here is a good read on how plate tectonics was shot down by physicist Scheiddiger (who's arguments were strictly theoretical) in 1953, some 41 years after Wegener (who was not a geologist) proposed the theory in 1912 after seeing how the continential pieces might fit together:

http://en.wikipedia.org/wiki/Continental_drift

Yes, there was very good evidence in 1968, but there was quite a bit of circumstantial evidence for 40 years prior and the extreme rejection of an idea that was considered fairly simple (the pieces fit together on a globe) may play out again in physics.

46. **Trulo**
December 20, 2011

> how professionals feel about discovering revolutionary empirical facts. Hint: Their initial impulse is often to try to bury them to avoid trouble.

Funny you would say so, when the entire particle physics community has been begging for decades for at least a single shred of a tiny departure of empirical data from the SM.
Revolutionary empirical facts is what everyone would love to see. The Higgs boson empirically excluded with 95% confidence from 115GeV all the way to 1TeV, for example, would have been pretty cool. Alas, it seems nature chose to stick to the SM. It's not the theoreticians' fault, just as it is not a government conspiracy that cold fusion was obviously wrong from the beginning, or that Opera needs to do a lot more work before their observation of superluminal neutrinos can be remotely believable.

Transgression may be valuable by itself in poetry, but science does not work that way and it never has.

47. **srp**
December 20, 2011

I agree that particle physics has been so starved for new findings that the situation is different at present. (BTW, I haven't been following the rumors closely, but aren't you jumping the gun on the Higgs?) And a systematic error at OPERA is also my best guess about what is going on with the neutrino claim. On the other hand, I don't sense great community excitement about the apparent huge proton transverse-spin anomalies, which appear to be well-verified. And I've seen little buzz about claimed anomalies in radioactive decay during solar flares–perhaps these are also assumed to be obvious experimental errors.

I don't think not finding the Higgs counts as an "anomaly" in the same sense because lots of people anticipated the possibility. When the organisms under your microscope spell out "take me to your leader" that's an anomaly. (Check your colleagues' propensity for calligraphically daubing growth medium on your slides before you call the newspapers.)

48. **Zathras**
December 21, 2011

Trulo: *"… the entire particle physics community has been begging for decades for at least a single shred of a tiny departure of empirical data from the SM."*

True. The question then has to be asked, why does there have to be anything beyond the SM. What necessity is driving a need to unify gravity with the SM? Maybe gravity is just different.

49. **Trulo**
December 21, 2011

@srp:

> but aren't you jumping the gun on the Higgs?

It might be so, that's why I said "it seems" there's a Higgs. More data and further analysis are needed to confirm the signal and, if it remains there, to find out what exactly it is.

@Zathras:

> Maybe gravity is just different.

Personally, I fully agree. But it is also true that I have no clue how that would work, so, as far as I'm concerned, it's not a terribly productive idea.

50. **Clay Farris Naff**
December 22, 2011

I'm probably chiming in too late with too little, but happily talk is cheap. I only want to say that I've been struck for quite some time about how loony much of the conjecture in theoretical physics has become. Worse yet, it worries me that theorists all too often seem to forget that they are merely conjecturing, albeit with the tools of math, and that experiment has yet to confirm gravity waves let alone any hint of the multiverse.

It led me to devise an extension of Occam's Razor, which I call "Clay's Clipper." It states that any proposition that tends to impair reason should not be accepted as true in the absence of compelling evidence. Everett's Many Worlds interpretation of QM is one example. It *may* be true, but its implications are such that we should not presume it to be true unless and until some evidence is produced. (Unfortunately, the one experiment that could convincingly establish Many Worlds only works for the person conducting it, and involves a gun, a lottery ticket, and the violent deaths of at least five versions of the experimenter.)

Clay Farris Naff
Science & Religion Writer

51. **Margaret Wertheim**
December 22, 2011

Dear Peter

Many thanks for the splendid and thoughtful piece about my book. Your own book, and Lee Smolin's, were important touchstones in the development of my thinking about the far fringes of science. As someone trained in physics I have been astounded by the rise of string theory, which has seemed to me for a long time to be little more than magical speculation. There is of course a role for magical speculation in out lives, the question in my book is does it belong in science?

You may be interested to hear that since the book was published I have received quite a few comments from outsider theorists who are distressed at my representation of themselves. They have defended their community as one that has shared concerns and methods – just like the insiders. Its rather strange that on the one had they are calling for a revolution, yet on the other hand they also crave some kind of continuity with the very thing they claim to be rejecting….

52. **Margaret Wertheim**
December 22, 2011

Peter

It occurs to me that your audience may be interested to know that I am currently putting together an exhibition of outsider physics theories. Some of these are graphically stunning – the show will be a visual version of my book. The exhibition will be on display at the Institute For Figuring in Los Angeles. Opening date will be in early March 2012. More information about the show can be seen on the Exhibition Page of the website for my book: physicsonthefringe.com

Let me know if you come to LA and I'd be delighted to show you around the exhibition and my collection of outsider theories.

all best
margaretw

53. **Peter Woit**
December 22, 2011

Thank Margaret,

Probably won't make it to LA next year, but if so, will definitely take you up on your offer.

It's interesting to hear about the "reaction" of the "outsiders" to your book. Sounds like you managed to get both "insiders" and "outsiders" distressed, a good sign…

54. **Margaret Wertheim**
December 23, 2011

Peter

Yes this book has proved to be a source of equal opportunity upset. On the other hand many people – especially nonscientists – have understood that the core of the book is the questions it raises. So many people are bamboozled and intimidated by contemporary theoretical physics, and not knowing where to turn for help. When I started working on the project I planned to write a much more academic book that addressed in depth the sociological issues raised by outsiders; but in the end I decided to, in a sense, stay true to the spirit of my subject and let my subjects speak for themselves. At one point I wanted to call the book "a scientific fairytale" – like many fairytales the story hinges around both a hero and a moral dilemma.

For me the appeal of physics was always its magical beauty. In this sense I agree with your remarks that outsiders are missing out on something really wonderful. That is a failure of their education I believe – one of the sad facts of our time is that so few people can gain the kind of education needed to appreciate aesthetic brilliance of general relativity. I wrote a chapter (that I didn't end up including) in which I proposed that Einstein is the Leonardo of physics and that Jim Carter could be seen as it Heironymous Bosch.

I hope to be coming to NY next year for an event about the book. Perhaps we could meet up then. Who knows, the LHC might have found something we both could celebrate.

all best margaretw

55. **harryb**
December 28, 2011

Peter, I also enjoyed your review, and when the book is available as an ebook on amazon, I'll promise to buy it. A trawl through arXiv recently shows at least some continued skepticism re String Theory – eg Hedrich's: String Theory – From Physics to Metaphysics – arXiv:physics/0604171

Admittedly from 2006, and (to me) a confusing paper – never sure if pro / anti the String Theory position – but extensive use of Lee Smolin's arguments.

A number of recent papers also give the Multiverse/Anthropic Princple/String (M) Theory axis short shrift also. Although you sense a wariness on being tough on string theory, whilst hammering away at the other two (odd).

I tend to agree with you re bias for building on the blocks of previous science – maverick ideas even on settled science surely still welcome, but most (all?) historical "mavericks" seemed to work productively against the common grain rather than bypassing it.

What Margaret Wertheim's book appears to offer (and I will read it fully) is that the deep efforts on String Theory are becoming more fantastical and magical the more it leaves behind the shackles of empiricism and measurement – hence are they any more worthy of detailed consideration than Circlons?

That is a very bad fate for a leading and prominent scientific theory, and it continues to have worrying implications – eg snuffing out diversity of ideas, disengaging the wider populace. On top of this, the approach seems destined for a final theory of unfalsifiable metaphysics (multiverse / AP) coupled with unskeptical and highly defensive approaches to any challenge. All the hallmarks of cultism that Wertheim's book seems to identify.

A poor end for fundamental physics potentially. Where to now – back up the hierarchy to the quantum / classical cut and start again? Top-down v bottom-up?

Short Items

December 21, 2011
Categories: Book Reviews, Experimental HEP News, Multiverse Mania, Uncategorized

A few short items:

- The Multiverse propaganda campaign continues this month, with a piece by Alan Lightman in Harpers entitled The Accidental Universe: Science's Crisis of Faith. The content is pretty much the usual: string theory implies an untestable multiverse, and the multiverse explains why string theory is untestable. The whole thing is wonderfully consistent, coherent, and justifies the world-view developed by leading theoretical physicists over the last 30 years. The main person quoted in the article is Alan Guth:

> Guth started his physics career in this sunny scientific world. Now sixty-four years old and a professor at MIT, he was in his early thirties when he proposed a major revision to the Big Bang theory, something called inflation…
>
> He wears aviator-style eyeglasses, keeps his hair long, and chain-drinks Diet Cokes. "The reason I went into theoretical physics," Guth tells me, "is that I liked the idea that we could understand everything—i.e., the universe—in terms of mathematics and logic." He gives a bitter laugh. We have been talking about the multiverse…
>
> "We had a lot more confidence in our intuition before the discovery of dark energy and the multiverse idea," says Guth. "There will still be a lot for us to understand, but we will miss out on the fun of figuring everything out from first principles."
>
> One wonders whether a young Alan Guth, considering a career in science today, would choose theoretical physics.

The only hint anywhere in article that some physicists might feel that there is something wrong with this picture is the passing remark that some physicists "remain skeptical of the anthropic principle and the reliance on multiple universes to explain the values of the fundamental parameters of physics."

- The FY2012 DOE budget has now been finally agreed upon (see here), remarkably not even that far into FY2012. HEP does pretty well, at $791.7 million, versus $795.4 million for FY2011, a small decrease, considering that the Tevatron was running all of FY2011, is off now. More from Fermilab director Oddone here, who describes the budget as "very good news".
- The recent evidence for the Higgs particle found at the LHC kicks up a notch the question of who might get a Nobel prize for this discovery. Whether there's something there at 125 GeV won't be confirmed until too late in 2012 for a 2012 experimental prize, maybe that will be on the agenda for 2013, with the main question being who would get the prize. ATLAS and CMS are looking at very similar data, with similar analyses, releasing results in a coordinated fashion, so they should both get the prize, but there's no obvious particular scientists to give it to.

A theoretical Higgs prize would likely take much longer, since it will take a while to be sure that whatever is found behaves the way a Higgs should. Guralnik continues his campaign for the prize here.

- Erik Verlinde's claims made nearly two years ago that gravity is an entropic force have gotten a lot of attention. He doesn't seem to have written up any elaboration of these ideas, but he comments very recently on Twitter:

> For those who wonder: the fact that the Higgs has (perhaps) been found has no influence on my ideas on gravity. These ideas remain correct.

- Some people send me books that I enjoy in one way or another, but don't have the time or energy to write about here. Maybe you should consider them as last-minute holiday gifts:

> A First Course in Loop Quantum Gravity, by Rodolfo Gambini and Jorge Pullin. This book explains the ideas behind loop quantum gravity at an introductory level, suitable for undergraduates, or anyone wanting as non-technical as possible of an introduction to the subject. Maybe it can be sold in a package with Barton Zwiebach's A First Course in String Theory.
>
> Fascinating Mathematical People edited by Albers and Alexanderson. This contains a wonderful interview with my colleague Dusa McDuff. There's also this exchange in the interview with Ahlfors:
>
>> **Mathematical People**: How about physicists?
>> **Ahlfors**: Well, I don't believe in physics!
>> **Mathematical People**: You don't believe in physics? Why not?
>> **Ahlfors**: Physicists are so close to physics, but they don't know mathematics.
>> **Mathematical People**: … There's also a great deal of mathematics used by string theorists.
>> **Ahlfors**: But it's the wrong theory. I like the knot theory aspects, especially the knot theory applied to string theory. The strings are knots now, and there are these ready-made knot theorems that can be applied. That appeals to me.
>> Probably physicists are important for mathematics, but they cannot be important for me in any sense. I don't think that mathematicians should take their inspiration from physics.
>
> Magical Mathematics: The Mathematical Ideas That Animate Great Magic, by Ron Graham and Persi Diaconis. ~~Comes with its own deck of playing cards~~. Diaconis is a magician as well as a mathematician, so this is written by experts.
>
> Division Algebras, Lattices, Physics, Windmill Tilting, by Geoffrey Dixon. Dixon tells his personal story about pursuing research in particle physics, trying to connect it to the mathematics of the division algebras over the reals. I'm sympathetic to the idea that this kind of algebra has something to do with the patterns we see in the SM symmetries and quantum numbers. Unfortunately I still think no one yet knows the right way to understand this.

Update: One more. See here for an explanation of why string theory is useful:

> Dr. Kaku explains that time machines do not violate Einstein's laws of physics, and that – difficult though it might be – future humans would be wise to build one and slip through a wormhole to one of the alternate dimensions proposed by string theory before the cooling universe extinguishes all known life.

Update: The Times has an article and series of letters about the Higgs/Nobel issue, see here.

Comments

1. **JC**
   December 21, 2011

Suppose there will be a Nobel Prize for the theory of Higgs particle and everything, I really don't see how Guralnik and his company can win over H, E, or B. They beat the GHK team in print. If no more than 3 people can share the prize, the HEB are the obvious choice.

Besides, none of them proposed the final theory for how electroweak symmetry breaking works in reality. They only provided a mechanism. It doesn't matter who did a better job (Guralnik thinks the GHK team had a more complete and rigorous paper).

I think the best Guralnik can achieve is that no one will win it for the theoretical part unless the number of candidate is reduced to 3. We'll see.

2. **Peter Woit**
   December 21, 2011

   JC,

   Brout is no longer alive, so that's one less. If those goes on long enough, mortality will reduce the number of contending candidates to 3.

   I should also point out that Philip Anderson actually has a better case than any of these people for a piece of such a prize, see
   http://www.math.columbia.edu/~woit/wordpress/?p=3282

3. **Shannon Starr**
   December 21, 2011

   I bought Magical Mathematics a little while ago. It is a beautiful book, also with many beautiful pictures of Graham juggling, as well as explanations of card tricks. But I am pretty sure my copy that I ordered from Amazon did not contain a deck of cards.

4. **Bernhard**
   December 21, 2011

   If the Nobel prize is disputed between 5 in theory, between how many is in experiment? I think a Nobel prize for the Higgs definitely should go to at least two theorists, or even 3 and leave the experimental Nobel prize for something that was not predicted that the experiments happen to find (if). And even in this case the most neutral thing to do is to give the prize to CERN (therefore to Rolf Heuer as its representative) , also because people forget there is a not so easy accelerator effort called LHC involved in this whole process and we would not a a Higgs without it. Tough call, but doable if the Nobel committee wants to be less unfair as possible (to some degree a Higgs Nobel prize is doomed to be unfair).

   A last comment is that I am not so sure I agree that it should take that long to give the prize for a Higgs. As I understand the prize should be given to those who conceived the idea of a Higgs field, not to some random model builder who happened to use the idea and hit the jackpot. So even without knowing its exact properties, we will know if it is some kind of Higgs or not and this should be enough.

5. **Peter Woit**
   December 21, 2011

   Shannon Starr,

   Thanks for letting us know. It's entirely possible the deck of cards was just a promotional bribe included in the package from my friends at PUP to get me to mention the book. Anyway, it's a fun book, even if you don't get an extra pack of cards with it…

6. **anon**
   December 21, 2011

   IMO any Nobel prize for the Higgs should go to theorists alone. Experimentalists already obtained Nobel prize for discovering W and Z particles in the electroweak sector using hadron colliders. I don't think they deserve another prize for discovering the Higgs simply by using a more powerful hadron collider, without revolutionary change in experimental method. If they discovered something groundbreaking using a future muon collider, that might be more Nobel-worthy.

7. **Bernhard**
   December 21, 2011

   One more comment before Christmas.

   Kaku multiverse and string theory. It´s incredible how these guys simply manage to sell the same story every week and still get attention. Kaku is the kind of author I like to read to relax because he has some fascinating stories (the lecture is almost certainly based on his "Physics of the impossible") that has nothing much to do with real physics problems that real physicists have like calculating parton density functions, so it´s really a relaxing "not thinking about my job" thing. Kind of read that is nice to tell my little kid about and that has the same value of us seeing Star Trek.

   Guth´s comments on the multiverse by the way gives me just yet another hint that they all already completely departed to a different reality that is not really connected with physics anymore. It´s hilarious to say "we will miss out on the fun of figuring everything out from first principles". Who is going to miss it? I think physicist will keep trying, also because most experimentalists (the only ones capable of making the real decisions where the filed will head to) are not even aware of the level of madness things went in string theory. The only thing that is unfortunately missing is to acknowledge that the multiverse thing is not theoretical physics and start an independent field with an independent name, maybe connected to the philosophy departments (I hope not to offend any philosopher here).

8. **Avattoir**
   December 21, 2011

   Peter, isn't the claim for Anderson rendered moot by his already having won in 1977?

   On the main point discussed in this thread (so far), I like the idea of distinct awards for the theorists & experimentalists, partly because in this case justice seems to demand it; but also because it allows for the possibility of the sort of 'politicized' award given in the case of the Peace prize involving Gore. An award specifically identified with CERN, such as to Heuer, maybe coupling it with Oddone (since Robert Wilson is long dead & Lederman's got one), might make for an effective slap at Congress for having cancelled the Supercollider, thereby exporting discoveries that link so strongly to the history of physics in this country.

9. **Peter Woit**
   December 21, 2011

   Avattoir,

   The Nobel is for specific discoveries, you can get it more than once (John Bardeen is an example, I don't know if there are others). What Anderson got the Nobel for in

1977 was a completely different topic, work on disordered materials.

10. **neo**
December 21, 2011

Has there been any update in SUSY @ LHC? Has SUSY been excluded to higher energies from the summer's previous announcement?

11. **Foster Boondoggle**
December 21, 2011

Don't you get tired of bashing popular hype? I mean, what's the point? No one takes Kaku seriously, if they ever did. It's almost like going after Fritjof Capra…

Regarding Guth: the thing is, inflation seems to be a compelling explanation for a number of observations – in particular, it's at least consistent with the concordance Lambda-CDM model and WMAP data. And there's really nothing else around to do the job. But once you take inflation seriously, you've got eternal inflation, and then you've got multiple universes. So even though they're unobservable (like "parallel earth" 10^20 light years away in this universe), this model that seems likely to be true also entails them. So why complain when smart & informed people draw out that extrapolation?

12. **Peter Woit**
December 21, 2011

FB,

Who's bashing Kaku or taking him seriously?

And, it's hard to believe, but it looks like I haven't written enough blog postings explaining why evidence for inflation doesn't imply the string theory multiverse, with different low energy physics in every universe.

13. **Foster Boondoggle**
December 21, 2011

re Kaku: OK, if I say "mock" instead of "bash" does that help? I just mean why waste the pixels?

On inflation & the multiverse, I suppose you are referring to a post like this one: http://www.math.columbia.edu/~woit/wordpress/?p=4043. I understand that inflation by itself doesn't imply the landscape. But eternal inflation is a pretty straightforward inference, and that gives multiple "pocket universes" as the lingo has it. Whether they're the ones implied by the landscape is another matter. Maybe they all look like this one. Why complain about this kind of speculation? Is it really that different from talking about the likely existence of parallel Woit all those many light years away?

14. **HI**
December 22, 2011

I'm not a physicist, but I wonder if the prize to Nambu could be considered a prize for the Higgs mechanism. Perhaps they could justify awarding the prize before the experimental confirmation of the Higgs boson because Nambu's work was general enough. (And perhaps they didn't want to wait too long – another prominent Japanese physicist (Yoji Totsuka) had passed away without winning the Nobel Prize earlier that year (2008).) But isn't Nambu's work important in large part because it lead to the Higgs mechanism and the Standard Model?

I won't be too surprised if no Nobel Prize is awarded for the theory of the Higgs boson. A Nobel Prize can be shared by only up to three people. There is no posthumous prize. It is too difficult to choose when there are six or seven contributors of which one is already dead (Brout) and one have already won a Nobel Prize albeit for a different topic (Anderson). And prizes have been awarded for related topics (Weinberg and Salam, 't Hooft and Veltman, and Nambu) already.

15. **db**
December 22, 2011

There is one person who will most definitely get the nobel for Higgs and that is Peter Higgs.
Could you just imagine the public ridicule the Nobel Committee would face if they didn't honour the man after whom the particle is named?

16. **Shantanu**
December 22, 2011

Foster, inflation has a whole bunch of conceptual problems. See talks by Brandenberger,Steinhardt, Turok, Penrose (many of which you can find online at KITP or PI). Plus I think a Harrison-Zeldovich spectrum + lambda cdm model is consistent with observations.

17. **Bobito**
December 22, 2011

My copy of the Diaconis/Graham book did not come with a deck of cards.

It's a nice book anyway.

18. **Oliver**
December 22, 2011

Good timing of this blog Peter.

Last week an interesting article ran over here in the Times by John Richardson on the topic Nobel issues and options. It was followed by two letters from 1) Frank Close (*of course*) and 2) Guralnik, Hagen, and Kibble (*ditto*).

GHK must be feeling the heat due to last week's results and Frank's comments. Close seems to be positioning himself as referee on all things "Higgs" – of course I thought we had John Ellis for that.

The Times
British physicist could be in line for Nobel Prize
John Richardson

December 14 2011

If the LHC experiments find the Higgs boson, the theoretical physicists who first suggested it are expected to win a Nobel Prize. There is a hitch, however: each Prize has a strict limit of three recipients each year, but six people suggested the particle's existence at almost exactly the same time.

Peter Higgs proposed the particle that came to bear his name in 1964, to explain why matter has mass. But a pair of Belgians, François Englert and Robert Brout, and three Imperial College London physicists, Gerald Guralnik, Carl Hagen and Tom Kibble, published papers containing the same idea within a few months of Higgs, in the same journal.

It is now accepted that all six conceived the Higgs simultaneously and independently, and all were awarded the prestigious J. J. Sakurai Prize for Theoretical Particle Physics in 2010.

The Nobel Prize's rules were laid down by Alfred Nobel a hundred years ago, when science was a much smaller and less international enterprise than today, and Erik Huss, of the Nobel Foundation, thinks they are unlikely to be changed. "You can't just rewrite something that's over a hundred years old," he said.

However, a compromise may be possible. Last year's Nobel Prize for Physics was awarded to three physicists, but at the announcement, the committee honoured the teams of which each was a member — though their colleagues did not receive any of the prize money.

There may be pressure on the committee to make an award sooner rather than later, to ensure all the potential recipients – aged between 74 and 82 years old — receive any recognition they deserve. The Nobel Prize cannot be awarded posthumously.

The Times
Letters to the Editor
December 16 2011

The problems faced by the administrators of the Nobel Prizes, and the huge possibilities opened up by the Higgs boson

Sir, You said (report, Dec 14) that six people suggested the Higgs boson's existence at the same time and that this is a problem for Nobel Prizes, which can be shared by at most three. As this assertion was adjacent to a commentary by me and is false, it needs expunging.

Peter Higgs uniquely drew attention to the boson, which now bears his name. While it is true that Higgs is but one of six (at least) who independently discovered how to give mass to fundamental particles, it is by studying the properties of the eponymous boson that the whole idea can be tested, as my book The Infinity Puzzle explains.

If the mass mechanism is regarded as key, then there is indeed an overabundance of candidates. However, if the boson is key to a Nobel Prize, there is no problem with the limit of three winners.

Professor Frank Close
Professor of Theoretical Physics, University of Oxford

The Times
Letters to the Editor
December 21 2011

Boson issue

Sir, while we are enjoying Professor Frank Close's recent book The Infinity Puzzle, we take issue with his letter (Dec 16) on some significant points. In this letter he implies that our paper "GHK" did not have the "eponymous boson". Our 1964 Physical Review Letters paper, written while all three of us were at Imperial College London, has the boson and describes it with what amounts to the same equation as that derived by Peter Higgs.

Additionally, the GHK paper was unique in that it explained in detail how the mass mechanism is consistent with the laws of causality and charge conservation along with other essential insights not presented elsewhere.

Gerald Guralnik, Brown University
C. R. Hagen, University of Rochester
Tom Kibble, Imperial College London

19. **Peter Woit**
December 22, 2011

Oliver,

Thanks a lot for pointing this out. Someone else should join in the fun and write to The Times about Anderson.

20. **Anonyrat**
December 22, 2011

Since number of Nobels have come up, here is from the web:

"…the International Committee of the Red Cross has won the most Nobel Prizes. The Red Cross received the Nobel Peace Prize in 1917, 1944, and 1963.

The only other people or organizations that have received more than one Nobel Prize are Marie Sklodowska Curie (for physics in 1903 and chemistry in 1911), Linus Pauling (for chemistry in 1954 and peace in 1962), John Bardeen (for physics in 1956 and 1972), Frederick Sanger (for chemistry in 1958 and 1980), and the Office of the United Nations High Commissioner for Refugees (for peace in 1954 and 1981)."

21. **anon**
December 22, 2011

I second Neo's question. When will LHC publish new SUSY results based on this year's data?

22. **Peter Woit**

December 22, 2011

anon and neo,

Maybe you should try the question at Matt Strassler's blog and see what he has to say about it. For the first ATLAS/CMS SUSY searches, the ones that were widely advertised before LHC turn-on as the best bet for finding SUSY, nothing showed up in the first 2 inverse fb or so. The reach of these searches won't go up very much with the analysis of the full 5 inverse fb of this year, so no one expects anything there.

SUSY proponents have been claiming that these first searches weren't the right ones, that it's only later, more difficult ones where they now think SUSY will show up. I'm also curious exactly which searches they're willing to claim as decisive ones, and what the state of those searches is. Maybe Matt or someone else can be encouraged to write about this. In general, I thought that the experiments weren't planning much in the way of release of new data until the winter conferences (e.g. Aspen in February).

23. **TimG**
December 22, 2011

True, the Nobel is for specific achievements, but even those who have multiple Nobel worthy accomplishments have historically not won two Nobels. (Einstein never won for either version of the theory of relativity, for example.) John Bardeen is the only exception (as far as winning two physics prizes is concerned). I assume this is because he worked in collaboration; the Nobel committee couldn't very well award Cooper and Schrieffer and ignore their co-author. But given that they already have too many possible winners for the Higgs mechanism, it seems especially unlikely that they'd take the essentially unprecedented step of giving a share of the award to a past laureate.

24. **Brathmore**
December 23, 2011

Peter,

As a somewhat informed layman trying to explain the fanciful idea of the multiverse to a bunch of smart humanities professors who know little about science, I found myself unable to answer a few of their basic questions, and I wondered if you could chime in. It goes without saying that like you, these professors and I think the multiverse idea is far-fetched. Still, we recognize that you and other readers of this forum, while not supporting the multiverse hypothesis, are likely knowledgeable enough about it to answer our questions.

1) If there are multiple expanding universes, do they collide? For instance, could a different universe's expansion collide with ours and, presumably, lead to all manner of destruction as stars from different universes run into each other? Wouldn't these events be observable in principle? If so, wouldn't that make the multiverse a testable idea, and assuming a lack of evidence for it, one that conflicts with, or lacks, experimental evidence?

2) I was asked whether space extends forever, and answered (hopefully correctly) that it does NOT — that the frontier of space in our universe is the outer reaches of expanding space caused by the big bang. This then lead to 2 questions:

(a) What is "beyond" that frontier (e.g., what if you're on the most distant object of the universe and throw a baseball outward…Does that act create new space?) Relatedly,

(b) What is the "stuff" that supposedly separates different universes of the multiverse? "Space," or something else? Given (by definition) that this "stuff" isn't part of any of the different universes, what is it? If the concepts of distance and location apply to such a substance (e.g., the notion of "between" different universes), then it seems unsatisfying to me to simply say that nothing exists there.

3) Are any/all of the different universes of the multiverse supposed to have originated from the same Big Bang as our universe's (and if so, why would they constitute a different universe than ours)?

4) One hears from the same writers who promote the multiverse that, in light of the accelerating expansion of our universe due to dark energy, one day our universe will be essentially "empty." Yet if there are 10^500 other universes that could potentially be expanding into ours, wouldn't the "stuff" from those universes potentially make our universe much more interesting than the barren wasteland depicted by the aforementioned writers?

I recognize you and many of your readers are not proponents of the multiverse (neither am I), but I think that discussing issues like these has value for either discrediting the multiverse or for finding ways to learn more about it. Thanks.

25. **EDR**
December 23, 2011

Brathmore,

The key to understanding many of these issues is to recognize that space does not need a meta-space (and then meta-meta-space, and then…) in which to exist.

In particular, expansion of space need not be expansion *into* anything else. Not also that the metric curvature of space is measured inside space itself; there's no notion of curving "up" or "down" in another dimension.

26. **Marty Tysanner**
December 23, 2011

Brathmore,

I'm not Peter, but I can try to answer some of your questions. I'll break it up into two comments — this one will try to paint a general picture of inflation and the multiverse, and with that context I'll talk about your specific questions in a second comment.

The general topic you are talking about is the creation of "bubble" ("pocket") universes within a total Universe, in the context of something called *eternal inflation*. Eternal inflation seems to be a generic prediction of most models of inflation. What I'll discuss assumes "false vacuum" eternal inflation, but the general issues that arise should be there for other ways currently considered for modeling inflation.

The inflation idea is that there is a "scalar field" that permeates all space, and it is in a state of high, essentially constant potential energy. (The origin of the potential energy, or more accurately potential energy *density*, is a "potential" which is a property of the scalar field itself.) According to Einstein's general relativity, under this circumstance of constant positive energy density space will expand exponentially fast. Obviously you won't get anything interesting if space expands exponentially forever, so inflation needs to end somehow. That is where quantum mechanics (and hence probability) comes in. The scalar field quantum mechanically "tunnels" out of the "false vacuum" (elevated potential energy) state in which it is trapped, then slowly decreases in potential energy until it reaches the minimum of the potential (the "true vacuum" state). But the tunneling event that leads to an end of inflation doesn't occur everywhere at once; it is *localized* to a region of space, i.e., it follows a probability distribution in each (exponentially expanding) region of space. It would be great if it ended everywhere at once, but that isn't the way quantum mechanics works.

When inflation ends locally this way, the event corresponds to formation of a “bubble” (“pocket”) universe. Because tunneling follows a probability distribution, bubble universes form at a characteristic average rate. This is analogous to the decay of radioactive atoms — a given radioactive isotope has a characteristic decay rate, but the decay process itself is random so you never know when or where the next decay will occur.

Maybe you can now see how eternal inflation comes about in this picture. Bubbles form at a particular rate, and as a consequence of the “equation of motion” for the scalar field they continue to expand afterward. Meanwhile space outside the bubble continues to expand exponentially at a *faster* rate than the bubble, so the total volume of empty space (i.e., not contained inside bubble universes) within the total Universe increases exponentially faster than the fraction of the total Universe that is occupied by bubble universes. This will continue to be true forever — because the probability of a tunneling event occurring within a given “box” is proportional to the volume of the box, and the volume of such boxes is increasing exponentially fast, there can never be enough tunneling events to end this runaway effect. Hence if inflation starts it is eternal to the future.

You can also see where the so-called multiverse comes about in this picture. Just as the volume of inflating space grows exponentially, so does the number of bubble universes in them.

I’ll make a couple of general comments about this picture. First, it should be clear that the inflation idea doesn’t depend at all on string theory — it comes from mixing scalar fields, quantum mechanics and general relativity. What string theory does in an inflation picture is vastly complicate what form the potential takes, so that it is possible for tunneling plus field evolution to occur in a huge number of different ways. You’ve probably heard of the string theory landscape of perhaps 10^500 different vacua — inflation gives a way to “populate” all those different vacua, at least in principle.

Second, since eternal inflation appears to be a generic feature of inflation models that are “up to the job” of accomplishing what inflation is “designed” to do, it is a very small step to conclude that the multiverse is a prediction of inflation. Except perhaps for string theory landscape enthusiasts, this proliferation of bubble universes is not desirable from a theory standpoint because it likely compromises the predictivity of the theory, at least somewhat. There doesn’t appear to be an easy way to escape the prediction that with inflation you get a vast number of bubble universes, i.e., a multiverse.

On the other hand, according to the most “natural” way of computing probabilities, i.e., the volume measure, we almost certainly don’t live in the universe we observe (!). The volume measure is a weighting by relative volume; for example, the probability of finding ourselves in a universe *at least* 13.7 billion years old is the total volume of all bubble universe aged 13.7 billion years or more, divided by the total volume occupied by *all* bubble universes. As you might be able to see from the discussion above, the volume fraction of universes much younger than ours is exponentially greater than the volume fraction of universes our age or older. This means that the natural probability measure predicts that with near certainty our universe should be much younger than we observe. This is a dramatic failure of an important prediction of (eternal) inflation. There are some very smart people actively trying to find a different way of computing probabilities that is also “natural” but that doesn’t predict our observable universe doesn’t exist. We’ll see, there certainly is good justification for skepticism…

27. **Brathmore**
December 23, 2011

Marty,

Thanks for the thoughtful reply. I admit that these issues are way over my head, so some of the questions I still have may not make sense, or may have been answered by your previous response…but here goes nothing:

If I understood your post correctly, bubble universes are contained within the larger universe (which began expanding about 14 billion years ago), and the bubble universes are expanding at a slower rate than the larger universe. If so, won’t there be objects in the bubble universe that will collide with objects in the larger universe? Wouldn’t we be able to observe this?

For instance, I imagine the larger universe like an ever-expanding solid balloon, and a bubble universe to be a small bubble within that balloon that itself begins to expand outward in all directions. But if so, won’t there be situations where the bubble universe is expanding in the opposing direction of the larger universe? (e.g., In a cartesian coordinate system, suppose the center of the larger universe is located at (0,0,0), the left-most edge of the larger universe is located at (-100,0,0), and the center of a bubble universe is at (-50,0,0) and has currently has radius 10. I would expect that the point (-40,0,0), the bubble universe is traveling in the positive X-direction, whereas at that same point the larger universe is traveling in the negative X-direction).

Shouldn’t we be able to observe these bubble universes? Wouldn’t some of them be expanding towards us and be observable as such (e.g., we see a pocket of stuff corresponding to the bubble universe that is blue-shifted compared to its surroundings?). Couldn’t there be collisions between the bubble universe and larger universe that are observable?

28. **Marty Tysanner**
December 23, 2011

Brathmore,

Now, on to your specific questions…

> 1. If there are multiple expanding universes, do they collide? Wouldn’t these events be observable in principle?

Yes, with an emphasis on “in principle.” If two bubbles formed closely enough to each other, their expansion could “outrun” the exponential expansion of space between them and the bubble walls would collide. This should create a big mess with lots of energy dissipated in the collision. However, almost all such events would occur so far away from Earth that the huge disturbances in the CMB or matter distribution would essentially be point-like, making them unobservable for all practical purposes. There is a very small but still finite probability that the aftermath of such a collision would be detectable by us. See this post by Matt Johnson on Cosmic Variance for more information:
Observing the Multiverse.

> 2) I was asked whether space extends forever, and answered (hopefully correctly) that it does NOT — that the frontier of space in our universe is the outer reaches of expanding space caused by the big bang.
> (a) What is “beyond” that frontier (e.g., what if you’re on the most distant object of the universe and throw a baseball outward…Does that act create new space?)

You are touching on what I think is one of the most non-intuitive aspects of the Big Bang model. A “bang” conjures up an image of an initial explosion somewhere in a larger space, and the debris flies outward into the larger space (otherwise, what would it fly into?). That isn’t the “real deal” in the Big Bang model. One of the central tenets of cosmology is that on large enough scales (say, several hundred megaparsecs), the universe is homogeneous and isotropic. (Obviously a lump of matter like a star or galaxy is an inhomogeneity; that’s why it’s important to average over much larger volumes.) Our observable universe started out homogeneous and isotropic, and it has remained homogeneous and isotropic since then.

There is a unique kinematical description of an expanding homogeneous universe — it is the Hubble law. It says no matter where you are in the observable universe, when looking outward *at sufficiently large distance scales* everything is moving away from you as though you were at the center of an expanding sphere. (To understand this better, read about the Hubble law.) But again, that's only a consequence of a homogeneous and isotropic expanding universe. This situation of uniformly expanding space can be modeled as space expanding according to a time-dependent *scale factor a(t)*, which governs how the volume of the universe increases with time. Roughly, think of $V * a(t – t\_0)$ as the the volume of the universe after a time $t – t\_0$ has elapsed, assuming you measured its volume as V at the time t_0.

A natural follow-on question is, "Then why does *a(t)* increase? What makes space expand if we aren't adding new energy/matter to the universe?" That one is harder and there is disagreement about the best way to answer that question. I don't think there is any consensus even among the most accomplished cosmologists. Some will argue that space really is expanding, whereas others will say the idea of "expanding space" is nonsense and a source of confusion.

> (b) What is the "stuff" that supposedly separates different universes of the multiverse? "Space," or something else?

Am not sure if I answered that satisfactorily in my previous comment. In the eternal inflation picture, you can think of the space between bubbles as space filled with a scalar field which is trapped in a "false vacuum" state.

> 3) Are any/all of the different universes of the multiverse supposed to have originated from the same Big Bang as our universe's (and if so, why would they constitute a different universe than ours)?

The Big Bang cosmology describes the evolution of the interior of "our bubble" universe, whereas the multiverse corresponds to the evolution of an eternally inflating Universe.

> 4) […] Yet if there are 10^500 other universes that could potentially be expanding into ours, wouldn't the "stuff" from those universes potentially make our universe much more interesting than the barren wasteland depicted by the aforementioned writers?

It seems you are referring to collisions between bubble universes. If the (eternal) inflation picture is correct, then presumably there have been a huge number of collisions of our bubble with other bubbles that "nucleated" nearby. However, according to the same picture even just our own bubble universe should be incredibly huge, far far larger than what we observe. Most such collisions (unless they occurred very early in our universe) would affect only an extremely tiny fraction of our bubble, so the amount of potentially interesting (i.e., probably catastrophic) mixing is very limited. Moreover, there would be a very limited region surrounding our bubble in which other bubbles could nucleate and eventually collide with ours. The thickness of that region depends on how rapidly the walls of our bubble and nearby bubbles accelerate toward each other after nucleation (this acceleration need not be the same for every bubble). But still, it is clear that if no bubble wall can move faster than the speed of light within the exponentially expanding "outside" space there is going to be a limit to how far away a bubble can nucleate and eventually collide with ours. This means that almost all bubble universes would never collide with ours.

If our universe were a bubble universe, by now the wall of our bubble would be far far beyond our Hubble horizon, and any collisions happening "now" would never affect us nor ever become visible. The accelerated expansion within our own universe would insulate us even more, since any effects of a collision would need to outrun the accelerated expansion. So you're almost certainly safe…

29. **Marty Tysanner**
December 23, 2011

Hi Brathmore,

Sorry I didn't see your follow-up comment before posting my second comment. Anyway, if I understand your follow-up questions I *think* I may have answered them in that second comment. As far as things being over your head, that's fine and expected if you haven't studied this stuff before. It just means you will probably have to think about the answers and do a bit of follow-up study to get the main ideas. (Wikipedia might be a start, but in my opinion it's a mixed bag because some articles can feel a bit technical if all you're looking for is a conceptual picture.)

I just want to make one clarification. You said

> If I understood your post correctly, bubble universes are contained within the larger universe (which began expanding about 14 billion years ago) […]

The 14 billion years ago would apply to our bubble and not the total Universe (or multiverse). We would have no way of knowing when eternal inflation started; all such information would lie well beyond our horizon, outside our "protective" bubble.

30. **Brathmore**
December 23, 2011

Marty,

Thanks so much for your extensive posts. I think a key source of my questions in my second post was thinking, incorrectly, that our universe was the "total universe" and that the other "bubble" universes were contained in ours. Now its clear to me that what is meant is that our universe is just one bubble in an ever-expanding total universe that we don't observe. Thanks for the clarifications.

31. **Andy**
December 24, 2011

Marty, the volume measure is in no way natural. It's terrible – if you use a volume measure on an infinite volume you get nonsense results – the most likely place to be, for example, is inside a black hole. Gibbons and Turok wrote a paper on this, using the Liouville measure which in a sense is the only 'natural' measure available to the theory. Again, they found bad news for inflation, but using a much more mathematically rigorous way of defining measure.

Of course, all this discussion has been about eternal, vacuum tunnelling inflation instead of the now normal slow-roll paradigm which seems to answer a lot of these questions quite easily. It's still got bad probability results, but I think some people have been looking at this in other contexts (Ashtekar and Corichi?) to show it becomes probable in modified gravity.

32. **Anonyrat**
December 24, 2011

Correct me if I'm wrong, but in eternal inflation without string theory, the bubble universes all have the same laws of physics (e.g., the same values of parameters in the standard model), but the string landscape problem is that each of the bubble universes is in principle different, one could have two species of light fermions, and another could have six. ?? Thanks in advance.

33. **Peter Woit**
December 24, 2011

Anonyrat,

Yes, that's the problem with the inflation implies unpredictive multiverse argument. Inflationary theory just uses a single scalar field, one that has nothing to do with particle physics. If the eternal inflation universe exists, it's a rather boring one, endless similar universes with the same physics.

To ruin predictivity, you need string theory, where the single inflaton field is replaced by some huge number of moduli fields governing the size, shape, and other aspects of the complicated "string vacuum" configuration. These are required to have scalar fields that give different low energy physics. Whatever you think of the eternal inflation multiverse, there's no argument from it that gives the kind of multiverse promoted as an excuse for string theory's failure.

34. **Marty Tysanner**
December 26, 2011

Andy,

I agree with you that the canonical measure worked out by Gibbons and Turok is more rigorous and deserving of being called the "natural" measure. I probably should have called the volume measure the "simplest" or "most straightforward" measure. I thought the volume measure conceptually easier to understand at the technical level of the rest of my response, since my goal was to make a simple point. (I probably shouldn't have even brought the subject up…)

However, if you assume that eternal inflation began at some finite time in the past rather than being eternal to the past, then the present-day volume of the total Universe would not be infinite (unimaginably huge, yes; infinite, no). So if one bases a volume measure on these finite volumes and takes this imperfectly defined measure to be representative of the measure you would obtain for an ensemble of pocket universes, then I think what I wrote is reasonable, i.e., that it predicts our observable universe should almost certainly be somewhat younger than it is. This conclusion can be modified by changing how relative volumes are computed. Anyway, like I said, I probably shouldn't have brought it up; the subject of measures on an eternally inflating Universe is complicated and controversial, and I am certainly no expert on it.

As you noted (and as I mentioned at the beginning of my initial comment), my discussion was in the context of false vacuum eternal inflation. You mentioned a "now normal slow-roll paradigm which seems to answer a lot of these questions quite easily," but I'm not sure what you mean in particular. Are you referring to chaotic inflation? You need slow roll in any workable inflation model I'm aware of in order to get the right spectrum of CMB perturbations, i.e., [tex]\delta \varphi/\/\varphi \sim 10^{-5}[/tex]. For example, in the "open inflation" variant of false vacuum eternal inflation, right after a bubble nucleates the scalar field slowly rolls down the potential for a "long enough" period to give the desired number of e-folds of inflation *inside* the bubble; this is a *second* stage of inflation (the first stage being the metastable local minimum where eternal inflation occurs).

35. **Andy**
December 26, 2011

Marty,

First a seemingly technical but actually important point: the volume of the universe could still be infinite even if inflation is not eternal. It depends on the topology of the spatial slice on which you perform the calculation – if you pick your space-time manifold to be R^4 with spatial slices R^3 you will always have infinite total volume. You then define volume with respect to a fiducial cell volume at a given time, and test the evolution of this cell to show expansion etc. In a closed model, or a T^3 X R model, you certainly do have finite volume, so the volume measure could make sense, but in the R^4 case you don't. Now at first this appears to be just splitting hairs, but in constructing a measure on an infinite space, the measure itself will depend crucially on how the limit of infinite volume is taken, and you can effectively sneak in any prejudices you like by taking the limits in different ways, something I think you're hinting at when you talk about how the relative volumes are computed.

When talking about slow roll I'm really meaning an inflaton modelled as a scalar field with a pure quadratic potential, which is what G+T talk about (admittedly a lot of my understanding comes from their paper, so I'm probably biased). Here you do see that although relative volumes do depend heavily on initial conditions, every point in the phase space does come to an end of inflation (or rather crosses \phi=0 at which point inflation is by hand brought to a halt as the inflaton couples to other fields here – this part always seems hazy). Likewise, the space-time has a singularity in the infinite past – there is no eternal inflation. I never really understood why people seemed to add the vacuum tunnelling part to this – just set a scalar field with a quadratic potential and inflation occurs. Of course, here I must admit my ignorance as there may well be a good reason for it, but for all I can tell you can't observationally distinguish between the models and the pure quadratic potential (ie just making the particle massive) seems the simplest to my mind.

36. **Marty Tysanner**
December 28, 2011

Hi Andy,

I agree with you about obtaining an infinite volume spatial slice in [tex]\mathbb{R}^4[/tex]. In fact, the example I mentioned of open inflation inside a bubble does just that. Open inflation is somewhat non-intuitive in that you have a finite bubble when volume is computed with respect to the exponentially expanding space outside the bubble, (i.e., where you have a scale factor which goes as [tex]e^{Ht}[/tex] with *t* the "cosmic time"), but by appropriate choice of slicing *inside* the bubble (e.g., as [tex]\mathbb{R}^3[/tex]) you obtain an infinite volume inside the bubble. The slicing is chosen so that just after nucleation and the *second* era of inflation occurs inside the bubble, the spacelike surfaces are hypersurfaces of equal scalar potential (homogeneous and isotropic); the later time hypersurfaces are the time evolution of those early-time hypersurfaces. Thus, the cosmic time inside the bubble is different than the cosmic time outside the bubble.

Outside the bubble, when I mentioned finite (but huge) volume for the total Universe, I was thinking of a particular kind of slicing, i.e., slices of constant cosmic time where the bubble volumes and the eternally inflating region are both finite for finite cosmic time; *t*=0 marks the start of inflation. I admit this isn't very general.

Slow roll inflation with the kinds of potentials that are usual in particle physics (e.g., [tex]V(\varphi) \propto \varphi^2[/tex] or [tex]V(\varphi) \propto \varphi^4[/tex]) don't seem to work well, in that they don't give the right amount and kind of inflation required for inflation to do the job it is designed to do — inflation typically ends too early and you don't get the right spectrum of CMB perturbations. Potentials that work better apparently need to be of the "hand crafted" variety, containing a long, gentle slope. (You also need [tex]\dot \varphi[/tex] initially small, which requires some way of obtaining that condition. Tunneling from a false vacuum provides one such way, as in the instanton formalism.)

Take the case of a slow-roll inflation model with no false vacuum or tunneling, but just a long gentle slope of the potential. I think this is what you were envisioning. Since the inflaton is a quantum field by assumption, it can behave differently in different regions. As the inflaton slowly rolls down the gentle slope, vacuum fluctuations can act on it stochastically, nudging it back up the slope in some regions (increasing the energy density) and thereby causing that region to tarry in its descent toward the end of inflation there. Inflation lasts longer in such a region than in one where the inflaton continues to descend normally or is nudged down the slope. Since the regions where the inflaton tarries will inflate more, the total volume of the Universe becomes dominated by them rather than by regions where inflation ends. Thus, you still get eternal inflation in this picture even though there is no false vacuum with tunneling.

37. **Anon_B**
December 31, 2011

Frank Close responded to the GHK letter in the London Times posted above. Point is around a "massive" vs. massless boson. Frank says GHK was massless (which is correct). GHK has stated such but claims the boson gets mass through leading order approximations to the 4 physical degrees of freedom.

GHK has not responded but certainly it will look like that below from Guralnik over the past summer.

The Times
Letters to the Editor
December 22 2011

Massive Boson

Sir, My letter specifically (Dec 16) referred to the "Massive" (sic) boson which bears Higgs's name.

GHK, the work of Gerald Guralnik, C. R. Hagen and Tom Kibble (letter, Dec 21), contains an equation for a boson without mass. While mathematically this might "amount to the same equation [as Higgs]", for physics the difference is … massive, in all senses of the word.

Only a massive boson can decay, and it is the decays that can prove the mass mechanism. Higgs first wrote the relevant equation for this decay in 1966. If GHK, or anyone else, made published mention of decays of the massive boson before that, I shall correct my book The Infinity Puzzle, where these arguments are outlined in greater detail. In the meantime I hope they continue to enjoy it.

Frank Close
Professor of Theoretical Physics
University of Oxford

Again, while we will have to wait to see if GHK responds, one can bet it will sound a bit like this below from Guralnik's recent APS talk/notes this past summer. It will be based on the fact that fundamentally the difference between massive and massless at lowest order is insignificant.

The Beginnings of Spontaneous Symmetry Breaking in Particle Physics — Derived From My on the Spot "Intellectual Battlefield Impressions"
Authors: G. S. Guralnik
(Submitted on 11 Oct 2011)

http://arxiv.org/abs/1110.2253

p. 9

…

Recently it has been claimed that the GHK paper does not have the "Higgs boson". This claim astonishes us. We, far more than any of the other groups, keep very careful track of the degrees of freedom of our scalar electrodynamics model. On the bottom of the right column of page 586 of the GHK paper are the three equations for the leading order approximations to the 4 physical degrees of freedom. We observe that the two degrees of freedom of the vector field combine with one scalar boson to form the three degrees of freedom of a massive spin one vector field. There is one remaining scalar field, 2 in our notation, which in our approximation has zero mass. That this mass is zero has absolutely nothing to do with any dynamical constraint including the Goldstone theorem. The Goldstone theorem, if valid here, would only constrain the mass of 1. The zero mass is an artifact of how we pick the explicit action and the leading order approximation. This is different from the Higgs paper in that he puts in an explicit pure scalar interaction. In a 4 dimensional renormalizable theory that interaction is limited to being pure quartic. As was our practice mirroring that commonly used by Schwinger and associates, we did not put in this explicit quartic term in scalar electrodynamics but were fully aware that such a term is generated in higher approximations. Ultimately because, of renormalization, the GHK choice of the action is operationally identical to the one used by Higgs.

In summary, our purpose was to show that the Goldstone theorem did not constrain physical mass in scalar gauge theories. We demonstrated this generally and in a specific example. The mass of 2 happens to be zero in leading order, but as was obvious to us and every other experienced field theorist of that time, this would change order by order as the theory was iterated in a manner closely related to how it changes in unbroken scalar electromagnetism.

…

Hagen also spoke about this briefly in the Sakurai lectures.

http://www.youtube.com/view_play_list?p=BDA16F52CA3C9B1D

Finally, this was found on ABC Radio. An interview with Lord Bob May of Oxford – not sure if he and Close know each other as they are both at Oxford. He comments a bit on his time at Harvard and with GHK.

ABC Radio National
December 24, 2011
Australian scientific superstars No.1 – Interview with Lord Robert May of Oxford
Robert May has achieved the pinnacle of scientific success: President Of The Royal Society, Chief Scientist in the UK, Order of Merit, the equivalent of three Nobel Prizes – yet he could have been a lawyer in Sydney like his dad, instead of Member of the House of Lords. This is the first of a series of interviews with top Australian scientists.

http://www.abc.net.au/radionational/programs/scienceshow/australian-scientific-superstars-no1—robert-may/3745700

….

But secondly I had this group of graduate student friends because they were more my age than the faculty people, and in particular a chap called Gerald Guralnik who, interestingly, along with Tom Kibble here in the UK and Higgs of the Higgs Boson, two years ago the American Physical Society gave its award essentially for the ideas of the Higgs Boson which were simultaneously arrived at by three different groups, the first of whom was not Higgs but was Kibble, Guralnik and Hagen. The other two groups proved the result in a special gauge. Kibble, Guralnik and Hagen had done it two years earlier, but Kibble is a really modest, meticulous person. He said, 'We're not publishing it until we have proved it with gauged generality.' So if you go to the website of people comparing this unusual…six people get the prize that it is thought may go to no more than three for a Nobel for the discussion, well, if it's going to go to any three, which three?

…

This Week's Hype

December 22, 2011
Categories: This Week's Hype

The Japanese are getting in on the string theory hype business, with KEK issuing a press release today with the title: The mechanism that explains why our universe was born with 3 dimensions: a 40-year-old puzzle of superstring theory solved by supercomputer. As usual for this kind of press release, the claim is that researchers at the institution issuing the press release have finally solved the age-old problem of string theory predicting nothing. In this case the prediction is that there are 3 dimensions of space (I think that, technically, this is a "post-diction"). According to the press release:

> A group of three researchers from KEK, Shizuoka University and Osaka University has for the first time revealed the way our universe was born with 3 spatial dimensions from 10-dimensional superstring theory in which spacetime has 9 spatial directions and 1 temporal direction. This result was obtained by numerical simulation on a supercomputer…
>
> … it is expected that superstring theory allows the investigation of the birth of the universe. However, actual calculation has been intractable because the interaction between strings is strong, so all investigation thus far has been restricted to discussing various models or scenarios…
>
> … It is almost 40 years since superstring theory was proposed as the theory of everything, extending the general theory of relativity to the scale of elementary particles. However, its validity and its usefulness remained unclear due to the difficulty of performing actual calculations. The newly obtained solution to the space-time dimensionality puzzle strongly supports the validity of the theory.
>
> Furthermore, the establishment of a new method to analyze superstring theory using computers opens up the possibility of applying this theory to various problems. For instance, it should now be possible to provide a theoretical understanding of the inflation that is believed to have taken place in the early universe, and also the accelerating expansion of the universe, whose discovery earned the Nobel Prize in Physics this year. It is expected that superstring theory will develop further and play an important role in solving such puzzles in particle physics as the existence of the dark matter that is suggested by cosmological observations, and the Higgs particle, which is expected to be discovered by LHC experiments.

This goes back to the pre-arXiv days, before many of our current graduate students were even born, but some of us are old enough to remember similar claims being made back in the late 1980s. For example there's the 1989 Brandenberger-Vafa paper claiming that string theory predicts 3 dimensions, using a "string gas" cosmology. I don't remember if there was a "finally, physicists find a way to make a prediction based on string theory" press release back in 1989 or not.

   Sang-Woo Kim, Jun Nishimura, Asato Tsuchiya
   (Submitted on 7 Aug 2011 (v1), last revised 7 Sep 2011 (this version, v2))

   We reconsider the matrix model formulation of type IIB superstring theory in (9+1)-dimensional space-time. Unlike the previous proposal in which the Wick rotation was used to make the model well-defined, we regularize the Lorentzian model by introducing infrared cutoffs in both the spatial and temporal directions. Monte Carlo studies reveal that the two cutoffs can be removed in the large-N limit and that the theory thus obtained has no parameters other than one scale parameter. Moreover, we find that three out of nine spatial directions start to expand at some "critical time", after which the space has SO(3) symmetry instead of SO(9). "

5. **Chris W.**
   December 22, 2011

   Rather than say that such a result explains why space is 3-dimensional in some absolute sense, one should merely say that it explains how space can be 3-dimensional in this particular theory, which prima facie implies that it is n-dimensional with n ≠ 3 — that is, implies that the observed dimensionality must be a dynamical consequence of the theory, and may be highly contingent.

   Of course we are not accustomed to theories in which the observed dimensionality must be a dynamical consequence of the theory — or rather, we are accustomed to having considerable difficulty recovering the observed 3-dimensionality of space in such theories, and therefore tend to be skeptical of all of them on this basis alone. From that point of view this is an interesting result, whatever its place in the sprawling and profligate theoretical mess that "string" theory has become.

   If a result like this — and others that the authors would like to pursue* in this framework — turn out to be generic, it might point to a path out of the morass known as the string theory landscape. I admit that is a faint hope, but given prior experience it will always seem like a faint hope until the path is actually found.

(* See their conclusion: "The next step would be to show that the four fundamental interactions and the matter fields appear in our universe at later time. For that we need to change the scale from the Planck scale to the TeV scale, which may require constructing a framework similar to the renormalization group or the low energy effective theory.")

6. **Peter Woit**
December 22, 2011

Chris W.,

You can come up with string theory models with any large number of spatial dimensions from 1 to 9 (10 w/M-theory). A large number of people over the last 25 years have come up with "arguments" to pick out 3, Brandenberger-Vafa is one example, Bee gives some others. I don't see what's supposed to be interesting about finding yet another one, since there's no more reason to take it seriously than any of the others.

As for their "The next step would be…", that is just bizarre. What do they think thousands of very smart people have been trying to do for the past couple decades? Exactly this of course, with zero success. These authors write as if string theory were some new idea, and they're the first to suggest that one should try and connect it to reality.

7. **lun**
December 22, 2011

To be fair, the Brandenberger-Vafa paper is one of the most beautiful papers in the history of string theory. Its main results, including the 3d explanation, can be "explained to your grandmother". There is very little in string theory, old or new, that meets this criterion.

8. **MathPhys**
December 22, 2011

Mitchell Porter,

That's indeed the paper that I had in mind. I held it the original publication in my hands in a library many years ago, and I'm glad to know that it's now available online. Thanks for that and best wishes on the Holiday Season.

9. **Thomas Larsson**
December 23, 2011

Some 20 years ago I saw a paper where someone had measured the dimensionality of space, with the result D = 3+epsilon where |epsilon| is less than 10^-20 or so. What they did measure was the power in Coloumb's law, but the result was phrased as a measurement of dimensionality.

10. **Proudmemberofthecult**
December 23, 2011

@ Thomas Larsson

If you permit measuring Coulomb's law exponent as a measurement of space dimensions, then you go to about 1769 or so:

http://en.wikipedia.org/wiki/John_Robison_%28physicist%29

Incidentally, you can make sense of non-integer dimensions: see "fractal dimension". This arises in some triangulation models for quantum gravity.

11. **plm**
December 23, 2011

Thanks alot for the post Peter, the research looks awesome, groundbreaking.

The article to be published is cited on PRL with the same title as the preprint linked to by Anonyrat:
http://arxiv.org/abs/1108.1540
They do not seem to have posted the official version, accepted november 21, 2011.

The conclusion is quite gripping: they propose investigating nonperturbatively the appearance of a local field theory on commutative 4-dimensional spacetime at low-energy (which is the only parameter of their simulation it seems), and then appearance of matter and the 4 fundamental forces, or some gauge theory at least I guess. That is: researching consequences of type IIB strings from nonperturbative simulations in the IKKT model -I think.

Perhaps the most exciting aspect is trying to explain these observations theoretically, mathematically. There is research into relating various models of quantum gravity (Rivasseau has a recent arXiv article), and these computational observations may definitely give us motivation to relate perturbative and nonperturbative formulations, to find limitations of perturbative string theory, and perhaps relate string theory to loop quantum gravity, and eventually understand something about quantum gravity. (We may optimistically take cues from lattice QCD to inspire us.)

Of course these are pipe-dreams, and I am pretty much ignorant of the little knowledge actual researchers may have of what I mention -I plan to learn. But this is honest work for theoretical physicists and mathematicians to do, and we could be grateful for that, in the current situation.

12. **Chris W.**
December 23, 2011

Also see section 7 of Wikipedia's article Spacetime for a discussion of spacetime's dimensionality, with references to two papers by Ehrenfest and one by Tegmark. (The latter employs a partially anthropic argument.)

The PDF document linked in Mitchell Porter's comment slightly misstates the title of Ehrenfest's *Proceedings of the Amsterdam Academy* paper.

13. **Plecostimous**
December 23, 2011

In *The Road To Reality*, Penrose writes that classical N+1 GR spacetimes with N>3 are unstable under a theorem he proved together with Hawking. Taking this together with T-duality wouldn't one then expect a spacetime with 3 large dimensions and 6 with Planck-scale ones to be dynamically stable?

The classical instability would presumably cause one of the existing small dimensions to collapse in on itself if it spontaneously became much larger than the Planck length, and by T-duality one might expect a natural corollary of this to be that it can't get much smaller than the Planck length either, as that would be dual to some other geometry with with more than 3 spacial dimensions and would likewise be classically unstable.

(One might further expect spacetimes with *fewer* than 3 large space dimensions to be vulnerable to the spontaneous expansion (or contraction) of one of their Planck-scale dimensions due to the absence of this instability.)

14. **abbyyorker**
December 24, 2011

    Layman question:

    Does anyone know whether this result, or its antecedents, would hold for all of the 10^500 false vacua? Or is that huge ambiguity just a perturbative artefact? If so, why so much dismay about the unscientific nature of the anthropic "landscape" if it will go away when when we do non-perturbative calculations?

15. **Peter Woit**
December 24, 2011

    abbyyorker,

    The IKKT matrix model the authors are using dates back to 1996, one of a class of proposals for a fundamental non-perturbative definition of string theory from around that time. These proposals don't seem to lead to low-energy physics that looks anything like the real world, so most people abandoned them after a few years.

    The landscape models of the last decade use a different philosophy. They don't start from a fundamental non-perturbative theory, but just assume the existence of such a thing, with various properties, and then try to construct "string vacua", which are supposed to be consistent low-energy solutions to the unknown fundamental theory, whatever it is. One can certainly take the point of view (Gross and many others do), that until you actually find the fundamental theory, claims about the "landscape" of solutions to it shouldn't be taken too seriously. The problem is though that if you take that point of view, you can no longer say much of anything at all about how string theory is supposed to connect to reality.

16. **Plecostimous**
December 24, 2011

    ^^^ meant to write "a spacetime with 3 large dimensions and 6 Planck-scale ones"

17. **Cesar Laia**
December 26, 2011

    About Kaku, funny response here: http://bigthink.com/ideas/41681

    It has some gems, such as "or finding experimental deviations from Newton's inverse square law which may prove the existence of parallel universes".

18. **Peter Woit**
December 26, 2011

    Thanks Cesar,

    I also like Kaku's definition of a superpartner: "higher vibration of the string".

19. **Bernhard**
December 26, 2011

    Would be interesting to know who, according to Kaku, would win the bet if SUSY were discovered, since he seems to make no distinction between it and strings.

2011: A Banner Year for Hype

December 30, 2011
Categories: This Week's Hype

Since every blogger seems to feel it necessary to have a year-in-review posting, I thought it appropriate to point out that 2011 has been a banner year for string theory and related hype, with about twice as many editions of "This Week's Hype" as in previous years. One reason for this is the LHC. When talking to journalists, string theorists are rarely willing to admit that the hopes of the past couple decades that string theory would make some predictions about LHC energy scale physics turned out to be a dismal failure, and this tends to lead to confused headlines. Besides the LHC though, there's a huge on-going effort to promote other bogus "tests of string theory". This has been going on since string theory's lack of testability problem first started to get a lot of attention a few years ago. I see no reason for either of these two driving forces to weaken in 2012, so expect more editions of "This Week's Hype" next year.

String theory supported by early LHC heavy ion results

Cosmologists expect the LHC to turn up evidence for the multiverse

M-theory shows that the LHC will be the world's first time machine

Neutrons could test string theory

Octonions explain string theory

The LHC tests string theory (more heavy ions)

M-theory is a big success, predicts behavior of 4 qubits

String theory and heavy ions, yet again

Multiverse observed in the CMB – Not

String theorists suggest space wormholes possible

String theory testable with black holes and pulsars

String phenomenologists come up with predictions testable at the LHC

Superluminal neutrinos evidence for string theory

Superluminal neutrinos could be explained by string theory

CMS multi-leptons provide evidence for SUSY

A new laser will tear apart the fabric of space

A nuclear clock will test string theory

The LHC will decide between two versions of SUSY

String theory research is going well, only problems are Garrett Lisi, Lee Smolin and Peter Woit.

Gordy Kane predicts the mass of the Higgs using string theory, just days before the announcement

Superstring theory predicts three space dimensions.

Comments

1. **chi_b(3P)**
   December 30, 2011

   Then again, one could blog something about the chi_b(3P) aka real physics.

2. **Yatima**
   December 30, 2011

   Let me take this occasion to wish everyone in Physics and Math community, whether their soul is laden by a large ego or not, a successful 2012, with lots of sigmas on the experimental front and important insights on the theoretical one.

   Hopefully the fiat money economy won't have collapsed, another few unnecessary wars won't have been kicked off and various civil liberties that one thought written in stone won't have been flushed down the drain.

   Godspeed – and Good Luck!

3. **Quantumburrito**
   December 30, 2011

   To me it seems pretty clear that string theorists are getting desperate and are sparing no efforts and platforms to peddle their wares (As you noted, Gordon Kane for instance has had at least three articles about the apparent "testability" of string theory in the last month or so alone). The question is how long this attempt at PR will last and how willingly a credulous public will buy the claims. Sadly, almost anything found by the LHC will be seen as a successful prediction of string theory and the public will have scant capabilities to call out the shenanigans.

4. **BJM**

December 31, 2011

chi_b(3P),

The title of this blog announces a different mission than just blogging about real physics.

While I enjoy reading popular accounts of cutting edge physics here and elsewhere, this blog provides a valuable service in pointing out "physics" that goes well beyond the edge.

5. **Zarrax**
December 31, 2011

Why do you have nothing to contribute to physics other than dragging down string theory? I am not saying there are not grounds to object to string theory, but as a physicist shouldn't you have some worthwhile research of your own to help the field in some way? We get it, string theory is untestable… but why on earth do you have to say the same thing over and over and over again, day after day, month after month, year after year? Don't you have any interesting ideas to share with others? It really is disturbing to see that there's someone out there who tried to be a successful theoretical physicist, failed (in the sense you don't seem to be adding any substantial research of your own), and now just lives to drag down string theory.

6. **KFP**
December 31, 2011

Zarrax,

Someone has to do this job such that the string theory research won't such in all the money and attention.

Also, why should we tolerate people like Brian Greene promoting a speculative idea like string-theory and multiverse as the only sensible answer to the everything.

I am glad somebody has the courage to do it.

7. **Brian Dennehy**
December 31, 2011

Zarrax,

It is called a `culture of criticism'! In a typical fluff piece about string theory you will seldom find much questioning of some of the zany claims some of these guys make. Regardless of what you think about Peter Woit's research record I think that this blog performs a very valuable function. Your use of the word`failed' in regard to him really does mark you out as someone who is involved in some of the stuff criticized here and ruffled by what you've read. You should learn to be able to accept criticism of your research and be able to engage with it. It is one of the most valuable parts of science.

8. **DaveC**
December 31, 2011

Someone (Zarrax) had a bad year.

Hype is in overdrive throughout science nowadays. I wish there were someone as intelligent, well informed, balanced and independent as Peter collecting examples of hype in condensed matter physics, for example. But there isn't and there probably never will be, because we all have out-yell our competitors in front of the program managers and editors to get funded and published, and those famous guys who are masters of hype are the reviewers of our manuscripts which will never get into Science or Nature if we don't suck up.

Happy New Year to my favorite blog!

9. **Peter Woit**
December 31, 2011

Zarrax,

I've been working for quite a while now on trying to understand relations between quantum field theory and the Langlands program in number theory. This has been going quite well and I'm in the middle of writing a paper about it, which will likely be titled "Automorphic Representations and Quantum Field Theory". A crucial part of the story involves the ideas about BRST and Dirac Cohomology which I've written about here

http://www.math.columbia.edu/~woit/brstdirac.pdf

Now that I can see where this project is going, I'll soon finish that paper finally. You may not like any of the ideas I'm investigating, but I do spend most of my time on them, very little thinking about the multiverse or string theory.

I agree that "string theory is untestable" is a boring idea to keep repeating. However, until string theorists stop issuing press releases claiming to have found a test for string theory, having some place which explains what is wrong with these press releases seems to me to be worthwhile. The day someone else takes up that task, I'll happily stop doing it myself. Even better would be for string theorists to stop issuing the bogus press releases, or for the science media and their colleagues to start laughing in their faces when they try and do this. I think we're getting to the latter, if not the former.

10. **Peter Woit**
December 31, 2011

chi_b(3P),

I try to stick to blogging about topics where I think I have something to contribute that isn't done better somewhere else. For lots of particle physics news, as in this case, I don't have anything insightful or interesting to say, and I expect that interested readers are also reading blogs that cover these topics very well (three good examples are Resonaances, Matt Strassler's blog, and Tommaso Dorigo's blog).

11. **Peter Woit**
December 31, 2011

Yatima (and all),

Best wishes for the New Year!

One of my New Year's resolutions will be to finally update my home page, that should get done very soon. Another will be to finish the BRST paper, and get the new paper I'm writing in some reasonable shape for others to read, maybe before classes start.

I'm very much looking forward to 2012. The ideas I've been working on for the last couple years are coming together enough to begin writing about them. Last fall our visiting Eilenberg lecturer was Dick Gross, and I learned a huge amount about representation theory and number theory from him. This spring, Edward Frenkel will be here, lecturing on the Langlands program and QFT, and I'll be teaching again our graduate course in representation theory. We should finally find out for sure about the Higgs. A very promising year indeed.

12. **Zarrax**
December 31, 2011

It's not really that believable that you will suddenly produce some major research after all of this time. Of course only time will tell how significant "Automorphic Representations and Quantum Field Theory" will be. But as they say, one's past research record is often the best indicator of one's future accomplishments. The fact that this work seems to have been dragging on for years without you producing much else is not encouraging.

On the other hand, you have kept up this blog full-throttle since 2004. You are highly motivated about some things at least. It is sad that this is what you care about the most, dragging down successful physicists because they may not deserve it. I don't think that lowering others raises you. Even if their success is unjustified. Maybe you should try to do something more constructive with your time, as this blog really does make you look like you're embittered over your position in the physics world and are trying to take others down who you don't think deserve it. Surely you can do something better with your time (and I don't mean gradually writing a math paper over a decade or more).

13. **Zarrax**
December 31, 2011

By the way, I don't agree with this idea that you need to counteract the publicity people like Brian Greene or Michio Kaku get… in the math and physics world many people do understand the limitations of string theory in the current form, and it has reached the mainstream media to some extent too. Does it really matter so much that Brian Greene can show up on TV wearing a trenchcoat and BS about the universe? I mean, I too roll my eyes when I see that kind of thing but I am not going to make a mission out of tearing him down.

14. **Brian Dennehy**
December 31, 2011

Zarrax,

You're coming across as rather bitter, nasty, and petulant. Your comments are terribly gauche, it makes for bad reading.

15. **Peter Woit**
December 31, 2011

Zarrax,

I don't know who you are, but if you think I'm "embittered", you definitely don't know me. Since you're hiding behind anonymity, we can't examine the record of your research and how it's going, but you sure sound like a string theorist embittered by the failure of the research program you devoted your life to, upset that this failure is becoming publicly recognized. If you want "embittered", take a look at Mike Duff's rant about me, Lee Smolin and Garrett Lisi.

It's New Year's Eve, and I'm not anonymously posting personal attacks on people I disagree with, but reflecting on how lucky I've been in life, rewarded professionally, personally and financially in all sorts of ways that I deserve much less than many others. Life is very, very good, right now, has been for many years, and there isn't anyone in the physics community I'd willingly change places with. To the extent anyone has managed to get professional or financial rewards from multiverse mania or making bogus claims about string theory, that's fine with me. My arguments are with their science, nothing else.

16. **Douglas Natelson**
December 31, 2011

DaveC, I try, though I tend to focus more on nano-hype.

17. **Henry Bolden**
December 31, 2011

You can tell it's the holiday season – Peter is generously allowing the nasty (and hence entertaining) comments to be posted.

18. **Zarrax**
December 31, 2011

I'm actually a mathematician in a field not related to string theory… but I think your wishful thinking does go to your true motives… you want to gloat in the failure of string theorists. This is your right, I suppose, but it doesn't really engender much respect.

Anyhow, one point I do agree with, is that it's getting a little late in the day of New Year's Eve to be arguing about this stuff. So have a happy holiday, and have an even better 2012…..

19. **Anonymous**
December 31, 2011

Zarrax:

If string theory were currently a worthwhile, productive research program, I don't believe one lone blogger criticizing it would really have attracted much attention, especially when the lone blogger was a not particularly famous mathematician/physicist. I know a few physicists who have held very dim views of string theory for some time, but for various political reasons have kept relatively quiet about this. Peter Woit has merely been playing the role of the child in the story of the *Emperor's New Clothes*, pointing out something that many people believed but were not particularly eager to be the first to point out.

20. **David Berman**
January 1, 2012

Its a new year so I can break my resolution (of last year) and make a post, something I don't intend to do often since I always end up getting frustrated. I for one feel very happy with progress over the last few years in string theory (more on this later). I suppose my string theory colleges are always a bit mystified by Peter's unwillingness to acknowledge progress that perhaps we subscribe his motivation for the Blog to other reasons. I won't speculate and like some many welcome some genuine work. But will Peter acknowledge how the attention of the relationship of the Langlands programme to quantum field theory came about through M-theory. In particular Witten's work which was clearly inspired by deriving S-duality from in quantum field theories through fivebrane compactifications. I suppose this is what is annoying, the insights into quantum field theory that keep rolling on are obviously valuable and come from string theory; our understanding of quantum gravity with holography and other developments continues; the applications to things like condensed matter systems, quark gluon plasmas and a whole host of things. Yes string theory deserves the headlines and progress contunes. I have no idea what weird eureka insights readers of this blog want but do people imagine that all those string theory papers really have no value? Do people imagine that the strings conference is like a meeting of the illuminati to discuss world domination through a conspiracy or perhaps actually many people are doing interesting work. If they or their universities publicise it then well and good, in an environment where society may values engagement with the sciences then communicating the enthusiasm we have for science if good for everyone. I congratulate my colleges for engaging with the press positively.

Happy New Year to all and looking forward to another productive one

David

21. **d4string**
January 1, 2012

Zarrax is very wrong ! Having more skeptical people like Peter Woit is necessary. New graduate students should become familiar with these sort of failures of string theory, and they should not believe all the hype. In the end it should help channel the research to more meaningful direction even within a string theory approach.

22. **MathPhys**
January 1, 2012

Happy New Year, Peter and all!

23. **CIP**
January 1, 2012

David Berman,

Did you look at the list of links in Peter's post? Do you really think all that hype was justified by this year's (or decade's) progress in string theory? I don't hear Peter saying that string theorists have produced nothing of value – but I do hear him pointing out (again and again) examples of claims unjustified by the facts. If guys like Kane and Duff would stop spewing BS, Peter would quite likely feel free to stop saying "BS." Figuratively speaking.

24. **BJM**
January 1, 2012

Re:
Zarrax : " Does it really matter so much that Brian Greene can show up on TV wearing a trenchcoat and BS about the universe?"

I am a consumer of these types of shows, and nowhere near knowledgeable enough to sort out the wheat from the chaff. This blog helps me enjoy the theatrical "what if's" while keeping my feet on the ground. I and apparently many others find this blog useful. There are other blogs out there for you.

25. **Peter Woit**
January 1, 2012

David,

You're making up straw-man arguments that I never make, and you're completely ignoring the ones I do make. Do you really think that the material linked to in this blog entry can be justified as an honest and accurate portrayal of string theory research? Is it honest or accurate to go to the press and claim to have found a "test of string theory", or is that a way of trying to mislead people about the fact that string theory unification is an idea that appears to have failed, as evidenced by its inability to predict anything about anything? String theory was sold to the public as a way to unify physics, but that's a project that has devolved into the pseudo-science of the landscape. I think you and most of your colleagues know this very well, and it would be healthy if you were to admit that and move forward, instead of complaining that I'm pointing this out.

I'm a fan of Witten's work that relates various QFTs to Khovanov homology and geometric Langlands (and often write about it on the blog), and sure, he uses M-theory and string theory ideas in that work. The exotic 6d QFT behind a lot of this plays a crucial role in M-theory, but it's also an important question to understand to what extent it can be understood independently of M-theory. While Witten does make an attempt to popularize some of this material (see his public talks on knot theory), and retains hopes for string theory unification despite its problems, he doesn't descend to misleading claims that what he is doing provides a "test of string theory".

Sure "string theorists" are often doing interesting things, although more and more often they have little to do with string theory. I noticed that several participants at Strings 2011 pointed out that few of the talks actually were about string theory. People doing good work in this area should think hard about the kind of hype that's in these links and whether it's really a good idea for them to try to defend the indefensible because it's coming from their "side". Duff is quite right that "string theory" is getting a bad name among the public and granting agencies, but it's largely because of the hype, and his idea that the way to fight this is with more hype is completely backwards.

26. **Ryan Budney**
January 1, 2012

Happy new-year Peter. I always enjoy reading your blog. The anonymous trolls are a bit annoying at times but I suppose having a small number of them about isn't unhealthy. That's the closest to a positive I have to say about them.

27. **Bernhard**
January 2, 2012

Peter,

Happy new year. This blog is one of the best services for the HEP community I know. As far as I understand your critics of string theory as not yet "old story" since, as you said, the string-hype goes on non-stop and a healthy critic counter-weight to all the lies being written everyday about bogus tests for string theory is still extremely valuable. You make many string theorists outraged and make enemies on the way, but critical and skeptical scientists (like they all should be!) support you and enjoy reading your views.

I´m looking forward to read your paper. One thing however that is predictable to me is that no matter how good you can make it, wait for unreasonable critics to it from the people that are angry with you.

Looking forward to 2012´s first entry.

28. **chris**
January 2, 2012

Peter,

keep up the good work. the hep literature is full of junk and you are one person dedicated to weeding it out. that is much more helpful than contributing to accelerate the growth rate of phys.rev. volumes until it reaches the speed of light 🙂

happy new year.

29. **Anonyrat**
January 2, 2012

Zarrax: It is my guess that if there was a headline "5-brane compactification in string theory leads to mathematical breakthrough" Peter Woit would likely not take issue with it. He might even promote it. Look at the two dozen headlines featured in this blog post, and compare them with this hypothetical one, however.

30. **Mike**
January 2, 2012

I have a feeling this will be the year that physics gets a lot of the experimental data it needs to sort out many brain twisters – we know the LHC will be the one to watch but I think we will see data from other simpler experiments come in that help us understand the universe better. Reminds me of a talk James Van Allen gave in the early 90s at a small satellite conference – "How to do science for (much) less than a million dollars". Thanks to Peter for providing such a fascinating discussion with this blog!

31. **Eric**
January 2, 2012

Peter,

Up until the end of last year, your position was that the Higgs probably did not exist and you promoted this idea relentlessly on your blog. Yet, it seems that it does exists and has been observed. You have had a similar position in regards to low-scale supersymmetry. How will you react whenever the first signs of SUSY show up at LHC? Will you attempt to dismiss this as "more hype"?

32. **Rob R.**
January 2, 2012

> Re:

Ditto, my fellow layman! Happy New Year and keep up the good work, Peter!

33. **Peter Woit**
January 2, 2012

Eric,

That's nonsense. My position has never been that "the Higgs probably did not exist". For a typical posting about this from last year, see (from after the summer release of data)

http://www.math.columbia.edu/~woit/wordpress/?p=3960

where I write: "nothing yet has changed my view that a Higgs particle scenario and a no-Higgs scenario are equally likely. " It's definitely true that I've often pointed out the the no-Higgs scenario would be a lot more exciting for particle physics, and was often hopeful last year that this was what the data would show. Unfortunately, it definitely now looks like it's going the other way.

I continue to strongly doubt that the LHC will see anything like conventional SUSY. If something new does show up, that will be fantastic. And, sure, whatever it is, my prediction is that early ambiguous signals will be promoted as evidence for SUSY, whether it turns out to be that or something else…

34. **Eric**
January 2, 2012

Peter,

When all is said and done, and the LHC has made its discoveries in the coming years, I think there is a high probability that your so-called skepticism will be revealed to be nothing more that close-mindedness. Now, it really should go without saying that the job of a theorist is to consider all possibilities in nature, and not to simply reject certain ideas just because you don't happen to like them (whatever your motivations happen to be).

Given that the Higgs exists in the mass range 120-125 GeV, there are really only two possibilities: 1) Supersymmetry (or something like it) exists and solves the hierarchy problem, or 2) The Higgs mass is fine-tuned. Possibilities such as technicolor and warped extra dimensions would appear to be ruled out. So really, I don't think that stories about supersymmetry should be considered hype. Granted, if the Higgs mass is 125 GeV, the MSSM is a bit strained to obtain such a Higgs mass. However, this just means that the MSSM should be extended in some way.

It would serve you and your readers better to have real discussions about real physics rather than continually droning on and on about how bad all of those theorists are for being excited about their ideas.

35. **Sheldon Pherris**
January 2, 2012

Peter,
Happy NEW Year!!!! (N for Not, E for even, W for Wrong). All of the opinions and links available on this blog have been and continue to be an incredible resource!! Thank you.

36. **derek**
January 2, 2012

Happy New Year all!

To PW's outspoken critics: I am genuinely curious… Why the (perceived) obsession and anger? Some claim PW's arguments lack merit; some resort to personal attacks? Why? If that were the whole story then why feel threatened? Indeed, why pay any attention whatsoever?
It astounds me to see so many highly educated scientists lashing out at a handful of critics. Perhaps they could benefit from a high school level general science course. I always thought of science as a melting pot of ideas and criticisms, and experiment as the ultimate arbiter. Stop complaining and prove

37. **Zarrax**
January 2, 2012

Derek, I'm not especially angry or obsessed… I just am witnessing a blog going back to 2004 which says the same thing over and over again. So I wonder if the source of Woit's obsession (and it is clearly an obsession) is some bitterness over his career. Maybe it is, maybe it isn't. But you have got to admit it's a little weird for anyone to beat this same drum thousands of times. There has to be some very serious motivation here, and to the outsider it's not so clear why anyone would be so obsessed with this one issue.

38. **Bob Levine**
January 2, 2012

from Zarrax: "There has to be some very serious motivation here, and to the outsider it's not so clear…"

Well, for starters, how about the enormous lack of intellectual candor and the embarrassing drop in standards of integrity in theoretical physics which have accompanied the dominance of string theory (sociologically, at least) for much of the past four decades? Peter adduces massive evidence (in the form of the hype-list 'Wall of Shame' he provides in the OP for this thread) that a sizable chunk of the string theory community has made grotesquely exaggerated claims for the framework's predictive success, and your response is that it's most likely career bitterness?? The field reflects serious intellectual corruption and duplicitousness, so blame the messenger and make snide insinuations about what his motives could be… *excellent* reasoning, Zarrax.

39. **John**
January 2, 2012

Zarrax, why are you intent on casting a reasoned objection as a pathological obsession? You might have a point if Peter just engaged in empty rhetoric against ST, but that clearly isn't true. Maybe you should engage the actual argument rather than casting aspersions…

40. **Anonymous**
January 2, 2012

Zarrax says:

But you have got to admit it's a little weird for anyone to beat this same drum thousands of times. There has to be some very serious motivation here, and to the outsider it's not so clear why anyone would be so obsessed with this one issue.

I don't think it's strange at all. The string theory hype has not stopped, so Peter Woit is not about ready to stop his campaign against it.

41. **Eric**
January 2, 2012

I'm curious, why is it such a problem if string theory gets a lot of attention and/or hype? I think this would happen anyway, if not with string theory then with some other area of physics. Up until about 15 years ago, most of the hype went to quantum mechanics and relativity. String theory fulfills a public niche for those who are interested in physics "on the edge". At the very least, this serves to get people interested in physics. On the other hand, blogs such as this one* and Smolin's books tend to create a negative impression for physics and physicists in general. If this infighting is left unchecked, this will ultimately have a very negative impact on scientific funding.

* I should say that this only applies to some of the posts. Many of the other posts are actually quite good and provide a forum for discussing real problems in physics.

42. **Bob Levine**
January 2, 2012

OK, Eric, try this on for size: the real problem with the Enron catastrophe wasn't the depth of the dishonesty in the financial sector's business practices or the corruption in the political system of this country that allowed it to happen in the first place; it was all those damned Wall Street Journal investigative journalists who kept nosing deeper and deeper into the story until the horror stories about Skilling and other executive felons emerged. It really made the American financial sector look awful, didn't it—-shook up our faith in the system and put the economy at risk. Does this interpretation sound absurd to you? Well, read over your own rationale in your previous note and tell me exactly how your spin on string theory/landscape hype differs in principle from that take on the financial crisis of a decade ago. Your story sounds *exactly* like the analysis of the Enron fiasco I just presented.

If string theorists go on making ludicrous claims, pretending that they really *can* predict anything substantial about the physical world, continue ad nauseum about how ST is still the 'only game in town' for unifying electroweak/QCD and gravity in a single formalism, and crafting press releases which in some cases border on (and into) fraudulence—when the truth is that there has been exactly zero progress on any of these fronts—then Lee Smolin and Peter are the baddies for spoiling people's profitable credulousness? Are you *serious*??

43. **Eric**
January 3, 2012

Dear Bob,

As a point of fact, string theory is the only known way to unite quantum field theory with gravity. In addition, it is possible for specific string vacua to make predictions. There is absolutely no dishonesty in any of the claims made by string theorists. In fact, this constant suggestion that string theorists somehow control some evil empire bent on deceiving the public and controlling science funding is one of the reasons that most string theorists find this blog and Smolin's books highly insulting. String theory and string theorists have been under continual unjustified assault and attempted character assassination now for many years. As best as can be ascertained, these attacks originate from those who have some sort of inferiority complex or feelings of jealousy in regards to high energy theorists.

44. **lun**
January 3, 2012

In 2012 it looks like loop quantum gravity has the edge on string theory
[on over-inflated misleading press releases]

Only 3 days into the year and LQG is already experimentally testable by "measuring Hawking radiation precisely".

45. **Peter Woit**
January 3, 2012

lun,

You're right, this seems to be an attempt to have LQG compete with string theory on the hype front. I'm curious if there's an actual press release behind this, if anyone has seen such a thing, let me know.

46. **Lee Smolin**
January 3, 2012

Dear Eric,

Since you mention my books, plural, I can't help but ask you a question:
Please tell me exactly which passages of my first two books in your view "tend to create a negative impression for physics and physicists in general."

I have been impressed that none of the people who read my third book as critical of string theory have ever expressed any appreciation for the very hopeful and positive picture of string theory drawn in my second book. Nor do most credit the first book for its introduction of the concept of the landscape.

Then lets go back to the third book, and please tell me exactly which passages in your view create a negative impression of physics or physicists in general.

Exact quotes would be appreciated.

The reason I ask these questions is that my third book has been brutally misquoted and mis-characterized by people claiming to disagree with it. I often find that people who think they object to something they think I wrote are actually responding to a rumor or a misquotation. I am happy to defend what I actually wrote, but I am very tired of being challenged to defend things I didn't write. Now it seems that the mis-characterizations of my third book are being sloppily attributed to all my books.

I can add that I have piles of emails and many reviews thanking me for writing books that give a positive and hopeful characterization of physics and physicists.

Thanks,

Lee

47. **Zarrax**
January 3, 2012

Lee: Even using the title "The Trouble with Physics" can create a negative impression of physics and physicists. I read your book (admittedly a while ago), and you really did sound very downbeat about the state of physics at that time. I don't remember passages anymore, but after I read the book it seemed clear that you felt physicists were on the wrong path.

Also, since the first two books aren't prerequisites for the third, and there are many like myself who only have read the third book as it was more widely distributed, it would be an easy error for people to make to assume your other books had a similar viewpoint.

48. **Zarrax**
January 3, 2012

Lee: One thing I do remember about the (third) book was you mentioning that people were looking for the next Einstein as if they were waiting for the coming of the Messiah. This really does convey an air of desperation. And the way so many people gravitated towards Garrett Lisi when he came out with his theory of everything just confirmed that impression for me.

49. **Peter Woit**
January 3, 2012

Zarrax,

Einstein is a huge model of success for theoretical physicists, so, hoping for the "next Einstein" is something people have always been doing. I've not noticed more of this now than at any other period. Also, I don't know why you think "so many people gravitated towards Garrett Lisi when he came out with his theory of everything". That's not true if you're counting theoretical physicists.

Fundamental physics made huge advances in the years leading up to the mid-seventies, much less since then, and this is not a controversial statement. If you're going to write honestly about the state of the subject, it's part of the story.

50. **Giotis**
January 3, 2012

Lee said:

"Then lets go back to the third book, and please tell me exactly which passages in your view create a negative impression of physics or physicists in general."

"What we are dealing with is a sociological phenomenon in the world of academic science. I do think that the ethics of science have been to some degree corrupted by the kind of group think explored in chapter 16, but not solely by the string theory community."

and later

"It may seem strange to be discussing academic politics in a book for the general public, but you, the public, individually and collectively, are our patrons. If the science you pay for is not getting done, it is up to you to hold our feet to the fire and make us do our job."

The public should make you do your job?! Well I can’t think of anything else that could create a more negative impression for physicists.

51. **Peter Woit**
January 3, 2012

Giotis,

Lee’s comment here was directed at Eric’s complaint about his “books” and specifically asked for an example of what Eric was complaining about from either of his first two books, to justify the plural. You’re completely ignoring this.

If Eric wants to provide such examples, or Lee wants to respond to you or Eric, they can do so. But the argument over Lee’s controversial book is really not only off-topic, but very old by now, so please don’t anyone try and carry it on here. I really doubt anyone has anything new to say.

About this topic, I do want to say though that when I wrote my own book (mostly in 2002), I tried to stick to the science and avoid what could be interpreted as personal criticism of string theorists (perhaps not always successfully, but still…). If I were to write an updated version (not damn likely), I would be sorely tempted to go on at length describing some of the huge number of examples of grotesque, unprofessional behavior that I’ve seen from string theorists in more recent years. My current view is that if there’s any criticism of string theorist’s behavior in Lee’s third book, it’s way too mild.

52. **Eric**
January 3, 2012

Dear Lee,

The books I am referring to are “Three Roads to Quantum Gravity” and “The Trouble with Physics”, both of which contain attacks on string theory. The attacks in the first book aremore subtle and more-or-less attempt to shade string theory in a bad light in comparison to alternatives, while the attacks in the infamous second book are more direct. The chapter on the “Sociology of Science” is particularly bad. I think it’s fair to say that the second book is basically a reworking of the first.

Best,

Eric

53. **Eric**
January 3, 2012

Also, I should emphasize that my point is not to continue the string theory vs. alternatives fight, but rather that the attacks on both sides of this debate are counterproductive to the credibility of the physics community. This also includes Lubos Motl counterattacks. The physics community is all better served if we attempt to work together towards common goals rather than fighting over whose approach is better.

54. **Peter Woit**
January 3, 2012

Eric,

Note that you’re not providing any of the evidence for your argument that Lee asked for. About his first two books, your only complaint is that one of them makes string theory look worse (as an idea about quantum gravity) than alternatives. This has nothing to do with creating “a negative impression for physics and physicists in general.” Evaluating which scientific ideas are working is a standard part of doing science, and it’s not criticism of scientists to do this.

55. **Bob Levine**
January 3, 2012

@ Eric: “The physics community is all better served if we attempt to work together towards common goals rather than fighting over whose approach is better.”

Eric, I am having a *very* hard time understanding your conception of science. There is an empirical domain, and there are competing models of it, and if one of them is correct, then either (i) the others are wrong or (ii) some subset of the competing approaches are in effect mathematical variants of each other (think Heisenberg vs. Schroedinger in QM, or Feynman/Schwinger as reconciled in the work of Freeman Dyson). But the conflict between plum-pudding model of the atom vs. the ‘orbital’ (energy-level shell) model, or the analysis of cosmic rays as high energy photons (Milliken) vs. charged particles (Compton) wound up with the defeat of one model and the victory of another, as determined by the tribunal of predictive success. QM displaced classical physics the same way, and there were plenty of classical physicists who viewed the ascension of QM not as progress, but as a bitter defeat. Unfortunately, it is a fact that some approaches will be better than others, at the end of the day, and science’s job is to attempt to find the truth about the material world, not to be a big tent where everyone has to make nice with everyone else. Not everyone can be right, alas. And when one side has presented enormously far-reaching claims with virtually no hard results to back up those claims (look again at Peter’s hype list), the other side(s) can hardly be faulted for pointing out that no, you haven’t even come close to justifying those claims. Debating (civilly but *fiercely*) about ‘whose approach is better’ is a necessary *part* of working together towards common goals.

56. **Lee Smolin**
January 3, 2012

Zarrax,

“The trouble with X” is a recurrent trope in literary and popular culture that carries overtones of affection and bemusement. It goes back at least to a 1955 Hitchcock film “The Trouble with Harry”. I am sorry if you missed the allusion, but many readers got it. In any case I insist that the characterization of physics I gave was balanced. There was a whole part of the book devoted to new directions. I’ve gotten lots of email from young physicists saying my books-and that one in particular-inspired them to go into physics.

I don’t know how to answer the rest of your messages because its hard to argue with people who insist on their vague misunderstandings. I am pretty sure I never said anything like, “people were looking for the next Einstein as if they were waiting for the coming of the Messiah”.

And how does this answer Eric: “it would be an easy error for people to make to assume your other books (which they had not read) had a similar viewpoint.” Yes, and would you assume all of Herman Melville’s books were about whales?

Similarly, no one I know of “gravitated to Lisi”. Since you think many did, please name one.

Thanks,

Lee

57. **Zarrax**
January 3, 2012

Lee: In the book jacket of the edition I have it says “Smolin not only tells us who and what to watch in the coming years, he offers novel solutions for seeking out and nurturing the best new talent- giving us a chance, at long last, of finding the next Einstein”. While technically you may not have written the book jacket, you can’t really blame the reader for thinking as I do since the book jacket is supposed to summarize what the book is about. And I don’t really have the time to go through the book looking for other corroborating comments.

And here’s something from viii of the introduction: “To put in bluntly, we have failed. We inherited a science, physics, that had been progressing so fast for so long that it was often taken as the model for how other kinds of science should be done. For more than two centuries, until the present period, our understanding of the laws of nature expanded rapidly. But today, despite our best efforts, what we know for certain about these laws is no more than what we knew in the 1970s.”

Quotes such as these (which I found within five minutes) do convey a negative impression of theoretical physics and physicists, namely that they are stuck and don’t know where to proceed, and are desperately seeking the next Einstein. (And to Woit: Note that a string theorist apologist wouldn’t say the kinds of things I am saying.)

Lisi did have plenty supporters. I am not a physicist so I don’t know the inside scoop but I did see many quotations at the time from scientists who at least took him quite seriously. I think a google search should still find them.

58. **Peter Woit**
January 3, 2012

Zarrax,

You clearly have absolutely no idea what you are talking about re Lisi, or the problems of theoretical physics, and the only thing you can find to back up your “next Einstein” business is something you know Lee didn’t write. If you want to launch stupid personal attacks on me, that’s one thing, but it was my mistake to not follow my usual policy of deleting anonymous attacks on others.

It’s now been a very long while since there was an on-topic comment here, so I’ll close comments on this posting.

New For 2012

January 2, 2012
Categories: Langlands

To celebrate the new year, I've finally gotten around to updating my home page, and have updated the blog theme to the latest wordpress default. I've added an "FAQ" feature, which is still under construction and should get additions as I find time. Please let me know of anything that doesn't work.

This coming semester I'll be teaching the second half of our graduate course on Lie groups and representations, following on from Andrei Okounkov's first semester. A tentative syllabus is here, and I hope to find time to update some of my older lecture notes as well as write some new ones.

The time I've spent the last couple years trying to learn about the Langlands program has finally gotten me to the point of thinking I understand enough to write something sensible about what the relationship might be between automorphic representations and quantum field theory. I'll be working on that and preparing the graduate course for the next couple weeks.

One thing that was extremely helpful was Dick Gross's lecture series here last semester. Video of the lectures is on YouTube here. Gross is an incredibly good lecturer, and this series was aimed at explaining exactly many of the things I've been having trouble understanding about this subject. Anyone who seriously wants to understand the representation theory point of view on number theory and the Langlands program should find these lectures helpful.

This spring the Eilenberg lecturer will be Edward Frenkel, who will be lecturing on geometric Langlands and quantum field theory. In some sense he'll be picking up where Gross left off. He was at Gross's last lecture, and there was a ceremonial handing over of the chalk. Of course I've very much looking forward to these lectures, and I expect that there will again be video available.

Comments

1. **pah**
   January 2, 2012

   my two cents: the banner graphic is way too big now.

2. **Peter Woit**
   January 2, 2012

   pah,

   I kind of agree, but the header height doesn't seem to be easily adjustable. For now I'm going to try just getting rid of the header. Should find a new one anyway…

3. **jorge**
   January 3, 2012

   My 2 cents:Congrats, great updates, but text font of this theme is not as easy to read as was before (arial/verdana)

4. **Bee**
   January 3, 2012

   Which banner graphic? I can't see one (using Google Chrome, 1280×800). It looks pretty awful altogether with my browser. All the spacing is far too large. There is also no sidebar (should there be one?).

5. **Bee**
   January 3, 2012

   Ah, correction, there is a sidebar on the main page.

6. **Jim**
   January 3, 2012

   Clean and sleek, if spare.
   Uncluttered, yes. Sparse, perhaps.

   I shall miss your classic masthead graphic.
   This post *What's That at the Top of This Page?* might not make sense without it.

7. **plm**
   January 3, 2012

   I like the new design, thank you. There is alot of empty space though, in many places, too much I find.

   Regarding ideas on ARep/QFT can you say a bit more -about yours and others' if related, perhaps with references?

   Thanks.

8. **cormac**
   January 3, 2012

   Sounds like a frightening teaching assignment! All of my own teaching is at undergrad level, thank God, plenty of time to work on other stuff. Though it must be great to have such a convergence of teaching and research.
   Re new design, I'm puzzled by the WordPress idea of putting all the links, headings on the homepage only – a lot of first-time readers may never make it to the homepage
   Best wishes for the NY, Cormac

9. **Joel Rice**
   January 3, 2012

Just a tad surprised at not seeing a reference to Pertti Lounesto's work on Spinors and Clifford Algebras, speaking of which, a long time ago somebody swore that the curvature of spacetime can actually be seen around Chevalley's book on theTheory of spinors.

10. **nitpicker**
January 3, 2012

A tad puzzled why you say "Spin(2n) as a double cover of SO(2n)". For example Spin(3) = SU(2) is the double cover of SO(3) is the classic example of spin angular momentum.

11. **Peter Woit**
January 3, 2012

I may yet try out some other wordpress themes for the blog. This one does seem to have way too much white-space, and no way to include a reasonably sized header graphic. We'll see, don't be surprised if you see some odd appearance tests over the next few days or so…

Joel Rice, nitpicker,
I don't want to get into the intricacies of spinors here. In the course I'll certainly discuss the relationship between SO(3) and Spin(3)=SU(2) and their reps, but for the general case of SO(n) and Spin(n), even and odd n behave somewhat differently. In the even case there's a beautiful parallelism with the symplectic group which I want to discuss, so that's the case I'll work out in detail. If you take a look at the old lecture notes linked to, maybe you can see what I'm doing.

The Lounesto book is nice, but this course isn't aimed at physicists, so I'm not covering the Lorentz group, or anything about spin groups and spinors in the indefinite metric case, instead just sticking to the case of compact Lie groups and their finite-dim reps.

12. **Peter Woit**
January 3, 2012

Reverted to older default theme. The new one seemed to not be an improvement.

13. **Peter Woit**
January 3, 2012

plm,

The kind of automorphic representation/QFT relationship I have in mind was first discussed by Witten in his 1988 paper "Quantum field theory, Grassmanians and algebraic curves" (the QFTs in question are 2d CFTs). It's something that clearly has inspired many of the people working on geometric Langlands (but it doesn't have anything obviously to do with Witten's work in recent years on geometric Langlands, higher-dim supersymmetric QFTs, and S-duality). Before trying to write more about this on the blog though, I'd first try and like to get something detailed down on paper. It's a kind of long story, so requires much more than a blog entry…

14. **Low Math, Meekly Interacting**
January 3, 2012

I like spare more and more with every passing year. Perhaps internet-induced ADD has left me so impaired I'm incapable of resisting distractions, but there's something almost comforting now about a white space filled with nothing but clean black text.

15. **SteveB**
January 4, 2012

FWIW. The old (now reverted back to) scheme constantly pops up an IE8 warning about a macro running that may be slowing down my browsing experience. I don't notice any slow down however. The temporary large-white-space scheme did not have that. I do like having your links available on more than just the home page, which the old scheme accomodates.

16. **Peter Woit**
January 4, 2012

Thanks SteveB,

The Windows machines I have access to run IE9, and that seems to work very well with the blog. If someone knows more about the IE8 problem and whether something can be done about it, let me know.

17. **Coin**
January 4, 2012

"there was a ceremonial handing over of the chalk"

Frivolous question: Y'all still using chalkboards in New York? I thought everybody had moved to whiteboards by now.

18. **Peter Woit**
January 4, 2012

Coin,

We've moved beyond whiteboards, to a much better technology: chalk. 20 years ago someone had a whiteboard installed in our lounge. 10 years later, one of the most popular decisions of the dept. chair was to have it ripped out and replaced with a chalkboard. At this point, they'll have to pry the chalk from our cold, dead fingers….

19. **Douglas Natelson**
January 4, 2012

Peter, your comment about chalk put a smile on my face. When we moved into our new physics building down here, I specifically asked for a chalkboard in my office. A little dusty, but totally worth it.

20. **Chris W.**
January 4, 2012

SteveB and Peter,

I am using IE8, and I see the slow-running script warning only after *refreshing* the page after initially accessing the site. I also get it on the search results pages, so the problem appears to originate in a page template.

See this [Microsoft Support KnowledgeBase article] (ID# 175500), which offers an IE configuration fix (with the expected caveats).

21. **Chris W.**
    January 4, 2012

    PS: See [this detailed discussion] of the long-running script issue by web developer [Nicholas Zakas].

22. **Richard**
    January 4, 2012

    If a web site consisting of plain text and a few diagrams needs to *run scripts on the computers of every visitor who stops by to read that text*, stealing valuable computrons from unsuspecting bystanders, then something is horribly wrong. It doesn't matter if the script runs for a second or 20 milliseconds: anything more than zero indicates something is profoundly broken.

    Stop the insanity!

    PS Yes, comment previewing – a nice feature – is something that needs more than static HTML, for unfortunately historical reasons. But 99.99% of visitors aren't commenting.

23. **Peter Woit**
    January 4, 2012

    I found a machine with an older IE, and think I identified the problem. It's the WP-dTree plugin, which puts the archive listings in a nice hierarchical format. I turned off the feature that allows it to list all postings in a given month, and that seems to fix things. It looks like it was building a list of all 1000+ postings on the blog whenever the sidebar was loaded. Maybe there's someway to make it more intelligent, and only generate listings of posts when you actually click on the month. Unless that gets figured out though, for now I'll leave it as is, which just gives access to links allowing you to go to month-by-month archives, but no list of the postings in each month on the sidebar.

24. **Bernhard**
    January 5, 2012

    Off-topic. I read this article thinking would be of little interest more than a curiosity about Hawking´s birthday, but it managed to find time for hype:

    "The Large Hadron Collider at Cern, the European particle physics laboratory near Geneva, could do more than anything else to revolutionise scientists' understanding of the universe, Hawking said. The machine could find "supersymmetric" particles, which are partners of the more familiar subatomic particles. Such a finding would be "strong evidence" for M-theory, a version of string theory that describes gravity and the other forces of nature in an 11-dimensional universe."

    http://www.guardian.co.uk/science/2012/jan/04/stephen-hawking-women-complete-mystery?newsfeed=true

25. **Peter Woit**
    January 5, 2012

    Thanks Bernhard,

    I saw that, was mainly impress by Hawking's claim that the thing he spends the most time thinking about is women.

    If TeV scale SUSY would be "strong evidence" for M-theory, I guess that means no SUSY at the LHC will be strong evidence against M-theory, right?

26. **Giotis**
    January 5, 2012

    " I guess that means no SUSY at the LHC will be strong evidence against M-theory, right?"

    Peter let me answer with a metaphor. God could perform a miracle and split the red sea. If the red sea splits in front of your eyes then this of course would be strong evidence for the existence of God. If the read sea does not split in front of your eyes that would be strong evidence against the existence of God? Of course not.

    This is just a metaphor, so please don't reply that String theory is like a religion belief.

27. **Peter Woit**
    January 5, 2012

    OK Giotis,

    Bu you're the one comparing our ability to test string theory with our ability to understand the ways of God, not me…

28. **Jeff M**
    January 5, 2012

    Giotis,

    Sorry, but in a relevant version of the metaphor, it would have to be that god (or someone) told you that to prove it's existence it would part the red sea. Then, if the red sea doesn't part, it *is* evidence for the non-existence of god. You're version of the metaphor doesn't have a prediction in it, hence has no relation to the actual issue.

    Peace

29. **swh bday**
    January 5, 2012

    Hawking birthday and LHC and "hype". Once again, such comments have to be taken in context. It's a celebration of Hawking's 70th birthday, of course the press will be there, many eminent physicists (Lord Rees? Saul Permutter? What do *they* say about the multiverse/string theory?), many others. Hawking will naturally be asked about the LHC, and he can hardly say "it will be boring" or "it will find nothing of interest to me". He will naturally say something with a spin of "optimism for great discoveries". So what if it's optimism about M-theory, whatever. If anyone here wants to get carried away with "hype", that's a reflection on you, not SWH.

Wish SWH a happy birthday. He's made it to 70. How many thought he would make it to 30?

30. **Mihai Pomarlan**
January 5, 2012

Uhm, what's wrong with whiteboards? Is this another of those vynil vs. CD silly shibboleths?

31. **aa**
January 5, 2012

my whiteboard complaints:
the whiteboard in my office has stuff on there for so long
it requires scrubbing to get it off. i believe it was the correct markers,
but we didn't have the fluid and left it there and now it seems cemented on.

the markers i find are always f-ng dried out and not working

i hate the smell

32. **Jeff M**
January 5, 2012

Let me second aa on everything about whiteboards. Even as chair, I can't get blackboards put in anywhere, only whiteboards are allowed. It was explained to me that this was because blackboard dust could damage computer equipment, which strikes me as ridiculous nowadays.

33. **Mihai Pomarlan**
January 5, 2012

Yeah well. All the blackboards I've encountered in (high)school and university had chalk caked into them, I hate the chalk dust, and trying to eke out the last few lines out of a crumpet of chalk is soo-oh delightful. I guess all of these complaints go both ways.

What I didn't know is that this is an actual issue at all ("save our blackboards" vs "whiteboard power"). A more relevant issue, at least in my background (engineering) was {white/black}board vs. projector. Any course that is heavy on math should, imo, rely heavily on {white/black}board, as seeing the flow of a proof being written in front of you is much better than just taking glances at slides. Especially when the presenter, who was an otherwise decent prof, had a monotone droney voice that discouraged wakefulness. Alas, progress marches on and where I studied, most courses that were not math pure and simple succumbed to projection.

34. **Peter Shor**
January 5, 2012

There were, at some point (shortly after the introduction of whiteboards) whiteboards that actually worked—they would be erasable for years and years, and you didn't have to worry about markers drying on them and becoming permanent. We had some of those installed at Bell Labs. Unfortunately, the company that made them—I forget its name—seems to have been driven out of business long ago by companies who made cheaper whiteboards which don't work.

35. **srp**
January 6, 2012

Blackboards are great when they're completely pristine and you have a big piece of chalk. Once you start erasing, they become cloudy and messy. Whiteboards require some forethought or strong community norms to assure a supply of good markers, but they are so superior in terms of erasing (especially if you use purple) and allowing multiple colors that I have no nostalgia for the northeastern US preference for chalk.

36. **ateixeira**
January 6, 2012

" I guess that means no SUSY at the LHC will be strong evidence against M-theory, right?"

By sheer logic the answer is a resounding yes.

37. **swh bday**
January 6, 2012

" I guess that means no SUSY at the LHC will be strong evidence against M-theory, right?"

By sheer logic the answer is a resounding HB to SWH, regardless of what the blogosphere has to say about SUSY and the LHC.

38. **Attitude_Check**
January 6, 2012

A "fix" for a bad whiteboard is Pledge spray wax. Spray it on and wipe off. It will remove old marks and improve resistance to future permanence.

39. **Artie**
January 6, 2012

> srp says:

> Blackboards are great when they're completely pristine and you have a big piece of chalk. Once you start erasing, they become cloudy and messy. Whiteboards require some forethought or strong community norms to assure a supply of good markers, but they are so superior in terms of erasing (especially if you use purple) and allowing multiple colors that I have no nostalgia for the northeastern US preference for chalk.

The Germans have a good solution to the first problem you mention: every lecture room has a sink in it, and instead of an eraser you bring a squeegee with you. When the board is full, you wash it, and voila! it's pristine again. It sounds absurd, but once you get used to it, it works rather well.

My major objection to whiteboards is encapsulated in your third sentence: in my experience those "strong community norms" are almost impossible to enforce. A stick of chalk never spontaneously vanishes while you're writing with it.

40. **Chris Oakley**
January 7, 2012

I cannot believe that such archaic communication devices are being promoted on a blog that purports to deal with cutting-edge physics. Surely the modern solution to the problem is having neural implants in the cerebral cortices of both the lecturer and the audience. These can communicate via an A-to-D converter and WiFi to the lecturer's smartphone which uses Kinect to report his/her gestures, gestures which are then recorded and re-broadcast by an appropriate smartphone App ("iLecture", let us call it). This scheme would have the additional advantage that one could integrate images from arXiv, or any other digital source, without further processing.

41. **Mark Bennet**
January 8, 2012

I think there is something about cognitive processing which is present when a lecturer has to make notes on a blackboard – even if they are in three different colours on three different boards just to draw attention to the three different notations – and there are lines between them which get displaced when the boards are shuffled – even so – and students have to make notes:

… which is a very different learning experience to downloading the contents of a whiteboard onto your iPad – which is a route of engagement which does not necessarily pass through the brain.

In other words there are some deep questions about the best use of technology which have not been thought through.

But once upon a time paper did eventually take over from clay tablets as the note-taking medium of choice. So technological changes are possible, even in the 21st century.

42. **Nick M.**
January 8, 2012

> **"**If TeV scale SUSY would be "strong evidence" for M-theory, I guess that means no SUSY at the LHC will be strong evidence against M-theory, right?**"**

Unfortunately, no SUSY at the LHC does not necessarily mean no SUSY:

See the recent January 6th, 2012 New Scientist article Higgs result means elegant universe is back in vogue.
Oh well, the beat just goes on.

43. **pig with lipstick**
January 9, 2012

Physicists (or HEP theorists at least, but it's really a much bigger set than that) have been searching for "elegance" and claiming "elegance" in their various theories/solutions since the birth of QM and probably much before that. So what else can one reasonably expect from a science magazine article?

Emerging Trends

January 9, 2012
Categories: Uncategorized

Most of the lectures from this year's Jerusalem Winter School in Theoretical Physics are now available online. David Gross was the main organizer, and the choice of topics reflects his point of view on what is interesting these days in theoretical physics. The landscape and anthropics were pretty much completely suppressed (although Michael Dine did manage to slip in a mention, his slides are here). The idea of "string phenomenology", i.e. getting the standard model out of a unified string theory and saying something about particle physics has fallen by the way-side.

In his summary talk (given at the beginning of the conference), Gross described the same point of view he has promoted for many years now. He thinks something is missing in our understanding of string theory ("we don't know what string theory is") which will somehow fix the failure of ideas about string theory unification. This failure though doesn't matter anyway, since he now claims that string theory = QFT, based on gauge-gravity duality, and thus "string theory cannot be killed". It's very unclear how this equivalence claim fits together with the "we don't know what string theory is" claim, since we do know what QFT is (we have a very good understanding of the Standard Model). It seems that Gross would like to define away much of the troubles surrounding string theory.

One idea that Gross has favored for a very long time is that string theory is telling us that we must give up our usual notions of space and time, only recovering them in some limit. Two of the series of lectures at the school were about rather grandiose attempts to do something along these lines. There were three lectures by Erik Verlinde on his ideas about "emergent gravity". I continue to not be able to make much sense of this program. He invokes the reasonable idea that gravity is an effective long-distance force due to unknown fundamental degrees of freedom, which may very well be true. But he doesn't seem to have anything specific to say about the fundamental degrees of freedom strong enough to get anything new out of this. There were some ideas at the end about dark matter and dark energy, but it was unclear to me whether these go anywhere.

Much more interesting was Nima Arkani-Hamed's series of lectures on *Scattering Amplitudes and the Positive Grassmannian*, which he said could have been titled "How you get spacetime from the permutation group". The first lecture started with a philosophical introduction that he said he would limit to 5 minutes, but which went on for 40. Only the first two lectures are now online.

Unlike Verlinde's ideas, here there are very specific calculations involved. The starting point is recent progress in understanding perturbative amplitudes for N=4 SYM (and for more general gauge theories). These involve working in twistor space, and more generally working with variables such that locality and unitarity are no longer manifest. The basic mathematics and geometrical principles at work are quite different than the standard formulation of gauge theories in terms of local variables and gauge symmetry. As usual, Arkani-Hamed makes wildly enthusiastic claims. In this case, he claims to have finally found a remarkable new understanding of the subject, based on some combinatorial objects and dramatic new mathematical ideas. He does note that this still hasn't been written up, and that it's the third time in the past year that he has thought he had things understood, with the last two times not working out.

I'm quite curious to see where this all goes, although I confess that I'm planning on waiting a while to try and follow the details, since this is clearly very complicated work in progress, and a 4th or 5th iteration of the fundamentals may very well be on its way over the next few months. Arkani-Hamed is talking to mathematicians, including his colleague Pierre Deligne at the IAS, and says that he is moving from the old-style of Atiyah mathematics to a new-style of Grothendieck-based mathematics. I'm not sure what this means, but suspect that Atiyah's ideas are still in there (Grassmanians, twistors and toric varieties are subjects he has been very much involved with), and that the Grothendieck business may be an artifact of talking to Deligne, who comes from that tradition. Grothendieck was the master of generality, so his ideas can be applied to a very large fraction of mathematics.

Also lecturing on amplitudes, from a much more down-to-earth point of view, was Zvi Bern. For more from both Bern and Arkani-Hamed, see the program of the recent Amplitudes 2011 conference in Michigan. Slides from Arkani-Hamed's talk give a better idea of what he is up to, and Bern's slides contain his summary comments about the state of the subject. He emphasizes the connections between amplitude calculations and other fields and seems to be arguing for more attention to practical results, less to "symmetry, beauty and aesthetics". He worries that while "Today our field is one of the hottest ones around", the long-term future is less clear: "Is our field just another (albeit long lasting) fad?", so attention to results relevant to the rest of physics is important for long-term health.

Lots more "Amplitudes" conferences on the way, including Amplitudes 2012 in March, a conference at the Newton Institute in April, and one at the IHES in December.

   January 9, 2012

   "He does note that this still hasn't been written up, and that it's the third time in the past year that he has thought he had things understood, with the last two times not working out."

   I happened to check the Arxiv yesterday to see if he had published anything lately. I was wondering if he took 2011 off. Hopefully the third (or fourth) attempt at understanding the twistor approach works out.

2. **Proudmemberofthecult**
   January 9, 2012

   Of course, both Nima and Zvi are just returning to the Analytic S-matrix program… whose biggest success has always been string theory 🙂

3. **anon**
   January 10, 2012

   It's very unclear how this equivalence claim fits together with the "we don't know what string theory is" claim, since we do know what QFT is.

   There is a class of conjectured correspondences between an established theory and a conjectured theory. Is that so hard to swallow?

   Since AdS/CFT was invented, we have discovered a large class of new conformal field theories which have no known Lagrangians, but are defined solely in bulk space via a gravitational action coupled with certain matter fields. In this case, our understanding of the particular QFT is limited, but it becomes transparent when we look at it from the gravity/string side, in stark contrast to what you said above.

4. **Peter Woit**
   January 10, 2012

   anon,

I’m well aware of the conjectured set of correspondences. My point is just that Gross is engaging in a bit of sophistry here. He’s trying to avoid acknowledging the failure of unified string theories (“string theory can’t be killed”) by saying that now “string theory” is identical with a well-established, successful QFT, the Standard Model. But if you ask what’s the string theory equivalent to the SM, you find it’s one that “we don’t know what string theory is” applies to. You can legitimately make the argument that “string theory” is now a set of ideas deeply related to our ideas about QFT, but the controversial question is whether these ideas provide a fundamental theory or not, and Gross is playing word games with this question.

5. **Mimi**
January 10, 2012

This was just a winter school. It is not necesarily relevant for the development of String theory.

6. **piscator**
January 10, 2012

@anon:

it is statements like this that make me queasy about the whole applied AdS/CFT business. AdS/CFT is well defined (and well checked) for certain, mostly highly supersymmetric, examples. I do not accept that writing down (say) the Einstein-Hilbert action plus a U(1) gauge field plus a scalar field with an AdS minimum defines a CFT. We generally don’t know whether the bulk theory exists as a limit of string theory, whether there are any subtle instabilities, whether the naive rules of AdS/CFT work here, etc etc….

7. **Anonyrat**
January 11, 2012

In the last two minutes or so of the video of David Gross’ opening talk, Gross answers a question, arguing that string theory is the ultraviolet completion of quantum field theory. He says that our modern understanding of QFT is in the Wilsonian sense; and that is understood only in the infrared.

8. **Peter Woit**
January 11, 2012

Anonyrat,

This kind of argument by Gross is much trickier than he is making it sound. He won a Nobel prize for showing that non-abelian gauge theories are asymptotically free, so extremely well-behaved in the ultraviolet (it’s in the infrared that they’re hard to understand). There is no need for string theory as an ultraviolet “completion” of QCD; if it’s of any use in QCD, it would be in the the infrared.

The “ultraviolet completion of a QFT” argument only makes sense if you insist on coupling your QFT to gravity and quantizing gravity. Then you have non-renormalizability problems (unless Zvi Bern shows some version of supergravity is finite and you can use that…), which the string theory “ultraviolet completion” might solve for you. But, as Gross well knows, string theory unification opens up multiple cans of worms, ones he hopes to argue away with “we don’t know what string theory is”. This is not a rock-solid argument…

9. **pah**
January 11, 2012

Peter, just to clarify: There is no problem with QCD in the infra-red, all IR divergences cancel when you calculate a cross section or other physical observable. There is no need for help from string theory, or any other new physics, here. There are UV divergences, which are removed by renormalisation of course. We don’t worry about this, because we know that QCD is just a low-energy effective theory, and this is how low-energy effective theories behave. It is an open question as to what is really going on at high energy. This doesn’t matter for day-to-day QCD calculations, thanks to renormalisability.

I’m sure you are in agreement with this, just thought I’d spell it out.

10. **Peter Woit**
January 11, 2012

pah,

Actually I’m not in agreement at all. QCD is asymptotically free, which means that its ultraviolet behavior is perfectly under control. Put it on the lattice and you know exactly how to define the limit as the lattice spacing goes to zero. There are no problematic divergences (non-asymptotically free theories like QED are a different story). In the infrared, there’s no problem defining the theory, but it is a long-standing hope that some sort of string theory provides a useful effective description.

11. **pah**
January 12, 2012

Right, you’re saying that string theory (or whatever) might help us understand low-energy, non-perturbative QCD, which is otherwise well-nigh impossible to calculate with. And that would be great. But it would still just be the QCD Lagrangian, so nothing would have changed in that respect, it would “just” be an effective description of QCD in this domain.

At high energy the theory (QCD) actually breaks down and requires renormalisation to make any sense. The property of asymptotic safety does not change the fact that scattering amplitudes are UV divergent. Renormalisation can be thought of as taking from experiment (in the form of the measured coupling and masses at a certain scale) the parts of the calculation that your theory does not predict – basically the parts which depend on what is going on at very high energies. It is here where new physics must come in, hence all this talk of UV-completion.

12. **Peter Woit**
January 12, 2012

pah,

No. QCD is not “asymptotically safe”, it is asymptotically free. The theory does not break down at high energy, quite the opposite: it becomes more and more weakly coupled and under better and better control. Any divergences in your perturbation theory calculations are artifacts of how you do the calculation and we understand how to deal with them. You need to learn more about the renormalisation group.

Think about how lattice gauge theory calculations in QCD are done. You take the continuum limit by taking the coupling to zero as you take the lattice spacing to zero, according to the renormalisation group, and this gives a well-defined limit, with non-trivial infrared behavior, but trivial ultraviolet behavior. This is not yet rigorously mathematically proved (that’s one of the Clay million dollar problems), but all numerical and other evidence is that this is how the theory works.

13. **MathPhys**
January 12, 2012

In my humble, uneducated opinion, the line of thought of Arkani-Hamed, Cachazo, Hodges, Mason, Skinner and friends is very exciting indeed, and I expect it to be more so over the next couple of years.

Galois Conference Videos

January 9, 2012
Categories: Uncategorized

Last October there was a conference held in Paris to celebrate the 200th anniversary of the birth of Galois. Some of the talks were quite interesting, giving an overview of the current state of areas of mathematics in which Galois theory plays a role, in particular the Langlands conjectures. The videos of the talks are now available, see here.

The closing talk, by Alain Connes, has a certain amount of wild-eyed speculation about the "cosmic Galois group", of the sort that I believe has inspired Arkani-Hamed recently (see the previous posting).

Roy Lisker reports (here, here and here) about his visit to Paris to attend the conference, as well as take a look at Galois's manuscripts.

Update: It appears the Connes video is no longer there. But on his web-site you can find the slides for the conference talk, as well as another talk about Galois for a more general audience.

Comments

1. **theoreticalminimum**
   January 10, 2012

   Don't get me wrong, but we're living in 2012, and although Paris is still a major centre for mathematics research, it is intriguing to see Connes give a talk in French during what was advertised, and what indeed turned out to be, an international colloquium. I am fluent in French, but I am convinced this very interesting talk by Connes would have interested more people were it delivered in English. Just my 2 euro cents 😉

2. **fp**
   January 11, 2012

   Sadly, it seems that the closing talk has disappeared!

3. **Peter Woit**
   January 11, 2012

   fp,

   That's odd. I watched the first part of that…

   Connes has put on his web-site his slides for the conference talk and another more popular talk. The first set of slides is the ones he was using in the video. I'll add links to the posting for these.

4. **Felipe Zaldivar**
   January 11, 2012

   May I suggest, as related reading, the monograph by P. Newmann "The Mathematical Writings of Évariste Galois" (EMS, 2011) that in addition to English translations of Galois publications and manuscripts contains transcriptions of the original French articles, with commentaries and appropriate discussions of them. I just got a copy of it and I am enjoying it.

5. **Thomas**
   January 12, 2012

   @theoreticalminimum
   I don't see what 2012 has to do with that?
   I think France is in a sufficiently strong position in mathematics to allow the use of french for french speakers in an international conference. One which is, moreover, taking place in Paris. Interested people only have to read the transcript (or better, learn french ! un merveilleux langage.).
   In addition, maybe the quality of the talk would have suffered from Connes giving it in english. His ideas might flow better in french, and this is what we are really interested in.

6. **theoreticalminimum**
   January 12, 2012

   To answer Thomas:

   I meant to point out that we're living in times (2012 is the present year in the Gregorian calendar, as you are probably aware) when it would be understood that a talk in an international conference would be normally delivered in English. These days, most people learn sciences in English, and write papers in sciences in English.

   I have spent many years learning French (I even studied mathematics in French at the ENS), so I don't need you to tell me how nice a language French is. It is, in fact, my favourite. Besides, your "un merveilleux langage" is wrong; one says "une langue merveilleuse". You should probably consider fixing your French ;-]

   I have heard Connes give talks of the same topic in both English and French, and I can tell you, as far as he is concerned, the message never fails to come across. Anyway, my comment had to do with the fact that many of my mathematical friends would have liked to understand the content of the talk (which unfortunately looks to have disappeared off the webpage), but do not know French.

7. **Thomas**
   January 12, 2012

   @tm
   Let's be constructive. Apparently you know and love both maths and french, and you also appreciate Connes' work. So: you should really write down the trasncript. This would please your interested-but-non-french speaking friends much more than to pester on this blog, and it would even help them learn french.

This Week’s Rumor

January 10, 2012
Categories: Experimental HEP News

The start of the LHC 2012 physics run is still a while off, scheduled for around the beginning of April, with beam energy likely raised a bit, to 8 TeV total in the center of mass. So, it’s going to be quite a few more months before the LHC experiments have enough new data to analyze that will allow a conclusive determination of whether the evidence seen for a Higgs around 125 GeV is confirmed, with a significance high enough to claim discovery.

The results announced on December 13 were preliminary, and more complete analyses are underway, with results to be announced relatively soon. This week’s rumor is that the full CMS Higgs to gamma-gamma analysis is showing a stronger signal than the preliminary version. The bump has moved up a bit, from 123.5 GeV to 124 GeV, and the local significance is up from 2.3 to 3 sigma, with look elsewhere effect up from .8 sigma to 2.0 sigma. This strengthens a bit the evidence for a Higgs around 125 GeV. However, the best fit size of the bump is, as with ATLAS, about twice what the SM predicts. The errors are large, so quite possibly both experiments just got a bit lucky, in which case the first few months of 2012 data may not quickly add much to the significance of the signal.

For detailed discussion of issues surrounding the Higgs analyses, see this week’s workshop in Zurich: Higgs search confronts theory.

Comments

1. **Mottled Lobush**
   January 10, 2012

   You meant 8 Tev c.m. energy.

2. **Peter Woit**
   January 10, 2012

   Ooops, fixed.

3. **A Physicist**
   January 10, 2012

   It sounds bit like that in the rush to include all the Higgs channels, CMS did not do a good enough job of the important ones …

4. **Paolo Valtancoli**
   January 11, 2012

   Is it possible experimentally to distinguish between a fundamental or a composite Higgs Boson ?

5. **Peter Woit**
   January 11, 2012

   Paolo,

   Theories where the Higgs is not the quantum of an elementary field will often have limits in which it behaves like one, so, generically you should be able to tell the difference in principle, but in practice you may just be able to put bounds on some compositeness scale. If there really is something at 125 GeV, the focus for many years will be on measuring its properties to see if they’re precisely those of an SM Higgs (or a SUSY variant). Hopefully some difference will be found, otherwise life will get very boring.

6. **Trulo**
   January 11, 2012

   Although the Higgs boson is obviously the star now, and for some time to come, I guess the collaborations are still working hard on putting bounds on SUSY parameters. Are there any news on that front?

7. **Peter Woit**
   January 11, 2012

   Trulo,

   I haven’t heard anything, but the time to expect announcements is probably Moriond in early March.

   My understanding is that the negative results of the initial SUSY searches won’t be strengthened very much by doing the same analyses with more data (since the cross-sections they were looking for were strongly-interacting, so large). So, now the question is about different analyses that look for SUSY in different ways, but I don’t know much about this. We’ll probably hear from Matt Strassler more about this as results get released.

8. **harryb**
   January 13, 2012

   Although most associated with the US Presidential Election betting, as we start the year I thought I would have a look at what Intrade markets put the odds at on the Higgs boson turning up in 2012 (“discovery published in major scientific journal” original criterion, now 5 sigma, peer-reviewed etc being added to the rules).

   Currently the market gives it a 40% chance this year, down from highs of about 70% in December (volatility presumably due to all the mid Dec announcements).

   Interestingly, there is also a market on SUSY particles being discovered. It has been inactive for a year, and the starting price offered is 25% chance.

   So if our String Theory colleagues want to fill their boots I assume they will now rush off to Intrade and buy heavily into those shares….except the market so far has seen no activity at all. Hmm, seems the iron faith in ST is not translating into even one adherent parting with a single buck.

   Even unbelievers ought to dive in at this level- if nothing else as an emotional hedge against ST actually pulling off a SUSY triumph. At least we would have money in our pockets as a consolation.

Of course, alternatively Mr Woit and colleagues ought to sell heavily at 25% – still good money if we are true to our convictions…

Be worth watching these markets from time to time in 2012 in line with hype / discoveries.

9. **Proudmemberofthecult**
   January 13, 2012

   @ harryb

   or the string theorists are too busy doing science to look for internet sites where one can bet…

10. **harryb**
    January 13, 2012

    @Proudmemberofthecult

    The comment re betting was not meant to be flippant – but I take your point.

    It was interesting to note that there is a live market on Higgs outcome which is remarkable given its potential obscurity. So Higgs acceptance or expectation appears to have entered to a certain extent the mainstream – so much so people will actually bet their own money on it being found.

    SUSY particles remain esoterica, but there is a market for them which you can argue is credibility of a sort.

    Genuinely intrigued that erstwhile obscure particle physics has already attained a status where likelihood of occurence or major announcement is being subjected to mainstream economic probablistics using buyer-seller dynamics ("betting"). However, markets remain thin which makes them of limited value – for now.

    Any odds offered on a solution to the Fermi paradox after the exo-planet discoveries of this week?

11. **Jason**
    January 13, 2012

    As an economist and peruser of physics blogs I thought Higgs at 40% for 2012 was a great bet a few weeks ago when I first saw it, but decided against wagering when I realized the total number of contracts available at that price was so small that it wasn't worth my time to click (even were you certain of a published 5-sigma result in 2012 and bought all possible shares you would stand to gain about $250, and the average share price would be around 70%).

    The lesson here is that you should look at the number of contracts offered before inferring that the listed Intrade price represents the market's assessment of the probability that the event will occur.

    January 13, 2012

    As for the Fermi paradox, not really sure why exactly this is a paradox. Assuming 1,000,000 advanced civilizations in the Milky Way right now, and assuming that only 1/2 the Milky Way is habitable (over compensating for the black hole at the center), a seat of the pants estimate gets me that the civilizations are separated by more than 300 light years on average. Can't see that the odds are very high we would notice anything. Boy that light speed limit is annoying 🙂

    Me, I figure there really are a whole lot of planets with life out there, and a whole lot with "intelligent" life too, since we now know that planets are ubiquitous.

13. **Peter Woit**
    January 13, 2012

    I better stop this Fermi paradox thing right here. It's really, really far off-topic…

14. **Jeff M**
    January 13, 2012

    Sorry Peter, couldn't resist, promise to stay on topic in the future.

What is your favorite deep, elegant, or beautiful explanation?

January 15, 2012
Categories: Uncategorized

Science publishing impresario John Brockman's Edge web-site each year runs a "Question of the year" feature, with short pieces from a wide range of people providing their answer to the question. The past few years I've passed on their invitation to submit something, but this year the question was one that I couldn't resist. It was "What is your favorite deep, elegant, or beautiful explanation?" and you can read people's answers here.

There are quite a few answers from various physicists, with General Relativity, inflation and the multiverse getting a lot of attention. To me though, the most satisfying answer to the question involves the remarkable role of symmetry principles at the foundations of both our everyday laws of mechanics and our deepest ideas about quantum mechanics. Far more so than in classical mechanics, in quantum mechanics these principles are built into the fundamental structure of the theory. This makes it clear why quantum mechanics works the way it does, and indicates that the structure of quantum mechanics is likely to always be fundamental to our understanding of the physical world, not some approximation like the classical picture. In addition, it links together fundamental physical principles and a fundamental set of ideas that occur throughout modern mathematics, a veritable grand unification of the two subjects.

Here's what I sent in:

> Any first course in physics teaches students that the basic quantities one uses to describe a physical system include energy, momentum, angular momentum and charge. What isn't explained in such a course is the deep, elegant and beautiful reason why these are important quantities to consider, and why they satisfy conservation laws. It turns out that there's a general principle at work: for any symmetry of a physical system, you can define an associated observable quantity that comes with a conservation law:
>
> 1. The symmetry of time translation gives energy
> 2. The symmetries of spatial translation give momentum
> 3. Rotational symmetry gives angular momentum
> 4. Phase transformation symmetry gives charge
>
> In classical physics, a piece of mathematics known as Noether's theorem (named after the mathematician Emmy Noether) associates such observable quantities to symmetries. The arguments involved are non-trivial, which is why one doesn't see them in an elementary physics course. Remarkably, in quantum mechanics the analog of Noether's theorem follows immediately from the very definition of what a quantum theory is. This definition is subtle and requires some mathematical sophistication, but once one has it in hand, it is obvious that symmetries are behind the basic observables. Here's an outline of how this works, (maybe best skipped if you haven't studied linear algebra…) Quantum mechanics describes the possible states of the world by vectors, and observable quantities by operators that act on these vectors (one can explicitly write these as matrices). A transformation on the state vectors coming from a symmetry of the world has the property of "unitarity": it preserves lengths. Simple linear algebra shows that a matrix with this length-preserving property must come from exponentiating a matrix with the special property of being "self-adjoint" (the complex conjugate of the matrix is the transposed matrix). So, to any symmetry, one gets a self-adjoint operator called the "infinitesimal generator" of the symmetry and taking its exponential gives a symmetry transformation.
>
> One of the most mysterious basic aspects of quantum mechanics is that observable quantities correspond precisely to such self-adjoint operators, so these infinitesimal generators are observables. Energy is the operator that infinitesimally generates time translations (this is one way of stating Schrodinger's equation), momentum operators generate spatial translations, angular momentum operators generate rotations, and the charge operator generates phase transformations on the states.
>
> The mathematics at work here is known as "representation theory", which is a subject that shows up as a unifying principle throughout disparate area of mathematics, from geometry to number theory. This mysterious coherence between fundamental physics and mathematics is a fascinating phenomenon of great elegance and beauty, the depth of which we still have yet to sound.

Comments

1. **plm**
   January 15, 2012

   In mathematics we have a classic anthology: Proofs from the Book, by Aigner and Ziegler, http://www.springer.com/mathematics/book/978-3-642-00855-9 .

   I guess we can pick many proofs from that book.

   I may select Cantor's diagonal argument, or a similar logic or computer science reasoning, like Gödel's liar paradox proof of incompleteness, or Turing's proof of undecidability of Halting.

2. **Hendrik**
   January 15, 2012

   This is a very nice proposal, but as your post on Weinberg's symmetry views shows, it is a bit idealized. The elegance is a bit less in broken symmetries, supersymmetry, and quantum local gauge symmetry is not even mathematically rigorous yet. There is also plenty of confusion in physics literature on what precisely constitutes a symmetry e.g. what is the difference between physical transformations and symmetries, must symmetries be automorphisms of the observables, or is it enough to be just derivations, and what about superderivations?

3. **Jeff M**
   January 15, 2012

   Well, as a geometric analyst, I should say the proof of the Selberg trace formula, which relates the lengths of closed geodesics, a geometric quantity, to the eigenvalues of the Laplacian, an analytic quantity. Not like there is any easy way to explain the proof though. Another would be the Hodge decomposition. But for pure elegance I'm going with plm, Turing's proof of Goedel's theorem is truly beautiful and shockingly clever.

4. **Peter Woit**
   January 15, 2012

   Hendrik,

   I think we're far from completely understanding many things about representation theory, as well as far from completely understanding fundamental physics. All that's clear is that the two subjects are closely related. I hope that in the future we'll understand this relationship better, allowing new ideas to flow both ways between math and physics.

5. **AcademicLurker**
   January 15, 2012

   Interesting coincidence with the timing of this post. I just started a book, "Emmy Noether's Wonderful Theorem" (Dwight Neuenschwander, 2011). It's not a popularization. Instead, it works through the proof and then explores some of it's consequences. It seems to be pitched at the level of an undergraduate physics major.

6. **JB**
   January 15, 2012

   Peter, can you recommend a good textbook on Representation Theory?

7. **Sascha Vongehr**
   January 15, 2012

   Symmetry is of course the underlying elegant reason for pretty much anything, say the tautological truth of many world modal descriptions (which you seem to actually not like). To reduce it almost mechanistically to something that is indeed more "representation" rather than explanation, is not so good. Especially not if it involves time/energy (as that very symmetry is not given in a general relativistic context) and phase transition/charges. A fundamental explanation kind of symmetry be better fundamental, and not these apparent and emergent symmetries you are talking about. With those, a mathematical modeling/representation/mapping into another language is not an explanation.

8. **King Ray**
   January 15, 2012

   Peter, you mean U = exp(iH), not exp(H), where H is self-adjoint aka Hermitian. iH is skew-adjoint.

9. **Peter Woit**
   January 15, 2012

   King Ray,

   I was trying to be concise and avoid equations, so at the level of precision of that text, you should take h-bar=i=-1=1.

10. **Bob Levine**
    January 16, 2012

    For my money, the prize has to go to Maxwell's incorporation in the expression for the magnetic field circulation of a term expressing the time rate of change in the electrical field flux, purely on the basis of mathematical parallelism with the relationship between the electrical field circulation and the time derivative of the magnetic field flux. There was absolutely no 'phenomenological' motivation for this modification in the original Ampere law, not one bit of experimental evidence for a 'displacement current' at the time; it was a matter of pure formal symmetry, yielding the wave equation for the propagation of orthogonal E and B fields that established the wave nature of light on the basis of the coefficient 1/c^2 in a wave equation that could *only* have been derived on the basis of that modification.

    We're used to this kind of thinking in the era of modern physics. But what Maxwell did was, so far as I can tell, virtually unprecedented in the context of 19th century physics—-and probably the greatest breakthrough in physics since Newton's original work. The key point is that Maxwell was guided purely on the basis of the principle that, as Dirac was famous for saying, 'it is more important to have beauty in one's equations that to have them fit experiment'—but followed that principle just short of a century before Dirac wrote those words. In context, his innovation ranks with the very best that Newton and Einstein achieved.

11. **Abbyyorker**
    January 16, 2012

    January 16, 2012

    @ Peter Woit

    I've heard that Seiberg refers to this as "string theory units" 🙂

    (for computational simplicity include 2=\pi=1)

13. **Frank Meulenaar**
    January 16, 2012

    Why call it "mysterious'? It might be 'deep' or 'unexpected' but I would never call it 'mysterious'.

14. **Chris Oakley**
    January 16, 2012

    Bob,

    I do not agree that Maxwell's displacement current was just plucked from thin air. It is, after all, the simplest extension of Ampere's law that makes the equation consistent with charge/current conservation.

15. **plm**
    January 16, 2012

    Peter, I find it interesting that you chose to underline how fundamental physical theories are selected by stability/symmetry among possible theories, while you are very critical of string theory.

It seems to me that the main argument in favor of string theory is that it adds degrees of freedom to quantum field theories (or so it seemed), which are then pruned by stability/symmetry conditions (conformal invariance) with mysterious (more or less attractive) consequences. Like for instance special relativity takes a point (or field or wave-function) in 4-space and asks for hamiltonians invariant under the transformations you mention.

I think this is also what makes string theory a little more attractive than canonically quantizing general relativity. (This may also suggest that some form of canonical GR may be recovered by either a generalization of string theory or even some existing formulation.)

So we have failed alot to find experimental evidence in favor of string theory, but it is mysterious and embeds this symmetry principle workhorse of theoretical physicists that you promote…
Then how do we weigh those things, what is the right bayesian framework? How does this mix up with the social structure of scholarship -e.g. personal interests?
I try to understand your attitude, and others'.

And thank you for the post, it was very interesting.

16. **plm**
January 16, 2012

I should add that quantizing GR is also based on the symmetry workhorse insofar as quantization is. We add probabilistic fuzziness to our objects and reduce by requiring (biological) observers. This results in projections onto preferred (superselected) states, like eigenstates of conserved observables, or the next best thing, coherent states. And decoherence is a mysterious mathematical ingredient, which affects how much we need to project.

(My perspective on the interpretation of quantum mechanics has been that experiment supports quantum physics and classical biology so I start with quantum theories for the quantum experiment and try mentally to model a simple quantum neural network coupled with the observed system, and then I ask that what happens is an observation, a neuron either firing or not, which technically can only be made projecting on some subspace of states, and this with some mathematical unraveling, explaining decoherence mostly, should be equivalent to projecting on just eigenspaces. So I usually tell myself "Why should we humans be all of physical reality and not just part of it, projections of states?". And I think a bayesian view of physics supports this, our experiments give ever-increasing support to QM and we just continually observe consciousness which we can formalize in models of neural networks -from single neurons, to perceptrons with feedback, to realistic full brain models as begin to appear- and which boils down to Born selection on complete sets of observables.)

With this in mind canonical quantum general relativity may be as attractive as string theory on the bayesian grounds I mention. I don't know.

17. **Bob Levine**
January 16, 2012

@ Chris—

I didn't mean to imply (and don't think my comment should be read as saying) that Maxwell's extension was 'plucked from thin air' (at least as I think of what that expression suggests) or had no physical basis. But, at least as I've read the history, his main concern was to make the E and B field equations as close to mirror images as possible in the context of the evident lack of magnetic monopoles corresponding to free electrical charges. Proceeding in that fashion, without substantial experimental support, was a completely different style of physics from standard practice and, I think one could argue, anticipates a strikingly contemporary approach—much closer to Dirac's approach to nature than Faraday's.

18. **Noah Smith**
January 16, 2012

Thanks for this Peter, it seems to summarize some of the most interesting ideas in your book. Years after reading it, these ideas are what I remember – interesting no? This may be a good opportunity to try asking a question, if it's possible to pose it properly. This is a sincere question and I'm genuinely interested in your thoughts. How about this: do you see a route by which these ideas will spread, so that they appear in undergrad physics and engineering courses? One example I think of is Lagrangian and Hamiltonian dynamics. In aerospace, it's interesting to see where and how they appear in very practical applications. Thanks.

19. **Joel Rice**
January 16, 2012

From a historical perspective, there was a big bang in physics and mathematics when Hamilton discovered quaternion algebra. I read somewhere that Maxwell did his thinking in quaternions, and later translated this into matrices. And where would Einstein have gone without Maxwell ? Pascual Jordan mentioned quaternions in an early paper that led to Pauli dealing with spin, without which atoms make no sense at all. All in all, it seems that a lot rests on Hamilton's discovery.

20. **Peter Woit**
January 16, 2012

JB,

I've listed some textbooks on the web-page for my course, and will be adding some more material there soon.
http://www.math.columbia.edu/~woit/LieGroups-2012/

JB and Noah,

I'm hoping to at some point teach an undergraduate course on this material, and would write something up then. Unfortunately I don't know of a good source now at this level (I'm thinking of "Hermann Weyl for undergrads"). There's a long history since the early days of QM of interaction between the physics and the math of representation theory. In practice though, most physicists end up just learning some very special cases that they need to do certain calculations, and nothing about the general story. I'm not sure what will ever change this, maybe if I end up writing something like a book about this it would have a small effect.

plm,

My argument is about representation theory, which does have to do with symmetry, not with stability. Discussing the various ways in which symmetry shows up in string theory is a huge topic. The bottom line though is that symmetry arguments get used everywhere in physics, but just because your idea uses a symmetry argument doesn't mean that the idea does what you want it to.

All,

Please try and stick to some semblance of the topic. This one does lend itself to people deciding to write here about whatever they want, but, as usual, I can't moderate a general physics discussion forum.

21. **Tim May**
January 16, 2012

Jumping in late, I'd say the "constancy of the speed of light" has been crucial to our understanding of how things work. General relativity and quantized gravity (and the various approaches, some wrong, some not even wrong (!), maybe one of them right?) get the attention in the comments in the Edge comments, but the combination of the constancy of c and quantum mechanics in the 1905-1930 period really had profound implications.

Dirac's effective predictions of anti-particles, based on light cone reasoning, must've been astounding to those at the time.

And at another level, the whole view of causality and light cones that comes from the constancy of c has implications about simultaneity, the impossibility of omniscience (in our space-time), and the inability to ever, ever, communicate with distant objects in any meaningful sense.

22. **harryb**
January 16, 2012

Peter

First – excellent piece you started, and fascinating (192) entries I trawled – quickly – through. @Abbyyorker has a good point re Evolution, and Boltzmann's entropy – I always think the Second Law of Thermodynamics ought to win these fests just because of its name.

Still – the entries on elegance and symmetry not being true or useful also rang home. Jamshed Bharucha's piece – The Beauty and Tragedy in the Mathematics of Music – had some interesting insights on the asymmetry or irrationality of the ratio of music (on strings, ho ho)

One insight – the elegant ratios are "Close but unequal. If you tune by octaves, the fifths are out-of-tune, and vice versa."

So I worry about the equation : symmetry = beauty, elegance, depth.

I see depth is the fact mathematics underpins so much of what we know.

The deep theory of evolution, for example, in Dawkin's entry, is offered in mathematical language:

"The ratio of the huge amount that it explains (everything about life: its complexity, diversity and illusion of crafted design) divided by the little that it needs to postulate (non-random survival of randomly varying genes through geological time) is gigantic."

I guess I am noting that asymmetry may have an elegance of its own, and a reality too. To exclude asymmetry from deep truths may be to fall into the dead space we talk a lot of in these blogs re strings and so on.

Daniel Kahneman (nobel laureate in Economics) discusses "theory-induced blindness" and over-adherence to "inside views" as ways in which groups stunt their progress. He also famously crafted an elegant theory on "loss-aversion" in economics which showed as humans we have an asymmetric view between losses and gains (reacting to losses typically twice as much as equivalent gains).

Its elegant, and asymmetric.

Close but unequal.

So, excellent blog forcing me to look at alternative deep thoughts out there – truly insightful.

23. **Chris W.**
January 16, 2012

1. The symmetry of time translation gives energy*
2. The symmetries of spatial translation gives momentum*
3. Rotational symmetry gives angular momentum*
4. **Phase transformation symmetry gives charge***

[* … conservation]

Whereas #1 – #3 can be approached in a strictly classical way, #4 has always struck me as the most interesting and mysterious. Why should quantum mechanical phase, a notion which is not bound prima facie to any assumptions about the *forces* affecting the evolution (propagation) of particle probability amplitudes, have anything to do with electric charge or charge conservation? The way the connection is made—through the global gauge invariance of the electromagnetic field—is clear enough, but the outcome is still strange; from early on the electromagnetic field seemed to have a particularly intimate connection to the structure of quantum mechanics. One feels there must be more to this story….

24. **Mike J.**
January 16, 2012

I am a non-physic under-graduate. Can you introduce a book/paper/article etc. that describes these symmetry in a more understandable way. Thanks.

25. **Peter Woit**
January 16, 2012

Mike J.,

My book "Not Even Wrong" has a chapter on this. But, honestly, if you haven't studied physics a bit seriously, these ideas aren't going to make much sense.

26. **Thomas Larsson**
January 16, 2012

Conformal field theory – using the representation theory of the Virasoro algebra to explain the spectrum of critical exponents in 2D. QED is often hailed as the most successful theory, because it predicts a handful of quantities to ten decimal places or so. CFT correctly predicts infinitely many quantities to infinite precision. 2D phase transitions is admittedly not a an extremely important field, but within its limited domain of validity, CFT is the ultimate theory.

27. **Geoff**
January 17, 2012

I'm profoundly biased in this regard as my first and foremost love has been and will always be general relativity. It is a never ending source of fascination that when translated literally the field equations simply say that physics is geometry and geometry is physics. I find it incredible that a mathematical discipline originally tasked with drawing maps of curved surfaces on flat pieces of paper has been so successful in describing the universe at large. Of all the theorems that Gauss proved, the one that he named Theorema Egregium turns out to be critical to the whole theory. (A beautiful article by Kuchar explaining some of this can be found here –)

http://arxiv.org/pdf/gr-qc/9304012

In a completely different field I always enjoyed listening to the recordings of Sidney Coleman where he would repeatedly and passionately say that if the PCT Theorem was wrong he'd have to go back to day one and start over. I must confess I haven't appreciated that fact in any meaningful way just yet.

Peter, as a suggestion perhaps you could give us some of the history behind the development of Noether's Theorem. It's my limited understanding that it came up in the context of General Relativity, specifically trying to understand gravitational radiation.

28. **Per**
January 17, 2012

Thomas Larsson:

Wouldn't you say that's a consequence of the symmetry argument? The reason CFT is so successful is of course because of its symmetries (which survives quantization).

29. **Fabien Besnard**
January 17, 2012

I quickly browsed the list of answers, and not surprisingly, the atomic theory (in one form or another), natural selection, Maxwell's theory of em field, and GR come several times. It's an opportunity to remember how much we owe to nineteenth century science regarding the explanations of natural phenomena.

I'm a bit surprised though that Kaluza-Klein theory does not appear on the list. To me that's still the best idea one ever had about unification. It is also at the root of the set of ideas that eventually led to gauge theories.

30. **Chris W.**
January 17, 2012

Following up on Fabien's comment, see arXiv:gr-qc/0012054 ("On Pauli's invention of non-abelian Kaluza-Klein Theory in 1953"), which seems to be widely cited.

I seem to recall reading somewhere that Pauli offered some rather strong criticisms of the Kaluza-Klein approach over a decade before the work described in this paper. I didn't find exactly what I had read previously, but I did find this paper [PDF, at cdsweb.cern.ch], containing excerpts from a correspondence between Einstein and Pauli in the late 1930s. Pauli and Einstein came to agree on the futility of the Kaluza-Klein approach in finding a classical basis for quantum discreteness. Pauli's 1953 work, and most subsequent work inspired by the Kaluza-Klein approach, had a rather different motivation.

31. **D R Lunsford**
January 17, 2012

Chris W,

Pauli began his career in the early 20s working with Veblen – or at least contemporaneously with him – on something that was known as "projective relativity", based on the "projective geometry of paths", where the geodesics in a Riemann space are given a sort of projective structure, and one works in a sort of system of homogeneous coordinates. He later showed that Kaluza's ansatz was just PR in a particular coordinate system. Since he had abandoned PR some time earlier, this reduced the Kaluza ansatz to the realm of the non-dynamical, and really, invalidated it as a road to unification. He also pointed out, in addition to this weighty argument, that the particular form of the action in Kaluza's work was arbitrary. These arguments, as far as I can tell, have never been superseded by more subtle ones.

-drl

32. **D R Lunsford**
January 17, 2012

Fabien B,

Kaluza theory and gauge theory could not possibly have had any more different origin. Kaluza was non-dynamical and was based on Riemannian geometry with a restricted (cylinder) geometry. Gauge theory emerged from Weyl's gauge invariant extension of Riemannian geometry, in which calibration changes enter alongside coordinate changes as logically independent operations. These two things have really nothing in common. In particular, the Weyl ansatz is completely local and needs no global assumptions, such as the cylinder ansatz.

-drl

33. **Thomas Larsson**
January 17, 2012

Per: Of course CFT is all about symmetry, but I would not say that the symmetries survive quantization, for two reasons.

1) The quantum theory (Hilbert space, correlation functions) is constructed directly, without classical crutches. So there is no quantization.

2) If there were a classical theory, it would presumably have zero central charge. So the classical form of the symmetry has not survived.

I like both of these aspects.

34. **Chris W.**
January 18, 2012

DRL,
Much thanks for that. On reflection, I think I was recalling a comment by you posted a long time ago on another N.E.W. post. (I tried locating it just now, without success.)

35. **jorge**
January 19, 2012

"…string theory is the first science in hundreds of years to be pursued in pre-Baconian fashion…"

Philip W. Anderson
Edge 2005: WHAT DO YOU BELIEVE IS TRUE EVEN THOUGH YOU CANNOT PROVE IT?

36. **Jess Riedel**
January 19, 2012

> One of the most mysterious basic aspects of quantum mechanics is that observable quantities correspond precisely to such self-adjoint operators, so these infinitesimal generators are observables.

One of the reasons I decided to come work for Wojciech Zurek is because he more-or-less solved this mystery. More precisely, he showed [PRA, ArXiv] that what is often taken to be a very mysterious postulate

> Observables are represented by Hermitian operators

can be derived from a much, much more natural postulate

> Outcomes are identified with vector components of the global wavefunction

along with the natural definition that an outcome must be amplified to count as a measurement. By the linearity of quantum mechanics, only orthogonal vectors can be amplified. If we label each vector with a real number, we are left with a Hermitian operator being the natural mathematical object to identify with an observation, i.e. the catalog of all possible measurement outcomes.

(Actually, from this we can see that it is better to identify observables with the *normal* operators, which include Hermitian operators as a subset. Indeed, the sensible operator when we measure the amplitude and phase of an electromagnetic wave is normal but not Hermitian.)

Incidentally, this argument would undoubtably be *my* choice for most elegant explanation in physics.

37. **Fabien Besnard**
January 19, 2012

D R L, of course you are right to stress the importance of Weyl's idea. Nonetheless dimensional reduction did play a role in this story, in particular in the works of Klein himself and also Pauli. You can consult O'Raifeartaigh's book "the dawning of gauge theory" about this, notably chapters 3, 6 and 7.

38. **harryb**
January 19, 2012

A good try, but no cigar?

http://imgs.xkcd.com/comics/string_theory.png

Picked up from Lawrence Krauss's latest work – A Universe from Nothing – interested in what you think of the book.

39. **Alberto**
January 20, 2012

As a first year student in physics in the seventies, I discovered the relation of symmetry and conservation laws in the first pages of the first volume of Laudau's physics course. An instructor told me to look for it (in those times, in Europe, the books of the famous Soviet physicists and mathematicians circulated widely among penniless students, in the translations into French printed by the state publisher MIR). I thought this was the closest one could get to seeing the hand of god in action.

40. **D R Lunsford**
January 20, 2012

There are two amazing things that come from the same person, Felix Klein, and I can't imagine their strange mystery or depth ever being exceeded.

One was the association of Platonic solids with the solution of equations of the fifth degree.

The other was the mathematical theory of the top, in which the best treatment necessitated the introduction of a 4d space of indefinite metric. Klein however pointed out that the required non-Euclidean geometry should not be taken seriously (!)

-drl

41. **Peter Woit**
January 21, 2012

harryb,

That drawing pretty much does sum it up, and it has become very famous.

I confess that the cosmological "why did something come from nothing" question never interested me at all (for one thing, the big bang singularity doesn't seem like "nothing" to me), and the arguments about religion really don't interest me either. So, I think I'm going to pass on reading that book carefully or writing about it.

42. **harryb**
January 22, 2012

Peter

Understood – but just to be clear Krauss's works including this latest one are very much negative on any religious, quasi-religious or even anthropic arguments (with a – supportive – Afterword by Richard Dawkins you can see where he is coming from.)

He is negative on string theory too as you can imagine from the cartoon for its lack of scientific rigour or evidence – a theory of anything, which is not science.

His recent biography on Feynman – Quantum Man – may be a better option.

43. **jorge**
January 22, 2012

Why do we need to postulate an infinite number of universes with all sorts of different properties just to explain our one?

Paul Steinhardt
Edge 2005: What do you belive is true even though you cannot prove it?

44. **chiz**
January 28, 2012

Geoff – Noether's original paper is here and it includes some discussion of the non-conservation of energy in GR.

Mathematical Foundations of Quantum Field Theory

January 17, 2012
Categories: Uncategorized

The Simons Center for Geometry and Physics at Stony Brook is having a workshop this week on Mathematical Foundations of Quantum Field Theory. I was hoping to find time to go out there and hear some of the talks, but the beginning of classes has kept me here today and tomorrow, and later in the week I need to make a short trip to Toronto. But luckily there are high-quality videos, and today Witten gave an interesting talk on What one can hope to prove about three-dimensional gauge theory. What struck me most though was how little we still know about even simple questions about 3 and 4 dimensional gauge theory. Witten expressed hope that studying these questions is something that will get re-invigorated and draw new attention. I hope he's right. Also worth watching is Arthur Jaffe's summary of the history and state of the art of constructive field theory.

Also in the category of talks that I'd love to hear, but they're a bit too far afield to get to this week are Jacob Lurie's Whittemore Lectures at Yale, dealing with the Siegel Mass Formula, Tamagawa numbers and Non-abelian duality. I fear they don't have video, but if anyone knows of a source of information dealing with what Lurie talked about, I'd love to hear about it.

Comments

1. **David Roberts**
   January 18, 2012

   Peter,

   Do you have a link/source/description/abstract for Lurie's lectures?

2. **Igor Khavkine**
   January 18, 2012

   I hope that video recording was not turned on only for Witten and Jaffe's sake and that videos for Monday's (and other day's) talks will appear eventually.

3. **Peter Woit**
   January 18, 2012

   David,

   There are some abstracts for the talks on the Yale math dept. calendar listings at

   http://math.yale.edu/mathematics-calendar

4. **Tim van Beek**
   January 18, 2012

   > I hope that video recording was not turned on only for Witten and Jaffe's sake and that videos for Monday's (and other day's) talks will appear eventually.

   Dito, hopefully the talk of Planck medaillist Detlev Buchholz will be put online, too. Maybe some of the AQFT specialists have something new to say about the connection of quantized gauge theories and Haag-Kastler nets.

5. **Marcus**
   January 18, 2012

   I hope that video recording was not turned on only for Witten and Jaffe's sake and that videos for Monday's (and other day's) talks will appear eventually.
   Igor,
   The site says Monday's talks were not recorded (because MLK holiday).
   But all Tuesday's are shown as recorded and the rest will eventually be available from the looks of it.

6. **Igor Khavkine**
   January 18, 2012

   Marcus, thanks for pointing that out. Still, that's an unfortunate, though clearly accidental, anti-AQFT bias.

An Introduction to Group Therapy for Particle Physics

January 24, 2012
Categories: Uncategorized

The latest CERN Courier book review section is out here. Besides a long review of Frank Close's The Infinity Puzzle, there are some short reviews, including one for Stephen Heywood's *Symmetries and Conservation Laws in Particle Physics: An Introduction to Group Therapy for Particle Physics*. That's one I really want to see: I'm all for symmetries and conservation laws (see here), and *Group Therapy for Particle Physics* (at least for particle theorists) seems like an excellent idea.

This semester I'm not doing Group Therapy, but I am teaching group theory and representation theory. The class has started and I'm trying to write up lecture notes. One discouraging/encouraging thing is that looking around the web one finds several places other people have done this better, links are slowly getting added on the class web-page. The course is mainly aimed at mathematicians, hoping to provide our graduate students the background they need for several different areas, including number theory. It will however have a physics flavor, with more concentration on topics like spinors, geometric quantization, the Heisenberg algebra and oscillator representation than usual. The Dirac operator may even put in an appearance, we'll see…

Update: Turns out there are more books on group therapy in particle physics. See here for J.F. Cornwell's *Group Therapy in Physics, Vol. 1*. John Gribbin's promotional *In search of superstrings* includes an appropriate appendix on Group Therapy for Beginners. Then there's Terry Tomboulis's Renormalization Group Therapy, which is something different.

3. **Mithras**
   January 24, 2012

   I picked up the Infinity Puzzle on your recommendation; I suppose I'll now have to pick up Heywood's book as well.

4. **AS**
   January 24, 2012

   What's the best opposite, say "Particle Physics for people who already know about groups and representation theory, and aren't afraid of functors" ?

5. **?**
   January 24, 2012

   Isn't hosting a link to an illegal download going to get you in trouble with Columbia? The link is definitely illegal.

6. **Barry Adams**
   January 24, 2012

   I liked S. Sternberg's, Group Theory and Physics, was on my reading list as an undergrad and its one I often return to.

7. **SteveB**
   January 24, 2012

   This is quite funny. But now I have to point out your typo in the Update. A new particle the: Renormaliz-a-ton, which is akin to the instan-ton or par-ton, I suppose. Sorry…couldn't resist.

8. **Peter Woit**
   January 24, 2012

   AS,

   I don't know a good answer for that, curious if anyone else does. I've always intended someday to try and write something like that, basically an explicit mathematical description of the standard model, aimed at mathematicians completely familiar with the technology of differential geometry.

   Not particle physics, but some of what I'll be doing in my class and hopefully writing notes about is basic quantum mechanics, expressed in the language of representation theory. This won't get really to particle physics, where the interesting groups are infinite-dimensional.

9. **Peter Woit**
   January 24, 2012

   SteveB,

   Thanks! Fixed. Typos are hard to avoid…

   ?
   The illegal download links for that turned up first, I didn't realize that the legal sites had the same title. I'm removing that link, putting in a legitimate one.

10. **Tim van Beek**
    January 25, 2012

AS asked:

> What's the best opposite, say "Particle Physics for people who already know about groups and representation theory, and aren't afraid of functors" ?

The slightly more general question [Quantum Field Theory from a mathematical point of view] has been discussed both on the theoretical physics stackexchange site (see link) and on mathoverflow (the link to mathoverflow is in the second comment under the question).

Peter wrote:

> I've always intended someday to try and write something like that, basically an explicit mathematical description of the standard model, aimed at mathematicians completely familiar with the technology of differential geometry.

Don't underestimate the amount of physics one needs to understand (Hamiltonian mechanics, classical electromagnetism, quantum mechanics, particle physics).

IMHO there is no easy way for mathematicians to understand the standard model.
But I would recommend to every mathematician to read the classic "Spin, Statistics and all that" (Wightman/Streater) in order to understand what a *QFT is, actually*, before trying to understand Lagrangian QFT heuristics.

(And next Schottenloher: "A mathematical introduction to conformal field theory").

11. **Chris W.**
January 25, 2012

I remember my first day in an undergraduate course in group theory and quantum mechanics many years ago, taught by a condensed matter physicist. A few minutes into the class, one of the students stood up (while looking quite embarrassed), collected her stuff, and quickly left the room.

The student never came back, so I assumed at the time that she had initially misunderstood the course's subject matter, and dropped it when she realized her mistake. My guess was that the term "group theory" had implied something else to her that she was more familiar with, but I never got a chance to confirm that. 🙂

12. **Peter Woit**
January 25, 2012

Tim,

Thanks for the reference. Looking at the mathoverflow version

http://mathoverflow.net/questions/57656/standard-model-of-particle-physics-for-mathematicians

I realize that I sent in a response there which is relevant.

I don't think giving a mathematician a fairly precise definition of the Standard Model in a high-level mathematical language is going to cause them to "understand" it, since there are all sorts of ideas implicitly packaged in such a definition that you really need more basic training in physics to understand. However, it might give them an entry-point to starting to learn more about the subject.

Streater and Wightman style axiomatic QFT is quite problematic for this purpose. It is very much dependent on exploiting Minkowski space symmetry, and it really can't handle gauge symmetry. There's also no path integral there. If you want to try and start understanding the SM from a geometric, coordinate-invariant perspective, the path integral is a much better place to start.

13. **cormac**
January 25, 2012

Hi Peter, Dad has a book on group theory for particle physicists called 'The Group Structure of Gauge Theories' (OUP) . It gets a lot of respect though I gather it's at quite an advanced level

14. **Andrzej Derdzinski**
January 25, 2012

"Geometry of the standard model of elementary particles" is a book I wrote over 20 years ago. It deals with the classical level only.

January 28, 2012

Hi, J.F. Cornwell's Group Therapy in Physics, Vol. 1 is essential imo to read for anyone interested in group theryapy & theory in physics. Although you probably have to read it more than once. 🙂

17. **Chirag**
January 29, 2012

Does anyone have any recommendations for an elementary discussion of phase transitions and group theory? From what I understand Morse theory is also important. I would be interested in knowing if there are any elementary survey papers on this circle of ideas.

18. **Jeff M**
January 29, 2012

@Chirag,

While I have no idea what the physics reference would be for phase transitions and group theory, for Morse Theory the great reference is “Morse Theory” by John Milnor. Truly beautiful book, really thin and you will not only learn Morse theory you will get a wonderful writeup of everything you need to know about differential geometry.

19. **former mathematician**
    January 30, 2012

    Fraser’s review omits any reference to Close’s discussion of Bjorken’s work. Strange, since Close’s table-pounding about Bjorken’s contribution was the single strongest impression I got from the book.

    The only other book by Close I have read is “Neutrino,” which has similar table-pounding for Bahcall. It seems that non-recognition of theoreticians in experimental Nobels is a hobbyhorse of his.

20. **Jon**
    January 30, 2012

    @Jeff M@Chirag

    There are online copies of Milnor’s Morse Theory available here and here. Not sure if they’re completely legit, but they’re hosted on university servers.

Short Items

January 31, 2012
Categories: Uncategorized

A few short items:

- No Higgs news on the LHC front, but on the BSM front today's CERN talk Update on Searches for New Physics in CMS provides more evidence against the various exotic scenarios heavily advertised over the last twenty years. No sign of extra dimensions, SUSY, or other exotics. For more, see Resonaances. SUSY proponents now seem to be somewhere between the first stage of grief ("denial") and the second ("anger", see e.g. here) and on their way to the third (Bargaining – "I'll do anything for a few more years").
- From Sean Carroll's Twitter feed I learned about this long description of a recent workshop bringing together philosophers and quantum field theorists. I guess my take on the "heuristic" vs. "mathematical" quantum field theory debate is that we need both, since there is still a huge amount we fundamentally don't understand about QFT.
- For a finite number of degrees of freedom, quantum mechanics itself is, unlike QFT, rather well understood. For a nice recent review of some topics in the mathematics of quantization, see Ivan Todorov's Quantization is a mystery.
- It's not only string theorists producing over-hyped university press releases, there's things like this. See more discussion here.

Comments

1. **Lee**
   January 31, 2012

   After browsing Todorov's text, I was reminded how such short shrift is given to the probabilistic and statistical nature of quantum theory. The virtues of group theory, symplectic spaces are extolled by virtually every mathematical physicist, yet, quantum theory is equally an exercise in probability theory. Looking back on grad school, I am surprised how little probability and statistics I was taught.

2. **Enrico**
   January 31, 2012

   Hey Peter, when are you going to review Lawrence Krauss's new popular science book?

3. **Peter Woit**
   January 31, 2012

   Enrico,
   See
   http://www.math.columbia.edu/~woit/wordpress/?p=4385#comment-103275

4. **Shantanu**
   January 31, 2012

   Peter, there continue to be talks/hype on extra dimensions.
   See
   http://pirsa.org/12010130/
   by C. Burgess

5. **Peter Woit**
   January 31, 2012

   Shantanu,

   I suspect that many if not most of the people who have been promoting this kind of thing their entire professional lives will stay stuck in the denial phase forever. The attempt by Burgess (and others) to claim the LHC not seeing anything as a success for their theory is pretty amusing.

   My TOE is that everything is turtles, very small ones, of size about (100 TeV)^-1. So, not visible at the LHC, thus the latest data there is a huge success for my theory.

6. **Low Math, Meekly Interacting**
   January 31, 2012

   When I read the abstract, I thought that Dr. Andrulis' theory could very well be a hoax. Then I scanned the manuscript, and am convinced that my first impression was wrong. Nobody would go to that much trouble to be a joker, no matter how deranged. Perusing his other publications, it's all quite solid and uncranky. I don't know what to make of it.

7. **Low Math, Meekly Interacting**
   January 31, 2012

   OK, having read a bit more, I do know what to make of it: the guy is nuts. Certifiable. It's monomaniacal crankery of the first water. No matter how coked up the guy might have been to hasten production, this thing must have taken many months of painstaking research, however bizarre the inferences he drew from his hundreds of references. He practically invented a new language just to convey the details of this…I don't even know what to call it; "theory" just isn't up to the task. It looks to be the mother of all crackpot opera, and somewhat disturbing to read.

8. **Avattoir**
   February 1, 2012

   low math, etc. – Could be a crying need for a journal for TOEs short on T, where O = 0, long on E, with peer-review standards fixed by xkcd; call it Doodles Review.

9. **Cesar Laia**
   February 1, 2012

   Andrulis' theory is not a theory, it is a completely useless language that tries to put everything under some kind of common ground. I have to say it: it is weird beyond imagination.

10. **harryb**
February 1, 2012

Interesting stuff . Add Gyres to Circlons – Margaret Wertheim would be proud of this stuff / guff.

Is this a harbinger of non-science becoming more difficult to combat due to a rapid veneer of internet credibility? I don't think so. Hyped for a moment, blogs like this refute it pretty quickly.

The pace of theory generation may have increased – but the testability / prediction filter now seems even more precious.

The comments on the CMS show also how String Ideology seems more and more a zombie theory – still going, unkillable, yet lifeless.

11. **harryb**
February 1, 2012

@Enrico

I did indeed suggest this book as Peter points out. I am afraid the invocation of multiverses is used quite a bit, and though I think Lawrence Krauss a charismatic author, this preference for multiverses continues to vex me. Its a giant hand-waving answer when more grounded unresolved basics such as quantum pressure seem to have much more life in them.

12. **Nick M.**
February 1, 2012

To quote from the article on the ARS Technica website that Peter has a link to above:

> **"**He's serious about the "not limited to" part; one of the sections describes how gyres could cause the Moon to form.**"**

So perhaps we will finally have an answer to the question of whether the Moon is there, or not, when nobody is looking!!

13. **Low Math, Meekly Interacting**
February 1, 2012

I just checked out Pharyngula, and the discussion there seems to confirm it: Dr. Andrulis is probably not well. Perhaps it's best I retract some of my harsher statements and hope he gets the help he needs.

So, better to focus on the real issue here, then (which I think was Peter's intent anyway): How? How in the bloody HELL did this get past Case Western's filters, or do they have none?

14. **Yatima**
February 1, 2012

>quantum theory is equally an exercise in probability theory

Along the lines of Lucien Hardy (http://arxiv.org/abs/quant-ph/0101012) and Ray Streater (http://arxiv.org/abs/math-ph/0002049) I suppose? Ray is way over my head here though.

15. **AcademicLurker**
February 1, 2012

LMMI:
How in the bloody HELL did this get past Case Western's filters

At least in my experience, academic institutions don't generally have filters that would prevent something like this. I've certainly always submitted directly to the journals, nothing was ever approved beforehand by some university level official (and a good thing too).

CWRU's screw up was in issuing the press release, assuming they're the one's that issued it. If that's what you meant, then I agree. *Someone's* alarm bells should have been set off before they reached the point of publicizing this stuff.

(stupid unrelated question: why do none of the standard methods for inserting line breaks seem to be working?)

16. **AcademicLurker**
February 1, 2012

Never mind…

17. **Low Math, Meekly Interacting**
February 1, 2012

Yes, I meant the hyping. It is not possible to avoid overstating the importance of Dr. Andrulis' work because, from a scientific perspective, it is utterly bereft. Anyone who reads even the abstract ought to be able to recognize that it is in the interests of all concerned to avoid public acknowledgement that it exists.

18. **Chris W.**
February 1, 2012

Low Math, Meekly Interacting,

As an RPI undergraduate many years ago, I recall coming across some curious little volumes among their physics books, the contents of which were quite similar to Dr. Andrulis' writing. I've sampled quite a few crackpot musings on the web since. They all seem fundamentally quite similar—a certain kind of barely coherent word salad that conveys a feeling that the author imagines himself in possession of a vast and indubitable insight into the nature of reality. I'll bet reams of this stuff get written every year, albeit rarely with the visibility granted to faculty at reputable institutions.

19. **Low Math, Meekly Interacting**

February 2, 2012

I guess it's old news on the interwebs, but a few of Life's editors, who were reportedly unaware of the paper until after publication, have resigned in disgust. Wonder if any heads will roll at Case.

20. **Shantanu**
February 2, 2012

Peter have you seen this?
Any comments?
http://blogs.nature.com/news/2012/01/us-physicists-call-for-underground-neutrino-facility.html

21. **Chris W.**
February 2, 2012

In my last comment I meant to say:

"As an RPI undergraduate many years ago, *browsing the university library*, I recall coming across some curious little volumes among …"

22. **Peter Woit**
February 2, 2012

Shantanu,

Interesting to see the strong endorsement from so many theorists. I haven't been following the LBNE story, had assumed that closing the Tevatron while keeping the US HEP budget fairly constant would free up funds for it.

23. **Shantanu**
February 3, 2012

Agree. however am surprised that the theorists in the letter still believe proton decay will be seen. Also I think we discussed here, non-0 neutrino mass really doesn't tell you much about physics beyond standard model.

24. **Tim van Beek**
February 3, 2012

Peter wrote:

> From Sean Carroll's Twitter feed I learned about this long description of a recent workshop bringing together philosophers and quantum field theorists.

Thanks for the tip, now I understand where the idea that "AQFT is a failed research program" comes from that I read about at several places in the blogosphere, it is from

*David Wallace: Taking Particle Physics Seriously: a Critique of the Algebraic Approach to Quantum Field Theory

While I *could* explain what Wallace gets wrong, in the spirit of the "string wars" I will instead mention that Ed Witten chose to use the framework to make some of his earlier ideas mathematically precise, see the arXiv. See?

While I agree with Wallace that philosophers of science should not limit themselves to theories that are mathematically precise (ignoring Lagrangian QFT and concentrating on AQFT, in this case), I get the impression that he (as several other theoretical physicists) actually don't understand what "mathematically precise" means – to mathematicians: He writes that Lagrangian QFT is, in this regard, on the same footing as QM, i.e. molecular and nuclear physics etc. From his paper:

> …the level of mathematical rigor in CQFT is basically the same as elsewhere in theoretical physics. So applying this standard even-handedly would invalidate practically all of the theoretical physics of the twentieth century: atomic physics, non-relativistic scattering theory, astrophysics, nuclear physics, etc, etc.

It would seem that this misunderstanding is also behind a lot of back and forth regarding the statement that "string theory is mathematically consistent".

25. **CU Phil**
February 3, 2012

Hi Tim,

I agree with you (in disagreeing with Wallace) that AQFT should not be considered a failed research program, and with Peter that people interested in understanding QFT should marshal any resources available. (As an aside, I was actually at the conference in question, and that tended to be the consensus view). However, I don't think the "failed research program" claim really originates with Wallace — I've heard it from physicists more than a few times, including some who I consider more concerned with rigor than most, as well as some wouldn't be caught dead reading a paper published in a philosophy journal. So my experience suggests that Wallace's claim is probably a symptom, rather than a cause, of the attitude you report seeing in the blogosphere.

26. **Chris Oakley**
February 3, 2012

Insofar as after more than 50 years one cannot calculate cross sections with AQFT, it is certainly a failed research program.

A bit more honesty about conventional QFT by Wallace, though, would be welcome.

QFT, as originally formulated, does not work when interactions are introduced. We therefore do not use it for this purpose. Instead our interacting theory comprises a set of invented fitting functions. Suggesting that these derive from quantum field theory is a nonsense as this would involve extracting unique finite values from the difference of two infinite ones. This is impossible, as all should know.

27. **Tim van Beek**
February 4, 2012

CU Phil said:

> However, I don't think the "failed research program" claim really originates with Wallace — I've heard it from physicists more than a few times, including some who I consider more concerned with rigor than most, as well as some wouldn't be caught dead reading a paper published in a philosophy journal. So my experience suggests that Wallace's claim is probably a symptom, rather than a cause, of the attitude you report seeing in the blogosphere.

Of course I do not know where this claim originates, but since Wallace does not cite anyone else, we could simply stick to discuss what he himself wrote.

Of course a research program can fail only in relation to a specific goal (some people seem to use the phrase to express their *dislike*, like in "AQFT is a failed research program, I don't like it because I have developed a metaphysical allergy against operator algebras". I hope it is possible to keep that out of the discussion).

Wallace claims that the goal of AQFT was to clear up the mess with infinities in QFT and especially the need of renormalization. That may have been the motivation of *some* researchers, but the core motivation for the program was and is to have a *mathematically precise* formulation of what a QFT is. One where you can actually *prove theorems*. As I said before, I now doubt that Wallace even understands what that means.

Then, if the goal is to "calculate cross sections before the year 2000" then the program has failed, too. Wallace keeps pointing out that there is no interacting 4D QFT that fulfills the Haag-Kastler axioms yet, and that he does not see any reason to believe that there ever will be. Well, the advanatage of the axiomatic approach is that you can go back to the drawing board and learn what was wrong with the axioms, in such a case.
I would really like to learn if people who say that the Haag-Kastler axioms don't describe (the Heisenberg picture of) realistic QFTs have specific ideas about what is wrong with the axioms?

28. **Peter Orland**
February 4, 2012

Hi Chris,

You said, "QFT, as originally formulated, does not work when interactions are introduced. We therefore do not use it for this purpose. Instead our interacting theory comprises a set of invented fitting functions. Suggesting that these derive from quantum field theory is a nonsense as this would involve extracting unique finite values from the difference of two infinite ones. This is impossible, as all should know."

No field theorist believes in QFT as it was originally formulated. The original formulation, as a Lagrangian or Hamiltonian with finite interactions is simply wrong. That's why regularization (is this what you mean by "fitting functions"?) must be introduced, then removed. If you do this in the right way, there are no infinities (see below) and the result is unique (we believe). The modern "conventional" viewpoint is that this IS the QFT – the limit of a regularized theory. Most field theorists are very comfortable with this.

A regularized QFT in a finite volume has an interaction representation. There is a "Haag's theorem" ruining the interaction representation, when crossing critical couplings, but we work away from these couplings, approaching them only as we remove the regulator. One never encounters anything infinite, provided renormalization is done this way. I want to stress that this is not the way Feynman, Schwinger or Tomonaga thought about QFT in the 1940s – that point of view is long obsolete.

My impression is that people who don't like regularization are repelled esthetically. They feel regularizations are somehow dirty. I don't know if this is the best analogy, but I think it's like hating Newtonian sums as way of doing integrals, wanting some "purer" method e.g. Lebesgue integration. That's great, if you know how to use the purer method to do calculations or prove theorems. Unfortunately, that's a tall order for algebraic/axiomatic methods.

I think that the point of axiomatic or algebraic approaches is to avoid regularization and start with the theory which already has the (renormalized) S-matrix and Green's functions. But the conventional approach has the same goal.

We have some understanding why results don't depend on the regularization. We define the theory as a limit of the regularized theory, in which we take couplings to zero (in the case of QCD). There are different ways of doing this, but there is numerical and analytic evidence (though not a proof) that the result is unique.

Some algebraic field theorists are looking at conformal or massive integrable theories in 1+1 dimensions. I suspect that's the best place for them to make progress, at least in the short term. These theories can be "constructed" (I am not sure that is the right term) with no regularization, but we know their S-matrices and something about their Green's functions.

29. **martibal**
February 6, 2012

@Chris Oackley:
"this would involve extracting unique finite values from the difference of two infinite ones. This is impossible, as all should know."

What about renormalization as a Birkhoff decomposition ? (work of Connes and Kreimer in the years 2000) ?

30. **Jeff McGowan**
February 6, 2012

@peter orland

As a mathematician who has aesthetic issues with regularization I have a question – does the Riemann sum/Lebasgue analogy hold in that there are cases in the QFT's you can't handle, but perhaps you could handle with a better formulation? The Lebasgue integral is clearly better than the Riemann one, since it works for a (much) wider variety of functions, is there some hope one might get a formulation of QFT which did the same thing?

31. **Peter Woit**
February 6, 2012

Jeff,
Maybe some new magical idea will appear, but the problem here doesn't seem to be with the kind of integral you are using, but with the fact that the effective behavior of the fundamental degrees of freedom is changing as you vary the distance scale.

For asymptotically free theories like QCD, what is happening is that the behavior is approaching that of a free theory on distance scales going to zero, so in principle under better and better control as you go to zero distance. We believe there is a well-defined limit for these theories and have a conjectural precise statement about how it works (and the way it works isn't just a technicality of properly defining a measure). Proving these conjectures though is hard (worth a million dollars from Clay), but the difficulty is not at short distances, but that you have to also understand what happens at large distances, where the physics is strongly coupled and perturbation theory is useless.

For non-asympotically free theories like QED, or the Higgs theory, and for non-renormalizable theories like gravity, the degrees of freedom are not weakly coupled as you go to short distances. So, understanding the continuum theory requires some precise understanding of the theory non-perturbatively, and we have very little to go on there. Maybe some new notion of "integration" will solve this, but it looks like it would have to be something much more powerful than a simple technical trick. People have tried many technical tricks, but I think the reason nothing has really worked is that your "trick" needs to essentially solve exactly a non-trivial quantum theory with infinite number of degrees of freedom, away from any limit we understand.

32. **Peter Orland**
    February 6, 2012

    Jeff,

    This is just to add to what Peter W. has said:

    To answer your question as to whether one can do better than the standard approach – it isn't clear. There are (non-rigorous) exact calculations in some field theories with no regularization at all. These exist only in one space and one time dimension. There is no powerful general method, except in the conformally-invariant case. In the massive case (sine-Gordon, nonlinear sigma models, Gross-Neveu models), a lot of guesswork is involved, though the results are remarkable.

    Such techniques don't generally work in higher dimensions, though there is good reason to be optimistic for conformally-invariant supersymmetric gauge theories.

33. **Jeff M**
    February 6, 2012

    Thanks Peters. First Peter, I wasn't thinking some clever new integral might work, just using it as an analogy, my thought being that perhaps one might come up with a new way of looking at things (as Lebasgue did) to eliminate the problems. Second Peter, I guess from what you say that this can be done, but only in 1+1 dimensions, which I would think are quite far from being in any way generalizable. At least in my field 2 dimensions is very very different from 3, which is very different from 4+…

34. **thomas**
    February 7, 2012

    I was watching Arthur Jaffe's Simons Center talk the other day. He motivated work on QFT by the enormous success of QED in predicting g-2, and then went on to lament the lack of effort devoted to rigorous algebraic results. To me, this seems like a rather strange argument. We strongly believe that QED is just an effective field theory, so presumably there will never be a rigorous algebraic construction of QED.

    What also strikes me as slightly odd is that we do think that Wilson successfully "constructed" QCD, as the continuum (and infinite volume) limit of the lattice regularized version. It would seem like an interesting research program for mathematically inclined folks to show that the limit exists, and that is satisfies certain axioms. (In fact, it seems to me that this would be the most promising avenue towards proving confinement, because we already know that the theory is confining at strong coupling). But somehow this is not emphasized all that much, possibly because it does not really fit in very well with the emphasis on algebraic methods.

35. **Peter Woit**
    February 7, 2012

    thomas,

    What you suggest is exactly what many mathematical physicists have tried to do, and I'd think it's considered the only known path to getting the million dollars. The reason you don't see papers about it is that no one has a good idea about how to do this. On a fixed finite lattice you have good control over the weak and strong coupling limits, but this isn't good enough. The problem seems to be that no one understands well the physics of how the weakly coupled behavior crosses over to the strongly coupled. There are ideas about large N limits, but for fixed N you just don't have a good idea. Lacking any real "physical" argument for what is going on, finding a rigorous mathematical argument is probably hopeless.

    One example of this kind of thing is the Tomboulis paper discussed back in 2007 here

    http://www.math.columbia.edu/~woit/wordpress/?p=576

    and here's a later critique of it

    http://arxiv.org/abs/0901.4246

36. **thomas**
    February 8, 2012

    Work like the Tomboulis paper is indeed what I had in mind. I was mainly commenting on the fact that the Simons people organize a meeting on the Foundations of QFT and it appears that this sort of thing is not even discussed (they did, admittedly, have a talk by Kaplan on lattice fermions and lattice SUSY) .

37. **harryb**
    February 8, 2012

    Peter

    On following your link to CERN book reviews, I downloaded John Marburger's Constructing Reality on the basis of the review. For the non-physicist a demanding but very engaging overview on QT and particle physics. Interestingly, in a long book he only devotes two or three paragraphs to ST, and in chapter 6 – The Machinery of Particle Discovery – he references ST explicitly, but the footnotes take the reader only to Greene's The Elegant Universe, and to yourself and Lee Smolin who "approach string theory with much insight and considerably less enthusiasm".

    Balance at last?

38. **Peter Woit**
    February 8, 2012

    harryb,

    Thanks, I haven't seen that book. On the whole discussion of string theory has been much more balanced the last few years, for whatever reason…

39. **Allan Rosenberg**
    February 9, 2012

    If philosophers can't solve the technical problems of QFT, why not let the lawyers have a crack at it?

40. **Thomas**
February 10, 2012

Do physicist not become very nervеous because of the open consistency questions in quantum field theory? Friends whom I had asked compared with the (for ca. a 1.5 centuries) unsettled similar problems with analysis in the past, but the intensity and time frame would put it more properly (and more uneasy) near the centuries of unclear foundational issues in geometry in the past. And until those open issues are not really solved, does physics not risk to run into a dead end, as one needs enough theory to learn what data tell – when I read about waiting for accelerator's or astrophysical data, I wonder if the situation could be actually worse. (I.e. even if current theories fit reality, only with missing better theory one can find that out). The "practical standpoint" one reads about sounds to me wrong, e.g. it happened science history in the disputes between ptolemaic and kopernican astronomy, where real insight and progress came with the "unpractical theory" only.

41. **Chris Oakley**
February 10, 2012

> The "practical standpoint" one reads about sounds to me wrong, e.g. it happened science history in the disputes between ptolemaic and kopernican astronomy, where real insight and progress came with the "unpractical theory" only.

I totally agree. If you are going to botch it (and I am not necessarily demeaning that activity), it should be with the simplest thing available, which is why I am not in favour of (e.g.) the Epstein-Glaser technique or Hopf algebras. I challenge anyone who thinks that "regularizing" pathologically divergent integrals is an acceptable activity to formulate their theory in a way that avoids mention of divergent integrals at all. Introducing extra, spurious parameters that were not present at the outset is not allowed.

42. **Thomas**
February 10, 2012

@Chris – But is renormalization not very nicely in the process of becomming clear, in the work of Connes, Kreimer, Marcolli?

43. **Thomas**
February 10, 2012

@Peter Woit: "non-renormalizable theories like gravity" – what do yo think about Kreimer's idea that it may be renormalizable?

44. **Peter Woit**
February 10, 2012

thomas,

I don't know what idea of Kreimer's about quantum gravity you're talking about, and I don't think recent work by Connes, Kreimer, Marcolli resolves the problems with consistency of QFT that are serious worries. They're all studying the perturbation expansion as far as I know, and I don't see how you can get a fully consistent theory even for QED that way.

45. **Thomas**
February 11, 2012

Hi Peter,

yes, that work on renormalization fits probably better into the process of extracting interesting "platonic ideas" from quantum field theory and where they arise in pure mathematics, but not into those consistency questions. My impression is that one can say that such use of ideas from physics just extends what the antique greek geometers did with intuitions about space coming from our biology for doing geometry and even Kant struggled much later with distinguishing mathematics, "platonic ideas", physics (I just remember that this confusion extends to Bertrand Russel too, his PhD-thesis was about "proving" from first, nessessary principles of space-concept constraints for the physical universe).

Kreimer's remarks on quantum gravity are linked to in his website: http://www2.mathematik.hu-berlin.de/~kreimer/index.php?section=research&lang=en

And the arxiv has some articles by Jack Morava on physics, I would like to know what physicists think about it (in mathematics, his genius is so highly esteemed that I can't imagine that his idas on physics are not deep and interesting too): e.g. http://arxiv.org/abs/math/9908006 , http://arxiv.org/abs/math/0407104 , http://arxiv.org/abs/1001.0965

46. **Igor Khavkine**
February 11, 2012

@Chris Oakley wrote:
"I challenge anyone who thinks that "regularizing" pathologically divergent integrals is an acceptable activity to formulate their theory in a way that avoids mention of divergent integrals at all."

The Epstein-Glaser method precisely meets your challenge. To see that, one need only study it. Other, more conventional methods, whether involving divergent integrals, also lead to the exact same result. Though, if extensive discussions on spr did not convince you of the soundness of renormalization, a few blog comments won't either. However, the false implication made in your comment is worth correcting.

47. **Chris Oakley**
February 11, 2012

Ivor,

As I understand it, the Epstein-Glaser method involves inserting c-number functions which generalise the otherwise-badly-behaved time-ordered product expressions that appear in the perturbation expansion. A limit is taken with these functions to obtain a finite "physical" result.
The renormalization I was taught (in Cambridge, 30 years ago) on the other hand typically involves cutting off an integral, and the limit one takes later is with respect to this cutoff parameter.
Whilst I cannot argue that the Epstein-Glaser approach is more highbrow, it still amounts to the same thing: introducing extra degrees of freedom midstream, and taking some kind of limit. Although one may *think* one can get a unique answer, the fact is that by applying a little creativity one can get any answer one wants. This makes the exercise little more than the application of invented fitting functions. I see no axiomatic basis.

48. **Peter Woit**
February 11, 2012

Enough about renormalization, please. At this level of arguing about whether perturbative divergences in general are

1. A serious problem indicating the theory is ill-defined
2. Things that can be eliminated with mathematical machine X
3. Not there if you use the renormalization group properly

the discussion is stuck in a 40-50 year old time warp. I don't think that endlessly repeating geriatric arguments is fruitful.

49. **Anon**
February 16, 2012

This is probably very naive, but aren't we blurring the boundaries here between showing existence of a QFT and actually solving the QFT? For QCD, isn't existence pretty much a consequence of the property that the theory has a well-defined continuum limit (which is a consequence of asymptotic freedom)? Do we have to actually have to require, as you state, Peter, that someone solve the collective degrees of freedom of the low energy regime to know that the theory is well-constructed? And if so, why draw the line at the energies at which low energy particle experiments are done, as opposed to, say, requiring a first principles construction of, say, fluid mechanics, or the folding of hemoglobin, from QCD, before we will accept it as mathematically rigorous?

50. **Peter Woit**
February 16, 2012

Anon,

The problem is that you have to show that when you take the continuum limit you get a non-trivial theory. If you don't know anything at all about the infrared behavior when you take the continuum limit it's possible that in the limit you get a trivial theory in which all physical degrees of freedom have masses that go to infinity. Or all masses are zero (this is what is supposed to happen for the N=4 supersymmetric case).

The Clay problem is carefully worded, just asking for proof of a finite mass gap. This is pretty much the minimal information you would need to see that you have something non-trivial.

The Langlands Program and Quantum Field Theory

February 1, 2012
Categories: Langlands

Edward Frenkel is here this semester in the math department at Columbia, and he's giving a series of lectures on a topic dear to my heart. Video of his lectures on The Langlands Program and Quantum Field Theory is starting to be available, courtesy of our graduate students Alex Waldron and Ioan Filip, as well as our staff member Nathan Schweer.

The first lecture last week was an overview, outlining the general picture of the Langlands program in the number field, function field and geometric cases, as well as two sorts of connections to QFT (to certain 2d conformal field theories, and to S-duality in 4d super Yang-Mills). This week he started to get more specific, giving some details about how the Langlands program works in the function field case, in preparation for moving next week to the geometric analog where a curve over a finite field gets replaced by a Riemann surface. As an indication of references covering much of the material to be discussed in lectures, Frenkel suggests this survey article and this Seminaire Bourbaki report.

Frenkel is also working on some other different but quite interesting projects. With Ngo and Langlands he has a program to "geometrize" the trace formula, for details see his very recent AMS Colloquium Lectures. With Losev and Nekrasov he has a fascinating program for studying certain field theories using instantons in a very different limit than the usual semi-classical one. See here, here, and here.

Comments

1. **Some Physics Bro**
   February 2, 2012

   Interesting links!

   I was reading through and on the 6th page of the first Frenkel, Losev, Nekrasov paper they rather off-handedly state (without reference) that "It is generally believed state that non-supersymmetric quantum field theories should be understood as non-supersymmetric phases of supersymmetric ones". Is this a common piece of wisdom? I have never heard anything along these lines before. What does this even mean? Is there any sort of talk or paper that actually lays out an argument about this? Or is this just some personal conviction the authors decided to slip in without having to explain?

2. **Peter Woit**
   February 2, 2012

   SPB,

   You're dropping the adjective "realistic" in that quote, it doesn't sound like they are talking about a general phenomenon in QFT. I'm not sure what the authors had in mind, but one possibility is that they are just referring to the idea that the SM is really part of a SUSY theory with broken supersymmetry. This certainly has been a popular idea among theorists, perhaps less so after the past year of LHC results…

3. **Ossicle**
   February 3, 2012

   To what extent does his work intersect (or whatever verb you like) with you own ongoing efforts? Is his presence at Columbia this semester potentially fruitful for your work?

4. **Peter Woit**
   February 3, 2012

   Ossicle,

   There's quite a lot of intersection of Frenkel's work with what I've been trying to do, and having him here is great for me. We've already talked a bit, that has been very helpful and I'm sure this will continue. The next few weeks he'll be covering in his lectures the topics closest to my interests (how 2d QFT gets used in geometric Langlands). The combination of the lectures and being able to talk to him about this should help clarify a lot for me and hopefully will lead to some significant progress (and to finally getting some of this written up…).

5. **Ossicle**
   February 6, 2012

   That's terrific, Peter, good luck. I'm rooting for you to accomplish great things! 😀

6. **Mike**
   February 9, 2012

   Peter,

   I was wondering if you'd seen the discussion at Sean Carroll's blog about Lagrangian QFT.

   Here is the link:
   http://blogs.discovermagazine.com/cosmicvariance/2012/02/07/how-to-think-about-quantum-field-theory/#more-7957

7. **Peter Woit**
   February 9, 2012

   Mike,

   I wrote about this here:

   http://www.math.columbia.edu/~woit/wordpress/?p=4408

   To my mind it's hard to overemphasize how poorly we understand QFT, and so "heuristic" as well as "rigorous" approaches are both worth pursuing.

Latest from the LHC

February 7, 2012
Categories: Experimental HEP News

CMS and ATLAS have just released final versions of their Higgs analyses for the 2011 data (the new CMS gamma-gamma analysis was previously discussed here). The preliminary versions of these were what was released last December, and the final versions don't differ in a major way. The bottom line is still the same: there's evidence for a Higgs around 125 GeV, of the sort that you would expect with this amount of data if it were really there, but the evidence is still too weak to claim discovery. The CMS papers are here, here and here, with the combination here. The ATLAS papers are here and here, combination here.
Check out Philip Gibbs to see if he updates his unofficial overall combination. Rumor is that the official CMS+ATLAS combination, along with the latest Tevatron Higgs results, will be released at Moriond (first week of March).

This week the people responsible for operating the LHC machine are meeting at Chamonix, slides here. Current plans are to start recommissioning the machine March 14, and run at 4 TeV/beam, a slight increase over the previous 3.5 TeV/beam. Projected integrated luminosity is 3-4 times that of 2011 (15-20 inverse femtobarns). After the end of the pp run in October, it will be quite a long time until proton collisions start up again (late 2014 or 2015?), since there will be a long shutdown to fix magnet interconnections and allow the machine to operate at or near design energy (7 TeV/beam).

On some other blogs you can find rumors of evidence for observation of an stop squark. I've heard nothing of the sort, but who knows? Informed rumors are encouraged. One of the things about the LHC results that has surprised me is the lack of any such claims over the past year or so. With all the searches being done, you'd think that someone, somewhere would find a fluctuation big enough to get SUSY enthusiasts excited, whether or not there was anything actually there.

Update: For more about this, see Tommaso Dorigo, Matt Strassler and Jester.

Update: A new unofficial combination from Philip Gibbs is now up here.

Update: Chamonix summary is here. The long shutdown starting this fall should last until at least September 2014. After this the hope is to run the machine at 6.5 TeV/beam. There seems to be little hope any longer of running at full design energy of 7 TeV/beam.

Comments

1. **Bernhard**
   February 11, 2012

   So, we will probably discover the Higgs this year and if nothing else shows up, be until 2015 without data again and still having absolutely no good idea what lies beyond the Standard Model. After the Higgs hangover passes, will be a depressing scenario.

2. **neo**
   February 15, 2012

   re "he long shutdown starting this fall should last until at least September 2014. After this the hope is to run the machine at 6.5 TeV/beam. There seems to be little hope any longer of running at full design energy of 7 TeV/beam."

   What are the ramifications to BSM physics for this?

3. **Peter Woit**
   February 15, 2012

   neo,

   The implications of the lower energy are not that large. Shouldn't significantly affect the study of the Higgs (if it really is around 125 GeV). The bounds on SUSY and other exotic BSM phenomena will be slightly weaker, but that's not of great significance for physics.

SUSY Still in Hiding

February 14, 2012
Categories: Experimental HEP News

Recent rumors supposedly coming from theorists at Harvard indicating that today would be the day that an announcement would be made of first evidence for a superpartner of a top quark have just been shot down. The talk at CERN on recent ATLAS searches for such a signal shows that nothing was found. An example of new limits is that if stops are produced via gluinos, the gluino has to have mass greater that 650 GeV and the stop a mass greater than 450 GeV.

Over the past year the LHC has conclusively falsified pre-LHC predictions that strongly interacting superpartners would easily be seen in the early data, with typical bounds on gluino masses now up to 1 TeV or so. One way to evade this conclusion has been to argue that the first two generations of squarks are quite heavy, with only the sbottoms and stops accessible to the LHC. A typical example of analysis of scenarios of this kind can be found here, where the conclusion is that naturalness requires that the mass of an stop be less than 400 GeV, and the mass of a gluino less than twice the mass of the stop. This is now starting to be in significant disagreement with the data.

The ATLAS analysis uses 2 fb^{-1} of data, with the promise of updated results using the full 4-5 fb^{-1} coming soon. The details of the new analyses were made public today here, here and here. For some background, see the latest posting at Resonaances. I hear that similar analyses now completed by CMS, with the full 2011 dataset, also show nothing. This week the earliest of the Winter conferences is going on, at Aspen, and tomorrow there will be talks updating the LHC SUSY situation from ATLAS, CMS, and theorist Matt Reece.

The LHC has done an impressive job of investigating and leaving in tatters the SUSY/extra-dimensional speculative universe that has dominated particle theory for much of the last thirty years, and this is likely to be one of its main legacies. These fields will undoubtedly continue to play a large role in particle theory, no matter how bad the experimental situation gets, as their advocates argue “Never, never, never give up!”, but fewer and fewer people will take them seriously. As always seemed likely, the big mystery the LHC will solve will be that of the Higgs: is it really there, and if so does it behave as the Standard Model predicts, or does it do something more interesting? Unfortunately we’re going to have to wait a while longer for more news on that front.

Comments

1. **manyoso**
   February 14, 2012

   With so many prominent theorists betting on SUSY over the last few decades and the continued null signal at the LHC… if this continues couldn’t you almost call it ‘New Physics’ discovered by the LHC in that so many expected to see SUSY?

2. **Harry**
   February 14, 2012

   “Never, never, never give up!”.. Is this supposed to echo Churchill’s “never, never, never […] give in except to convictions of honour and good sense” ? 🙂

3. **physicsphile**
   February 14, 2012

   Having spoken to someone working at the LHC, apparently crazy seeming results are always turning up but they have always gone away on closer examination. So it would probably be better if the rumor mongers rather wait to get the official word from CERN.

4. **MathPhys**
   February 14, 2012

   In my humble opinion, the belief that there is susy and it solves many problems, but we don’t see it because it’s softly broken, and if we go to high enough energy, we’ll see it again, is one of the most simple-minded ideas in modern physics.

   I have to believe that God is more imaginative than that.

5. **Peter Woit**
   February 14, 2012

   physicsphile,

   Or they could get higher-quality rumors from more reliable blogs…

   MathPhys,

   What’s odd is that since following this logic leads you quickly to something quite ugly that explains very little (105 extra parameters???). I’ve never understood why people found that route attractive. There’s some fascinating mathematical structure going on, and I can see why people want to take that seriously, but there’s also clearly some big ideas missing about how to relate this to the real world.

6. **MathPhys**
   February 14, 2012

   Peter,

   In my very humble opinion, people take the susy road for two reasons

   1. The mathematically-minded types find supersymmetric quantum field theories extremely attractive because you can do some stunning things in them.

   In QCD, you work so hard for so long to compute some radiative correction to low order in perturbation theory, then you go to super YM and use relatively simple arguments to obtain some deeply non perturbative results. It’ hypnotic.

   2. To the rest, it’s a good way to generate a steady stream of papers.

   I think that things are getting really exciting in high energy physics now. I am very curious how things will be like 5 years from now.

Can such a wonderful, elegant and extremely useful mathematical structure turn out to be physically totally irrelevant? Did the "unreasonable effective of mathematics in the physical world" finally let us down? Very exciting times ahead.

7. **MathPhys**
February 14, 2012

I went to a talk on some topic in a hyperbolic universe. The speaker started by saying that of course we know that the universe is not hyperbolic, but it's still important to learn as much as we can about that topic regardless of the parameters.

I think that that's how people will continue to work on many topics long after LHC discredits them. My point of view is that, if it's harmless and makes you happy, go for it.

8. **Cesar Laia**
February 15, 2012

I don't understand why they used only 2 fb-1 of data, when they have already 5 fb-1. If the 5 fb-1 data will come soon, I guess they already have an idea of it's coming. So… would it make any sense to announce now they saw notting just to say a few months later that actually there is something new?

9. **Peter Woit**
February 15, 2012

Cesar,

It takes a lot of work to analyze this data. They need to completely understand the behavior of their detector and all the possible sources of background. And the data was gathered over 2011 under changing conditions (luminosity was increasing, triggers changing). So, possibly quite a lot more work is needed to analyze the rest of the data set.

Right now ATLAS has the best bounds on SUSY of this kind, which is presumably why they announced now. They're in a competition with CMS, which provides pressure to release results once they have confidence in them, not wait for something better.

10. **Angel Naydenov**
February 15, 2012

Dear Peter,
I am currently reading Chapter 12 of your book and to be honest, I was hesitating to continue once the stop rumour surfaced.
However, it looks as if apologies are in order for letting you down. All seems so logical when you explain it, it's fascinating that your view is not shared by the majority of scientists.
Do you believe a paradigm shift is on its way? Which direction shall we choose to make a step forward?
Thanks, and please blog more! 🙂

11. **Eric**
February 15, 2012

There are actually two separate issues which are being confused here, the rumors regarding the stop having been seen at the LHC and the speculation of one blogger that these rumors were to be addressed in a seminar this past Tuesday. The speculation regarding the Tuesday seminar did not pan out, however it does not then follow that there is nothing to the rumors. Be patient and let the experimenters complete their analyses.

12. **Anonyrat**
February 15, 2012

Eric, Tuesday's seminar set more stringent bounds on sTops, so……

13. **Eric**
February 15, 2012

Anonyrat, this is only with 2 fb-1 of data, whereas 5 fb-1 of data has been collected, so…

14. **Anonyrat**
February 15, 2012

sigh, if the 2 fb-1 showed some hint of something, then its strengthening in 3 additional fb-1 of data would be plausible.

15. **MathPhys**
February 15, 2012

Is there a way to put money on whether susy will or will not discovered, let's say by end of 2012?

I want to bet $100.00 that there will be NO evidence of susy by end of 2012. `Evidence' here means an official announcement from LHC. Rumours do not count.

16. **Peter Woit**
February 15, 2012

Angel,

Thanks, though I should point out though that my views about SUSY, string theory, extra dimensions, etc. have never really been minority ones, and definitely aren't now. I think MathPhys is going to have trouble finding anyone willing to bet $100 on SUSY this year, or maybe even on SUSY this decade.

One big lesson of the LHC I think is going to be that the Standard Model is just too good. None of the ideas of dramatically adding lots of complicated structure to it are having any success. It would be a good idea to concentrate on what we don't understand about the Standard Model itself (one example: how to formulate chiral gauge theories non-perturbatively). Personally I'm enthusiastic about new ideas I'm working on about how to handle gauge symmetry with a variant of BRST called Dirac cohomology, as well as related ideas about the relationship of QFT and Langlands theory in math. But, people should work on whatever they enjoy and think is promising. It's getting harder and harder though to claim that SUSY ideas like the MSSM are in any sense "promising" these days.

17. **anon.**

February 16, 2012

Two brief comments:

* The original rumors *I* heard, at least, were about CMS, not ATLAS. Further attempts to ferret out what's going on haven't turned up anything, and the rumors exist in several contradictory strains, so I doubt there was any substance to them.

* Tuesday's seminar didn't set more stringent limits on stops, it set limits on *gluinos* decaying to stops, and not really more stringent ones than previous same-sign dilepton analyses had set.

18. **sUP**
February 16, 2012

Dear Peter,

if there is no SUSY out there, what would be most promissing explanations for so called dark matter/energy puzzle?

19. **Peter Woit**
February 16, 2012

anon.,

I'm still curious about where these supposed Harvard-originated rumors came from. I've seen one soon-to-be-released CMS SUSY analysis very similar to the new ATLAS ones, and they see nada.

It always seems to be though that as new ATLAS/CMS analyses are released, we hear "move along, nothing new to see here". Is there an analysis to be released at Moriond that SUSY proponents can point to as likely to provide a signal according to one of their favorite scenarios? If not, what is the time scale for such an analysis: Summer 2012? Winter 2013? Winter 2016?

sUP,

SUSY never gave an explanation of dark energy. For dark matter, I know of no explanation that could be called "promising", SUSY or otherwise.

20. **Shantanu**
February 16, 2012

suP, dark energy could be a plain cold cosmological constant or just back reaction
due to density inhomogeneties (which has nothing to do with SUSY)

Also dark matter could be axion or primordial black holes (nothing to do with
SUSY) or massive graviton and many other such candidates nothing to do with SUSY.
none of these are ruled out.
Or maybe dark matter also could be due to modified gravity (yes, people
always cite bullet cluster as a counter-evidence against this, but that is oversold
and bullet cluster observations pose problems for dark matter).

21. **anon.**
February 16, 2012

Rumors I heard originated with CERN theorists.

A few results so far that were *not* "nothing to see here," in my idiosyncratic opinion:
* First 1/fb jets+MET results
* First 1/fb same-sign dilepton results
* ATLAS limit on sbottom -> bottom + invisible
* Limits on R-hadrons
* The potential Higgs signal

All of these wiped out huge chunks of parameter space. I don't know if Moriond will give us anything as dramatic or not. Direct stop searches are more difficult, but will be very interesting, whenever they start to appear.

22. **harryb**
February 16, 2012

@MathPhys

"Is there a way to put money on whether susy will or will not discovered, let's say by end of 2012?"

Yes. Go to Intrade.com and you will find a potential market there. I raised this before in this blog a month ago, and was chastised for leading people to a market that is too thin for real gains. Whatever, acorns, oaks etc.

I still believe that if there was an active "market" for current theories then as in sports that were latterly opened up to proper markets, interesting bets might take place. (Who would believe a left tackle is the second highest paid position in American football etc).

If capitalism / market theory (flawed or nor depending on your political flavour) is essentially a human endeavour, as is science, then a consilience between the two ought to be at least explored. If nothing else it would take esoterica more mainstream and if String Theory stock fell miserably, we all might feel a bit more comforted (and if it rose, then we would have explaining to do).

Anyway – I think the market test you propose is very good. Good luck at Intrade.

23. **SpearMarktheSecond**
February 16, 2012

Well, if there is thermal equilibrium between quarks/leptons and the dark matter, a weak interaction cross section between quarks/leptons and the dark matter is indicated.

Hence the promising WIMP conjecture.

That SUSY implementations got this right along with detailed Big Bang modeling was also promising.

But SUSY has lots of nutty adaptations in it… like 5 squarks degenerate in mass. Also… left handed scalars and right handed scalars. Lots of people have trashed SUSY for a long, long time.

24. **MathPhys**
February 17, 2012

@SpearMarkTheSecond,

Can you give us more details of how susy model building was abused? This has always been my impression as well, but I don't know enough phenomenology to say something meaningful. I go to their talks and I hear what I consider to be unimaginative science fiction, but everyone else sits there nodding.

@harryb

Thank you. I will.

25. **Cesar Laia**
February 17, 2012

I would like to make a question. Everyone seems focused on the LHC results, but what are the chances in the near future that other experiments could give hints about SUSY and other theories? E.g., I wonder what relevance the results from the Planck Telescope will have, but being a laymen I am not aware of other promising experiments. It seems to me that what you need are clever experiments right now.

26. **Shantanu**
February 17, 2012

Cesar, short answer is no. Planck can only potentially detect tensor modes, from
which you can potentially say something about inflaton potential. but susy says nothing about it.
In theory if proton decay is detected that could be an indication for SUSY. but again
the current limits have already ruled out many promising models and I doubt even the SUSY enthusiasts who post on this blog are sanguine about proton decay been detected.

27. **anonymous**
February 17, 2012

Planck is likely to nail 2 important and largely unknown parameters, N_eff and n_s, and is likely to observe f_NL. N_eff is the effective number of neutrino species, which is 3.04 in the standard model. Other CMB experiments (ACT/SPT/WMAP) have been reporting a higher value, albeit with large error bars. Higher N_eff could be evidence for sterile neutrinos. The other two parameters, n_s and f_NL, are important for understanding cosmic inflation or alternative theories. Planck is probably not sensitive to the other inflation parameter, r, although BICEP2/Keck Array or some of their up-and-coming competitors may have something to say about it in a couple years. Cosmic inflation is thought to occur around the GUT scale — a lot of new physics to learn there.

Direct dark matter searches often say they're in the business of looking for SUSY. These experiments usually postulate the existence of a WIMP and try to observe it scattering off a nucleus. Ones that use aggressive cuts to make sure that all they ever see is WIMPs tend to report negative results (e.g. Xenon-100). Ones that just look for seasonal variations in signal tend to report positive results (e.g. DAMA). Some theories say dark matter annihilation can give excess background in the Fermi telescope, which looks at gamma rays although you shouldn't take a result based on a too-high background all that seriously.

One of the more interesting but ignored experiments I see coming together soon is AEGIS, which wants to look at the effect of gravity on antihydrogen. Any surprises there would tell us a lot about the equivalence principle and basic assumptions of particle physics.

28. **Shantanu**
February 17, 2012

anonymous, does super-symmetry actually predict the existence of a sterile neutrino?
(and conversely if no sterile neutrino is found, does that mean SUSY is ruled out?).
from what I understand non-0 neutino mass, whether sterile neutrinos exist,
whether theta_13 is zero or not is completely decoupled from TeV scale physics
and models for EW symmetry breaking.
Also I disagree with
"Cosmic inflation is thought to occur around the GUT scale — a lot of new physics to learn there."
This may have been true before WMAP results. but current limits on energy scale of inflation have already ruled out GUT models as I understand.

29. **Rick Ryals**
February 17, 2012

MathPhys,

If harryb's market doesn't do it for you, try Longbets, "The Arena For Accountable Predictions":

http://longbets.org/

You may or may not find a taker, but it'll be on record, regardless. John Horgan, and more notably, Martin Reese, have predictions there. So do I:

http://longbets.org/476/

30. **anonymous**
February 17, 2012

Yes, those properties of neutrinos should be independent of most SUSY theories. However, neutrino oscillation is the one piece of "Beyond the Standard Model" physics that has been observed concretely.

As for the GUT comment, nobody really knows for sure. There's a lot of parameter space that experiments are actively exploring. The state of the art is the

SPT+WMAP+H_0+BAO result at http://arxiv.org/abs/1105.3182 , which has a solid 3.6 sigma evidence of n_s < 1 and the best published upper limit on the tensor-to-scalar ratio (r < 0.21), with figure 8 showing how some of the more optimistic models are getting ruled out. You need to measure r, though, if you really want to learn the energy scale of inflation. With r~0.2, the energy scale of inflation still could be as high as ~10^15 to 10^16 GeV (very approximately), which SUSY people will tell you is the GUT scale. These SPT+WMAP attempts to measure r through CMB temperature only (as opposed to polarization) are running out of steam because cosmic variance ultimately gets in the way (http://arxiv.org/abs/astro-ph/9407037). If r<0.01, then polarization experiments will also start running into lensing and galactic foregrounds. Hopefully an exciting signal gets discovered before then…

31. **Shantanu**
February 18, 2012

Anonymous, you said

"However, neutrino oscillation is the one piece of "Beyond the Standard Model" physics that has been observed concretely."
This is what everyone says in any neutrino talk, but that's incorrect.
PDG lists it as part of standard model.

See the discussion between me, Tomasso and Andrea here on this in the comment section. (At that time this was news to me also).

Plus as you yourself agree models of neutrino mass such as seesaw mechanism are completely decoupled from BSM physics.

32. **MathPhys**
February 18, 2012

Okay, so even neutrino oscillations are part and parcel of the standard model. Is it safe to say that we don't know of anything, anything at all, that requires 'beyond standard model' physics?

33. **Thomas Larsson**
February 18, 2012

I gave an undergradutate seminar about neutrino oscillations in the spring of 1981, as part of course which nominally was about nuclear physics, but which we students generally called CERN physics because of the trip that ended the course (Cernphysik statt Kernphysik, same thing in Swedish). Assuming that I did not originally came up with the idea of neutrino oscillations, it must have been pretty mainstream at that time.

34. **Ravi K**
February 18, 2012

Shantanu — I think there is no "standard" model for the neutrinos yet. If there is one what is it?

35. **Ravi K**
February 18, 2012

Cesar — I am looking forward to the neutron edm experiments — for a good recent update please see this http://www.nature.com/news/dipole-hunt-stuck-in-neutral-1.9943 I hope they will provide clues as to how P and CP symmetries got violated in nature…..

36. **Shantanu**
February 18, 2012

Ravi, for some reason the link I pointed to did not come out well.
See the comment section of
http://dorigo.wordpress.com/2008/10/31/cdf-publishes-multi-muons/

esp. comments by Tomasso and Andrea Giammanco
Also as mentioned above seesaw mechanism (or whatever other mehanisms
you invoke to give neutrino mass) is completely decoupled from TeV scale physics,
ew symmetry breaking.

37. **Ravi K**
February 18, 2012

Hi Shantanu,

I think the argument by Andrea in that link that neutrino mass is like any other particle's small mass, only smaller, is not quite right.

Basically there is new physics because the standard model has only one mass scale — the Higgs VEV. I dont think you can get the neutrino mass from this single mass scale by multiplying it with a small dimensionless number. The problem is not that the number is too small — the problem is that such a procedure will also make the right handed neutrino light. We need to introduce a second mass scale — large or small — to explain the neutrino mass.

The mechanism may be decoupled from EW symmetry breaking — but so what? why should that not make it BSM. However nothing really is decoupled from anything as we have the hierarchy problem…..

38. **Shantanu**
February 18, 2012

Ravi, I disagree, but let's agree to disagree. I have yet to see a single prediction from
any of the BSM theories about theta_13, whether sterile neutrinos exist or not etc.
(Note also that by this logic do you consider existence of gravity
is also beyond the standard model physics).

39. **Ravi K**
February 18, 2012

Agreed! — and anyway whether it is SM or BSM its just a name.

You dont have a single more or less agreed upon prediction because there is no consensus on the model with neutrinos. But each model by itself would have some predictions for example on whether sterile neutrinos exist or not. Also some of these models have gotten ruled out (or constrained) because of their predictions.

But what is the standard model prediction for neutrino mass/mixing scale — that is a question that should have an agreed upon answer, and any deviation from it can be attributed to BSM.

Quantum treatment of gravity would be BSM in my view — If gravitons are found would that be considered SM physics? Currently there are two parallel standard models – one for the quantized forces and one for gravity.

40. **David Broadhurst**
February 19, 2012

> neutrino oscillation is the one piece of "Beyond the
> Standard Model" physics that has been observed concretely
Neutrino oscillations were envisaged before the standard model.
Bruno Pontecorvo [JETP 33 (1957) 549; 34 (1958) 247]
originally suggested oscillation between \nu{e} and
\bar{\nu}e. Later he suggested [JETP 53 (1967) 1717]
oscillations between \nu{e} and \nu{\mu}, before Ray Davis
had firmly established a deficit in the solar neutrino flux.
This was elaborated with Gribov [Phys. Lett. B28 (1969) 493].
Reading this as student, I found it natural to assume
that all quarks and leptons are massive and that neutrinos,
like quarks, may mix. Growing up along side the SM, I saw
no reason to exclude that possibility and, when I started
teaching the SM, I used to remind students that the number
of its free parameters had (then) been underestimated.
I find it odd to read, nearly 40 years on, that neutrino
mixing is now supposed to be BSM.
David Broadhurst

41. **Ravi K**
February 19, 2012

I guess what I am trying to say is that there are two ways of extending the standard model to accommodate the observed neutrino physics. One way is by adding 2 or 3 right handed singlet neutrinos to the standard model quark and leptons and providing them with a very heavy mass — maybe even like at the GUT scale — which will in turn see-saw into the observed small masses of the already known neutrinos. The other way is to not add any right-handed neutrinos keeping the usual fermion content of the standard model with only the left-handed neutrino and try to accommodate the neutrino masses.

Until one of these ways is experimentally ruled out it may be difficult to claim there is a standard way of dealing with the neutrinos though theoretically the see-saw way seems to be the more standard way.

However in either way of doing things a new mass scale for quantized forces is implicated by the neutrino data.

42. **David Broadhurst**
February 20, 2012

Ravi K wrote, on February 19, 2012 at 11:40 pm:
> a new mass scale for quantized forces is implicated
> by the neutrino data
Yes, I tend to agree with that, if one regards the SM as an
effective theory. Yet, if one adopts the R-G viewpoint that
no term in the Lagrangian density can have its coefficient
specified a priori; rather it must be taken from experiment
(as in pure QED), then the SM may still be regarded as
formally complete. I guess that we all hope that the SM is
merely an "effective theory", with something (as yet utterly
unknown) lying above it, at some (as yet utterly unknown)
energy scale. But that is, at present, pure hope. All we
know, at present, is that, within the rigid formalism of
renormalizable QFT and the discipline of experiment, the
standard model is theoretically and empirically flawless.
It seems to me that only experiment can modify that strange
success. Else, I can only agree with Hamlet that "there is
nothing either good or bad, but thinking makes it so".

43. **Mark**
February 22, 2012

I just went through Matt Reece's slides and was a bit surprised to see the claim that in Type IIB the tree-level gauginos are down by the Log[M_Pl/m_32] relative to the scalars, which is not the conclusion of the paper he is referring to. Has he actually checked the reference http://arxiv.org/abs/hep-th/0610129 that he is citing? At the bottom of page 24 it clearly states that because parameter p=1 for bifundamental matter, which is what the MSSM scalars are, "the scalar masses are comparable to the gaugino masses rather than logarithmically larger". There is even a sample spectrum for the this Large Volume scenario on page 30 and for the KKLT type scenarios on pages 31 and 32 where one clearly sees that in these Type IIB vacua the squarks and sleptons are as light as the gauginos. It's disappointing to see incorrect information presented in such important review talks.

44. **Mark**
February 22, 2012

I just realised that Matt is actually referring to an earlier paper of Conlon and Quevedo, http://arxiv.org/abs/hep-th/0605141 where the computation of the scalar masses was estimated before the authors found the form of the Kahler potential for bifundamentals. Sorry Matt, I guess you were a bit misled by that earlier paper, but I hope you'll take the time to read the subsequent paper as well.

45. **Henry Bolden**

February 22, 2012

At least we finally have definitive news on the Higgs:

[Dilbert discovers the Higgs.]

46. **Matt Reece**
February 22, 2012

Sorry for the sloppiness, Mark. I'm not an expert on string constructions. A later reference, 0906.3297, also makes the claim that there may be "a minor version of split supersymmetry," and I was trying to grab the earliest such claim in the literature. Looks like I picked the wrong one. (The '06 references, as far as I understand, all suffer from the chirality vs moduli stabilization problem pointed out in 0711.3389, so I probably should have stuck with just citing the later one.)

Anyway, the point wasn't to single out a specific construction so much as to observe that these small hierarchies often fall out of models, and that we should maybe understand a little better precisely when it does or doesn't happen. Your later reference reinforces that point, I think—it seems to me that there should be a 4d effective field theory explanation of why, on doing a more careful calculation, they found the expected leading term ~m_{3/2} canceled.

47. **Joseph Conlon**
February 23, 2012

Matt,

One comment to make here is that many of these cancellations of terms of order M_{3/2 } relate to an underlying no-scale susy breaking structure. No-scale has many neat features: it cancels both tree-level and loop corrections to soft masses (such as arise in anomaly mediation). The fact that no-scale also arises naturally in string constructions further marks it out as a very special structure.

There should be a right way of looking at supergravity so that the no-scale cancellations all become obvious. Unfortunately I don't know what that way is, but there is manifestly a structure present in no-scale models that is obscured by the conventional presentation of supergravity, where these cancellations appear just as a series of terms that happen to add up to zero.

48. **Marko**
February 23, 2012

Thank you for your reply, Matt! I see Joe has already tried to answer your question. As far as I understand, in the KKLT case the suppression of the scalar masses relative to m_3/2 is due to warped sequestering, which does have a 4D interpretation as conformal sequestering, as explained here: http://arxiv.org/abs/hep-th/0703105 . In the LV scenario of Joe et al, the no-scale structure does play the crucial role and specifically arises in Type IIB due to the particular scaling of the Kahler potential. However, the LV scenario is also unique because SUSY breaking there is moduli-dominated. So, these two properties, when combined, lead to the above cancellation. This remarkable property disappears in, e.g. G2 vacua, where the scaling of the Kahler potential wrt to the moduli is completely different and even if one could construct a G2 analogue of Joe's LV vacua with moduli-dominated SUSY breaking, the corresponding scalar masses would look like m_i^2=[(1-7/3)+\epsilon_i^2]*m_32 so the scalars would remain as heavy as m_3/2. As for the reference for string models with slightly split spectra, check the papers of Acharya et al.

49. **Marko**
February 23, 2012

the m_32 should be m_32^2

50. **Mark**
February 23, 2012

@ Matt, for stringy models with split spectra I'd recommend checking out this paper http://arxiv.org/abs/hep-th/0701034 or the more general version of the same construction http://arxiv.org/abs/0810.3285

51. **Mark**
February 25, 2012

@Matt, I must correct one of my previous statements. After a more careful checking, it turns out that for moduli-dominated SUSY breaking when the moduli F-term contributions nearly cancel the -3M_{3/2}^2M_{Planck}^2 term in the scalar potential, the cancellation of the leading contribution to the scalar mass squareds a la LV scenario of Joe et al does happen for the G2 case as well! In Type IIB, the moduli Kahler potential is K=-2Ln(V) and the bifundamental chiral matter Kahler potential scales as 1/V^(2/3), where V is the CY volume, and these two things, when combined with moduli-domination and CC=0 constraint, lead to parameter p=1. In G2 compactification case, K=-3Ln(V) while the Kahler potential for fundamental chiral matter scales as 1/V, where V is the volume of the G2 manifold, and when combined with the assumption of moduli-dominated SUSY breaking and CC=0, also lead to p=1 and the suppression of the scalar masses! These cancellations look completely mysterious from the 4D point of view though. That said, the G2 vacua of Acharya et al do not have this feature and do exhibit a split spectrum because in that case SUSY breaking is not moduli-dominated.

52. **John Baez**
February 26, 2012

MathPhys wrote:

> Okay, so even neutrino oscillations are part and parcel of the standard model.

The original Standard Model had massless neutrinos, and thus no neutrino oscillations. The new Standard Model has neutrinos whose masses and oscillations are described by the [Pontecorvo-Maki-Nakagawa-Sakata matrix]. I'm not sure how convinced the experts are that neutrino physics is adequately captured by this new Standard Model – I haven't been keeping up with that.

> Is it safe to say that we don't know of anything, anything at all, that requires 'beyond standard model' physics?

No, that'd be going too far. Many astrophysicists believe there's 'cold dark matter' made of some particle or particles not included in the Standard Model. Many believe in 'dark energy', which can be modeled simply by including a cosmological constant in Einstein's equations, but might arise from some particles we don't know. And many believe in 'inflation', which requires some physics beyond the Standard Model and general relativity.

In short, astrophysics and cosmology seem to require physics beyond the Standard Model and general relativity.

53. **Eric**

February 26, 2012

In addition to the excellent points made by John, one shouldn't forget that a certain amount of CP violation is required in order to generate baryogenesis/leptogenesis. The Standard Model does not provide enough CP violation, and so presumably this is generated by new physics.

54. **Shantanu**
February 27, 2012

Eric,
Note that one thing which is not usually well known/advertised among particle physics/HEP audience is that there are modifications/extensions to GR which can potentially explain baryogenesis. Two examples are Einstein-Cartan-Kibble-Sciama theory(see http://arxiv.org/abs/1101.4012) and Chern-Simmons theory (see http://arxiv.org/abs/gr-qc/0308071).
so in that case you don't need beyond SM physics, but we do need physics beyond SM+GR.

55. **Vince**
February 27, 2012

Eric,

Judging from the abstract from http://arxiv.org/abs/1101.4012, this is only a classical theory and the theory is supposed to apply at the very early universe, for which you absolutely need a quantum theory of this theory that also incorporates the SM, as well as any other possible interactions between this scale and the SM scale.

56. **Marty Tysanner**
February 28, 2012

> the theory is supposed to apply at the very early universe, for which you absolutely need a quantum theory of this theory […]

Just to be clear, this is the conventional wisdom and it may very well be true, but it isn't an established fact. We don't have a "real" quantum gravity theory yet, and don't know what will ultimately describe the very early universe…

String Theory Skeptics and Multiverse Mania

February 21, 2012
Categories: Multiverse Mania

My endless rants here about the hot field of multiverse studies are mainly motivated by concern about the effect this is having on particle theory. Multiverse scenarios all too often function as an excuse for not admitting that string theory/extra-dimensional ideas about unification have failed. Such an admission would encourage people to move on to more promising ideas, but instead hep-th is stuck in an endless doldrums with the high profile public face of the subject dominated by excited claims about what a wonderful discovery this region is.

Independently of the string theory problem, I'm personally a skeptic that multiverse studies have any promise, simply due to the fact that the subject lacks a viable theory, any experimental evidence, and any plausible prospects for getting either. Others feel differently though, and very recently two of my fellow string theory skeptics have written about the subject much more positively.

The first is Lee Smolin, who has written an essay for the *Foundations of Physics* "Forty Years of String Theory" volume with the title [A perspective on the landscape problem](). Smolin's interest in multiverse models goes way back, to long before the current string-theory-based mania. He's got a good argument that he was the originator of the term "landscape" itself, which he wrote about back in his 1997 book [The Life of the Cosmos](). If you're interested in the multiverse at all, Smolin's article is well-worth reading. I very much agree with his emphasis on the principle that one has to be careful to stick to ideas that can legitimately count as science, by conventional standards of testability. He is pursuing "cosmological natural selection" scenarios which he argues do have testable consequences. I'm not convinced there's enough there to ever lead to solid evidence for such a scenario, although there may be enough structure there to sooner or later make it clear if the idea is simply falsified by one fact or other about the universe.

Today's New York Times has an [article by Dennis Overbye]() about Lawrence Krauss and his new book [A Universe From Nothing](). Much of the book is an excellent discussion of cosmology and the physics of the vacuum, but it also devotes a lot of effort to discussing the meaningless question of "Why is there something rather than nothing?" and arguing against the invocation of a deity in order to answer it. Krauss is no fan of string theory, which he regards as overhyped, but he seems to have developed an attraction to multiverse studies recently, perhaps motivated by their use in arguments with those who see the Big Bang as a place for God to hang out.

Personally I've no interest in arguments about the existence of God, which epitomize to me an empty waste of time. Given the real dangers of religious fundamentalism in the US though, I'm glad that others like Krauss make the effort to answer some of these arguments. I'm less happy to see him and others adopting the multiverse as their weapon of choice in this battle, since it's a lousy one and not going to convince anyone. In the New York Times piece we're told:

> "Maybe in the true eternal multiverse there are truly no laws," Dr. Krauss said in an e-mail. "Maybe indeed randomness is all there is and everything that can happen happens somewhere."

Given the choice between this vision of fundamental science and "God did it" as explanations for the nature of the universe, one can't be surprised if people go for the man in the white robes…

Comments

1. **Low Math, Meekly Interacting**
   February 21, 2012

   This one also troubles me. There appears to be an urge among skeptics to fill the gap of universal origins, where the theists God resides, with something else, rather than admitting it must remain empty. I seems somehow unacceptable to have no answer but an admission of ignorance when confronted with claims that the ultimate hows and whys of existence are the purview of religion and not science. For me it's perfectly acceptable to reject mythology whilst having no clue myself what the "truth" of the matter is. When engaging in such debates, it's clearly better to be ignorant than wrong, because the theist's argument cannot be disproven, while the scientist's can. The theist holds the scientist to such rigorous standards, while needing none for himself. All the worse when the scientist proposes ideas that are not even wrong. If God is untestable and the multiverse is untestable, then claiming superiority as part of the scientific enterprise and using abstruse equations to make the case for untestable hypotheses cannot exonerate one from accusations of hypocrisy.

2. **Nige**
   February 21, 2012

   "There appears to be an urge among skeptics to fill the gap of universal origins, where the theists God resides, with something else, rather than admitting it must remain empty."

   Premature uncheckable speculations which harden into an orthodoxy have founded some of the world's greatest religions. The replacement of a single God with a multiverse of them goes against Occam's Razor, and it isn't new either.

3. **JE**
   February 21, 2012

   Interesting post, right to the meat of the matter… in this pseudo-obscurantist era? All in all the multiverse and the man in the white robes provide similar circular answers to the same old question. Ironically, most scientists wear white aprons, as opposed to black soutanes, and some seem to be taking the analogy too far. Either the LHC sheds light on the landscape of particle physics, with the God particle explaining EWSB and reinforcing the SM as the framework into which to try to accomodate deviations (or from which to build a larger framework that can accomodate escapologist deviations and unsolved issues), with SUSY being largely ruled out and black robes and circular thinkers being gradually ousted from the scientific arena, or this neverending multiverstring idea may end up synergizing with God to last another 2,000 years. Unless, please, someone comes out with a better idea.

4. **emile**
   February 21, 2012

   I like the multiverse idea. It may well be true. A priori, I don't see why there should be only one universe. In general, I would be careful about just bashing this idea: it's not as if it does not make any sense at all. Granted, it is clear that, at this point, this type of speculation is not science and may never will be. And of course, scientists should be careful if/when they discuss this idea. They should make it very clear that this is not science until we know how to test it. The public is already on to scientists who make claims without evidence: they turn around and say they can also make similar claims about the supernatural world.

5. **Peter Lynds**
   February 21, 2012

   Hi Peter,

Good post. One thing puzzled me though. Why do you think the question "why is there something rather than nothing" is meaningless?

Also, I think I should note that, unless one believes that a universe can be magic'ed from truly nothing a finite time in the past (whether by a non-physically existing, timeless, eternal God, or by non-physically existing, timeless, eternal laws of physics, with both being to said to somehow magically bridge to the physical to create a universe out of nothing), eternal physical existence is the only other option, whether it be in the form of an eternal multiverse, eternal cyclic universe, or a finite universe in which time is cyclic. That is, and although it is very difficult to see how any of these models could realistically be confirmed empirically, they are still on a much firmer footing than any theory that posits physical existence had a beginning a finite time in the past. Also, multiverse obviously need not mean string theory.

Best wishes

Peter

6. **Anonyrat**
   February 21, 2012

   Why "Why is there something rather than nothing" is meaningless:- how do you formulate it as a scientific question which can have an experimental or observational test?

7. **David Metzler**
   February 21, 2012

   @Peter Lynds: I think you may be confused about what a universe with a finite past means. It doesn't mean that there was nothing, then there was suddenly something, in some dynamical process—that would involve a notion of time that went back before the big bang. I think the error is the common one of assuming that any space or spacetime must be embedded in something larger (and usually more familiar)—what mathematicians call the extrinsic point of view. But from the intrinsic point of view, a universe "starting with a big bang" is completely self-consistent, and need refer to no notion of "how it got started".

   (To use a pure-mathematical example, a finite open interval is just as natural a Riemannian manifold as the real line is, and neither needs to be embedded in something larger to be made sense of.)

   Pardon me if that misrepresents what you were saying, but I know that it is a major point of confusion with the lay public.

   Now, the likely quantum-gravitational nature of the initial few Planck times is still a huge source of uncertainty, so quite possibly the pure classical relativistic notion of a singularity is not realistic. But I feel that that is a different issue from the resistance many people have to the very notion of a finite (in time) universe.

8. **Peter Woit**
   February 21, 2012

   All,

   Please avoid the temptation to turn this into an opportunity to discuss your favorite ideas about the big bang and pre-big bang physics. I'm in a bad enough mood already. If it's not about what Krauss or Smolin have to say, it's probably off topic…

9. **Peter Lynds**
   February 21, 2012

   Hi Anonyrat,

   Yes, I agree that it cannot be formulated as a scientific question that can be experimentally or observationally tested, but as long as nothing rather than something is a possibility, it is still a meaningful question and in need of an answer. If one perhaps disagrees with this, one would need to show why nothing isn't a valid possibility (and in doing so, they would also actually provide an answer to the question). I've got my own ideas on this, but I'll keep them to myself here.

   Hi David,

   Yes, of course, but almost every modern cosmologist would agree that the big bang needs an explanation. What caused it? If the universe arose from truly nothing, we have 2 options (laws of physics or God). As I explained earlier, both require magic.

   Best wishes

   Peter

10. **Giorgio**
    February 22, 2012

    Peter,

    a simple question about the multiverse shows how nonsensical the idea is (I got it from a physics book for free download somewhere):

    Why do you believe in only ONE multiverse?

    Real men believe in many.

11. **Marcus**
    February 22, 2012

    Peter L, anonyrat, David, I don't think inflation has been mentioned in the current discussion. Part of the impetus towards multiverse thinking comes from the inflation mechanisms people dream up.
    As Peter L said cosmologists confronted with visible features of the early universe generally agree there should be an explanation for the big bang. That's not an impossible job there are a bunch of models—but the catch is that to get results that look right a lot of cosmologists think a period of exponentially rapid expansion has to be included. Once you think up and include a mechanism it becomes a headache, it keeps happening, or you need to fine tune it so it lasts long enough but then stops etc etc. So far most of the imagined inflation mechanisms tend to drag multiverse in on their coat-tails. Try to think of an explanation not just for the start of expansion but for the usually assumed amount of inflation, and try to make it not give you a multiverse.

12. **Marcus**
    February 22, 2012

I think too often people confuse the job of explaining the big bang with deep/ultimate questions like why do we have these physical laws and why does existence exist.

Explaining the big bang is just an obvious next step in gradual growth of understanding. Get rid of the singularity, go back in time from there, fit the available data. It's physics business as usual, no need to get philosophical and confuse it with ultimate questions.

13. **Sascha Vongehr**
February 22, 2012

What Krauss holds is similar to the reason why I have always expected the multiverse. Simply, a modest agnostic will. Apart from that, multiple world models are anyway tautologically true. This I have explained both here and in links:
http://www.science20.com/alpha_meme/modest_agnostics_expect_multiverse_and_hold_many_worlds_true-85038
The multiverse/MWI cannot excuse everything and string theory must not be beyond the reach of criticism, but it is time that those who poo poo the multiverse at every opportunity also address fundamental arguments that were never based on their pet peeve.

14. **Bane**
February 22, 2012

Is Krauss still a physicist of the first rank? Christopher Hitchens (his friend) used to say Krauss was the greatest living physicist. Not sure if he was right…

15. **Anon**
February 22, 2012

Krauss: "Maybe […] everything that can happen happens somewhere."

This is the kind of statement that makes my blood boil. Seriously, nobody calling himself a physicist should be allowed to poison the minds of the public with this nonsense. I have started hiding the fact that I am a physicist from new acquaintances from sheer exasperation at the futility of having to try to unteach them these kinds of ideas that they pick up from the media and believe to be mainstream.

16. **hdz**
February 22, 2012

Peter, I share your reservations regarding the many-worlds-hype (as far as it is a hype), but you have to differentiate:
Max Tegmark's level 1 appears trivial, since any possible state must exist within any given approximation at sufficient distance in a presumed infinite universe. However, proposed numbers for distances are usually quite unrealistic, since they are based on mere chance configurations (such as "Boltzmann brains") and do not consider an evolutionary universe of given age. (I have never seen realistic estimates for the rate of evolution of specific life forms per volume, for example, but I don't actually care for such trivial doppelgängers.)
If you give up homogeneity (as you do in inhomogeneous inflationary models, usually presented at level 2), you may speculate about all kinds of "landscapes" and ages, but any estimates must depend on your specific speculation – so here is the true hype.
The original many worlds concept is given by level 3 (Everett). They do not exist somewhere in space and time, but somewhere else in what we classically call configuration space. In contrast to all other levels, these many worlds are NOT science fiction, since they are solely based on the empirically well founded Schrödinger equation. (I would instead regard collapse theories or hidden variables, when used to avoid Everett's conclusion, as science fiction.) Unfortunately, David Deutsch introduced considerable confusion, when he turned Everett's proposal into science fiction by considering time travel between different "worlds" (in conflict with Schrödinger and decoherence, for example), or when he regarded quantum computers as calculating in parallel worlds. This parallelism would be no more than the superposition principle. If quasi-classical "worlds" split according to decoherence, quantum computers have to remain in one and the same world in order to be able to produce results that may be used in our world.
Tegmark's level 4, finally, seems to be based on a confusion between the concepts of physical existence (to be based on observations and experience) and mathematical existence (which means no more than consistency of a definition – usually within a given axiomatic system). This level does not seem to be relevant for physics at all (except that inconsistent formal concepts cannot be used in physics either).

17. **Peter Woit**
February 22, 2012

hdz,

Thanks for the clear outline of the various "multiverses", which seems quite sensible to me.

One of the more annoying aspects of multiverse mania is the tendency to throw some very different things all together. In particular, there's

1. The "multiple worlds" of decohered quantum phenomena, which are an interesting and very real topic we know a lot about theoretically and experimentally.

2. The cosmological "multiverse" of causally separated parts of what used to be called the universe. These may exist, but require a serious theory, since we have no direct experimental evidence. These are the ones that get exploited by string theorists, giving them whatever properties (different values for anything string theory should be able to explain but can't) they find convenient.

3. Different laws of physics. Once we understand what the fundamental consistent mathematical structure is behind the laws of physics, we may very well find out that it contains pieces disconnected from ours (with different values of some constant, different numbers of dimensions, different gauge groups, etc.). Then if one wants to think of these pieces as "existing", I suppose one can. But we're a long way away from this…

18. **hdz**
February 22, 2012

Peter: so we seem to agree!
I guess when you talk about the "laws of physics and the consistent mathematical structure behind them", you mean the empirically founded laws (that we hypothetically and consistently extrapolate beyond what we have observed). We should also be aware that some parameters in what we regard as laws may have come into existence by some "symmetry breaking". They would then not form fundamental laws, but characterize either specific Everett worlds or, if locally different, just regions of a "landscape" (without necessarily requiring string theory). Yes – we are very far from understanding it!

19. **Peter Woit**
February 22, 2012

hdz,

I agree. We have no idea now what determines the parameters of the Standard Model. Most of them just appear as mass/mixing matrices in the Yukawa terms coupling the Higgs to fermions. These may be calculable from first principles in a better version of the theory, or they may be characteristics of one particular state of the fundamental theory that we happen to locally be in. In either case though, you need a better theory than anything we have now.

20. **Kent Traverson**
February 22, 2012

According to this piece, one may be able to detect neutrons from another universe, thus a testable hypothesis. Is there any validity to it?

http://www.technologyreview.com/blog/arxiv/27517/

21. **Vince**
February 22, 2012

Sorry, this is off topic, but I think you should know that the supposed faster-than-light neutrinos are no more:

http://news.sciencemag.org/scienceinsider/2012/02/breaking-news-error-undoes-faster.html

Many pet theories have now been ruled out!

22. **Peter Woit**
February 22, 2012

Vince,
Thanks for posting the news!

Kent,

If one feels like it, one can certainly devote one's life to carefully watching particles, and if one suddenly disappears, you can then announce that it jumped into another universe. The problem of course is that you need to have some plausible consistent theory that would predict that this would happen. I don't think there is such a thing here.

You can easily come up with absurd theories that are completely implausible and explain nothing, then make a big deal that they're testable because they predict something bizarre will happen someday (even though such a thing has never happened before). I don't think this can really be called doing science though.

23. **Kasuha**
February 22, 2012

Personally I don't need God or Multiverse to explain our origin. Anthropic principle in the form "we see our universe because we are here to see it" makes me perfectly happy. And regarding arguments about fine tuning of fundamental constants – imagine a Julia set, the classic one. It is driven by just two constants. Change them just a little and you get a very different picture – may be similar overall for tiny changes but the better look you take at it the more fundamental differences you find. If fundamental constants were different, the universe would probably be very different as well but that does not mean it would not support its "fractal edge" on which we are all living. The edge would just be very different from what we are used to and there would be some totally different life forms contemplating how comes their universe's fundamental constants are just so exactly fine tuned.

24. **Bourgeois Nerd**
February 22, 2012

Having read Krauss's book, I do have to stick up for him a bit and say that he's neither convinced of, nor happy about, the possibility that all is randomness and there are no fundamental laws. He's simply resigned to the possibility.

As someone who is haunted by the question "Why is there something rather than nothing?" I'm curious why you think it a meaningless one, Peter. I also think the multiverse answer that Krauss and others give not terribly convincing. That one universe somewhere might be "nothing" seems rather besides the point.

25. **Shantanu**
February 23, 2012

Vince, thanks for the link.
Someone should ask all those who claimed that this is evidence for string theory,
whether now they think string theory is ruled out.

26. **Thomas Larsson**
February 23, 2012

The anthropic explanation of the Michelson-Morley experiment: a non-zero ether wind is incompatible with human life.

27. **harryb**
February 23, 2012

Peter

Back to topic.

I read Smolin's article and I'd agree its is much more balanced than most in this arena. Krauss's book, which I mentioned a few weeks ago on this blog, is also good stuff, but I also agree when he gets to the multiverse issue, its all arm-waving fluff, which is disappointing given the solidity he shows when discussing more standard physics.

Smolin appears to hinge his arguments on a philosophical maxim that he describes as "Laws must evolve to be explained". This allows him the space to therefore discuss landscape theories such as Linear Cyclic Cosmology, Eternal Inflation etc on the basis that our (current?) laws may merely be the latest manifestation of previous ones that were in existence in "deep time".

He finishes the piece with:

" The main lesson which can be drawn from the successes and failures of at-
tempts to resolve the landscape problem surveyed here is that theories which embrace the evolution of laws have a better chance to make falsifiable predictions than do theories which try to hold onto to the notion that law is eternal. "

I must admit I felt after this in a bid of a bad mood too. The obvious question of – well, what was the original law / theory? in deep time seems to be given over to String or M theory (or something else) by Smolin. At least he only discusses this and posits no others in detail.

True , Smolin points out that S/M theory is still unproven and not really going anywhere, and true he demands testability (eg he seems to rule out cosmological natural selection on observed data).

But although much more rigorous than Krauss, it still seems to be, in summary, something along the lines of – only a multiverse argument will provide the answers to deep principles, and those deep principles may well have something to do with string theory followed by evolution of its laws to create us.

I am sure Smolin would say that is too simplistic, but it sort of comes through no matter how many subtle caveats are used.

I can buy the argument we need to be more thoughtful re how we look at the early universe and what may have changed since then, or at that point. The current answers posed seem a long way from being a graspable deep truth however: Unless we embrace the multiverse, string vacua and symmetry breaking, and evolution via endless cycles.

Some may find this uplifting. For whatever reason, not sure why, I do not. There must be better answers than this. On a day when many grand, fluffy theories attached to faster than light-speed neutrinos have been brushed aside by faulty wiring, I remain in the camp of hoping for more straight-forward solutions.

28. **Paolo**
February 23, 2012

Thanks for recommending Lee Smolin' paper. I found it very clear and useful, in particular I liked the comparison between the various cosmological scenarios and the observations about AdS/CFT (By the way, I noticed a few trivial typos, nothing worth mentioning)

29. **Joel Rice**
February 23, 2012

That profusion of speculative hypotheses would be more convincing if they had a theory that dealt with what we observe. One can complain about the Anthropic Principle, but at least we are pretty certain that we exist, and it does point to curious properties of Carbon, but going on about possible different regions or epochs having different laws sounds like giving up on the idea that Nature knows more math than we do. GR explains the redshift of the CBR but not the spectrum, and QM explains the Planck spectrum but not expansion. That one gets from this predicament some need for different laws sounds like one is desperate to save the bacon. Are they willing to throw out Arithmetic ?

30. **Dan Winslow**
February 23, 2012

Doesn't what we think of as 'knowledge' have to run out at some point? Since no matter what explanations we derive, it's always possible to then say 'Yes, but what explains *that?*

It seems to me that we must inevitably arrive at the end of what is possible for us to know. That point might look somewhat like what we are seeing now. I personally don't like the idea, and I'm not suggesting we've reached it, but I think it needs to be acknowledged that we might at some point.

31. **JC**
February 23, 2012

The problem with all these BS from so-called high-energy/cosmology experts is the lack of any experimental guidance. I'm so happy that I work in a different area of physics where fascinating emergent phenomena can be studied both theoretically and experimentally.

I totally agree with the suggestion that we should put multiverse, landscape, … in the same category of the ideas of God(s), or the world is supported by infinite elephants, turtles, etc.

And I also think really smart math-oriented people should just do mathematics.

32. **Peter Woit**
February 23, 2012

JC,

I'll just repeat my usual comment that you can't blame the multiverse on mathematical physics. I don't think there are any equations in Smolin or Krauss, and that's par for the course in multiverse studies. The people who find the multiverse idea appealing tend not to be those fond of using sophisticated mathematics in physics, but those looking for "physical" ideas they can easily explain to their grandmothers. While I share skepticism about string theory with Smolin and Krauss, I suspect their attitude towards the relationship of math and physics is quite different than mine.

By the way, I don't completely disagree with the idea that if you really understand something you should be able to explain it to your grandmother. It's just that the explanation of some ideas would require said grandmother to sit still and pay close attention for quite a while. Others, like the multiverse, can be explained in minutes, with perhaps a few hits from a bong to help the understanding along.

33. **IT**
February 24, 2012

"Its much too a wild a night to travel in."
"Wild nights are my glory," Mrs. Whatsit said, "I shall just sit down for a moment and pop on my boots and then I'll be on my way. Speaking of ways, pet, by the way, there is such a thing as a tesseract."

But then Peter Woit appeared in the Murrys' kitchen, proclaimed "No there isn't" and shot Mrs. Whatsit dead.

34. **harryb**
February 24, 2012

Peter

How the web works…

Here is a cut and paste of your comments above already showing up in pro-Christian faith websites. It really is depressing to see Multiverse speculation undermining science in this way. Playing into the theologists hands it seems. No wonder you felt in a bad mood.

http://christian-apologetics.org/2012/peter-woit-on-the-multiverse-as-a-weapon-against-religion/

For interest here is the Dawkins / Krauss talk on the "something from nothing" debate from a few weeks ago. More nuanced.

http://richarddawkins.net/videos/644930-dawkins-krauss-discussion-from-asu-4-feb

Maybe you are right. Multiverse / string etc now urgently need data and equations. Otherwise its tennis with the net down, and priests and mullahs hitting it back easily from the other side.

35. **Anon**
February 24, 2012

hdz says: "Max Tegmark's level 1 appears trivial, since any possible state must exist within any given approximation at sufficient distance in a presumed infinite universe. "

This is not so trivial as it is often made out to be, since it depends on speculative assumptions regarding ergodicity, mixed in with speculative assumptions of infinite volume and even more speculative assumptions regarding QM and quantum gravity as applied to the cosmos as a whole.

36. **Allan Rosenberg**
February 24, 2012

Vince, all we can say with confidence is that the FTL neutrinos haven't been discovered in THIS universe.

37. **Nancy Reagan**
February 26, 2012

Thanks Peter,
I have been trying to get kids to: "Just say no to the Multiverse" for years. Maybe your message will help.

38. **pierre**
March 7, 2012

I too like the poster above am haunted by the question 'why is there something rather than nothing' and don't find it a meaningless question to ask. It seems to show the limitation of what we're capable of, in the sense that not only do we not know, but we can't even imagine an answer. I suspect if we were ever told the answer by some higher intelligence , we would look at them like a dog being shown a card trick, to quote the late Bill Hicks.

The problem I suspect is that the answer must be 'logical' for us to accept it, and we're confined to just one system of logic. We're trapped in logic flatland.

39. **Hansl**
March 9, 2012

Why is there something rather than nothing?
– Because the Man In The White Robe had a higgup
(sorry Peter, I had to get this out)

40. **Marcus**
March 9, 2012

Most apt, Hansl. The hiccup analogy underlies multiversal reasoning: once Andrei has imagined one hiccup he cannot think how the hiccups will stop. So the hiccups must go on forever—producing a multiverse.

Various and Sundry

February 27, 2012
Categories: Uncategorized

- Lots of people seem to be unhappy with my characterization of Lawrence Krauss's question "why is there something rather than nothing?" as meaningless. I'm well aware that one can give this question a non-trivial meaning, I just don't think Krauss does, nor do the many commenters here on the topic whose comments I've deleted. Happily for those of you who want to discuss this topic, the Templeton Foundation has funded a whole new institution, the Rutgers Templeton Project in Philosophy of Cosmology , and they now have a blog, called What There Is and Why There Is Anything. They give a long list of questions they want to address which are pretty much orthogonal to ones I find interesting, ending with

  > 13) Why is there something rather than nothing?
  >
  > I imagine that all of these will be discussed during the course of our project. However, I suggest holding off definitively answering question 13 until our grant has expired.

  So, go right ahead and help them out, but hold off on your definitive answer to this question for at least 3 years (if not more, they might want a grant renewal).

- Another new website is the all-new, shiny, WordPress-based website for the Columbia Math department. We needed a new site since the university software running the old one ("Hypercontent") was about to die. The new university plan, involving Drupal, didn't seem ideal to me, so I convinced our staff that WordPress was the way to go. Web designer Matthew Kressel did a great job setting up the site for us, and our staff member Nathan Schweer has turned it into a huge improvement over the old one.
- In other Columbia news, tomorrow there will be a panel discussion on Recent Developments in Access to Research, which will discuss the Elsevier boycott amongst other things. I'll be on the panel, not sure how much I'll have to contribute, we'll see.
- A correspondent sent me a link to this wonderful piece centering around Fred Hoyle and film.
- For interesting video to watch, I recommend this interview with Yuri Manin at the Simons Foundation, and videos from the Clay 2010 conference in Paris about the Poincare conjecture proof.

Update: I hadn't realized that "Why is there something rather than nothing?" studies is now a burgeoning field, with heavy Templeton funding. Besides the Rutgers Templeton Project in Philosophy of Cosmology, this past fall Yale hosted the Templeton + Yale Divinity School funded "WITA" (Why is there Anything?) conference (see whyisthereanything.org), which has its own blog here. As Multiverse Mania gets to be old-hat, perhaps WITA studies will take over as the cutting edge of this kind of science.

Update: This news from a "Cambridge University spokesman":

> It is not true that Professor Hawking is a "regular" visitor to the club in question.
>
> 'This report is greatly exaggerated. He visited once a few years ago with friends while on a visit to California.'

Comments

1. **Dave B**
   February 28, 2012

   Adam Curtis makes some superficially interesting documentaries, but they always leave me with the feeling that he is making the same mistake as internet conspiracy theorists.

   His films tend to establish tenuous sets of connections between interesting events, turn them into a narrative of "what really happened" and ignore everything else that might have been going on at the time. Cherry picking + over simplification essentially.

   The films are interesting, and contain plenty of fascinating trivia but after a while it becomes obvious that the visual style is mostly designed to distract the viewer so they don't notice the unfounded assertions and flawed logic.

   Having said all that I did like the quote about fish comprehending Yarmouth. Having been there I suspect that they might be able to 🙂

2. **CU Phil**
   February 28, 2012

   A group of philosophers/physicists at Oxbridge got a similar Templeton grant for philosophy of Cosmology:

   http://www.philosophy.ox.ac.uk/news__events/news/philosophy_of_cosmology_-_new_field_of_study

   I think the Rutgers grant and the Oxford grant are each in the neighborhood of a million dollars.

3. **Peter Woit**
   February 28, 2012

   Thanks Phil.

   By the way, I just noticed this:

   http://rationallyspeaking.blogspot.com/2011/11/templeton-foundation.html

   Not all our local philosophers are interested in Templeton funding….

4. **Bob Levine**
   February 28, 2012

   Peter notes:

   "As Multiverse Mania gets to be old-hat, perhaps WITA studies will take over as the cutting edge of this kind of science."

I'm not sure that the hardcore MM enthusiasts will let that happen. An obvious option would be to *subsume* WITA under MM by asserting that the MM predicts that there are universes within the multiverse where there is nothing, rather than something. (The question of whether or not there can be more than one such universe is left as an exercise for the reader) An elementary application of the Anthropic Principle then yields the observed state of affairs. The WITA problem thus simply goes away… a wonderful demonstration of the far-reaching explanatory power of cutting edge science, eh?

Don't laugh. I'm sure at least one of the MM heavies has already thought of this one. We'll know how bad things are when arxiv papers exploring this 'solution' start appearing.

5. **Guillaume**
   February 28, 2012

   I didn't know this Adan Curtis; he's got some pretty fascinating stuff on his blog! Dave, History his all about cherry-picking and interpretation, so unless you can show that Curtis' choice of facts and interpretation doesn't stand up, your criticism doesn't go very far…

6. **Dave B**
   February 28, 2012

   Watch the films and make your own mind up. I'm not saying he is definitely wrong, but while I do find the films interesting and entertaining, I can't really take the conclusions seriously. The connections are just too tenuous and far fetched for me.

7. **Christian Takacs**
   February 28, 2012

   When someone studies or examines "Why not something instead of nothing?" it is called Existential Angst, and can be cured by growing up and getting a good job. When someone studies or examines "Why not nothing instead of something?" it is called Nihlism, and can't really lead to anything (by its own definition), except perhaps a fatal overdose of drugs or self inflicted gunshot to the head (or foot). If a contemporary Mathematician wanted to model either of these "Why not" scenarios, all they would need to do is take the possible number of speculations in this universe and multiply by the number of multiverses, then multiply by (n+1) dimensions in an infinite series, divide by the number of papers that could be produced with "X" amount of funding in "T" amound of time, then multiply by zero. This formula should provide an extremely predictive and accurate answer.

   I must disclose that this experiment has actually already been performed by the very well funded "Deep Thought" Project. Unfortunatly, their results diverge from mine by exactly 42, and took… slightly longer to calculate. It has already been proposed that with even greater government funding and resources a third research venture might take place that will settle the discrepency between the two answers and maybe snag a nobel prize in the process!

   P.S.
   It saddens me that physics has come to the point where Douglas Adams begins to sound more visionary and less absurd than current theory.

8. **Giotis**
   February 28, 2012

   This is indeed a great initiative by Templeton foundation.

   I can't imagine a nobler human activity than to ponder about these fundamental questions exploring the origin of the Cosmos.

   This is what defines an advanced civilization.

9. **Bernhard**
   February 28, 2012

   Peter,

   this is a really nice response of yours to the critics and thanks a lot for the links to the proper places to discuss the question. As always, you do a a better job then asked for.

10. **harryb**
    February 28, 2012

    The Templeton funding issues has been around a while – plenty controversies eg between Richard Dawkins and Paul Davies because of the latter's Templeton funding and his view science is never free of "faith". MM and ST does not help Dawkins' view.

11. **Steven M.**
    February 28, 2012

    Regarding your involvement in "Recent Developments in Access to Research":

    As a Ph.D. physicist who works in applied science and not associated with any university or major industrial lab, I cannot access most journals unless I am willing to pay ~$25 per article. Needless to say, this hinders me from doing serious research (for free… my day job pays the bills). The question I have is why do journals need to charge at all? Reviewers (I am one) work for free. The editing is mostly done by the authors—for free. Publication is electronic and automated and costs almost nothing. Does anyone use printed journals anymore? So where is the cost that justifies the high price? This is a wall that prevent people on the "outside" from participating in scientific progress.

12. **Peter Woit**
    February 28, 2012

    Steven M.,

    This is what is behind the Elsevier boycott, and this has been an issue among physicists and mathematicians for a long time.

    In more and more fields, people are putting everything on the arXiv, making this literature freely available. To the extent they aren't, you also need to ask the scientists themselves why they aren't doing this.

    My impression, at least in math, is that mathematicians are moving toward non-commercial journals, and these are going to be cheaper, but not free. There is a significant amount of work involved in running a journal, even on the cheap, and someone has to pay for it. Note that there never was an ideal age in which journals were free. People's time is an expensive item, and even when journals are "free", someone somehow is paying for it. The existence of an arXiv of unrefereed, unedited papers is the one way you're going to get close to really "free" (although someone has to pick up the tab for the arXiv itself).

13. **Bane**
February 28, 2012

Hey Peter, your colleague, Briane Greene, gave a scintillating talk on the multiverse at TED in Long Beach this morning. You hear him speak?

14. **Peter Woit**
February 28, 2012

Bane,
Missed that one. For one thing I was here in New York with other things to do. I see there's a report here:
http://blog.ted.com/2012/02/28/the-multiverse-in-three-parts-brian-greene-at-ted2012/

15. **Geoff**
February 29, 2012

Brian Greene was scheduled to speak here tonight at the University of Utah. A massive storm rolled just prior to his talk so I'm not sure if it was cancelled. Regardless, and despite my scepticism of string theory, he took time out this morning to speak to the physics undergraduates which I thought was pretty classy.

John Morgan was out a few weeks ago and gave a talk to the math department. Out of curiosity does he ever need notes when he lectures or does he simply carry everything around in his head? It was pretty amazing to watch.

I'm grateful your colleagues took time to visit our little corner of the world.

16. **anonymous**
February 29, 2012

Briane spoke at the University of Utah tonight – sort of a lecture on general science (http://www.physics.utah.edu/index.php/component/content/article/105-2012/477-the-nature-of-things-keynote-lecture-dr-brian-greene) – no multiverse in this talk but I am guessing he worked in a special lecture for the physics department that covers more detail.

17. **Nicky Nichols**
February 29, 2012

There are other places on the internet where you can talk about speculative concepts in a rigorous way without being made to feel foolish. But not WITA which appears to be as blinkered as anything else I've ever seen. They won't want to get to the answers too quickly.

If you want to see something really impressive take a look at the incredible efforts of the amateur mathematicians over at the Xkcd bigger numbers discussion.

18. **Geoff**
March 2, 2012

I spoke entirely too soon. The first line of the student newspaper describing Greene's visit reads: "We are all holograms existing in multiple universes simultaneously, said Brian Greene, a renowned theoretical physicist, at a lecture Wednesday night".

Thanks for ignoring
http://www.science20.com/alpha_meme/why_there_something_rather_nothing_studies_now_burgeoning_field-87641

22. **ajkem**
March 5, 2012

@Sascha
How terrible for you that no one should notice your article in the 2 hours after you posted it.

23. **Sascha Vongehr**
March 5, 2012

@ajkem
You misunderstood. My meaning is that PW always ignores any argument I make that on fundamental grounds (not string hype) criticizes his consistent pooping on multiverse and many world concepts. So here I thanked him in advance for what he will surely do, namely ignoring. Which is fine; he will have his reasons; just that I will henceforth also ignore him more. Nice links here often, but it sometimes sounds way too much like creepy crackpots' "oh those establishment physicists with their obviously wrong nonsense left common sense behind".

24. **Peter Woit**
March 5, 2012

Sascha,

Yes, I'm really just not at all interested in the sort of multiverse argumentation that you are, hope you find useful the links to other places on the web run by people that are interested.

I’m not attacking here “establishment physics”, since my impression is that it’s a majority opinion among “establishment physicists” that most arguments about the multiverse are a waste of time and not really science. Lenny Susskind may disagree with me, but I’ll bet David Gross and Edward Witten are closer to my point of view on this than Susskind’s. You don’t know very much about “establishment physicists” if you think Susskind is more of one than Gross and Witten.

I can also assure you that the Templeton Foundation is definitely not the scientific establishment. No matter who they get to agree to take their money, it’s a well-funded fringe organization trying its best to muddy the distinction between science and non-science, for its own ideological purposes.

25. **Sascha Vongehr**
March 7, 2012

Wow – a reply.
“the sort of multiverse argumentation that you are”
If you knew(understood) *my* argumentation, you would either reject it with arguments or become much more receptive to the concept.
“I’m not attacking here “establishment physics”, …”
I wrote: “sometimes *sounds way too much like* creepy crackpots’ “oh those establishment phys…”
Thanks for lecturing me about Templeton and who Lenny and Ed are as if I don’t know them personally, all proving that you do not know “the sort of multiverse argumentation that” I am interested in (for example my harsh critic against Lenny and Max Teg).
I am out of here – your answer was arrogant.

Try not to behave like a petulant child and others might be more receptive to you.

Moriond 2012

March 4, 2012
Categories: Experimental HEP News

The LHC will next week enter a Machine Checkout phase for the 2012 run at 4 TeV/beam, with beam commissioning scheduled to start March 14, the physics run April 7. Meanwhile, the LHC experiments have been for months targeting the Moriond conference which starts today as the time to release their latest analyses of the 2011 LHC data. There is likely to be not much new on the Higgs front from the LHC, since the Higgs results were fast-tracked and released back in December. One thing to expect is further evidence that supersymmetry is hiding very effectively.

The big news is likely to come from the Tevatron, with D0 and CDF releasing their combined Higgs results based upon the full Tevatron data set (the machine was shut down for good last September). The Tevatron data is not enough to provide convincing evidence for a Higgs at the 125 GeV mass now expected based on LHC results. The most likely result is something much like the last one (the Summer 2011 combination is here, and they only have 25% more data since then). Some excess would provide a bit more support to the possibility of the Higgs at 125 GeV. More interesting would be the much less likely result that the Tevatron could rule out a 125 GeV Higgs, in some contradiction with the LHC results, although the Tevatron is mainly sensitive to a different channel than the LHC.

The initial schedule had the big news this morning, SUSY tomorrow, but a revised schedule has put off the most newsworthy announcements until Wednesday (Tevatron Higgs) and Thursday (SUSY).

For some reason, no one has seen fit to leak to me the Tevatron results. If this changes soon, rumors will appear here. Otherwise, since on Wednesday I'm heading off for a 10 day spring break vacation in Paris and Iceland, your best bets for Moriond news will be the usual reliable locations: Resonaances, Tommaso Dorigo, Matt Strassler and Philip Gibbs.

Update: Moriond slides are here. LHCb has a new result constraining CP violation in Bs decays to close to the SM value, see here, press release here. Jester reports on some details from last week about new CDF Higgs results, indicating that maybe the Tevatron will report an excess as expected. Matt Strassler also discusses results from last week, these from CMS, reporting that the multilepton events he got so excited about last year weren't anything to get excited about.

A reliable rumor-mongering commenter here warns us to take a look at the new LHC fermiophobic Higgs results coming this week.

   What is a fermiophobic Higgs ?

7. **Anon**
   March 5, 2012

   You've missed the : after http in the link to the slides.

8. **Peter Woit**
   March 5, 2012

   Anon,

   Thanks, fixed.

   pakri,

In my not well-informed understanding, in “fermiophobic” models, the Higgs couples to itself and gauge fields to give electroweak symmetry breaking, but it doesn’t couple to fermions (no Yukawas). Maybe an expert can say more, I’m definitely not one, and it’s not clear to me that it makes sense to set Yukawas to zero once you have something coupling like a Higgs to gauge fields. We’ll probably hear a lot more if there’s an unexpected LHC result about this.

9. **jon**
   March 8, 2012

   About fermiophobic Higgs: there is this new ATLAS paper where with 4.9 fb-1 of data they see a 1.6 sigma excess at 125.5 GeV. So while not at all definite I’m quite curious to see what will happen with more data…

10. **jon**
    March 11, 2012

    Apparently CMS in a recent paper about their own fermiophobic searches have looked at 4.8fb-1 of data, and saw a 1.2 sigma excess at about 126 GeV. Very similar to what ATLAS sees then, but of course these are small excesses.

    Still, I wonder what experts think. And also, how many sigmas the combination would provide (hopefully someone like Phil Gibbs may be interested in doing a quick unofficial one…).

Tevatron Higgs Results

March 5, 2012
Categories: Experimental HEP News

The combined D0 + CDF Tevatron results on the Higgs are scheduled to be announced Wednesday, but it looks like this web-page may have jumped the gun a bit, listing the new results (based on "up to 10 inverse fb") as:

> SM Higgs is excluded between 147 and 179 GeV there is a greater than 2-sigma excess observed at low mass.

The summer 2011 combination excluded at 95% the mass range 156-177 GeV, so the new results extend this slightly higher and ~~11~~ 9 GeV lower. The most intriguing aspect is the "2-sigma excess at low mass", which is about what you might expect them to be seeing if there really is a 125-6 GeV Higgs as the LHC data suggests. In the H->b bbar channel that the Tevatron is most sensitive to (and that the LHC is not sensitive to) the expected signal is very wide, not allowing much of a fix on the Higgs mass (see Resonaances for more of an explanation of this).

Details to appear Wednesday, at

http://tevnphwg.fnal.gov/results/SM_Higgs_Winter_12/

Update: Matt Strassler has written a long posting to provide context and caveats for these results here.

Update: Results described here a couple days ago now official (2.2 sigma). Details at the usual recommended places (Dorigo, Gibbs, Jester, Strassler). I'm teaching a class, then off on a plane…

Comments

1. **Nex**
   March 6, 2012

   If more LHC data eventually rules out Higgs around 125 GeV the fact that pretty much every experiment is seeing some bump there will need good explanation.

2. **E.S.**
   March 6, 2012

   156-147 = 9 …

3. **Peter Woit**
   March 6, 2012

   E.S.,

   Oops, I supposed I should proof-read these things… Fixed.

4. **Craig**
   March 6, 2012

   Nex,
   Re a good explanation. There were a bundle of experiments that reported observation of a pentaquark a few years back. Eventually some negative searches were reported, from Fermilab experiments and elsewhere, and the pentaquark disappeared. I don't recall any of the experiments that reported positive sightings providing good explanations, or any explanations, of why they saw something. Of course, although the pentaquark "discovery" did make the news, it's not quite the Higgs!

5. **JRPS**
   March 8, 2012

   To Craig:

   You are right not all experiments for the pentaquark gave detailed explanations of why they saw something. But some people closely related to the experimentalists did, despite initially supporting the pentaquark . Some of these papers appeared in nucl-th and may have been unnoticed to people reading hep-th or even hep-ph. For instance I would suggest Phys.Rev.Lett. 105 (2010) 092001, e-Print: arXiv:1008.4978 [nucl-th] (To my view that was the last nail in the coffin, but came out too late, when basically just one experiment still supported the pentaquark). Of course, showing why a result which nobody believes anymore is wrong, does not get much attention. But that kind of works are done. I agree with you it would be nicer if the experimentalists had done it themselves. Some of them do and some don't.

   This is an example of why I give little significance to the "confidence level" claims. But there are many others. Quite often in Particle Physics we have seen "many sigma" and "99% C.L." claims that go away due to some systematic effect, which is well explained later… or not (the pentaquark, R_b, FTL neutrinos, and so on…). You can make a fantastic job with statistics, that is useless if you do not understand your systematics.

6. **guest**
   March 8, 2012

   Hype about strings=BAD. Hype about the Tevatron=GOOD.

7. **guest**
   March 8, 2012

   Or in other words: when will you tell your blog readers that the latest splash on Higgs searches at Moriond came from ATLAS results?

8. **jpd**
   March 8, 2012

   results from strings=NONE. results from the Tevatron=INTERESTING.

9. **Peter Woit**
March 8, 2012

guest,

1. I'm on vacation.
2. As usual I suggested other places that do cover these things much better than I do, including the ATLAS results in detail.
3. I try to post news here that is not available elsewhere. The Tevatron news was a good example
4. It's great that ATLAS is able to rule out lower mass ranges, but that now is not where people are expecting to see something. The big question is what is going on at 125 GeV, is it the Higgs? And ATLAS has nothing much new to say there.
5. The Tevatron seeing a marginal signal in a new channel, consistent with 125 GeV Higgs, is news.
6. This is probably the last major Tevatron result we'll ever hear. The victors at CERN who have put it out of business should be gracious.
7. I don't think there's any danger that ATLAS and CMS results at the LHC will receive insufficient attention.

Back to vacation…

10. **guest**
March 8, 2012

Thanks for the detailed answer!

1. Apologies.
2. Yep.
3. OK
4. Strongly disagree. Among other reasons ruling out that extra chunk increases the significance of the bumps, by reducing the LEE. And ATLAS had also the potential of directly reducing the significance by enlarging the dataset analyzed.
5. Yes, it's news. Marginal news.
6. On this I agree.
7. Right.

Thanks in any case for the info.

11. **anonymous**
March 8, 2012

Who cares about puny 2-sigma Higgs results? Have you seen Daya Bay's very convincing 5-sigma neutrino result? That just killed the tribimaximal mixing theory dead and gone and opens the door to studying CP violation in the leptons!

12. **guest**
March 9, 2012

Who cares? Anyone with the right understanding on what's more fundamentally important.

13. **A.**
March 16, 2012

Totally off-topic, sorry, but I just saw this postdoc ad. for a position in "the philosophy of cosmology" in DAMTP. Is this just a very silly choice of title or has Cambridge really gone down hill?

http://www.damtp.cam.ac.uk/vacancy/#RAPhilosophyCosmology

14. **Chris Oakley**
March 16, 2012

A,

I would opt for the latter explanation.

15. **Andym**
March 16, 2012

Definitely, downhill all the way.

Templeton Millions

March 16, 2012
Categories: Multiverse Mania

I'm still on vacation for a few days, but will take a quick break from sitting in a hot tub watching the Northern Lights here in Iceland for a short blog entry.

The Templeton Foundation has just announced a plan to honor the centenary of the birth of Sir John Templeton by giving $5.6 million dollars to physicists and astronomers willing to work on four "Big Questions" of a philosophical sort about cosmology. The multiverse is of course one of them. This program will be run out of the University of Chicago and led by astronomer Donald York, who surely was chosen for this partly because he's an evangelical Christian:

> …plenty of scientists are religious. Take Donald York, PhD'71, the Horace B. Horton professor in astronomy & astrophysics, the Enrico Fermi Institute, and the College. Founding director of both the Sloan Digital Sky Survey and the Apache Point Observatory, York is also an evangelical Christian who served as Intervarsity's faculty sponsor from the mid-'80s through mid-'90s. "I don't try to make the literal resolution" between science and Christianity, he says. "We're always changing and growing, and some things are acceptable at different times." To him, "Science is a story just like the religious stories."

A commenter points out here that DAMTP at Cambridge has just posted a job ad for Templeton-funded hiring in "Philosophy of Cosmology". Note that this hiring is not in the Philosophy department but in the physics department. The announcement says that there will also be a similar job at Oxford. The "Philosophy of Cosmology" grants used to fund this and similar positions in the US seem to involve at least a couple million dollars, more here and in my earlier blog entry about this.

Normally I try and avoid editorializing directly about news like this, but this time I'll make an exception. I think what is going on here is very dangerous. The Templeton Foundation's agenda is not the advancement of science, it is the advancement of a particular religious point of view about what science is and how it should be done. They are very cleverly putting large sums of money into backing theology and pseudo-scientific research at the most prestigious academic institutions in the world. One reason that these places are happily taking the money is because public funding is drying up. The organization is extremely wealthy, and now led by Templeton's son, who when he isn't spending his father's money on this is spending it on promoting Rick Santorum's political career or other far-right causes (see here for example).

At least in physics, some of those who can usually be counted on to do battle with the forces of religion have gone quiet. See for example Sean Carroll's posting about this recent funding, where he discourages commenters from criticizing the source of this money, since it's being spent on something he approves of. Seems to me that people in this field need to start seriously talking about the implications of this large new funding stream and its source, not suppressing such discussion.

Update: I'd be curious to hear from anyone at the University of Chicago who knows what the university's involvement with this actually is. The main page claims it is a project "led by the University of Chicago" and their logo is all over the site, but Donald York is the only University of Chicago affiliate listed (actually, he seems to be the only person listed, others are just "honorary"). Who at Chicago would have had to approve this, and is the university getting part of the grant funds from Templeton?

Comments

1. **Deon Garrett**
   March 16, 2012

   Part of my problem with this sort of thing is that I know that it's very purpose is to promote things I think are ultimately harmful. That's the major issue I have, and it's enough for me to oppose this sort of thing on its own. But even if you take Carroll's approach, there's such an overt agenda here that even if all intentions are honorable, it just invites skepticism. If you're going to do a real study showing that tobacco use isn't correlated with cancer risks, you can't work for a cigarette manufacturer.

   By the way, how are you enjoying Iceland? I've been here about 1.5 years, and I'm always interested in other people's impressions of the place…

2. **Nex**
   March 16, 2012

   I don't have the problem with this as long as I am getting my share of the money 😛

   No, but seriously, it does invite skepticism but I still think the balance is positive. I mean it's not like those funded by templeton will be able to sneak some false premises past their peers or falsify some data, all their work can be easily scrutinized by everyone else.

   The only valid risk I see is in promoting nonsense to the public, but that has been going on even without the templeton.

   Also I am genuinely interested if anything sensible can be said about some of the topics they fund and I don't see anyone else paying for that that kind of research.

3. **birth cry**
   March 16, 2012

   Robert Millikan was a devout Christian (Baptist I think). He honestly believed that cosmic rays were a signal of the `birth cry of the Universe', from the Book of Genesis. There is a Wiki page about this
   http://en.wikipedia.org/wiki/Birth_cries_of_atoms
   Millikan was quite serious in his belief, and went to Chicago (his hometown) many times to give public lectures to raise money for his cosmic ray experiments (this was in the 1920s or so). Whatever his motivations, and the source of his funding, Millikan produced serious science on cosmic rays with the money. Eventually Carl Anderson and others at Caltech had to distance themselves from Millikan. Millikan eventually recognized the indisputable scientific results from his work. He produced serious science whatever his personal religious beliefs and motivations.

   I suppose the big difference is that Millikan set his own agenda (of science) and found people to fund it. The difference today is that the funding agency (Templeton foundation) sets the agenda. It remains to be seen what actual science is produced, and if it does not support any evidence for the Templeton foundations religious point(s) of view. Yes this is all very much a product of the drying up of public funding. The science labs/institutes have to get money from somewhere. In earlier years (pre WW2?) eminent scientists did get funding from religious sources.

4. **Bernhard**
   March 16, 2012

   Following Sean Carrol's logic we should accept science being funded with drug money as well. If we continue on this path we will end up in the dark ages again.

5. **Foster Boondoggle**
   March 16, 2012

I think the main issue for scientists or other academics is the provenance of the funds, not what other things the Templeton foundation might support. The $ came from building a mutual fund company – not from selling addictive drugs or some other nefarious business.

And the funds aren't being used in some lame attempt to bribe practicing scientists to change their beliefs. No thoughtful person is going to decide to become a fundamentalist Christian just because they get offered a grant – or if they do, they're unlikely to retain the respect of their peers, and they also don't care what you think about them. From googling around about what science Templeton has spent $ on to date, it seems definitely biased towards origins and foundational questions, but hardly for trying to convert people.

Religion seems to be a basic feature of human society – you find it everywhere and in all cultural histories. Atheist though I am, I see no real problem with scientists taking money from believers to do their (the scientists') work, on the modest condition of showing up at conferences to talk across the divide about the philosophical implications of their studies.

6. **Peter Morgan**
   March 16, 2012

   Although you imply that the "point of view about what science is and how it should be done" is a "particular religious" point of view, I take ideas such as Donald York's, that "Science is a story", to be culturally more widely held than merely religious. Comparable ideas are, to limit it to my first hand experience, fairly common amongst academics in the humanities. Some of the claims one hears for various mathematical models are fabulous enough to be generously open to critique by a rhetorician.

7. **John Romeo Alpha**
   March 16, 2012

   In economic terms, it's probably a positive thing that these funds are being circulated from the religious sub-economy into the scientific, rather than the foundation just sitting on them, or spending them strictly within their own sect in a "buy-" mindset. If there's a net cash flow from religion to science, too, that seems like a better direction for the deficit than the other way. When scientific institutions and foundations start financing religious research to the extent that the net flow goes the other way, we should worry more. Like all that money Steve Forbes spent on presidential campaigns, rational reflection recognizes it to be a waste in terms of first order return on investment, but all the baristas and bus drivers and advertisers on the second and extended orders of economic activity supported by those funds benefited.

8. **Alp**
   March 16, 2012

   Surprisingly, I find that the scientific goals of such scientists might often align with the rest. For instance, from the movie Religulous:

   > Maher meets with both a Vatican astronomer and a priest, both of whom challenge the stereotype of Catholics. Maher asks why the Vatican would have an astronomer or be interested in science and the priest says that "Well, I can tell you that we are not here trying to find other planets just so we can get to them and convert everyone — and beat the Mormons to it.

   Even though I am not religious and I would be happier it did not happen, I have no right to impose my views on what others should choose as worthwhile. I acknowledge that people have every right to support *any* kind of research with their own funds. After all what good would wealth do if one cannot support the ideas one believes in? This is also true for funding of political candidates. I see this as a consequence of sacred economic liberties. On the other hand it's quite dubious if people have any right to spend others' wealth for a particular kind of research (i.e. taxpayer funding).

   Although it's sad that appointments might've been made not entirely by merit, that is often the case in many academic research positions. It's easy to see the hypocrisy of liberal academic establishment when they choose to ignore certain elements deciding research. Politics, just like religion, play a tremendous role in research. Just look at what motivates the so called climate science.

9. **Brathmore**
   March 16, 2012

   Peter,

   Normally I'm a staunch supporter of this blog and your viewpoints, but this time I think you're over the top. It almost sounds like you'd like to blacklist any scientist with a specific religious belief, which seems at odds given that you're upset about the blacklisting of physicists who criticize string theory.

   You refer to the "dangerous…advancement of a particular religious point of view." And what, precisely, is that "particular" point of view? Evangelical Christianity? Christianity more broadly? Theism? Any belief in God? It's hard for me to believe that the Templeton Foundation is really now a front for Evangelical Christianity. (Surely you recognize that there are widely different strains of Christianity, right? To equate an evangelical christian with a Catholic, for instance, is as absurd as a lay person equating a physicist and a biologist, simply because both are scientists).

   In my view, dogmaticism itself is an evil – whether it be found amoung the religious believers or scientists. One should be careful that in attempting to replace religious dogmaticism, one doesn't simply replace it with dogmaticism of a different kind. Your most recent post seems to do just that.

10. **TCSF**
    March 16, 2012

    I'm sorry to comment in a thread that's rapidly decaying (we already have the usual attempts to deflect the slightest criticism of religion with accusations of dogmatism, and it didn't even take 10 posts for what looks like climate denialism to show up).
    However, I think Peter Woit is spot on. Templeton millions pumped in is going to make it less likely people will feel free to speak their minds if they are critical of religion. The Templeton people have an agenda, and there's no question that buying some scientists is meant to favor that agenda–whether or not there are explicit strings attached. Now they (Templeton) are free to do what they want with their money, but can't people be free to criticize them–and their agenda?

11. **Dan D.**
    March 16, 2012

    I also very much enjoy this blog, but I also disagree with Woit's stance on this. I don't see how the mere funding of physics research by a religious institution is dangerous in and of itself, no more than any government funding for applied research where a certain end goal is envisioned is dangerous.

    Actually, I was about to say that I appreciated some of the comments that were defending religious believers, or at least not outright attacking them. I'm more used to science blogs these days taking potshots at them whenever they can, and the comments section being a cesspool of irrational anti-religious rage. I found this thread to be on the whole balanced by those who both agree and disagree with the idea of Templeton funding physics research (though I agree with TCSF regarding the climate denialism).

    I myself am a scientist who is also a religious believer. Now I'll be the first to admit that there is a fundamentalist anti-science strain in Western Christianity these days, and I'll link arms with my non-believing colleagues to promote the cause of science over and against these influences. But, I part ways when I start hearing non-religious scientists imply (note: NOT saying that Woit is doing this) that to be a “pure” scientist, one has to eschew religion, or even that being religious and a scientist at the same time is grounds for suspicion of one’s scientific integrity (though, I sometimes get the opposite from certain religious circles!). I would think that folks would welcome religious institutions becoming interested in science again and wanting to fund it, or at least not immediately cry foul. After all, for the vast majority of the history of science, this was often the case. There are other models for the relationship between religion and science other than just warfare. Not every religious institution that wants to get involved in science is doing it for nefarious reasons. Maybe Templeton is, maybe it isn’t, I don’t know. I guess it remains to be seen.

My $0.02.

12. **Low Math, Meekly Interacting**
March 16, 2012

If the researchers can ignore the source of funding, it’s not dangerous. If they can’t, it is. The latter possibility is a legitimate criticism of research being funded by pharmaceutical companies, and the intense scrutiny such research is subjected to is warranted. I figure the same standard should be applied to any funding agency which has other mandates besides the advancement of pure science. Whether it be a profit motive to satisfy shareholders or a philosophical motive to satisfy a particular religious viewpoint, vigilance is hopefully a reasonable countermeasure. I’d stop short of advising people to refuse the money. If one can get both the money and assurances that the research needn’t make the funding entity happy, then there’s reason to be optimistic a healthy balance can be struck. In essence, I’m saying if the recipients of these funds can be good at gaming the funders, why not take the money?

13. **Roger**
March 16, 2012

How can it be bad for Templeton to spend money on multiverse research when the NSF and others are spending 10x or 100x as much on it. Do you want the govt to be funding the foolish research for some ideological reason?

14. **harryb**
March 16, 2012

I have to say I am with Peter on this one. And in many ways the concerns this blog has with String Theory is the concerns it should have with Templeton-Science (I suggest we distinguish it clearly).

Freeman Dyson commenting in this months New York Review of Books on Margaret Wertheim’s Physics on the Fringe notes that the weirdness of the theories proposed (including in Wertheim’s view ST) is “what happens when imagination loses touch with observation”.

When this happens religion and other faith-based obsessions eg circlons, ethers, etc are as good as any science, because neither has to provide observable evidence.

Religious belief and Multiverse theories are thus inter-changeable, and the Templeton funding, clearly recognising this, will provide the impetus for unconstrained conjecture via “faith-based” science. Watch this space.

I believe ST, Templeton-funded, and other faith-based science should be clearly labelled as such.

One will argue that great science (as Dyson does in the article above) especially in frontier fields, often uses imagination and creativity about things yet unknown and unseen. Fine.

But those pursuing those answers should at least declare up front – I believe in a traditional Christian position (or other equivalent religious story) about ultimate truth which underpins my over-arching theory about life, and the universe, and my personal moral and intellectual belief-system, and/or am funded by a trust so disposed –

– before we read your arXiv paper.

Or,

I am not religious, do not believe in a Christian or any other diety, and am not funded by any religious or quasi-religious group, and have carefully, objectively, as far as is possible on this earth, produced this paper for your consideration.

Now read on…

harryb said:

> I believe ST, Templeton-funded, and other faith-based science should be clearly labelled as such.

But the entire problem is who decides what is faith based and what is not. Some would say ST is a religion and some would say the same for Keynesianism or warming activism.

This appointment in question is an entirely voluntary. If Mr. York was not happy with the strings attached, he has every right to seek alternative employment.

Surely one can pass judgment on the credibility of the research. But people have a right to research whatever they want to, especially if somebody but the taxpayer is willing to fund it.

16. **harryb**
March 16, 2012

@Alp

I don’t disagree – of course – that you are free to research what you will.

My concern is more basic.

If Templeton millions are passed into faith-based science, then it is very likely that such science will grow in importance in the public debate, which is in America at least , pre-disposed to that way of thinking.

Your examples are interesting:

String theory – indeed, I made the same point and I am very depressed by ST having lead us to this predicament – the string theorists have let imagination, images of mathematical "beauty", and so on take the fundamental of physics into a meta-physical minefield. It used be said that if a scientist from the 1700s walked into a science lecture today, he would be utterly bemused, but a philosopher from that era would see the same debates underway in today's lectures. I think now Saint Thomas Aquinas may be very comfortable attending Strings 2012.

– Keynesianism – fair enough, but no-one is invoking biblical stories in economics (much)

– Climate activism – now there is the problem. Chip away at particle physics, and you can have a go at it all. Super-luminal neutrinos – hah, the scientists got it wrong again! Oh wait, its been corrected – but anyway, they're probably wrong again so why believe in light's speed anyway. Evolution, same thing. And so it quickly goes.

No-one seems to argue about eg the tensile strength of steel, and inorganic chemistry. These seem to be value-neutral science pursuits. Albeit they rely on particle theories.

But take cancer therapy – that's still hotly debated, and in the Emperor of All Maladies Siddhartha Mukherjee notes how the ideology of radical surgery pursued by physicians possibly held progress back for decades due to their unswerving faith in the procedure, resistance to data and so on

So I agree we should sniff out biased (faith-induced) thinking wherever we see it.

My point is the Templeton approach just exacerbates and supports that style of bad science – data-free, issue-fixated – in potentially a confrontational way.

And propels it towards an American public already clearly predisposed to hear that science that conflicts with their moral / life-style belief system is not worth listening to and shoul be actively resisted eg climate change, evolution, stem-cell therapy, (and vice-versa – if creation myths are as good as or better than Big Bang – says a scholarly article funded by Templeton – and, even better, written by a declared Christian, why then should the believing public at large resist and question it? Its better than that string nonsense…)

We created the science method surely to stand outside that situation and it has brought us many gains. But, as David Deutsch notes in the Beginning of Infinity, Enlightenments in science and thought are by no means certain to survive, and historically all previous instances were eventually snuffed out by pessimistic ideologies.

It may be an exaggeration to state that ST and Templeton-Science could start the process whereby our present scientific advances back inside the ideological tent, and stifle progress once more.

But it may not, and our sensitivity to even the chance of it should remain high.

Let's see where the $5.6m dollars-worth of articles and conferences etc takes us in the coming months and years. I hope to be proved clearly wrong in my cynicism – but the balance of proof is with Templeton-Science for now.

17. **Eric Habegger**
March 16, 2012

Bait and switch is a time honored tactic not just in advertising, but in all human affairs. Many of the tactics written about by Machiavelli for overcoming ones adversaries were simply variations on this theme. While many people claim reasonable people can come together on important topics such as science it should be noted that people both fundamentalist scientists and atheist scientists who investigate and theorize about the multiverse have a lot in common: they have both given up the ground that science must ultimately be about things that have the potential to be observed and measured.

Who is to say that some time in the future after everyone has been cajoled into believing that the multiverse is science that both fundamentalist and atheist sides agree that both heaven and hell are legitimate subjects of science to investigate as part of the multiverse environment.

What's next? How many angels are there on the head of a pin?

18. **Alp**
March 16, 2012

@harryb

Good points and I definitely understand what you are getting at. I gave the examples ST, Keynesianism, climate debate just because I see credible people on both sides of the argument — despite some academics would disagree. For the same debates, I also see examples of data fudging/truth distorting to fit the desired intentions. All of these people would claim they were being as objective as possible as well as the racial scientists of world war 2 era.

Even though I'd like to agree there must be good criterion for testability as to what good science is, I am more worried if we push in this direction we may end up with a future where science is decided by the government or elites and debate is suppressed. This is not as farfetched a nightmare as I often see academic bullies who want to suppress contrary opinions on ST/Keynesianism/warming debates. I always thought Peter has been a victim of such behavior by others and that is why his post surprised me.

As I mentioned before I am not religious. But we are all human and being entirely objective is often impossible. Should the government have warned Einstein when he said "God does not throw dice" because he was letting religion cloud his judgment? Every researcher comes with their own baggage of bias. And often times such bias might've been instrumental in their reaching unique results. Shouldn't we let the results speak for themselves? Anything else would be self righteous.

19. **Typhoon**
March 16, 2012

Grant-whoring has a long and venerable tradition in the sciences.

The Templeton Foundation is simply making good use of this reality.

20. **Ryan Budney**
March 16, 2012

Rather than looking at this through the eyes of using grant money to endow a particular religion or religious perspective with the approval of a research institution, you could turn your perspective on its head, Peter.

This could be an admission that the multiverse as an idea is inherently religious. The acceptance of religious funding frees them from the constraint of living up to scientific standards, in a certain formal sense.

21. **Peter Woit**
March 16, 2012

A few quick comments from Reykjavik.

I don't have any particular problem in general with religion or with religious people as scientists or funders of science. I do think though that it is very much in the interest of scientists to keep religion and science separate, and this is why an organization spending as much as hundreds of millions of dollars on a well-targeted campaign to erase distinctions between the two seems to me problematic.

Hi Alp,
I'm not calling for suppression of the ex-Sir John Templeton's right to have his money spent on whatever research activities he wanted. I'm just exercising my own right to criticize what he and his heir are doing and encourage others to think about the issues involved.

Roger,

On the whole, NSF/DOE panels mostly refuse to fund multiverse grants, because most physicists think this is not science. With Templeton funding of multiverse studies probably long ago passing the $10 million mark, it's Templeton that is putting up a large fraction of the money promoting this. The goal of course is to make this subject academically respectable and well-entrenched at leading institutions. Once that happens, the NSF/DOE panels will change their behavior. So, this is seed money targeted to changing the facts on the ground.

Deon Garrett,

It's a spectacularly beautiful place (and the hot tub thing was not a joke, pretty amazing experience…) Just got into Reykjavik this evening, will see more of it tomorrow.

22. **z**
March 16, 2012

About Iceland — is it true what they say about the water and showers – does it stink?

23. **Peter Woit**
March 16, 2012

z,

At a high-end hotel in the middle of nowhere, no (excellent water conditions in the hot tub). In Reykjavik, yes.

24. **paddy**
March 16, 2012

Tis the stink of satanic sulfur….and I meant it humorously.

25. **Joy**
March 16, 2012

As other major science funding sources include DOD, DOE, DARPA, DHS … I am hard pressed to consider Templeton as being any more toxic to humanity or science than the others.

@Bernhard
Re: "science being funded with drug money" Just ask the researchers at Columbia University Medical Center who pays their bills. I suspect you meant to say illegal drugs. However, according to the U.S. Centers for Disease Control and Prevention, annual US deaths due to prescription drugs now exceed deaths due to motor vehicle accidents. Not an innocent funding source either.

26. **Chris**
March 17, 2012

@Peter Woit
„*I don't have any particular problem in general with religion or with religious people as scientists or funders of science*…. but you would prefer the money to come from the taxpayer via the government with the choices being made by atheists whose views on what is acceptable science conform with your own.

27. **Paulibus**
March 17, 2012

I note that to Donald York, who will run the Templeton scheme, "Science is a story just like the religious stories." Science is indeed a story (that's what evolution has conditioned us to do; talk stories, endlessly). But science is a quite different story to religion. Except for outbreaks of la haute poppicocquerie (as the French might call string theory), science is based on the Baconian tradition of observing nature and making verified predictions about it. Religion makes some predictions about the physical world (often that it will end soon) but generally shuns this risky occupation. Perhaps that's why religion is fragmented, while science trends towards unification.

Better the two cultures each tend to their own knitting. Financally as well as morally.

28. **Peter Woit**
March 17, 2012

Chris,

I don't care much about the source of science funding, and not at all about whether atheists or believers are making funding choices. I do care if pseudo-science is funded and promoted as science, with the goal of institutionalizing it as such.

29. **harryb**
March 17, 2012

@Chris

You suggest funding from "atheist taxpayers" would be as problematic as Templeton funding. OK, as a thought experiment, let's say I win a major lottery and come into $100million. I decide to set up a 10 year funding of $10million a year on the following basis:

– no declared follower of an organised faith is acceptable – so Donald York, sorry no, and indeed LeMaitre in years gone by, but there you go, I am sure he would have got Templeton-esque funding, science would have got by

– no multiverse or ST allowed – well-funded already (see above) – unless it meets the next condition
– only Baconian principles of at least testifiability in some form in the near future – (this will be judgmental for sure)
– declared atheists acceptable / encouraged to apply – no need to be coy about it. People of uncertainty in religion fine as well, otherwise we have entered Orwellian territory.

Now. No doubt much to antagonise folk here – but let me note that as a card-carrying non-religious person, I would personally feel uncomfortable taking Templeton funding and wondering what type of peer review I would actually be coming under from Mr York et al. Its not that I would try to block its funding – but I am within rights surely to attempt to impose an alternative world-view as well.

One will argue that there is no such thing as objectivity and hence any ideology above is just as constrictive as any religion.

That is indeed a real problem the experiment exposes. But I would argue the key difference is this fund starts out with a belief in Nature that is objectively testable. And I would argue assessing criteria for fund money will constantly be a hot debate and so it should be – any faith-based person can go to Templeton with stories if they want. This fund ought to constantly test its own principles to ensure its not slipping down an ideological slope – hence testifiable / potentially testifiable ST is in.

It does not attempt as a starting point that ST, multiverses, or for example, Christian religious teachings, are received wisdoms, and hence undeniable. And it does not set the bar so low that any untestable multiversey landscapey billion-dimension stuff gets dollars.

I actually take a stronger position than Peter on this, because I think overtly religious funding with such low criteria will just expand bad science – watch next for a flurry of intelligent design arXiv papers. Almost by definition religion / faith is bad science and I have always had a problem with the attempts to reconcile the Two Magisteriums as Stephen Jay Gould tried.

I see I am heading towards Dawkins territory – so be it. I think both religion and science can handle such a fund being created.

The fund runs of course the risk of missing great strides in ST – but again Science sees no such risk as Templeton etc funding will allow ST to carry on.

Anyway – young physicists, whose million do you take ?

30. **Giotis**
March 17, 2012

But the multiverse refutes the apparent intelligent design as a mere illusion.

Normally Templeton should fund anti-multiverse research.

So Peter’s allegations don’t make much sense to me.

Question: FQXi is controlled by Templeton?

31. **Peter Woit**
March 17, 2012

Giotis,

Not all religious people reject evolution and embrace intelligent design. In particular, the Templeton Foundation explicitly supports evolution research and rejects intelligent design. Their agenda is to institutionalize not fundamentalist religions, but their “theology and science are all the same thing” philosophy (which is fine with the multiverse and evolution). They’re having great success at getting even scientists like Sean who don’t like theology to get into bed with them. Enough money will do that…

FQXI was started with Templeton money and seems to have been mostly funded by that in recent years. I don’t know what the current situation of FQXI’s funding is, and would be curious to hear from someone who does know.

32. **BJM**
March 17, 2012

Re:
Peter Woit says:
“I don’t care much about the source of science funding, and not at all about whether atheists or believers are making funding choices. I do care if pseudo-science is funded and promoted as science, with the goal of institutionalizing it as such.”

This seems at odds with what I thought was your previous concern that believers making funding choices could muzzle scientists on the subject of religion. If your real problem is any funding of pseudo-science, this is not how it was presented in your blog.

33. **Danny**
March 17, 2012

There’s a difference between Templeton funding researchers and Templeton funding Oxford/Cambridge researchers. As a result of smoking-causes-cancer, climate change, and a zillion poorly-excuted-but-overstated psychology experiments, the public is skeptical of scientists; however, the top academic brand names retain respect. I’m disappointed the heads of Oxford, Cambridge, and the other universities are willing to allow their brand to be attached to the sort of papers and headlines we’ll surely be seeing.

“Oxford physicists prove existence of God”, and so forth.

34. **harryb**
March 17, 2012

I read the pingback reference on Templeton funding to Jerry Coyne’s blog at whyevolutionistrue web site. In the reference he points to the Metanexus foundation website, part-funded by Templeton. If this website is the future (well-funded) face of science, then oh dear.

Chilling mix of spiritualism, brief riffs of scientific comment and then back to religious poetic sentiment. What to do with all that? – But many solid names have signed up, and no doubt will sign up.

Lot to be said for contrarianism.

35. **Peter Woit**
March 17, 2012

BJM,

I don't see what was unclear about what I wrote about this:

"I think what is going on here is very dangerous. The Templeton Foundation's agenda is not the advancement of science, it is the advancement of a particular religious point of view about what science is and how it should be done. They are very cleverly putting large sums of money into backing theology and pseudo-scientific research at the most prestigious academic institutions in the world."

As anyone who has followed my blog for a while can tell, I have zero interest in arguments about the existence of God, or who believes what on that topic.

36. **pakri**
March 17, 2012

Whatever the agenda maybe, surely the people who attend these meetings, and I assume they are scientists, will have to decide for themselves what they want to achieve in their life as researchers in science and what else in their more personal religious life. Whether the foundation continues to receive their support will depend on the scientists only.

37. **Dave Miller in Sacramento**
March 18, 2012

Peter,

I am a much more rabid atheist than you are: I grew up attending a fundamentalist church and am still angry about being subjected to years of threats of eternal torture in Hell (I never did agree to join the church as a child, but I did have ongoing nightmares due to the constant threats of Hellfire).

Nonetheless, I am much less concerned than you about the Templeton matter for a very simple reason: they are going to fail. I myself am a bit fond of occasionally musing over questions such as "Why is there something rather than nothing?", but we all know that such questions have pretty much nothing to do with serious, contemporary science.

All that Templeton is going to do is to add a small amount to the meaningless nonsense already published on such subjects, not just in the popular media but also coming from many academics in philosophy, theology, literary theory, etc.

Templeton will get some scientists to announce that God might exist? Old news – anyone who looks into the issue already knows that some scientists think God might exist. Maybe most scientists think God *might* exist, even many of us who think he probably does not.

The major war between science and religion is already over: old-time, literalist religions is dead for good among intelligent, educated people. Templeton cannot change that (and does not even seem to want to). All Templeton can do is encourage vapidly pointless declarations of the possibility of some higher "spirituality."

If I understand you correctly, your main fear seems to be that this will divert scientists from real, productive scientific work. First, the Templeton spiritualism really should not take much time, energy, or effort: playing soccer twice a week should hardly interfere much with scientific productivity, and it is hard to see why churning out some vague nonsense for Templeton should be much more demanding. And, any scientist who really has a good idea (not that common!) should find it so consuming that Templeton is unlikely to really distract him much.

I have trouble seeing Templeton as anything more than a very tiny addition to the cultural pollution in which everyone is already immersed.

Dave Miller in Sacramento

38. **Friend**
March 18, 2012

Peter,

I think you may be a little too dismissive. It's entirely possible that Templeton's religious views may inform them to seek the truth, whatever that may be, with the expectation that it will ultimately justify their faith at least in some part. That's their prerogative and does not interfere with scientific truth. It's difficult to prove the existence of something that is not well defined. The concept of "God" is not well defined. Some think in anthropomorphic terms which may seem silly to scientist. And others may think that God is some overriding principle of reason that governs how the universe works, which may seem like the antithesis to some religious views. So I don't think one can prove or disprove the existence of God. Ultimately we will have to judge by what is predicted by whatever theory is proposed by science or religion. Let's wait until we have all the facts or until we have mathematical proof one way or the other. Thanks.

39. **paddy**
March 18, 2012

To sum up my opinion: Galileo Galilei. He took his "grant money" and took his chances with more a potential downside than not being funded next year. But (in line with what I think D. Miller implied), Galileo (perhaps apocryphally) died saying "and still it moves". This is always the choice of a scientist…to take patronage but to remain independent nonetheless. And we pardon those who cannot sacrifice themselves…and those like Galileo who compromise a wee bit. Because they have been better than we probably could ever have been.

40. **Marion Delgado**
March 18, 2012

I posted a link to this on Chris Mooney et al.'s "Intersection" Blog at scienceprogress (was at scienceblogs, then Discover) He got a more proper Templeton grant, but it seems it's time to bring them up again.

41. **Sammy Coleridge**
March 19, 2012

Hello Peter:

There are many decent people who are concerned that the public schools seem to be teaching their children that they are no more than sentient robots existing briefly in a pointless universe. Scientists need to find neutral ground on which to engage these people in civilized debate. Analytical philosphy, which addresses words like the first person singular nominative pronoun and, again, 'universe' is that ground.

Great website, thanks.

SC

42. **chris**
March 19, 2012

wow.

the blog comments are a true testament of how far right the us has moved recently.

thanks peter for keeping it up and don't worry, there are readers who understand that perfectly simple and valid point you are making.

43. **Christian Takacs**
March 19, 2012

Hello Peter,

Your latest blog entry is a bit puzzling for multiple reasons.

#1. Newton, Descartes, Einstein, Bernhard Riemann, Pascal, Yes… even Galileo, Maxwell, Faraday, Cantor, Planck, etc… all of them and many, many, more believed in Religion and God. You would be wise to refresh yourself with the beliefs of a few of your predecessors in the fine sciences of Mathematics, Physics, Biology, Chemistry, Astronomy, etc. if only to gain some perspective of whose shoulders you are presently standing on, and perhaps realize that many before you found their Belief a source of inspiration, not an irrational impediment to understanding as you would entertain.

#2. Your elitist disdain of religion is quite evident, borderlining on contempt… But Peter, you are yourself a follower of a set of beliefs/premises based mostly in the completely abstract numerical reasoning you favor that entertains creation ex nihilo or Big Bangs from timeless voids, point particles that have zero extension but are assigned infinite mass, treat infinity like a mere number that can be operated on, and sing praises about quantum mechanics which requires renormalization in order to even function, a process it's own creators admitted was 'dippy' or wasn't mathematically valid.

#3 Your reaction to research being funded by the Templeton Foundation reveals your dog in the hunt, or political bias. Yes, you too have an axe to grind Peter. I am well aware of what politics pervades most universities, and how they depend from their mostly governmental sponsors. (You should review the farewell speech of President Eisenhower when he warned of the intellectual stagnation and group-think nepotism which would result from government funding of research.) You dislike the idea of anyone you are politically/philosophically opposed to competing with you for favor in your field. I'm kind of amused by this considering the irony of you going on at some length in your book about 'diversity' as being a possible solution to the present impasse in the field of physics. Perhaps you should have defined 'diversity' differently to keep the riff-raff out of your ivory tower.

#4. You have written a book about how ridiculous and wacko things are getting in the house of physics. Endless multiplying Multiverses, time travelling nonsense, logical paradoxes and contradictions galore, extra-dimensional loop de loops tied up with super strings… This was all done with your fellow peers in peer reviewed approval in your 'correctly' funded research, just the way you like it.

For you to look down on other people who are scientists, physicists, philosophers, and happen to have religious beliefs as corrupting and 'pseudo-scientific' when your own non-religious peers believe in things they can't prove, and want to redefine science so they don't have to, and fund it with the taxes of people 'clinging to their guns and bibles' whom it would both you and your peers have contempt for … it boggles my mind how you can't see the hubris and hypocrisy of your own argument.

44. **Peter Woit**
March 19, 2012

Christian,

I don't know how many times I need to keep repeating this: unlike many scientist bloggers I've nothing against religion in general or religious people, or religious belief. My attitude about theological issues is very simple: I just don't care at all. Other people do, with variable results.

I do care though about what people's religious beliefs cause them to do that affects our society in significant ways. The culture war going on in the US driven by fundamentalist religion is a big problem and one look at this year's US presidential campaign should convince anyone of that. About Templeton, I don't care at all what they believe, I do care about what effects their beliefs have on a field that I care about, and I've explained what my concerns are repeatedly here.

And, obviously, I'm well aware that Templeton is not the only problem here. There are very unfortunate tendencies in modern theoretical physics, that I go on and on about here and elsewhere. The Templeton problem is that they're effectively putting their money to work to make things worse.

45. **Friend**
March 19, 2012

Peter, it might help if you could point to at least one example where the influence of the Templeton foundation has lead to scientific error. Thanks.

46. **Peter Woit**
March 19, 2012

Friend,

The problem isn't "wrong" science, it's "not even wrong" science. More specifically, pseudo-scientific studies of the "Multiverse", masquerading as science, something that I'd guess Templeton has spent over $10 million dollars supporting in recent years. It's hard to quantify how much effect Templeton money has had, but the rise in Multiverse Mania has been significant, and the Templeton money behind it is part of the story. This topic has been exhaustively (some would say, obsessively, way beyond what is necessary…) discussed on this blog.

47. **person**
March 19, 2012

@ Friend:
Here's one example where Templeton funding has led to scientific error.

http://newsinfo.iu.edu/news/page/normal/14990.html

In this case the error stems from a misunderstanding of statistics and of the scientific method. Templeton apparently funding motivated someone with no understanding of science to "try their hand at it". It gives an example of what garbage can result when a science funding organization has a non-scientific agenda.

48. **Spencer Tracy Jr.**
March 19, 2012

Times sure have changed.
I used to say: "Show me someone trying to bridge the gap between science and religion and I will show you a religious person."
Now we have to add physicists shamelessly looking for a payday to the list.

49. **harryb**
March 19, 2012

Person,

Thanks for the post, depressing though it is. Takes us right back to the fundamental point of this blog and Peter's book.

Not even wrong – and I blame string theorists for letting this metaphysical claptrap get a more serious outing (and funding) – as they have played into its hands. The more Templeton funds ST receives, the more they should be viewed as contributors to the metaphysical / spiritual realm – Not Even Physics.

As a partial antidote I read Ian Stewart's 17 Equations that Changed the World. The familiar ones are all there – but the point he makes it that these equations (either relating two quantities, or providing information regarding an unknown quantity) really have impacted the world – for good, sometimes ill. Some writers suggest plausibly over 30% of US GDP is now indebted to QM.

Point is – where is all this well-funded conjecture / spiritualism type research taking us? I am not advocating a simplistic show the immediate pay-back type approach. But I worry the other extreme could take hold – well funded introspective guff about spirituality and hidden meanings. And whilst they fiddle about on this, research into other areas such as condensed matter that could improve people's daily lives may go abegging. So if Templeton wants a moral high ground, they ought to be careful of their preachy graciousness in this context.

They have no equations.

50. **Shantanu**
March 19, 2012

Peter, forget all this. Haven't seen any comments form you on Daya Bay result.
(Is it because neutrino physics doesn't excite you?) maybe someone should see if string theorists regard this as evidence for string theory 🙂

51. **Peter Woit**
March 19, 2012

Shantanu,

Well, I was on vacation, sitting in that hot tub…

More importantly, I just don't know that much about this, prefer to leave writing about it to those who know more. It's a significant advance in the subject, but I don't have anything of much interest to add.

Dyson on Fringe Physics, String Cosmology and Hermann Weyl

March 19, 2012
Categories: Uncategorized

The latest New York Review of Books has a review by Freeman Dyson of Margaret Wertheim's recent book Physics on the Fringe (which I wrote about here).

Dyson is much more sympathetic than most physicists to "fringe physicists" like Jim Carter who is the main figure in Wertheim's book. He compares Carter to William Thomson and Peter Tait, well-known 19th century scientific figures, while making clear that Carter's "Circlon" theory is not worth taking seriously. He then goes on to discuss two cases of "fringe physics" that he had personal experience with:

> In my career as a scientist, I twice had the good fortune to be a personal friend of a famous dissident. One dissident, Sir Arthur Eddington, was an insider like Thomson and Tait. The other, Immanuel Velikovsky, was an outsider like Carter. Both of them were tragic figures, intellectually brilliant and morally courageous, with the same fatal flaw as Carter. Both of them were possessed by fantasies that people with ordinary common sense could recognize as nonsense. I made it clear to both that I did not believe their fantasies, but I admired them as human beings and as imaginative artists. I admired them most of all for their stubborn refusal to remain silent. With the whole world against them, they remained true to their beliefs. I could not pretend to agree with them, but I could give them my moral support.

About the later speculative work which he was exposed to as a student in Eddington's class at Cambridge, Dyson writes:

> Two facts were clear. First, Eddington was talking nonsense. Second, in spite of the nonsense, he was still a great man. For the small class of students, it was a privilege to come faithfully to his lectures and to share his pain. Two years later he was dead.

This sympathy for a great physicist who headed down a wrong path in his later years is easy to understand, but the case of Velikovsky is less so. Velikovsky was a well-known author of crackpot best-sellers starting in the 1950s (lots got explained by Venus and Mars moving out of their orbits and colliding with the Earth a few thousand years ago), and a neighbor of Dyson's in Princeton. Here's what he wrote as a proposed blurb for Velikovsky in 1977:

> First, as a scientist, I disagree profoundly with many of the statements in your books. Second, as your friend, I disagree even more profoundly with those scientists who have tried to silence your voice. To me, you are no reincarnation of Copernicus or Galileo. You are a prophet in the tradition of William Blake, a man reviled and ridiculed by his contemporaries but now recognized as one of the greatest of English poets. A hundred and seventy years ago, Blake wrote: "The Enquiry in England is not whether a Man has Talents and Genius, but whether he is Passive and Polite and a Virtuous Ass and obedient to Noblemen's Opinions in Art and Science. If he is, he is a Good Man. If not, he must be starved." So you stand in good company. Blake, a buffoon to his enemies and an embarrassment to his friends, saw Earth and Heaven more clearly than any of them. Your poetic visions are as large as his and as deeply rooted in human experience. I am proud to be numbered among your friends.

He goes on to explain:

> Why do I value so highly the memory of Eddington and Velikovsky, and why does Margaret Wertheim treasure the memory of William Thomson and Jim Carter? We honor them because science is only a small part of human capability. We gain knowledge of our place in the universe not only from science but also from history, art, and literature. Science is a creative interaction of observation with imagination. "Physics at the Fringe" is what happens when imagination loses touch with observation. Imagination by itself can still enlarge our vision when observation fails. The mythologies of Carter and Velikovsky fail to be science, but they are works of art and high imagining. As William Blake told us long ago, "You never know what is enough unless you know what is more than enough."

Dyson's sympathy for mystics, even ones spouting nonsense, is of a piece with his views on religion and science (which helped win him the Templeton Prize for 2000). These views are hard to do justice to here, if interested to know more, his 2002 review in the NYRB of a book on theology by physicist John Polkinghorne is a good place to look.

The review goes on to address a different sort of "fringe physics", the somewhat mainstream topic of "string cosmology", which Wertheim compared to the work of Jim Carter.

> Over most of the territory of physics, theorists and experimenters are engaged in a common enterprise, and theories are tested rigorously by experiment. The theorists listen to the voice of nature speaking through experimental tools. This was true for the great theorists of the early twentieth century, Einstein and Heisenberg and Schrödinger, whose revolutionary theories of relativity and quantum mechanics were tested by precise experiments and found to fit the facts of nature. The new mathematical abstractions fit the facts, while the old mechanical models did not.
>
> String cosmology is different. String cosmology is a part of theoretical physics that has become detached from experiments. String cosmologists are free to imagine universes and multiverses, guided by intuition and aesthetic judgment alone. Their creations must be logically consistent and mathematically elegant, but they are otherwise unconstrained. That is why Wertheim found the official string cosmology conference disconcertingly similar to the unofficial Natural Philosophy conference. The insiders and the outsiders seem to be following the same rules. Both groups are telling stories of imagined worlds, and neither has an assured way of deciding who is right. If the title *Physics on the Fringe* fits the natural philosophers, the same title also fits the string cosmologists.
>
> The fringe of physics is not a sharp boundary with truth on one side and fantasy on the other. All of science is uncertain and subject to revision. The glory of science is to imagine more than we can prove. The fringe is the unexplored territory where truth and fantasy are not yet disentangled. Hermann Weyl, who was one of the main architects of the relativity and quantum revolutions, said to me once, "I always try to combine the true with the beautiful, but when I have to choose one or the other, I usually choose the beautiful." Following Weyl's good example, our string cosmologists are making the same choice.

I strongly disagree with Dyson that "string cosmology" is beautiful, and suspect that he hasn't bothered to look closely into it. Even the people most enthusiastic about the anthropic string theory landscape don't generally characterize it as beautiful. Brian Greene's characterization of string theory as "Elegant" concerns the idea of a highly predictive unified theory based on a Calabi-Yau, but I don't think he has tried to characterize the Multiverse in this way. There's lots to say about the problem of "beauty" and string theory, at one point I wrote a whole book chapter about it, so won't say more here.

The Hermann Weyl quote is very famous, and I had always assumed that it was something that Weyl wrote somewhere. It turns out that the source is not Weyl, but Dyson himself, who wrote after Weyl's death in the March 10, 1956 issue of Nature:

> Characteristic of Weyl was an aesthetic sense which dominated his thinking on all subjects. He once said to me, half joking, 'My work always tried to unite the true with the beautiful; but when I had to choose one or the other, I usually chose the beautiful'. This remark sums up his personality perfectly. It shows his profound faith in an ultimate harmony of Nature, in which the laws should inevitably express themselves in a mathematically beautiful form. It shows also his recognition of human frailty, and his humor, which always stopped him short of being pompous.

The "half-joking" and "his humor" part of this quote just about always gets left off, making Weyl sound, well, kind of pompous.

The Institute for Advanced Study now has some new web-pages devoted to Weyl and his work, the main one is here.

   March 19, 2012

   Have you seen Ira Flatow's documentary "Big Ideas" about the IAS? He interviews several string theorists including Witten, and Dyson emerges as the lone dissenting voice on string theory. He says that he thinks that string theory might end up being like Lie groups, a very interesting and elegant piece of mathematics that may find unexpected applications in physics a hundred years from now.

2. **Peter Woit**
   March 19, 2012

   Curious,

   Yes, I did see that documentary, and noticed that Dyson was the only one at the IAS expressing skepticism about string theory. This was nearly 10 years ago, it would be interesting to see the results if Flatow went back and asked what people think now. I suspect Dyson wouldn't have changed his views, other people might have…

3. **Bee**
   March 20, 2012

   Here's what Heisenberg had to say about Weyl's book…

   I'm not sure though Dyson is being fair to string cosmology. He seems to be talking about the multiverse, but for me that isn't really the interesting part. String cosmology is imo presently the most promising area to make contact between string theory and experiment, see eg this paper. For a very brief summary see also this paper, section 2.4.8 and 3.3.

   March 20, 2012

   On mathematical physics "crackpotism", can I point out that Weyl invented the key idea of first quantization quantum mechanics in his quantum gravity gauge theory of 1915. Weyl scaled the metric for curvature in general relativity by exp(iX) where X is a function of the electromagnetic field (the periodic real plane solutions to the complex exponent do the quantization). [Weyl, "Gravitation und Elektrizitat", Sitzungsberichte der Preussischen Akademie der Wissenschaften, v. 26 (1918), pp. 465-480.]

   After Einstein dismissed this Weyl quantization of gravity, Schroedinger applied Weyl's exp(iX) in 1922 to model the quantized energy levels in the Bohr atom [Schroedinger, "On a Remarkable Property of the Quantum-Orbits of a single Electron", Zeitschrift f. Physik, v. 12 (1922), pp. 13-23], from which he derived the Schroedinger wave equation – the solution to which shows that the wavefunction is proportional to exp(-iHt), simply Weyl quantization – in 1926 to explain de Broglie's work on wave-particle duality.

   Naturally, nobody dismisses Weyl as a crackpot who first misapplied gauge theory to the metric rather than the wavefunction, because the wavefunction didn't exist in 1915. This is typical real world science: people do the best they can, sometimes make mistakes, and others correct those mistakes, ignoring the errors and trying to build on what is useful. There is nothing "professional" about subjectively picking out straw man trivia to "ridicule" someone for making errors. That is just paranoid.

6. **Peter Woit**
   March 20, 2012

   Bee,

   From what I've seen, the only possible "contact between string theory and experiment" coming out of forseeable cosmology experiment is results like "this class of string theory scenarios is ruled out, this class isn't". In a situation where a huge variety of string theory models can be constructed, matching any plausible experimental result, falsifiability and distinctive predictions are gone, so you're not doing conventional science. All you're doing is parametrizing experimental results in a rather baroque way, chosen to keep a certain speculative framework alive rather than admit it doesn't really tell you anything.

   More specifically, Planck results are probably already known to some (who aren't telling). When they're announced, what will they tell us about string theory? I don't see how it can be anything significant.

7. **Bane**
   March 20, 2012

   Speaking of all things Dyson, Peter, have you read, and will you review, "Turing's Cathedral" by George Dyson, son of Freeman? I think you might enjoy it quite a bit.

8. **Tom**
   March 20, 2012

   Opening paragraph – "John Carter" ?

9. **Tom**
   March 20, 2012

   Oops, hit enter too fast!
   "John Carter" is the protagonist in the Edgar Rice Burroughs "Barsoom" books, and the title of a recent Disney scifi film based on the books.
   Dyson's book review refers to "Jim Carter" !

10. **Peter Woit**
    March 20, 2012

Thanks Tom!
Fixed. I must have had that film name somewhere in the back of my mind…

11. **harryb**
March 20, 2012

Re Dyson's review in NYRB – I felt he was soft on string theory at the end: having mauled it with the "imagination detached from experiments" line, he then seems to imply its search for beauty saves it, suggesting it may actually be Visionary. Frustrating fence-sitting.

12. **Peter Woit**
March 20, 2012

Bane,

Probably worth reading, but life is short and I don't think I've got time to really ever learn about computability…

13. **harryb**
March 21, 2012

Bane / Peter

I started the book, and persevered for several chapters, but – sorry – gave up. Its central story was interesting, fair enough – but its digressions and historical asides were bizarrely long and irrelevant. For example before getting to some material on computer development at Princeton NJ we get a whole chapter on its history from native American indians onwards. Why? How many books were being written here?

Life is indeed too short I think for this book – TL:DR as 4chan would have it (too long / didn't read)

14. **Margaret Wertheim**
March 25, 2012

Hi Peter

I am utterly delighted by Freeman Dyson's poetic review of my book in the current NYRB and am charmed by his anecdotes about his own encounters with physics dissidents, especially his story of his friendship with Immanuel Velikovsky. What I like so much about Freeman's piece is the sympathy he shows for people who have "aberrant ideas" but who are so passionately concerned with finding meaning in the world around them. Dyson compares Velikovsky to the poet William Blake: "Your poetic visions are as large as his and as deeply rooted in human experience."Though Dyson "profoundly disagrees" with much of Velikovsky's science, he nonetheless writes that "I am proud to be numbered among your friends."

What a beautiful jewel of kinship is on display here – one of the great physicists of the past century and one of the great outsider science visionaries, profoundly disagreeing yet capable still of affection for one another.

In an age when theoretical physics has sometimes come to seem like an elite competitive sport, Freeman Dyson reminds us of the enterprise's intrinsic links to poetry. My book also aimed to foreground the aesthetic roots of this science. My intention was not to adjudicate the rightness of wrongness of any particular ideas but rather to raise the question of how we, as a society, decide which theories, and which experts, to listen to. I am deeply grateful and proud to class Dyson among my reviewers.

15. **harryb**
March 27, 2012

Margaret

That's all very poetic and conciliatory, but such an approach might be the death of progressive science. Your view seems to be to find all theories worthy irrespective of their predictive and empirical power. I find that a very pessimistic approach to science, assuming there are no theories "better" than others (ie more predictive, more insightful, more useable and so on).

I love poetry – and view it somewhere strangely between fiction and fact – but I love science too, and want to lean heavily on its predictive reality as far as we can. Blending science with poetry and philosophy can create a great consilience, but only if we avoid rounding science down.

I don't believe that physics is now an "elite competitive sport". Blogs like this developed from Peter's book challenge any elite String Theorists for example – the Solvay group who spawned QM were surely more of an elite.

But let me try to get half way – I do agree that if physics for example tried to be a bit more polymathic these days and embraced other arts such as biology or economics it might create some new BSM insights and bright leaps.

However – that is a far cry for going further down the unidimensional dead-ends of strings or circlons – where is the – true – poetry in ersatz mainstream physics? I'd love more for the grafting Woits or Deutschs's of this world to have a Eureka moment after watching the Hunger Games or reading a magical realism novel.

And why isn't your book in e-form yet?

16. **srp**
March 28, 2012

From an economic theory point of view, so long as individual seekers of truth and recognition decide which other work to pay attention to solely on the basis of what will best advance their own personal quests for discoveries and citations, all the incentives line up perfectly well. Everyone has an incentive to be sincere in a personal assessment of others' work–useful, sloppy, genius, crackpot–because that work is only relevant to him as an input into his own project of inquiry and publication. His attention allocation to different sources of information is dictated by his best guess about what will aid his research. The impact of a decision to ignore another's work as crackpottery is borne by the individual making it. (Similar incentive compatibility works for such issues as how much to disclose about one's methods in a publication–each individual worker is led, as if by an invisible hand, to pick a level of detail and openness that collectively maximizes the rate of discovery.)

This perfect incentive structure breaks down when an individual seeker becomes concerned with the behavior of third parties–funders, policy makers, the public–who are not themselves part of the scientific process. Now the sincerity principle fails to hold, because the individual seeker's incentives include not only the desire to maximize his own rate of discovery and citation, but to influence these third parties. In a battle for resources, for example, getting a competitor's funding cut off by calling him a crackpot, even if you're not sure about whether he's right, becomes a possible motivation. In a battle for public recognition, it may "pay" to disparage others' work beyond one's sincerely-held beliefs. (It may also pay to feign greater agreement than one actually has with some other ideas.)

Short of returning to the days of wealthy, self-financing scientists whose only audience was a small number of cognoscenti, these imperfections in the “market” for scientific opinion will be with us always. Unquestionably, the expansion of science beyond the narrow aristocracy that once sustained it has been a huge net boon. But there has been a price to pay for that expansion, one aspect of which is the incentive distortion in assessing others’ work, leading to bigger problems with getting the crackpot/visionary boundary demarcated correctly.

Particle Theorist in Argentine Jail

March 21, 2012
Categories: Uncategorized

Particle theorist Paul Frampton of the University of North Carolina was arrested in Buenos Aires January 23rd on charges of attempting to smuggle two kilos of cocaine out of the country. He denies the charges, but is in jail in Argentina, and UNC has suspended his pay since he could not return to teach his spring semester class. More about this here.

I don't know Frampton personally, but he has commented on the blog here in the past, and is well-known in the particle theory community. He is the author of a standard textbook in the subject Gauge Field Theories.

Update: From reports with more information, like this one, it seems clear that Frampton was the victim of a scam. Hopefully friends and colleagues will be able to help him regain his freedom.

Comments

1. **Bernhard**
   March 21, 2012

   This is a complete absurd, it is more than obvious that this was someone framing Frampton. What is extremely concerning is the attitude of the North Carolina University which is doing absolutely nothing to help him, as one can read here:

   http://www.foxnews.com/world/2012/03/20/decorated-north-carolina-physics-professor-in-argentine-jail-on-drug-charges/

2. **UNCgrad**
   March 21, 2012

   While I am sure that Dr. Frampton did not know about the cocaine in his luggage, I am annoyed that people like Bernhard are getting the wrong idea about this story. Since the faculty is under orders to respond with "no comment" and no graduate students have been interviewed that are not dependent on Frampton for funding/advising, the articles about this case have pretty much presented Frampton's viewpoint unchallenged. The truth is that the University HAS helped Frampton as much as could be reasonably expected. I know for a fact that it was arranged to have money sent down to Frampton, and that an associate dean of the university spoke with a judge in Buenos Aires to try to get Frampton out.

   [*rest of comment deleted. Please, anonymous personal attacks not welcome here*]

3. **Another UNCgrad**
   March 21, 2012

   I don't think I am qualified to comment on the quality of Dr. Frampton's professional work, but on a personal level he was not well liked by many graduate students (and some, if not most, faculty) in the department. There were several who were quite pleased with the prospect that Dr. Frampton might not be returning to teach in the fall (or ever). If there are more comments from grad students at UNC it will be hard to find some that do not include "anonymous personal attacks".

   This is a difficult situation since it places his two graduate students in a tough spot. It also has the possibility to make the department look bad, even if they really did do all they can do. From the news articles it seems that the decision to stop Dr. Frampton's pay was taken on the university level, and not at the departmental level. I think for many of the faculty they really don't know how to respond to this one way or the other. Consider this, how would your department and university respond if this happened to a noted professor in the department?

4. **Trulo**
   March 21, 2012

   From the link:

   > "I have never been in prison before, so I have no way of making an accurate comparison," he said.

   This statement seems to be inaccurate, according to this link

5. **Trulo**
   March 21, 2012

   From the link:

   > "I have never been in prison before, so I have no way of making an accurate comparison," he said.

   That statement seems to be inaccurate, according to this other link here

6. **Trulo**
   March 21, 2012

   In any case, and regardless any mistakes he may or may not have made, I hope he'll be released as soon as possible. If he was arrested on Jan. 23, as the article says, he's been in Hell for two months already. That's terribly bad. I wish him good luck.

7. **Interested Observer**
   March 21, 2012

   It has been obvious for quite some time that Frampton has been losing his grip on reality. For example, he devotes quite some time in his paper arXiv:1004.1910 to argue why he has accomplished more than Isaac Newton. The argument appears to be serious and does not seem to have been made in jest.

   It appears likely that someone tricked him into carrying something in his luggage and his warning bells probably did not go off owing to his diminishing grip on reality.

8. **Yet another UNC Grad**
   March 21, 2012

Firstly, I would like to address the “discontinuation of pay” concerns, which should be called “unpaid leave”. UNC is a public institution, funded by taxpayer dollars. If the governor, the legislature, the people learn that UNC is paying $100K/year to someone is in an Argentinian jail awaiting trial for drug trafficking, is it unreasonable to believe that Chancellor Thorp will be dragged through every oversight committee in the UNC system? Is it unreasonable to believe that the legislature might cite such incident in its decision to further decrease UNC’s funding? Is it unreasonable to think that Chancellor Thorp will be forced to resign if Dr. Frampton is found guilty? How can UNC justify keeping on staff and paying someone who is accused of smuggling cocaine, is abroad for an undetermined amount of time, and cannot explain the purpose of his trip? If he was on an official UNC business or a conference, that would be another matter. The University chose to act this way to minimize the damage to its reputation and funding. I believe it is a correct thing to do.

Secondly, addressing “UNC does nothing to help him” assertions. Again, UNC is a public institution. To accuse it of not helping him is the same as to accuse The State Department of not helping him. UNC must maintain neutrality in much the same way The State Department must.

I agree with the first UNCgrad: I see not a single interview with the staff, graduate students, former faculty, etc. The only comments are form Dr. Frampton, his former wife, friends, and a graduate student whose career currently depends on Dr. Frampton. Many former and current graduate students are willing to speak on condition of anonymity, and a few will put their name on their words.

9. **Yet another UNC Grad**
   March 21, 2012

   It would be nice if the media obtained the police report.

10. **abbyyorker**
    March 21, 2012

    He’s been in the field for many years. Cant some of his friends/colleagues fly down there to help?

11. **Steve**
    March 21, 2012

    Innocent until proven guilty of course but why would drug smugglers stuff cocaine into a random tourist’s luggage if they could not collect it States side? And what was he doing down there anyway on a private trip? It’s not looking good for him esp. with his money cut off, and their courts and criminal justice system don’t have the rigor and efficiency of their US equivalent. Section 3 of Arxiv/1004.1910 where he talks about his brilliance as a student, and claims to be smarter than Newton, actually does look like it was written by someone “coked up” or someone who is losing it. If he is innocent then I do hope it all gets sorted out. Unfortunately, sh–t sticks, even If one is exonerated and proved innocent. Someone that smart is simply not expected to get themselves into a horrendous mess like that. Whenever you lose your integrity and reputation in high professional circles you are finished.

12. **Interested Observer**
    March 21, 2012

    From what I understand (through a somewhat informed source), Frampton was in Argentina to meet a “model”. And apparently she asked him to take one of her bags back with him to the US. One can speculate why a “model” might want to meet with a 68 year old physicist earning only about a $100k a year, but she may have been impressed by his physics accomplishments that have surely dwarfed Newton.

13. **A.J.**
    March 21, 2012

    Steve,

    Trashing someone’s reputation is a public forum — when that person is in jail in a foreign country and likely unable to respond — and then saying that they should be expected to protect themselves or they might lose their reputation…. Does this not induce cognitive dissonance?

14. **Yatima**
    March 21, 2012

    More seriously, why should anyone object about someone else carrying cocaine or not?

    Oh wait, we are in the era of the “War on Drugs” psychosis created by a state employees looking for politically easy enemies to justify their paychecks.

    Ok, carry on, then.

15. **Steve**
    March 21, 2012

    A. J. You misinterpret me. I much respect the prof and his achievements. It is not a personal attack and whether someone takes/uses/smuggles cocaine is not something I judge. It is their decision but there very are serious consequences to that esp. abroad. I’m not even saying he did that. But I’m looking at it purely from the point of view of how the law, the legal/justice process, and the media will see it. Law, like science, goes on the weight of evidence and it does not look good unless some good defense lawyer(s) has some good evidence to clear him. UNC are cutting themselves off from him, or so it seems so how does he pay for that? He is in a very serious legal situation. And I’m afraid sh-t does stick as far as reputation goes. Any enemies he does have–certainly not me, I don’t know him–will use it. It’s not right but that’s how it goes.

16. **Steve**
    March 21, 2012

    Let me say I think this is a horrible situation I would not wish on anyone, and I really hope it gets sorted out for him and he can return home.

17. **anton nymos**
    March 22, 2012

    >> he talks about his brilliance as a student, and claims to be smarter than Newton,
    >> actually does look like it was written by someone “coked up” or someone who is
    >> losing it

    this sounds just like e.g. Lubos Motl and some others, it seems to be a string theorist thing so I would not hold it against Prof. Frampton.

18. **Anonyrat**

March 22, 2012

Let's quote fom 1004.1910 since others have mentioned it:

It would be a wonderful to have lunch, may be at L'Atelier de Jo¨el Robuchon in Roppongi Hills, with Murray Gell-Mann, Isaac Newton, and Grigori Perelman to compare notes on personal fulfillment. What does Grigori Perelman mean, when he tells journalist, in turning down a million dollars, I have all I want. I'm not interested in money or fame? This seems to baffle some americans, whose idea of happiness, as an inalienable right, is a three-comma net worth. Yet, a two-comma net worth suffices, for all practical purposes.

Fame can hardly exceed that of the singer and entertainer, Elvis Presley (1935-1977), whose name, from my non-scientific studies in public transportation, is still recognizable by one billion people. He died, when he was only fourty-two, so his fame was not very useful.

—– speaks to lack of motive.

19. **Peter Woit**
    March 22, 2012

    anton nymos,

    The conviction that one is smarter than everyone else isn't exactly unusual in academia, not just among string theorists. It's also the kind of delusion that can make a good target for a scam, which is what may have happened here.

20. **Anonyrat**
    March 22, 2012

    UK Telegraph
    http://www.telegraph.co.uk/news/uknews/law-and-order/9160448/Distinguished-British-scientist-faces-16-years-in-Argentine-jail-after-being-caught-with-suicase-of-cocaine.html

    Quote:

    But respected Argentine newspaper Clarin reported he has told investigators he was set up after flying to the country to meet a woman he been romancing over the Internet.

    He is said to have made a statement to investigating judge Juan Galvan Grenway after initially refusing to answer questions.

    He claimed in his statement, leaked to the Argentine press: "The reason for my trip to south America was to meet a female friend, who is a well-known model, but I wasn't able to meet her.

    "I believe my friend's representative, who was the one who gave me the flight tickets, is probably the person responsible for the drugs found in the suitcase."

    Mr Frampton, who arrived in Argentina on January 21 from Bolivia, says he agreed to check the suitcase in on his return flight to the States on the understanding it belonged to his friend.

    Investigators who confirmed his prison remand order last week justified their decision saying: "It is improbable and it wouldn't be likely that a 68-year-old man with a solid university education, has come to the country to meet up with a female friend, and despite not having had contact with her, has agreed to carry a suitcase apparently belonging to her with him."

    University friends of Mr Frampton are now fighting to get him freed from prison while the investigation into his alleged wrongdoing continues.

    Former colleague David Stallard said: "I knew Paul professionally and socially for 17 years.

    "He never showed any interest in drugs and it is inconceivable to me that he intentionally smuggled cocaine. He must have been duped.

    "I fervently hope that he will be exonerated and then reinstated in his university."

    Retired lawyer John Bird, a former neighbour of Mr Frampton, said: "There's no-one in the world more improbable who would smuggle cocaine.

    "He got set up. I would bet my life on it. It would be contrary to everything in his background."

    End quote.

21. **Bernhard**
    March 22, 2012

    "It is improbable and it wouldn't be likely that a 68-year-old man with a solid university education, has come to the country to meet up with a female friend, and despite not having had contact with her, has agreed to carry a suitcase apparently belonging to her with him."

    And how probable it is that "a 68-year-old man with a solid university education, has come to the country" to smug cocaine? Really.

22. **Bernhard**
    March 22, 2012

    smuggle

23. **Anonyrat**
    March 22, 2012

    This page in Spanish from clarin.com is relevant.
    http://movil.clarin.com/policiales/narcotrafico/reconocido-fisico-ingles-cocaina-Ezeiza_0_668333271.html

    The google translation of an excerpt:

    "For starters, Frampton is a recognized and respected theoretical physicist, professor at the American University of North Carolina, who even signed several papers with Nobel laureate Sheldon Glashow (see worked …). But also, as he explained in his defense, the suitcase with the cocaine would come into his possession as a last step in a long series of deceptions of those who says he was victim: a woman who posed as a model contacted him via the Internet with the months came to him love, and he was following his trail to meet her in person to get to South America.

So far, his alibi for Justice is unlikely. So Frampton-prisoner for two months in the prison of Devoto-and has a preventive imprisonment pending trial (more than 1,350,000 pesos in foreclosure), confirmed by the Hall B of the House Economic Criminal.

The funny thing is that your story is strikingly similar to that made at the time Sharon Mae Armstrong (54), a former official of the Government of New Zealand Maori-language expert, who was arrested at Ezeiza the April 13, 2011 with 5 kilos of cocaine in his suitcase when he went to take a flight to Spain.

In the case of Armstrong, but ended up being convicted, the Court took it for granted that he had been deceived by a man who fell in love via the Internet, offered her marriage and, with an excuse, made travel to Argentina with the promise that after would meet in London to meet in person. Because judges believed in her story, Sharon was imposed almost the minimum penalty for the crime of drug smuggling (see The Case of New Zealand). "

—
Looking up Sharon Mae Armstrong, whose story is similar to Frampton's
http://www.stuff.co.nz/dominion-post/news/6589959/Family-eases-strain-for-jailed-Kiwi

She's been in jail since April 13, 2011. Her not guilty plea was entertained Nov 10, 2011.
http://www.3news.co.nz/Alleged-drug-mule-Sharon-Armstrong-pleads-not-guilty/tabid/423/articleID/232343/Default.aspx

Quote: "Mr Piripi said advisers warned her to plead guilty, as "with her circumstances and mitigating factors she might get three years".

"But she just could not plead guilty, she couldn't, which means she's looking at two to three years waiting for a trial and absolutely no leniency if convicted," he said."

—– If Professor Frampton's case follows the same course, things don't look good.

24. **Anonyrat**
March 22, 2012

This last – I hope I am not abusing our host's hospitality –
http://www.argentinaindependent.com/currentaffairs/newsfromargentina/caught-with-cocaine-drug-trafficking-in-argentina/

on Sharon Mae Armstrong –

Quote:

"The courts will assess her innocence said Claudio Izaguirre, president of the Argentine Anti-Drugs Association, a non-governmental group in Buenos Aires.

"It depends on the judge's mood, the attorney's mood, her personal background, her previous lifestyle. Quite a few things will have to be evaluated," he said. "But the reality is she was trying to leave the country with five kilos of cocaine.""

25. **Trulo**
March 22, 2012

> And how probable it is that "a 68-year-old man with a solid university education, has come to the country" to smug cocaine? Really.

It could be very plausible, if the man in question is a cocaine user, and it is cheaper and of higher purity in that country than in the US. As an example of a mature man with a solid university education who was known to be a consuetudinary cocaine user you can take Sigmund Freud.

To be sure, I have no idea whether Prof. Frampton was duped as he says or not. But his story seems to be so weak from a legal point of view. If that's all he has to say in his defense, he will probably be found guilty and given a term in prison, hopefully the minimum. Which, by the time he is sentenced, he will have probably already served.

A very sad story, indeed.

26. **Anonyrat**
March 22, 2012

viXra log weighs in: http://blog.vixra.org/2012/03/21/paul-frampton-drug-case-could-take-years-to-resolve/

"Everyone passing through international airports will know that they must pack their own bags and be responsible for the contents. Travellers are continually warned and asked about it. It is easy to be befriended especially in honeypot traps. The details of how Frampton may have been tricked are not yet known but similar stories are well-known. Cases have even been turned into films such as Bangkok Hilton. It will be hard for an intelligent professor to persuade his prosecutors that he was naive enough to innocently accept to use a suitcase with cocaine stuffed into the padding. We wish him luck."

27. **Bernhard**
March 22, 2012

Trulo,

it is however even more plausible that he got himself involved in a scam, which the authorities are contesting the plausibility of. If the story Frampton is telling sounds unconvincing, the alternative that he is lying and was indeed smuggling drugs seems to be worse, at least to me.

28. **Trulo**
March 22, 2012

Bernhard, Prof. Frampton was caught in the act of committing a crime. As far as I understand the legal system, which is not much, the fact that he was unaware of what he was doing may constitute a mitigating circumstance, if the judge believes him, but it cannot exonerate him. Mitigating circumstances can help reduce the term he is sentenced to serve. But trying to go across an international border with a significant amount of an illegal drug is legally a serious crime, regardless of what you and I think about it, and I'm afraid even the minimum could be a few years. Let's hope I'm wrong.

29. **Bernhard**
March 22, 2012

I unfortunately agree with you about this.

30. **Peter Woit**
March 22, 2012

Trulo,

I'm no more of a lawyer than you are, but I'd guess that not suspecting at all about the cocaine would be not just a mitigating factor, but would make one innocent of the crime. Unfortunately for Frampton, he may have trouble convincing the authorities of this, and they may want to make an example of people caught up in drug smuggling, even if they are the victim of a scam.

31. **Trulo**
March 22, 2012

Peter,
you may be right, but I doubt it. If that were true, then carrying bags and boxes full of stolen paintings, fake dollar bills, and even military-grade plutonium through international borders would be a trivial matter: It would just require a temporary suspension of disbelief. As long as you don't suspect anything you'd be innocent.

32. **Bugsy**
March 23, 2012

From what everyone says, he's probably the victim of a scam. But if they were clever,
it might be very hard for him to identify them; and if he could- well, I suppose his life might be in danger.

It reminds me of the famous Nigerian email scams-
http://en.wikipedia.org/wiki/Advance-fee_fraud
which nearly sucked in a friend of mine- a very smart guy who fits the profile (the overconfidence of arrogance). Finally he swallowed hard and called the FBI and told them all; it must have been embarrassing to admit how stupid he had been, and also frightening thinking he might be in trouble for the various small, embarrassing or illegal things they had got him to do along the way. In fact
they just gave him sound advice (under NO circumstances meet with them; lives have been lost, these people can be very dangerous) and didn't blame him at all.

BUT…what was he doing in Bolivia before that, which is more or less cocaine central?

33. **paleface**
March 23, 2012

Imagine that a Colombian physicist tried to enter the US through La Guardia Airport with a suitcased loaded with four pounds of cleverly concealed cocaine. And imagine that, once caught, he would declare that he was the innocent victim of a scammer taking advantage of the fact that he was madly in love with Britney Spears. I wonder if anyone would believe him. And I wonder how the US judiciary system would react to that. Would they try to use him to set an example? Or would they just apply the law?

34. **Bernhard**
March 23, 2012

paleface,

if this Colombian physicist were a 68 year old world renowned theorist with a extreme solid career in Academia and no record of involvement with illicit drugs and complete lack of motive to out of the blue start smuggling cocaine, I believe they could believe him. Needles to say he would still be in a lot of trouble as Frampton unfortunately also is.

35. **Bernhard**
March 23, 2012

What surprises me is that, so far, I believe the HEP community is not yet very much engaged in helping him. There was a dedicated conference in his honor in 2003 (his 60th´s birthday) where Nobel prize´s like G Hooft attended. I hope that it is only that I am not yet aware of the efforts as I cannot believe the majority of these people can think Frampton is really guilty. See for example:

http://server.physics.miami.edu/~cgc/2003CGC.html

And what is even more curious is that the banquet photos are suddenly unavailable…

36. **Interested Observer**
March 23, 2012

The difficulty with the law is that once they do something stupid, such as sentence the unfortunate Sharon Armstrong to prison even after accepting her version of events, they have to continue doing that same stupid thing. Otherwise they risk appearing stupid by reversing course on their previous stupid action. This is unfortunate fact about the law, where precedence has more traction than reason, is endemic to many legal systems. While not a lawyer myself, I suspect that if Frampton's lawyers pursued the theory that he was tricked by this model's agent, he would find himself in prison for sometime (with perhaps some allowance made for his ill health).

In my opinion, they ought to pursue the claim that Frampton is mentally incompetent . This will at least give the Argentinian Judiciary a legal excuse to allow them to set him free without establishing a legal precedence that they will be uncomfortable with. And in fact, considering many of Frampton's recent actions, his mental incompetence can be plausibly argued.

37. **Steve**
March 23, 2012

Peter, I appreciate this is a touchy subject, that deletions are justified, and I won't attempt to post any more opinions . However, the following news story this week about an extradition block of a UK citizen to Argentina on drug charges, on the grounds that her human rights would be violated, is very relevant. He therefore may be refused bail. Also, the political situation between the UK and Argentina is unfortunately bad and he is firstly a UK citizen. I am hoping he gets a fair and unbiased hearing/trial and humane/respectful treatment even if sentenced, and the rest of the community should at least insist on that too.

http://www.guardian.co.uk/law/2012/mar/20/pregnant-briton-lucy-wright-wins-extradition-appeal?newsfeed=true

38. **Mike Vaughn**

March 23, 2012

Bernhard :"What surprises me is that, so far, I believe the HEP community is not yet very much engaged in helping him." Since the story has become public only since March 21, as nearly as I can tell, I wonder what Bernhard thinks the HEP community is supposed to do? We cannot organize a SEAL team to go to Argentina and free him. According to published reports, he has legal counsel and seems to be confident that he will emerge in due course . He may not be fully aware of the deliberate pace of Argentine justice (not that American justice is exactly speedy). I certainly hope the matter can be cleared up soon, but the issue is not political and we should not try to make it so.

I send him my best wishes.

39. **paleface**
March 24, 2012

The very similar case of Sharon Armstrong reported at the end of that Telegraph article looks like a very bad precedent. Left to his own means, Prof. Frampton would probably end up in the same situation as Armstrong. Let's hope the most influential academics in the US are trying to get their government to support Prof. Frampton at high diplomatic levels.

40. **BJM**
March 24, 2012

The Professor was carrying a bag given to him by a stranger. A definite no-no and specifically screened for by questioning in airports. The results could have been much worse than just a drug bust of one person.

41. **Trulo**
March 24, 2012

From the Telegraph article linked to in the update, referring to Sharon Armstrong,

> Judges convicted her despite accepting her claim she had been duped by a man she met over the Internet.

This is exactly what I meant in my posts above. If you try to board a plane carrying illegal stuff and you get caught, you're roast. If you are technically innocent because you didn't know about the stuff, then you're tender roast, but roast nonetheless.

Having ten million academic citations will help you about as much as having a cat named "Fuzz". Now, having friends very high up in government will make things extremely smooth. If Hillary took an interest in the case, Prof. Frampton would be out for lunch with the judge in no time, eating the best barbecue money can buy in Buenos Aires, all expenses paid by the court.

42. **AnotherUNCer**
March 24, 2012

[From a UNC student, first part removed. I've had all too many experiences with character assassination by anonymous comment to not be sensitive to why it's a really bad idea to allow it on blogs. Please keep this is mind.]

My friends and I figured that he was taken in by a sex-related scam well before Prof. Frampton's defense became public. We came to that conclusion based on several factors. Number one, regardless of whether or not one considers Paul Frampton to be a good physicist, it is hard to deny that he happens to be a singularly clueless individual when it comes to street smarts and common sense. The idea that he could somehow get involved in cocaine smuggling seemed ludicrous for the simple reason that he appears to lack the wherewithal. Secondly, Prof. Frampton's relationship to the opposite sex is well known within the department, and the idea that he could be taken advantage of in this way is, sadly, almost overwhelmingly reasonable.

All in all, I would say that while none of us wish this upon Prof. Frampton, few of us are surprised that it happened.

43. **Chris Oakley**
March 25, 2012

From Prof. Frampton's web site:

> The three most important exams were one in 1954 and two in 1961.
> In 1954 I sat for the 11+ exam and achieved the highest mark out
> of 250,000.
> In Spring 1961, I sat for GCE A-level exams and received the
> highest A-level marks ever at King Charles I School.

He is going to bring the British educational system into disrepute.

44. **Anonyrat**
March 25, 2012

A. Is Professor Frampton an American citizen?
B. If yes, will there not be approachable high level members in the US government who can be approached for help?
C. Can some big name physicist or other academic start the ball rolling?

45. **Bernhard**
March 25, 2012

Mike,

"I wonder what Bernhard thinks the HEP community is supposed to do?"

I agree with you that the news came not so long ago but public opinion in his favor specially from powerful friends could have an effect in his favor. So far, I have seen only mild explicit declarations to support him which indicates either they don´t want to get involved with it or believe he might be actually guilty. It is also possible they just did not have time to act, but time is passing…

46. **Visitor**
March 25, 2012

“Now, having friends very high up in government will make things extremely smooth. “If Hillary took an interest in the case, Prof. Frampton would be out for lunch with the judge in no time, eating the best barbecue money can buy in Buenos Aires, all expenses paid by the court.”

Not necessarily. While I might not know the specifics, it is possible to imagine a situation in which Argentine public opinion reacts negatively to American political interference in a judicial process involving an American who, wittingly or unwittingly, _was_ carrying two kilograms of narcotics. And an upshot of this might be, not that Frampton would be liberated, but that he would received a harsher sentence than he might otherwise have received.

47. **Martin**
March 25, 2012

There is an article in an argentinian newspaper. The comments that people are making about the professor are quite bad. I even read someone saying “He should go to jail because he is british”. The Falkland/Malvinas thing will only make things worse.

I’m sure he didn’t mean to do this and I hope he is released as soon as possible.

Here is the link of the article if any of you wants to check it out:

http://www.clarin.com/policiales/narcotrafico/reconocido-fisico-ingles-cocaina-Ezeiza_0_668333271.html

48. **Bernhard**
March 26, 2012

It´s good to see that he is anyway still very positive:

“Frampton said he will likely leave prison in a week thanks to evidence in his favor, though he will still be detained in Argentina.”

http://www.dailytarheel.com/index.php/article/2012/03/drugs_prof

Hope he is right…

49. **Mike Vaughn**
March 26, 2012

Bernhard,

This not a political case where public posturing might be helpful. It is a case that appears highly likely to be a setup, and quiet work through the Argentine legal system seems to be the best course to follow. Some of the stories suggest that such work is going on and we can only hope that it will be effective.

50. **Bernhard**
March 27, 2012

Mike,

I still have my doubts about this, but perhaps you are right and I really hope you are. To a certain degree my reaction is also driven by the frustration I feel when I hear the comments from the Argentinian investigators (“It is improbable and it wouldn’t be likely that a 68-year-old man with a solid university education, has come to the country to meet up with a female friend, and despite not having had contact with her, has agreed to carry a suitcase apparently belonging to her with him.”). It is clear to from this statement they do not yet understand how actually probable this is. Understanding Frampton´s character and position, I would think, could help them with this. But again, I might be wrong and political interference might have a negative impact on the whole case and I certainly don’t want that. So, in the end I agree with you we should wait for the moment and let the case follow its course.

51. **Rocketgal**
March 27, 2012

This may seem like an obvious question to some…

*HAS ANYONE CHECKED HIS PERSONAL COMPUTER FOR EVIDENCE???

Seems like an easy enough thing to do. If the Professor IS TELLING THE TRUTH (and I tend to believe he is), then I would think his family or friends would fly down to Argentina to give it to his personal lawyer immediately to get him out of there!

Just sayin!

52. **MathPhys**
March 27, 2012

A man exercised a serious error of judgement (as many of us do on a regular basis) and will regret that for the rest of his life. Let’s leave it at that.

53. **mesolimbic reward pathway**
March 28, 2012

Completely off-topic, but a search for “cocaine” in arxiv revealed this… interesting “paper”: http://arxiv.org/abs/astro-ph/0204013

54. **Jack B**
March 29, 2012

This is nuts. Good luck to him.

55. **King Ray**
March 29, 2012

As Heraclitus of Ephesus said, “Character determines destiny.”

56. **Bernhard**
April 3, 2012

I believe these are good news:

http://www.stuff.co.nz/world/americas/6635954/Drug-courier-may-be-freed-next-year

The bad news is that he is likely wrong he will be freed by the summer…

57. **Trulo**
April 5, 2012

Interestingly, there's a third case of a foreigner duped with the same trick, presumably by the same criminal gang in Argentina. Besides Sharon Armstrong and Paul Frampton, the nurse Catherine Blackhawk (that's a cinematic name, isn't it?), a US citizen, was caught on June 29 2011 in Buenos Aires airport (Ezeiza) trying to board a plane to London with eight pounds of cocaine. The story is more or less the same as in the other two cases. She met a supposedly English guy on the Internet, whom she was supposedly going to marry, and who asked her to meet him in London. But before that she was to make a stop in Argentina to pick up documents related to an inheritance he had received. Those documents were in a suitcase she was to take to London… the rest of the story is obvious.

58. **Trulo**
April 5, 2012

Both women, the New Zealander Armstrong and the Texan Blackhawk, traveled to Buenos Aires at the request of their supposed twin souls with all expenses paid. Both were lodged in the same hotel in the Once neighborhood of Buenos Aires, and both were contacted by a woman named Esperanza, apparently the same woman in both cases. The judge(s?) in those cases have already begun an investigation based on those leads.

Blackhawk (I still think there might be a mistake in the name quoted by the Clarin newspaper) is still awaiting trial. Armstrong has been sentenced to four years and ten months, but apparently there's the possibility that after serving one year she'll be expelled from the country.

2012 Abel Prize

March 21, 2012
Categories: Uncategorized

The 2012 Abel Prize was awarded this morning to Endre Szemerédi. I know nothing about him or his work, but there's a webcast going on right now with Tim Gowers providing explanation.

Update: The written version of the Gowers talk is here.

Comments

1. **Sakura-chan**
   March 21, 2012

   A very deserving recipient!

2. **paddy**
   March 21, 2012

   All I can say is that the Gowers discussion of Szemerédi works (which you provided link to) was fascinating. TY

   Should have gone here instead!

F-theory Phenomenology

March 23, 2012
Categories: Uncategorized

In the years before the LHC start-up, one heavily promoted claim that "yes, string theory can too make predictions, and here's what it predicts the LHC will see" was based on a class of models known as "F-theory". Detailed superpartner mass spectra were produced and shown around the world at conferences and departmental colloquia. For an example, take a look at figures 3 and 29 of this paper.

Early LHC results showed that nothing like these mass spectra corresponds to reality. For the latest such results, see Resonaances, which describes new SUSY limits from ATLAS, now wildly out of agreement with the F-theory "predictions".

At this week's F-theory Workshop, there seems to have been little acknowledgement of this failure. I didn't notice either any reference to the fate of the "predictions", or even an attempt to come up with new, updated ones. The closest I could find was this comment by Michael Dine in a discussion of the state of F-theory phenomenology":

> A lot of us I think are resigned to the idea that maybe there's supersymmetry and it's going to look tuned, or maybe there's not low energy supersymmetry. I think a challenge I've always said for string theory is to try and think about theories without supersymmetry and that has proven to be hard. But you know, that's certainly a direction which maybe we're being confronted with.

So, the long-standing ideology that supersymmetry stabilizes the weak scale, and seeing its effects will finally give evidence for string theory unification looks like it is crumbling. With this hope gone, string theory unification becomes a completely unpredictive subject, with no hope of connection to experiment. One has an infinite array of mathematically highly complex models one can spend time studying, but it's hard to characterize doing so as any recognizable form of physical science.

This situation hasn't slowed down string phenomenologists, who will follow up the F-theory workshop with a summer school for graduate students to train them in the failed techniques of the subject. I have a hard time understanding why any sensible graduate student would want to attend such a thing, or why any responsible advisor would encourage them to do so.

Comments

1. **Marcus**
   March 23, 2012

   In case anyone's curious that quote from Michael Dine begins shortly after minute 52:30 of this video discussion:
   http://media.scgp.stonybrook.edu/video/video.php?f=20120322_1_qtp.mp4
   If you drag the button to minute 53 you miss the start of it.

   This was the Thursday 22 March 10:15-11:15 am session with Dine, Moore, Seiberg,
   titled "A Critical Look at Phenomenological Issues in F-theory"
   that you can find the link to in the overall program here:
   http://scgp.stonybrook.edu/archives/1493

2. **Shantanu**
   March 23, 2012

   sigh, such a sad situation. how do these guys get funding! Someone should really attend
   some of these talks and ask these hard questions.
   OTOH I know a colleague who has been looking for jobs for last seven years without luck and only because the work he does is not trendy.

3. **abbyyorker**
   March 23, 2012

   Great post IMHO. I am surprised at the level of dismay – after all, susy proponents could just claim we need higher energy (but maybe it is absolutely essential to see things at LHC scale? I don't know – I'm kind of ignorant). I have to be honest: I really like SUSY except for the experimental non-validation.
   But, to be frank, you have been puzzled for 20 years as to behaviour of responsible advisors. I mean that in a neutral, not negative way.

4. **Giotis**
   March 23, 2012

   "One has an infinite array of mathematically highly complex models one can spend time studying, but it's hard to characterize doing so as any recognizable form of physical science."

   "We seem to be at a critical point in the history of science, in which we must alter our conception of goals and of what makes a physical theory acceptable."

   Stephen Hawking, THE GRAND DESIGN.

   You may reach a point where your physical theories cannot be verified directly via experiment due to their very nature and the nature of their general predictions. What do you do then? You abandon the theory? Of course not, the theory could be right. Then you need new criteria to decide when a theory is acceptable as scientific. These criteria are set by the people who are doing the actual scientific work i.e. the physics community. You can't live in the 19th or 20th century forever following blindly a strict dogma of what science is and what isn't. This just stalls progress.

5. **emile**
   March 23, 2012

   Giotis,

   Science without experimental verification isn't science. Period. It may very well be that some theories can't be tested with current (or future) technology, but then don't call those scientific theories. Call it math, call it natural philosophy, or whatever. But don't call it science.

6. **Chris W.**
   March 23, 2012

Giotis: *You can't live in the 19th or 20th century forever following blindly a strict dogma of what science is and what isn't. This just stalls progress.*

Progress? Progress in what, exactly?

Of course not, the theory could be right.

Could be right? In what sense? Have you utterly forgotten that the whole point of testability is to have a way to determine from empirical evidence that a theory is *wrong*, and that **no amount** of confirmation, if it could be had, cold ever definitively establish that a theory is "right"? If "right" means anything, it means "has been subjected to many empirical tests, and has passed them". That's all you can hope for, and string theory hasn't even found its way to the examination room. However, it sounds like F-theory has, and it flunked. I guess that would be something, if the grade wasn't being disputed or ignored. 🙂

7. **Peter Woit**
   March 24, 2012

   abbyyorker,

   You can just claim that SUSY breaking is at a higher mass scale, but then you give up the main argument used for why you want SUSY. It starts to become just one more unmotivated, complicated extension of the SM which doesn't explain anything. Why spend any time on such things?

   Giotis,

   You're joking, right?

8. **Peter Shor**
   March 24, 2012

   There is an important theoretical question to be answered, which is: how is it possible to reconcile quantum field theory and general relativity? Some string theorists claim that string theory answers this, but judging from the number of people working on how information gets out of black holes, for the most part, they seem to have either given up on the question or declared victory and moved on.

9. **Peter Shor**
   March 24, 2012

   And maybe, before we start working on the question of how to mathematically reconcile quantum field theory with general relativity, we should really try to answer the question of how to mathematically reconcile quantum field theory with itself.

10. **A.**
    March 24, 2012

    Re: Giotis' comment, a senior mathematician/string theorist once said almost exactly the same thing to me, following it up with "The definition of `science' was invented to satisfy Marxism. It has nothing to do with modern physics."

    I responded with "or you could say that modern physics has nothing to do with science" and _that_ was met with genuine shock. And a protracted silence.

11. **Giotis**
    March 24, 2012

    I just want to make a clear distinction between constructive criticism which is a healthy endeavour and a Taliban-like preaching in the name of some scientific orthodoxy which demands the theoretical research to stop if it doesn't follow some strict definitions and dogmas. These rules were made by the physics community and could be bent or re-adjusted by the same community if necessary in order to face the new difficult challenges of Planck scale physics.

12. **P**
    March 24, 2012

    To play devil's advocate and also to ask a question . . .

    Pretty much everyone here is being critical of F-theory, which is respected and worked on by many of the brightest in the scientific community. It has made a resurgence since 2008, at which point many good people who hadn't worked on it started working on it because of apparent promise. This all happened *after* Peter's book.

    Who of you critics can actually state cleanly what F-theory is, what the status of the field is, and why people believe it is promising compared to (say) the heterotic or type II superstring.

    I'm interested to hear your responses.

13. **Peter Woit**
    March 24, 2012

    P.,

    Personally I don't see any point in arguments over the relative merits of heterotic/type II/F-theory models since they've all now failed more or less equally miserably, and all show no hope of leading anywhere.

    I claim no expertise in F-theory, beyond that coming from sitting through several promotional talks (the topic is a favorite at math/physics conferences), and spending some time carefully looking at the supposed "LHC predictions" of the theory before writing about them here. At one of such talks, a prominent string theorist I know who was sitting next to me after the talk explained to me in detail how it showed that I was just wrong: string theory does make predictions about LHC physics, and the LHC results would change my mind. I was polite.

    The resurgence of F-theory since 2008 was based to a large degree on the strong and explicit claims being made for LHC predictions based on F-theory models. I'm still waiting to hear the people who made those claims acknowledge what has now happened.

14. **P**
    March 24, 2012

    Peter,

It’s a bit irresponsible of a prominent string theorist to claim that F-theory definitely makes LHC predictions, in my opinion. On the other hand, there are definite reasons to believe that it gives rise to more promising models for particle physics (GUTs in particular) than the weakly coupled type II string, so it’s simply wrong to say that they’ve all failed “equally miserably.” Regarding the failure of the authors to address what their papers said in light of experimental data, I can’t speak to why they haven’t. I did take a look at Heckman’s talk, though, and it’s interesting to notice that F-theory did give rise to the correct Theta_13 angle that was recently measured in the PMNS matrix.

I took a look at some of the other videos and recent abstracts of speakers, and I think it’s important to point out that most people in the field are currently working on very hard problems having to do with the global aspects of F-theory compactifications. Many of the properties of the “local” GUTs studied over the last few years have things to say about GUT physics, but of course GUT physics isn’t everything and there are other effects in the vacua which must be taken into account. This is probably why the workshop at Simons didn’t seem as phenomenological as similar programs in the past.

15. **Peter Woit**
March 24, 2012

P.

“It’s a bit irresponsible of a prominent string theorist to claim that F-theory definitely makes LHC predictions…. F-theory did give rise to the correct Theta_13 angle that was recently measured…”

Right. Glad to hear you’re opposed to irresponsible claims about F-theory.

As for why “the workshop at Simons didn’t seem as phenomenological as similar programs in the past”, I think it would be a reasonable conjecture that maybe the unmentioned LHC results that torpedoed and sank all the F-theory “predictions” of recent years might have something to do with this. Then again, it was a Math/Physics program, not a pure physics one.

16. **Shantanu**
March 24, 2012

P, can you point me to the F-theory paper which made the correct prediction about theta_13? I am curious. Also you said that F-theory predicts GUTs. So what does it predict for proton lifetime and which modes should one look for a signature?

17. **Anonyrat**
March 25, 2012

Offtopic, but the Krauss thread is closed. If you have access to the New York Times, philosopher David Albert takes on Krauss.
http://www.nytimes.com/2012/03/25/books/review/a-universe-from-nothing-by-lawrence-m-krauss.html

18. **P**
March 25, 2012

@Peter:

Right, I am opposed to those claims about F-theory that are, in fact, irresponsible. Given the current state of the field, I would put “definite LHC predictions” on that list.

The problem is that the overall situation is much more nuanced, particularly as the field is still developing (again, F-theory for particle physics only since 2008), and to make blanket statements is not appropriate and doesn’t do justice to the dozens of very bright people working on the subject.

As I’m familiar with some of the literature, it’s worth correcting your conjecture about the mathematical (not obviously phenomenological) nature of the Simons workshop.
Most of the phenomenological scenarios of 2008 and on were so-called “local” models that focus on the physics near a stack of GUT 7-branes, where (say) the SU(5) gauge theory lives. This approach has its merits, as much of the GUT physics is described locally (GUT matter, Yukawas, and so on), but there are important “global” issues of the physics and of the compactification which are missed by the local picture. This isn’t surprising: the local picture isn’t a full blown F-theory compactification, but instead is a subset of the mathematical data which controls the GUT physics.

The reason for the more mathematical and “global” Simons workshop seems to have been to report on progress in understanding these global issues, including the description of chirality inducing G-fluxes. It’s only by understanding these global issues that one might hope to address moduli stabilization and (ideally) vacuum selection. It’s not that people have abandoned hope in the role of F-theory for phenomenology. It’s that they’re studying hard mathematical aspects which give rise to a deeper understanding.

@Shantanu:

I’m not sure, it’s likely a paper by Heckman and Vafa, though, and has neutrino or PMNS somewhere in the abstract. If you can’t find it I’ll let me know and I’ll google around a bit.

19. **Mark**
March 25, 2012

@ Shantanu, see http://arxiv.org/abs/0904.1419 for \theta_{13} prediction

20. **Peter Woit**
March 25, 2012

Anonyrat,

Thanks. I read that over my coffee this morning and just wrote a short posting about it.

21. **chris**
March 26, 2012

P,

it is by no means irresponsible to produce concrete LHC predictions. on the contrary, that is the essence of the theory being predictive.

what is irresponsible is the failure to acknowledge that these predictions and, consequently, the underlying model is now falsified.

22. **P**
March 26, 2012

Chris,

Sorry, I wasn't clear enough. You missed the point.

The local F-theory models that produced LHC "predictions" are "local models", not globally defined F-theory compactifications. This approach has it's advantages, though, as many aspects of GUT physics can be understood, but global effects can change the physics and are completely missed by the F-theory models you're referring to. People are making progress in understanding the global aspects, and they matter.

I completely agree that making concrete LHC predictions from a very well understood theory is of crucial importance and is absolutely the responsible thing to do! The point is that F-theory is still getting there (yet again, concrete particle aspects only since 2008) . . . and the authors of the mentioned predictions tried to understand as much of the low energy physics as they could from the local picture. But we know the local picture isn't the whole story.

P

23. **Bugsy**
March 26, 2012

As a mathematician (not in math physics) I wonder how it feels to invest enormous amounts of time working on theoretical physics models which may end up being complete failures.

Math people have the advantage of using pure esthetics (and correctness) as the main criteria of interest- so anything you do which is interesting to you (if you have reasonably good taste) will not only be of interest (eventually!) to the community but will remain so in perpetuity.

Maybe math physics on the speculative fringe should give up on the supposed connections to the real world and ALL of the hype and just try to do good work instead?

Question is, whether it still makes sense to do it in a "physics way"- without precise definitions and proofs….standards are way way different. But if the hype were removed it would help clear the air of junk. Maybe that's part of what Peter is about: trying to ridicule the hype out of HEP.

24. **Peter Woit**
March 26, 2012

Bugsy,

That's about right (although I think I reserve ridicule for only the ridiculous cases…)

F-theory is a good example. Lots of algebraic geometers have gotten involved in it, because questions about algebraic geometry arise in the subject. The hype about bogus progress can encourage them to spend their time and effort on questions of little real mathematical interest, whereas this time and effort would be better spent pursuing issues of mathematical interest that come up. This is independent of the question of rigor and proof. That's another question, one where most mathematicians are aware of the dangers of getting too far away from what is precisely understood.

25. **P**
March 26, 2012

Peter,

Again, you're not being specific enough. What precisely do you mean about the "the hype about bogus progress"? If you mean specific, completely unique LHC predictions, then I agree.

But from the point of view of the relationship between gauge theories in F-theory and mathematics, the relationship is deep, which is why the algebraic geometers work on it. For example, the heterotic F-theory duality gives an equivalence of moduli spaces of vector bundles on Calabi-Yau manifolds and elliptic K3 fibrations (roughly). The study of such moduli spaces actually governs gauge theories, including both the gauge symmetry and matter content in four dimensions. If string theory has anything to say about the real world, these things are clearly of great importance.

Mathematicians aren't studying F-theory because of grandiose claims about local models. It is interesting to them because well-defined geometric moduli spaces correspond to concrete things in low energy gauge theories.

P

26. **Peter Woit**
March 26, 2012

P,

I don't disagree. I just think all mathematicians who get involved in this area need to realize that some of the talks they're exposed to on this subject need to be consumed with a massive grain of salt. Especially ones that claim F-theory "predictions" about observable physics.

27. **SA**
March 26, 2012

I really don't see the point in the especially caustic rhetoric denouncing the mainstream BSM theories. You really should start complaining if/after the LHC significantly disagrees with the SM in an important way and this can be explained by theories simpler than SUSY.

28. **Peter Woit**
March 26, 2012

SA,

If and when the LHC data significantly disagrees with the SM, I and everyone else will be too excited to complain about anything.

Right now though, I don't see what's wrong with pointing out which "mainstream BSM" models promoted as making LHC predictions have been shown to be wrong by experiment. When this happens, maybe they should stop being "mainstream" (if they ever were..), don't you think? Or, if the predictions were bogus, maybe the question of why that was so should be examined. I understand that people whose models have recently died may still be in one of the earlier stages of grief and not yet at acceptance and ready to move on, but they should be encouraged to do so.

29. **P**
March 27, 2012

Peter,

Agreed, and this is where it is the responsibility of physicists to be honest with them: string vacua do make low energy predictions (and even sometimes stringy ones depending on M_string), but the big "predictivity" problem involves not individual vacua but instead the landscape and vacuum selection. Hopefully there is some mechanism. Of course, this is an extremely difficult but important problem and is even a problem in quantum field theory – effectively the same as asking "why the standard model?" from an enormous class of possible quantum field theories.

The role of mathematicians in this process includes helping to understand string vacua and the low energy predictions of certain vacua or classes of vacua. To say that a certain vacuum or class of vacua look something like the world (e.g. F-theory vacua can at certain regions in their moduli space) is not the same as addressing the landscape problem.

Do you agree?

P

30. **Peter Woit**
March 27, 2012

P,

Sorry, but I think the problem is much worse than you describe it. I just don't believe that constructing ever more complicated "string vacua", designed to evade obvious conflict with experiment and using poorly controlled approximations to claim "predictions" about physics is a worthwhile activity. It's been going on for nearly 30 years, and the results are clear. I'm quite serious that I think training graduate students to do this is irresponsible. The hope that somehow a "vacuum selection principle" will be found that will change the situation is based on nothing but wishful thinking.

The people doing this had a shot at showing they could get somewhere. They just needed to say something, anything, about what the LHC would see. That's gone now, time to fold tent and give up.

31. **P**
March 27, 2012

Peter,

I think this is where we fundamentally disagree, and that's fine.

For the last 30 years, every 3-5 years (or even shorter) there is a very serious development in the understanding of string theory that improves the our understanding of string vacua and the associated low energy physics. So it's not just that people have been beating their heads against the wall for thirty years. There has been progress in understanding (I can cite papers and ideas, if you wish), and to me the irresponsible thing is to ignore this progress and completely stop the subject.

That being said, I agree that training hordes of graduate students in these techniques probably isn't the way to go. The real progress in the subject over the last 15 years has been made by a relatively small number of people (order 100-200 worldwide?) and if the problem is to be solved, I don't think it's just by adding bodies. There are other interesting things to study as well, particularly with the data coming from LHC.

Cheers,
P

32. **Peter Woit**
March 27, 2012

P,

My impression from following the field is that, yes, every 3-5 years there's a new idea, but that these new ideas all go in the wrong direction: they show you some new sort of "string vacuum" to look at. The whole field started out in 84-5 with some very tight constraints on what a string vacuum could be, and since then the possibilities just keep multiplying. This is not a good thing…

In any case, there's no danger that people will be forced to stop doing this, based on what I or anyone else thinks. It will likely be a major industry for quite a while, until an actual good idea about BSM physics and unification appears, at which point it will get dropped like a hot potato…

33. **SA**
March 27, 2012

Peter,

Insofar as the only problems with the LHC are theoretical in nature, it makes sense to develop theories that mitigate these issues and explore their consequences. The most obvious extensions of the SM have been considered already: fourth generation, technicolor, more trivial extensions of the gauge group, more dimensions, or SUSY.

In the case of SUSY, all of the predictions of course depend on the mass spectrum, and the current limits on superpartner masses simply do not disqualify even the simplest SUSY models from solving the theoretical concerns that motivated them.

34. **SA**
March 27, 2012

Er, sorry by LHC I meant SM.

35. **Peter Woit**
March 28, 2012

SA,

"the current limits on superpartner masses simply do not disqualify even the simplest SUSY models from solving the theoretical concerns that motivated them."

I just don't think that is true. The main motivation given for SUSY pre-LHC was that it would stabilize the weak scale. Assuming this, you can go back and listen to talks from people like Arkani-Hamed explaining that SUSY should already have been seen at the Tevatron, so it was a sure thing that it would be there in the early LHC data. Now that it's not, people are trying desperately to find ways around their earlier predictions. I don't think it's going to work. The argument that "well, we didn't really mean it when we said SUSY had to show up at the LHC if it was going to stabilize the electroweak scale", or "so what if SUSY doesn't stabilize the electroweak scale" is going to be tried by SUSY proponents, but I don't think it's going to fly.

36. **SA**
March 28, 2012

Peter,

This is not really a matter of opinion. We can be specific here. If the light CP-even Higgs has a mass of about 125 GeV, then even in the case of minimal supergravity, one can stabilize the electroweak scale while being totally consistent with other experiments. The task is even simpler if we allow the gaugino fields to have different masses at the high scale.

Indeed, we have no evidence to believe that SUSY is correct. However, the only accurate statement to make at this point is that if SUSY is correct, the scalars must be very heavy, in most models. It would of course be useless to keep studying SUSY if additionally we need the spinors to be very massive also. This is not the case yet, and certainly hasn't been so due to Tevatron data.

I am not sure exactly what statement you are referring to by Nima, but it's possible that he is referring to a very specific model or he is considering other qualities such as naturalness.

37. **SA**
March 28, 2012

I would like to add that the main issue that I see with the minimal forms of local SUSY is that there is a tension between the heavy scalars implied by both the apparent Higgs mass and indirect limits from B-physics, and the need for larger corrections to g_\mu.

38. **Peter Woit**
March 28, 2012

SA,

See for instance his talk at Strings 2005 (link and discussion here:

http://www.math.columbia.edu/~woit/wordpress/?p=3492

It seems to me that the definition of "minimal SUSY" you are using is a new one, which actually means "obscure corner of the large SUSY parameter space that is the hardest for the experiments to rule out, so they haven't got there yet".

39. **SA**
March 28, 2012

Peter,

No. Look at the mSUGRA model. Suppose that the Higgs is 125 GeV. Then, you are in the region to which you are referring. Coincidentally, the other constraints are satisfied.

40. **Peter Woit**
March 28, 2012

SA,

I see. But I guess according to Arkani-Hamed, these would just be models too fine-tuned for SUSY to explain what is stabilizing the electroweak scale, so the answer is that SUSY doesn't do that.

It's unclear to me then what SUSY actually does for you other than make your model much much more complicated than the SM. I suppose if the LHC sees no hint of SUSY, these models will still live, but there won't be much motivation for them.

41. **SA**
March 29, 2012

Yes, exactly!

Nothingness Smackdown

March 25, 2012
Categories: Uncategorized

Theoretical physics, as practiced in the mainstream media, seems to be moving from a mania about multiverses to a religious battle over nothingness. On one side we have physicist Lawrence Krauss, with his best-selling new entry into the atheism book sweepstakes: A Universe from Nothing. Krauss is backed by Richard Dawkins, who compares the book's devastating effect on religion to that of Darwin's.

On the other side we have philosopher David Albert, backed by a million dollars from the Templeton Foundation (see more here), who has a review out this morning in the New York Times characterizing Krauss as "pale, small, silly, nerdy" (his ideas, not him, I think).

The big debate here is over what one means by "nothingness", which seems to me characterizable as nothing of interest. I guess though that there is a lot of money to be made in the nothingness business. The next opportunity for a big payday from nothingness will be on Thursday, 11 AM GMT, when Templeton will announce who gets this year's $1.7 million dollar prize. I've no idea who will get it, just that it won't be Krauss.

Comments

1. **uair01**
   March 25, 2012

   I have never risen above the technical level of the "Not even wrong" book but I seem to remember that "nothing" does not really exist in modern physics. Isn't vacuum a seething mass of appearing and annihilating particles? And isn't empty space not some kind of weird background-generating quantum foam? So is "nothing" a viable concept? If some expert could clarify this for me in simple language 🙂

2. **Giotis**
   March 25, 2012

   Contrary to what some people might think little progress has been made in the area. Krauss to answer the question uses Hatrle's Hawking good old 'No boundary proposal' and Vilenkin's tunneling wave function which by the way don't agree with each other. These proposals however are 30 years old and not much have been found since. In fact spontaneous creation of a Universe from nothing (no space-time) is poorly understood and these proposals are semiclassical approximations.

   Of course we have learned some things, for example that eternal inflation can't be past eternal and thus a beginning is needed even in a eternally inflating Universe. LQC guys have found that their models predict a bounce instead of a singularity for FRW metrics at least but they don't have a clue on what triggered the Universe at the very beginning. String theory on the other hand has little to say about cosmological singularities.

   Lacking a theory of Quantum Gravity physicists can't brag that they have answers (or even hints) for these profound questions.

3. **Marcus**
   March 25, 2012

   Giotis: "LQC guys have found that their models predict a bounce instead of a singularity for FRW metrics at least but they don't have a clue on what triggered the Universe at the very beginning."

   What do you mean by "at the very beginning"? We have no reason to imagine a "very beginning", certainly not on the basis of a conjecture like "eternal inflation".

   What the LQC guys aim to do in this respect is simply to resolve the cosmological singularity in a testable way–that predicts features of the cosmic background radiation that can be looked for–and provide for adequate one-time inflation. So the goal is not to explain "why existence exists" :-D.

   I think it's naive and premature to ask "why existence exists" at this point. A more reasonable goal is simply to model what nature was doing shortly before and after the start of expansion, in a way that makes predictions. It's important to be able to judge when a question is ready to be asked.

4. **Giotis**
   March 25, 2012

   I meant the simple fact that a bounce presupposes a collapsing Universe but what gave birth to this Universe? They don't have a clue but since their 'difference equation' approximates the Wheeler de Wit equation and the Harltle-Hawking wave function is a solution of the Wheeler de Wit equation I guess they have to to resort to the usual method to answer the question regarding the birth of the Universe. I know though that they are on trying to answer such questions.

5. **emile**
   March 25, 2012

   That last sentence of the review that includes the "nerdy, pale, small, …" should have been left out. It undermines the review, which I thought made some good points, and makes the author sound like he is insecure. In any case, I'm kind of partial to Steven Weinberg's comment on the unreasonable ineffectiveness of philosophy in physics (to be contrasted with the unreasonable effectiveness of mathematics in the physical sciences of Wigner). If you are going to blur the line between science and scientific speculation and then philosophy or even religion, you'll have to argue with philosophers without solid experimental evidence to back you up. Good luck…

6. **Mike**
   March 25, 2012

   It seems like we should exorcise the mysticism in physics before hammering out issues with the religious philosophers – when we are battling things like F-theory (because the mathematics is "beautiful") and multiverse mania where experimental evidence is seen as a 19th century thing, we don't stand much chance proposing the use of logical reasoning.

7. **Joe**
   March 25, 2012

   I saw this review on Friday already, and left this post on my FB page:

   "This is possibly the WORST review EVER in the NYT — He completely trashes the book simply because he disagrees with the premise; and the last sentence is virtually incomprehensible (from a Columbia Philosophy Professor !!!). NYT, you're scraping the bottom of the barrel with this one."

The Templeton connection at least now explains the idiotic review. What remains unexplained, is why the NYT would publish such claptrap, much less pay someone good money for it, especially since the politico-religious leanings of the NYT is surely far more toward the viewpoints of the author, rather than this inane critic.

8. **Bernhard**
March 25, 2012

"Richard Dawkins, who compares the book's devastating effect on religion to that of Darwin's."

That is an awfully silly comparison to make an Dawkins should know better. Darwin had a solid theory backed-up with overwhelming amount of scientific evidence while what Krauss is discussing, while could be interesting in a philosophical level, it seems to make no harm at all to religion as any arguments he might have, are not backed-up by any evidence (as far as I know, someone can correct me here, but I find it hard..). I believe this is the part that actually matters about Darwin, i.e., a scientific theory that actually does tell something about who we are with evidence to corroborate it. What Krauss is doing refers to very old philosophical debate, which will make no smart religious person lose the appetite.

9. **former mathematician**
March 25, 2012

The language "pale, small, etc." did not refer to Krauss. Nor did it refer to his ideas, exactly.

It referred to an attack on religion because, as the reviewer paraphrased, it can be dumb. Rather than, say, cruel, oppressive, destructive, or any of the various big things that anticlericals used to cite.

The reviewer attacks Krauss's notion that the absence of material particles is a reasonable definition of "nothing." I found the attack convincing. Am I missing something?

10. **Peter Woit**
March 25, 2012

former mathematician,

The exact quote is

"all that gets offered to us now, by guys like these, in books like this, is the pale, small, silly, nerdy accusation…"

which does explicitly refer to Krauss's ideas, not his physique. However, it is a fact that Krauss is physically rather short, rather pale, and, like lots of us, rather nerdy. In addition, Albert makes it pretty clear that "silly" is what he thinks of Krauss in general. I don't think it's a coincidence that the four terms he uses could be applied to Krauss as a physical person. In particular, the term "nerdy" actually makes little sense except as a personal comment. Who has ever heard an academic criticize a scholarly argument because it is "nerdy"? All scholarly arguments are "nerdy", by the definition of "nerdy" common among people I know.

As for the argument about whether it's accurate to refer to a physical state with "nothing" in it as "nothing", that seems to me about as intellectually empty as the vacuum is physically empty.

11. **CU Phil**
March 25, 2012

I think "former mathematician" has read Albert's review entirely correctly — in particular, the significance of the "pale, small, etc." comment — while some of the other misreadings on display here are somewhat startling. Albert simply thought Krauss's argument was a bad one, which is worlds apart from defending the religious viewpoint that Krauss is attacking.

Peter's describing the review as part of a "religious battle over nothingness" and mentioning Albert's Templeton funding strikes me as extremely disingenuous. Albert himself is an atheist, and has spoken in the past at conferences such as Beyond Belief. Again, Albert simply thought that Krauss's argument was a bad one, and that many "new-atheist" criticisms of religion seem to be misdirected, ignoring the most pernicious aspects of religion by focusing on the fact that it can be dumb. Short of willful misreading, I'm not really sure how one could understand the review to be saying much more than that.

12. **Brathmore**
March 25, 2012

Peter,

This blog used to be critical of polemical, imprecise attacks on people, ideas, etc. When it comes to your recent discussions addressing religion, however, it seems that you don't hold yourself to this same high standard. Quoting fragments out of context? Come on. Please. Here's the full, final paragraph of the article, so that people can read the full context of the reviewer's words.

"And I guess it ought to be mentioned, quite apart from the question of whether anything Krauss says turns out to be true or false, that the whole business of approaching the struggle with religion as if it were a card game, or a horse race, or some kind of battle of wits, just feels all wrong — or it does, at any rate, to me. When I was growing up, where I was growing up, there was a critique of religion according to which religion was cruel, and a lie, and a mechanism of enslavement, and something full of loathing and contempt for everything essentially human. Maybe that was true and maybe it wasn't, but it had to do with important things — it had to do, that is, with history, and with suffering, and with the hope of a better world — and it seems like a pity, and more than a pity, and worse than a pity, with all that in the back of one's head, to think that all that gets offered to us now, by guys like these, in books like this, is the pale, small, silly, nerdy accusation that religion is, I don't know, dumb."

13. **Anonymous Atheist**
March 25, 2012

I think the idea was that Darwin gave us an alternative explanation of how the astounding complexity of life could have come into existence *without* an intelligent creator crafting biological machines, and a universe from nothing likewise is supposed to provide an alternative route to the creation of energy and matter in the first place.

The difference is Darwinism is accessible to controlled experiment and observational confirmation and has proven to be a central organizing principle of all biology. It provides a framework of understanding that advances biological science.

It is hard to imagine any tome on how the universe came to be having a similar impact, I believe it is in essence an untestable assertion, and there is no price to pay for the religionists simply continuing to claim that God initiated the whole shebang.

14. **Peter Woit**

March 25, 2012

Brathmore,

I should perhaps make clear, if it isn't already, that I have equally little sympathy for or interest in either side of this argument, and plead guilty to making fun here of both of them because of this. As far as I'm concerned, theoretical and experimental cosmology is an interesting science, but trying to drag arguments about religion into it just leads to wasting your time on meaningless nonsense. This is true whether you are trying to sell books with your arguments about God, or review said books by going on about whether their theological arguments are sufficiently colorful, large, serious and manly.

15. **Peter Shor**
March 25, 2012

Couldn't we agree that the question "why is there something rather than nothing?" is outside the purview of science? Physicists who start trying to answer it are only going to end up making fools of themselves and giving the creationists and other religious extremists more ammunition.

16. **abbyyorker**
March 25, 2012

I'd like to read the Krauss book and see if it says anything im interested in. But i look on amazon and the kindle version is more expensive than hardcover. I just cant buy it! Guess ill be rethinking my kindle addiction.

17. **Christian Takacs**
March 26, 2012

@Anonymous Atheist,
Your moniker reveals your own faith, which is just as strained as any other belief to prove something in the absence of evidence. Your belief depends from something you can not confirm, so it is strange you hold such disdain for others who share your justifications. As to what Charles Darwin said, or tried to demonstrate, please try reading what the man wrote before making such statements. Darwin never said his theory explained the orgin of life or sought to say it could, it attempted to explain how EXISTING life might change through natural selection, not how it came to be in the first place. To this day Evolutionists really do not know how life started, and have speculated life might not have originated on this planet but traveled here on meteroites or ???… this only keeps kicking the question down the hall of course and is of course based entirely on speculation.
@Peter,
I think you should think about what you have written in your own book before you make light of what is in other peoples books. Considering some of the amazing things people who call themselves Physicists are saying these days, and using the most tortured of logics to support their theories, or claiming they no longer have to even provide testible evidence, or claiming computer mathematical modeling predictions are equal to or more valid than physical experimentation, I have to wonder, do even you know now where the line is between mathematical abstraction and testible reality?? Since quantum mechanics and maybe even before, physics has tried it's best to jettison all mechanical underpinnings to the massless point where not much is based on anything anymore, except perhaps the 'interpretation' of a few men in a very small shibboleth who told their devout followers to 'pay no attentioon to the man behind the curtain!' and later to "shut up and calculate" . You should not say one word about religion being meaningless nonsense Peter, or looking down your nose at those like Albert Eisnstein who even humbly admitted "Everything that can be counted does not necessarily count; everything that counts cannot necessarily be counted." You may know your math, but you seem to not know a great deal of your mathematical history or philosophy concerning those who came before you and what they believed. You presently stand on the shoulders of many far greater than you who you would sneer at. If you really want to help physics Peter, try cleaning up the hubris that seems to have infected it. The smug and arrogant are not ever likely to catch their own mistakes or be capable of making corrections. People such as yourself depend on the good graces of funding, from many many people… Most of them who believe in something you have shown disdain for. I don't think I need a large hadron collider or a quantum computer fiasco to see a large part of the physics community has become detatched from the people who would fund it through their taxes. Money for research into how many superstrings can dance on the head of esoteric singularities in the nth dimension is going to be in short supply very soon, so I suspect some financial re-evaluating will soon take place that will bring the HEP fabulists back to earth in their own unique version of "The Hunger Games". It would be nice if when this 'big crunch' occurs, someone like youself has some suggestions on where to start over and try again from.

18. **Ray**
March 26, 2012

I love the title of the article.

19. **Anonymous Atheist**
March 26, 2012

Christian Takacs:

Your moniker reveals your own faith, which is just as strained as any other belief to prove something in the absence of evidence.

There is no strain. As a scientist, in the absence of evidence I do not believe anything; including claims of the existence of something for which I believe there is no evidence whatsoever, like a creator. I am comfortable with the stance that we do not know how the universe began.

Your belief depends from something you can not confirm,

You have this backwards. Atheism is a **lack** of belief in magical beings. I refuse to believe in something that cannot be confirmed. it is religionists that believe in something they cannot confirm, the essence of religion is "faith," which is a belief immune to evidence, even contradicting evidence or logic.

As to what Charles Darwin said, or tried to demonstrate, please try reading what the man wrote before making such statements.

I have read "On the Origin of Species" cover-to-cover twice.

Darwin never said his theory explained the origin of life or sought to say it could,

Neither did I. I said he gave us an explanation for how the *complexity* of life could have come into being, which I think refuted the vast majority of arguments for God that depended on what is now called "intelligent design." IMO very few scientists of any stripe remain that think "functional complexity" demands any intelligence to design at all, not even something as functionally complex as intelligence itself: The human mind.
As it happens, however, as with many scientific discoveries, Darwin's principles would indeed provide a route to the origin of life, because all we really need is the random assembly of a barely functional and laughably inefficient Rube Goldberg self-replicator, somewhere in the vastness of the universe, to get natural selection started. IMO, that in turn reduced the majesty of the "creation of life" considerably. Because of Darwin, one can imagine life started as a simple microscopic entity as small as a virus. That puts the "creation of life" firmly into the realm of a chance chemical reaction.

To this day Evolutionists really do not know how life started, and have speculated life might not have originated on this planet but traveled here on meteroites or ???…

By analogy, to this day, physicists have not quite figured out quantum gravity either. That does not mean these problems are insoluble for all time, or that God gave us gravity and we should not question it. Science advances by testable speculation, and testable speculations evolve from less testable speculations.

It is not based entirely on speculation, it is informed speculation based on observation. Various chemical compounds necessary to the amino acid bases of RNA and DNA are found (by spectral analysis) in distant interstellar clouds. Some are unexpectedly complex. So life may have had more than just a few billion years on Earth to evolve; the ingredients of life, the chemical basis of RNA replicators, may well have been cooking for billions of years before that. That is speculation based on evidence, and informs the debate by doubling or tripling the time line within which complexity could have evolved and matured.

March 26, 2012

Atheists and Believers alike,

There are a thousand other web-sites devoted to endless debates about religion/evolution etc, please take these to one of them, and stick to the topic here.

21. **Anonymous Atheist**
March 26, 2012

@Peter: I apologize; I was originally responding to the hyperbolic praise of Krauss' book by Dawkins, which was in your post.

22. **Nihilist**
March 26, 2012

if you want to know what "nothing" means in physics, you should read this paper

http://arxiv.org/abs/1111.0301

23. **The Vlad**
March 26, 2012

Nihilist,

Thanks, that made my day! I thought the paper was a joke when I read the following line in the abstract:

"bubble solutions that are close to this limit, bubbles of next-to-
nothing, give us a controlled setting in which to understand nothing"

But then I skimmed the manuscript and realized the authors were serious. Wow, has theoretical physics really come to this? You guys really need new data, bad!

24. **cormac**
March 26, 2012

Read the book recently, enjoyed it very much. Simple ideas, simply explained. I don't agree with all of it but it is beautifully written.
Just read the review. Poorly written, full of sciency jargon and not very clear. I've never heard of this philosopher but I don't think he has a good understanding of the area, nor does he express himself very well. Are you sure he's not a novelist?

25. **pakri**
March 27, 2012

Why can't we just accept the present evidence of a universe that is expanding
at an accelarating rate and move on from there? Of what use is it to the study of
Physics to ask whether it all came from nothing ?
The questions which seem to be troubling experienced, serious physicists
were asked more than 2500 years ago. The unequivocal answer was that (without
the use of our complex maths) such questions were profitless.

26. **Jadine**
March 27, 2012

I don't think Karuss' efforts should be belittled. I would even say that they're admirable.

There are, as far I can see, two reasons why some would describe this discussion as pointless:

1- Thinking that the specific question is silly.

Well, I agree. And to be fair I think so does Krauss (one can certainly criticize his book if this much wasn't stated clearly). When one cannot speak meaningfully about something, then one should not speak at all. But one still ought to explain why certain things are meaningless and propose more meaningfull questions. The way I see what Krauss is saying is this: "Look, it's completely meaningless to speak about 'something coming form nothing (as in physical non-existence)', we don't know whether such a thing as 'nothingness' exists
and it's not clear whether it's even a possible abstraction. However, I can tell you how something which is pretty darn close to nothing can possibly give rise to an entire universe".

This is no different than Darwin saying that he can't explain to you how non-life becomes life, but that he can illuminate how something pretty darn close to being inanimate can evolve into millions and millions of species. Sure, Darwin had a testable, predictive theory, and Krauss doesn't. But theories start as speculation, and all that Krauss is doing is explaining that all of this is possible (I'll leave it to a physicist to comment on the validity of the science); initiating a more meaningful discourse in the public about a view that should not be discounted.

2- Thinking that the whole subject matter (religon vs skepticism) is pointless

As silly as both parts of the debate can be, it's not pointless. We might think it's an issue which has been settled a long time ago, but obviously some don't agree. And they will use everything in their arsenal, including butchering science, to attempt to justify their claims. These claims have a real impact in the world, from public policy to people brainwashing children. Certainly scientists, at least those interested in educating people, ought to say "Here's what science has to say about that bit" every once in a while. Dismayed as they may be for putting impircal science behind them for a bit to venture into lands of philosophical speculation, it is ultimately something that will educate people on how the cutting-edge science of their time informs other areas. I see no harm arising from this, only good when scientists are clear about what is based on evidence and what is speculative.

27. **Danny**
March 27, 2012

That seemed more like a spell-checked Youtube posting than a NYT book review. In the third paragraph, David Albert seems oblivious to Bell's work; in the fourth and fifth, he seems to reject the meaningfulness or even usefulness of canonical formalism (Hilbert space, states, operators, etc); and throughout, he's got an axe to grind — consider the first sentence of each paragraph.

Positivist atheist scientists have been picking a lot of fights lately, between the battle over intelligent design in the USA, the "new atheism", these sorts of cosmological statements, the abundance of underemployed math/physics guys trying to apply their techniques to the humanities and financial marks, and the closer ties to philosophy departments. Unfortunately, theologians and philosophers are quite well-trained in rhetoric, and "pale, small, silly, nerdy" scientists don't exactly have the public on their side. If we're doing research that doesn't have direct applications, we'd better not be seen as ridiculous and expendable, either in the classroom, in academia, or in the public sphere.

28. **Bernhard**
March 28, 2012

Peter,

off-topic: I just read this review on "Echoes of The Big Bang", looks quite interesting. The best is that the guy seems unsympathetic to the multiverse thing, so potentially a serious book…

29. **Phil**
March 28, 2012

The vacuum and the laws of physics undelying it are sort of like a bank account with no money in it(or perhaps in the quantum case one which has tiny daily deposits and withdrawals that average out to zero), which of course still has a bank and all the underlying banking rules supporting it. Trying to posit the vacuum as "nothing" and positing the ultimate existence of everything out of it it really about as silly as trying to "explain" the existence of the bank as arising from the empty bank account.

30. **xristy**
March 31, 2012

I don't think that the big debate is over the meaning of "nothingness." The big debate is over using scientific credentials to lend authenticity to absurd claims.

I read Krauss' book and in parts it was a workable overview of some of the current thinking in cosmological theory. On the other hand Albert is completely correct in questioning the futility of trying to chase the indefinite regress of how it comes to be that there are laws or that there are unstable vacuum states or whatever. Krauss doesn't offer an answer to this and I agree with Woit that there is little point in trying to argue one side or the other of such origins.

On the whole I thought Albert's review was reasonable. There's really no benefit to most of us in this battle of pseudo answers to ineffective questions.

31. **TB**
April 2, 2012

Pakri said: "Why can't we just accept the present evidence of a universe that is expanding at an accelarating rate and move on from there? Of what use is it to the study of Physics to ask whether it all came from nothing ?"

There is utility in speculation – it can point us in directions we might not think to go. But I kind of agree with Anonymous Atheist when he says "it is religionists that believe in something they cannot confirm, the essence of religion is "faith," which is a belief immune to evidence, even contradicting evidence or logic."

The question I have is when does speculation cross the line to religion? One thing I disagree with AA is in his definition of faith. It doesn't have to be immune to evidence or contradictions. It can be belief with an absence of evidence, and I think we need to be careful about defining things based on how people misuse it. After all, people put their faith in many earthly things now and are not disappointed.

To get this back in topic, my concern is when the rate of adopting a speculative idea is inverse to the likelihood that there can be evidence to support/refute that idea. When does the adopting become faith? At what point can we say the multiverse stands in for god in this new religion?

32. **Jamie Portsmouth**
April 5, 2012

> As for the argument about whether it's accurate to refer to a physical state with "nothing" in it as "nothing", that seems to me about as intellectually empty as the vacuum is physically empty.

Peter,

Are you saying that in your view, the vacuum ("a physical state with nothing in it") should be regarded as self-evidently identical to "nothing"? You seem to imply that arguing against that assertion is "intellectually empty".

It seems to me that Albert is quite correct in pointing out that the vacuum state of a relativistic quantum field is manifestly *not* nothing, but a particular state of a well-defined physical entity, which obeys some non-trivial mathematical rules (the origin of which we are completely ignorant of). The quantum field is also embedded in and evolving with a background spacetime with its own dynamics, and since we don't have a compelling theory of quantum gravity/spacetime, we don't really understand in detail how the interaction between spacetime and quantum fields works (except in semi-classical approximation). It seems likely that spacetime and the quantum fields therein both arise from some deeper theory which we don't currently have access to (but it isn't string theory, I'm sure you would agree).

So to argue that since the vacuum is unstable in relativistic QFT implies that we fully understand how the universe might arise from literally nothing (which is how Albert characterizes Krauss' core argument) is indeed pretty silly isn't it?

Anyway, in my view, Albert's critique is an interesting and important one, not remotely "intellectually empty".

33. **Peter Woit**
April 5, 2012

Jamie,

Krauss is using the word “nothing” in one perfectly legitimate way according to the dictionary (“nothing”= no thing there = perfectly good way to define the vacuum), Albert is using it in another. There doesn’t seem to me to be even a slightly interesting question at stake in this argument over this word. If others think this is an interesting and non-trivial argument, that’s fine. I just don’t.

34. **Bob Levine**
April 5, 2012

Peter—

I think you’re doing your *own* point of view a disservice by conflating Krauss’ and Albert’s discussions of ‘nothing’ and rendering a symmetrically negative judgment on both their houses. So far as I can see, you and Albert are on the same line of the same page. He’s doing what any good analytic philosopher does: attempt to eliminate spurious philosophical (or, as in this case, putatively scientific) problems by locating the source of these non-problems in the category errors people make in the way they talk about the issues in question. What Albert sees as Krauss’ bogus solution arises from conflating (i) the vacuum state of a universe loaded with fields, fluctuations, curved spacetime etc. on the one hand with (ii) the absence of any entities whatever. The result of this error is that Krauss appears to be making the question itself one which has scientific content; Albert’s point—which is exactly yours, no?—is that the question has no scientific content whatever, and that this is apparent once one sees that Krauss has confused the physicist’s vacuum state with the complete absence of anything, anything at all, which is what the theologians and metaphysicians are talking about when *they* pose the question. So, like Jamie, I’m surprised that you regard both Krauss (who propagates the error) and Albert (who tries to show the source of the error, and that the question, once Krauss’ confusion is eliminated, has no scientific denotation) as equally irrelevant from your own perspective….

35. **Peter Woit**
April 6, 2012

Bob Levine,

I just don’t think there’s an “error” here. Krauss is talking about one thing, Albert about another. Neither of them is interesting.

36. **Science_is_Testability**
April 9, 2012

Peter –

you are of course fully entitled to find this issue uninteresting, just as others find it uninteresting whether there is a multiverse or not, or whether string theory is good science or not. But what is at issue here is that Kraus is claiming to give scientific proof for things that are not scientifically provable: indeed he is claiming to solve philosophical problems that are thousands of years old by scientific methodology. This category error falls smack in to the “Not even wrong” category, claiming to give scientific proof when in fact he is offering philosophical speculation. Albert’s book review nails this pretension beautifully.

37. **Peter Woit**
April 9, 2012

Science_is_Testability,

I just can’t get interested in the philosophical/theological problem Krauss is claiming to solve, so don’t really care about the argument between him and Albert over whether Krauss has anything worthwhile to say about it.

I do care about whether the anthropic multiverse models Krauss is promoting as a solution to a scientific problem actually work (I think they don’t). If Albert and other “philosophers of cosmology” would address the question of whether these models are science or pseudo-science, that would be much more worthwhile.

Implications of LHC Results

March 28, 2012
Categories: Experimental HEP News

The winter conferences are now come and gone, with any dramatic new LHC results now likely to wait until more data is on hand. First attempt to collide beams at 4 TeV/beam is now scheduled for Friday morning, with stable beams for physics a week or so later. Results from the 2012 data should first start to arrive at the summer conferences.

This week at CERN there's a workshop on [Implications of LHC results for TeV-scale physics]. Lots of detailed information in the slides about the latest LHC bounds on non-SM physics. For a summary of the situation with the Higgs, SUSY and what it all means, you could do worse than take a look at the slides of [Alessandro Strumia], which include the sobering:

> Implications for European Strategy for Particle Physics: The Higgs could be the last particle. Carpe diem.

He describes the SUSY situation as "the naturalness motivation for weak scale SUSY is mostly gone", with the one loophole not yet ruled out a stop particle at accessible energies. This scenario has now been dubbed "natural SUSY" and will be a major focus of searches going forward.

There was a similar workshop organized last week at the University of Maryland, slides are [here]. Matt Strassler reports [here], [here] and [here]. Evidently there was a final panel discussion for which video may appear at some point.

Update: One more thing on the same topic, a very recent review of the implications of LHC results for SUSY phenomenology is [here].

Comments

1. **Bernhard**
   March 29, 2012

   Peter,

   the link for Alessandro´s talk is not working (you forgot an "i").

   But now, with a likely Higgs at 125 GeV what are the best options to stabilize the electroweak scale? When people finally throw in the towel on SUSY, I am not sure what the best options are. The problem is now really there, before we could always conjecture the whole Higgs idea was incorrect in the first place.

2. **Peter Woit**
   March 29, 2012

   Bernhard,

   Thanks, fixed.

   It's never been clear to me that "stabilizing the electroweak scale" is actually a real problem. Yes, the ratio of electroweak scale to the GUT scale and the Planck scale is a small number you would have to explain, but you don't know there even is a GUT scale, and who knows what the significance of the Planck scale is.

   To me the main problem with the Higgs is that it looks like an effective field for something more interesting we don't understand, and this shows up as a long list of undetermined parameters (most of them the Yukawas). The fact that the LHC is starting to actually see the Higgs and measure its couplings is what is really exciting, hopefully something non-SM will turn up there.

3. **Dave Miller in Sacramento**
   March 30, 2012

   Peter,

   I'd be very curious to hear you elaborate some time on Strumia's point: "Implications for European Strategy for Particle Physics: The Higgs could be the last particle. Carpe diem."

   It seems pretty clear that much of the wackiness in theory in recent years has been due to a lack of new experimental data to chew on. Assuming the Higgs really has been found, and behaves much as it should, Strumia's point would seem to imply that we are in for many, many decades of repeating recent experience.

   Do you agree? What are your constructive suggestions?

   My own guess is that the best we can hope for is a long period, a half-century or more, of digesting everything that has happened since 1900: everything from figuring out how to do better calculations in QCD to figuring out better ways to explain, present, and understand renormalization, symmetries, general relativity, the "weirdness" of quantum mechanics, etc. Continuing work, including experiments, can continue on topics such as quantum computing, quantum teleportation, entanglement, etc., but almost certainly all that will again and again confirm the predictions of quantum mechanics.

   Of course, there are times when reflection and consolidation can be of value.

   And at worst? Well, let's just say the "landscape" might be just the beginning!

   Do you see a brighter prospect?

   Of course, nobody can predict the coming of a Newton or an Einstein, but, on the other hand, surely Newton and Einstein arrived at times when their genius could be applied to productive ends.

   Dave Miller in Sacramento

4. **Shantanu**
   March 30, 2012

   Dave, there are alternatives. Unfortunately people working on alternative ideas are considered mavericks and usually get no funding/jobs (with a few exceptions).

Even institutes like PI, which originally encouraged non-mainstream thinking are now focussing mainly on trendy stuff such as branes etc.for a few random examples, look up Einstein-Sciama-Kibble gravity, non-commutative geometry etc.
See BJ Bjorken's article at last year's Fermilab conference on this.

5. **no**
   March 30, 2012

   "the best we can hope for is a long period, a half-century or more, of digesting everything that has happened since 1900."
   Holy cow, I hope you're not doing research!

6. **Peter Woit**
   March 30, 2012

   The "SM Higgs and nothing else" LHC scenario has been looming on the horizon for a while, and its probability has been increasing, so Strumia's concern I think is on many people's minds. I'd prefer though to hear if people have any substantive comments on the discussions at these workshops. It's not like there's not enough discussion on this blog of the problems with current popular BSM scenarios or the need to encourage alternatives…

7. **Peter Woit**
   March 30, 2012

   From what I can tell, first collisions at 8 TeV center of mass energy are happening right about now. Still a few days at least though before stable beams and physics.

8. **Eric**
   March 31, 2012

   Time to eat crow, my friend.

9. **Eric**
   March 31, 2012

   On second thought, perhaps this is an April Fool's joke.

10. **Peter Woit**
    March 31, 2012

    Eric,

    Very exciting. I guess I was all wrong. Oh well.

    Can't possibly be an April Fools joke. It's only 11:48 March 31 in Geneva.

The Darth Vader Theory

March 30, 2012
Categories: Uncategorized

This week at Caltech there's a workshop celebrating the 35th anniversary of N=4 Super Yang-Mills theory. George Musser of Scientific American is covering the workshop here . He reports that N=4 Super Yang-Mills is being describe as the "Darth Vader theory", I guess by Nima Arkani-Hamed. The conjectural 6d (2,0) superconformal theory gets called "the Emperor Palpatine of theories".

Perhaps slides from the talks will be posted at some point. Witten will close the workshop tomorrow with a talk not about Darth Vader or the Emperor Palpatine, but about "Superstring perturbation theory revisited".

Update: Clifford Johnson reports on the conference here.

Update: Someone at the conference confirms that the "Darth Vader" description came from Arkani-Hamed, who in his talk said something like:

> "The relation between 4D N=4 SYM and the 6D (2, 0) theory is just like that between Darth Vader and the Emperor. You see Darth Vader and you think "Isn't he just great? How can anyone be greater than that? No way'.Then you meet the Emperor".

Update: A couple reports from the conference banquet. During his presentation Dan Freedman unveiled his new textbook on Supergravity (see here) and offered to sell copies to those attending the conference at 20% off. Stephen Hawking was there. He's in Pasadena for his yearly visit and to appear in an episode of "The Big Bang Theory". The show's writers and producers are very excited about the "Darth Vader/Emperor Palatine" thing and planning on working it into the show's script. Afterwards Hawking invited many people to join him and some of the cast of the show on a trip out to his favorite club in San Bernadino.

Update: Given that the previous update was written on April 1, readers might want to have some suspicions about whether it is completely accurate.

Update: Some slides from the talks are now available here.

Comments

1. **Anonyrat**
   March 30, 2012

   "Perhaps most intriguingly, (2,0) theory is irreducibly quantum."

   What does that mean? Does it mean it cannot exist in classical space-time, or indeed any classical manifold?

2. **A.J.**
   March 30, 2012

   Nope. It means that the (2,0) theory has no small parameters in flat 5+1 dimensional spacetime. It can't be approximated in the usual, using perturbation theory around a classical limit, in this setting. But the spacetime is classical.

3. **Anonyrat**
   March 30, 2012

   ^^^ What is so strange then about being "irreducibly quantum"?

4. **Giotis**
   March 31, 2012

   I think it should be emphasized why these top physicists are so interested for these local Quantum field theories.

   The N=4 Super Yang-Mills is the QFT which appears on the world volume of multiple D3 branes in 10D String theory. This theory gave birth to the notorious AdS/CFT correspondence. Similarly the (2,0) is conjectured to live on the world volume of multiple M5 branes in 11D M-theory. String theorists have already found the QFT living on the world volume of multiple M2 branes, the famous ABJM theory. It is amazing that string theory predicts the existence of certain consistent highly non trivial QFTs and then the theorists go on and prove its existence and consistency by explicitly constructing its action.

   This can't be a coincidence and this is one of the main reasons the elite of the physics community believe in String theory as the ultimate TOE.

5. **Bernhard**
   March 31, 2012

   Giotis,

   the notorious AdS/CFT correspondence seems to be more and more in tension with data.

   As for "String theorists have already found the QFT living on the world volume of multiple M2 branes, the famous ABJM theory" , this means only that string theory is able, from time to time, to connect with QFT in order to be alive, seems it has nothing else, no single prediction all. Well bravo for ST! The mathematical connection with QFT is an obligation not a merit and says absolutely nothing about its correctness. As far as I know, is ST´s only business now. I have my doubts on a TOE which the only power is to find increasingly difficult ways to connect to the theory that actually works (QFT).

   And last "theorists go on and prove its existence and consistency by explicitly constructing its action. " This is your idea of proving the existence of a theory? Construction of an an action?

6. **Peter Woit**
   March 31, 2012

   Anonyrat,

The “irreducibly quantum” business is often used as an explanation for why this theory is poorly understood (as AJ explains, there’s no usable semi-classical approximation).

It’s not really strange though. Another example would be the world’s simplest quantum system, a 2-d spin.

7. **Dan**
March 31, 2012

Recently I heard Nima describe N=4 SYM as “the harmonic oscillator of the 21st century”, which is probably my new favorite tongue-in-cheek hep-th joke…

8. **Anonyrat**
March 31, 2012

The Darth Vader and Emperor names given to those theories by Arkani-Hamed are really apt, for apart from string theory aficionados, everyone else is waiting for the Return of the Jedi.

Peter, exactly what I thought, but wasn’t sure – the “irreducible quantumness” of a theory hardly makes it more profound. Thanks!

9. **Giotis**
April 1, 2012

Bernard,

The prediction of the existence of certain highly non trivial QFTs does not prove of course that the theory is the correct paradigm of Nature, this is extremely difficult to achieve especially for theories in these extreme energy regimes; it does prove though that the theory is internally consistent and cohesive. This is an extremely important aspect of a TOE and characterises its theoretical quality.

10. **Thingumbobesquire**
April 1, 2012

I think you might have posted this a day early…

11. **Thingumbobesquire**
April 1, 2012

Oops, I should have said this was published two days early…

12. **Peter Woit**
April 1, 2012

Thingumbobesquire,

Yes, it is very hard to tell parody from reality in this business. However, I stick to absolute accuracy all the time here, with some exceptions one day a year. Here the posting was not written on that one day, although the updates were written later so I can’t vouch for them completely corresponding to reality.

13. **Giotis**
April 2, 2012

I’m confused…

Could you clarify the false parts of this post?

It seems that you have mixed truths with lies and this makes it difficult to find where the lies are.

14. **Peter Woit**
April 2, 2012

Giotis,

That’s funny. It appears that the goings on at string theory conferences are so bizarre that real events and outrageous fantasy can’t be distinguished…

15. **John Doe**
April 2, 2012

Are there any comments on the talk by Witten? It’s always interesting to have a clue as to what he’s up to…

16. **PerfectDigit**
April 2, 2012

@John Doe,
Here are slides of an earlier version of this talk by Witten:
http://www.princeton.edu/~masahito/confs/2011/Witten_PCTS2011.pdf

17. **John Doe**
April 3, 2012

PerfectDigit, thanks. Those slides are pretty detailed…

18. **gigel**
April 6, 2012

Spin systems aren’t “irreducibly quantum”. You can start from a classical system with degrees of freedom living on an internal sphere and quantize to get any spin you want.

19. **Peter Woit**

April 6, 2012

gigel,

The classical limit is when you take the spin quantum number to infinity, that's where you'll get an algebra of observables that looks like functions on a phase-space of a sphere. For the spin-1/2 rep, and the algebra of 2 by 2 matrices acting on it, you're in a situation not at all like the classical one, not in any sense a perturbation of it.

Nothingness in LA on April Fool's Day

April 1, 2012
Categories: Multiverse Mania

The media and blogosphere today are full of April Fool's Day jokes of various degrees of funniness. Then there's the Los Angeles Times, which used the date to publish a piece by Lawrence Krauss entitled [A Universe Without Purpose](). It promotes the argument that the multiverse is science's answer to religion, with in this case backing coming even from the LHC:

> Out of this radically new image of the universe at large scale have also come new ideas about physics at a small scale. The Large Hadron Collider has given tantalizing hints that the origin of mass, and therefore of all that we can see, is a kind of cosmic accident. Experiments in the collider bolster evidence of the existence of the "Higgs field," which apparently just happened to form throughout space in our universe; it is only because all elementary particles interact with this field that they have the mass we observe today.

Maybe it's just my defective sense of humor, but I'm not finding this funny.

Comments

1. **Low Math, Meekly Interacting**
   April 1, 2012

   Then there's this quote:

   "Perhaps most remarkable of all, not only is it now plausible, in a scientific sense, that our universe came from nothing, if we ask what properties a universe created from nothing would have, it appears that these properties resemble precisely the universe we live in."

   If we're the products of an accident in the multiverse, these properties are, at best, a parochial curiosity among a vast ensemble of "universes" with unimaginably diverse properties, right? Does this not imply that if we ask what properties a universe created from nothing would have, it would appear that anything goes? How does anything remotely resembling "precision", beyond perhaps a basic need for mathematical consistency, follow?

2. **billy the skeptic**
   April 1, 2012

   Okay – let me see if I've got this right:

   In order for us to explain our universe as NOT being part of some grand design or intended creation with a purpose – we have to assume that there are many of them? Meaning that some athiests are conceding that "how" our universe popped into existence is so unlikely that there must be many because if this is the only one, then it could possibly be due to purposeful creation? Really???
   How many other universes would need to exist in the multiverse in order to find our random but good fortune statistically plausable?
   I myself am an agnostic, which means the religious folk don't like me because I'm a nonbeliever, and the athiests don't like me because I have a fear of commitment.

   If you believe this multiverse nonsense, then I assume you must also believe we are far luckier than those 3 Powerball winners this weekend!

3. **Yatima**
   April 1, 2012

   >I'm not finding this funny.

   That's because it's not an April Fool's joke, I reckon.
   But I don't see where the problem is. Only a person deeply encumbered by religion would find anything to object here.

4. **Anonyrat**
   April 1, 2012

   Lawrence Krauss writes: "Asking why we live in a universe of something rather than nothing may be no more meaningful than asking why some flowers are red and others blue."

   In order to come to this conclusion, he has to invoke the latest in cosmology and speculative particle physics theory.

   But I would say that "asking why we live in a universe of something rather than nothing" is a priori without meaning. It did not have and does not have any meaning within a scientific framework. The question is meaningful in the framework of one particular theology which, however, is hardly universal.

5. **Aidyan**
   April 1, 2012

   "…. all that we can see, is a kind of cosmic accident."

   And what is an "accident"? What is in the eyes of a tiny ant the world outside of its anthill if not an unintelligible stream of random "accidents"?

6. **paddy**
   April 1, 2012

   Pardon me for waxing a wee bit pop-ish on this april fools day..but:
   (A) Just when did the jester steal the thorny crown of physics?
   (B) When did some physicists think it was okay to jump the shark?
   (C) How valid are their opinions in the face of the "Julie Andrews assertion": i.e., "Nothing comes from nothing, nothing ever could".

7. **SpearMarktheSecond**
   April 1, 2012

   Krauss has always hopped on the publicity machine… \`The Physics of Star Trek'. For a publicity guy, he knows a lot of physics, but he doesn't care to mention that most of the mass in our own matter has nothing to do with the Higgs, but originates in dimensional transmutation in QCD, and that we have no idea whether or not the Higgs has something to do with the mass in dark matter.

N-rays, polywater, faster-than-light-neutrinos, cold fusion… hype and hokum are always out there and always will be.

Meanwhile new interesting physics always breaks out in areas overlooked by the publicitarians…. 100 or so earth like planets! Now that is real and exciting. Good that SETI got some money to point at them!

8. **Peter Woit**
April 1, 2012

SpearMarktheSecond,

Yes, but even giving Krauss the simplification of ignoring QCD and dark matter mass contributions, my problem is with the remainder. I don't see what the justification is for claiming LHC Higgs results as evidence that the Higgs and its Yukawa couplings are "a cosmic accident", "which apparently just happened to form throughout space in our universe". The question of what the Higgs really is and where its Yukawas come from is a deep mystery we don't understand. The multiverse philosophy is to sweep everything we don't understand under the rug as a "cosmic accident". You can do this if you want, but I don't think you should claim experimental backing for this pseudo-scientific procedure.

9. **pfogle@tiscali.co.uk**
April 1, 2012

there's science and there's speculation… each can give rise to the other. Maybe all speculative ideas should be written in red type, just to remind us that they're not science!

10. **SC**
April 1, 2012

"Only a person deeply encumbered by religion would find anything to object here."

I don't think it's the case that only religious people care about abuses of science. If someone runs around saying "science shows" what science doesn't actually show (and may, in fact, be unable to show even in principle), anyone who values science should be annoyed. Even if the sentence is "science shows God doesn't exist!"

It's as bad when an atheist does it as it is when a creationist does it. Perhaps worse, since at least one can easily identify the creationist's bias.

11. **Bee**
April 2, 2012

I've figured it out: We live in a computer simulation, and it has a loose cable.

12. **Christian Takacs**
April 2, 2012

I am not a believer in creationist Mythology, but I certainly am not a believer in the Big Bang Theory ex nihilo ad nauseam either, because quite frankly, knowing with certainty anything that happened fourteen or more billion years ago is quite speculative to the point of absurdity, and claiming it popped out of nothing is "Credo quia absurdum". Are the leaders of the scientific community really so scared of "I honestly don't know, we still have to find out" that they debase themselves with the inaccurate bravado of "Oh yes, we know almost everything, we just have a few last calculations to work out" ? Think of it this way, if you can't admit the limits of your knowledge, how are you going to actually to learn anything that will allow you to extend this limit? I think many potential scientists are discouraged from going into the sciences and making real discoveries because of the arrogance and hubris of the present scientific community that makes wild claims to knowledge they don't possess, Much like Bohr telling Einstein "it is the best we can do and the best we can ever do"… Hogwash, pure and simple, it's the fallacy of the appeal to (scientific) authority telling future generations not to look for answers anywhere that might challange todays dogmas.

13. **Emanuel Derman**
April 2, 2012

It is deeply dishonest to pretend he understands the mysteries of the Higgs, even more so to claim it follows from the multiverse. Probably it's just PR.

But, you don't have to be a believer to see the wisdom of the following two statements:

> "When people stop believing in God, they don't believe in nothing — they believe in anything." – G.K. Chesterton.

And, from Saul Bellow:

> The philosopher Morris R. Cohen was once asked by a student, "Professor, how do I know that I exist?"
>
> "So?" Cohen replied. "And who is asking?"
>
> Thanks to Professor Cohen I feel that I stand on firmer ground, and can do what I have done all my life: i.e., to fall back instinctively on my first consciousness, which has always seemed to me to be most real and easily accessible. For people who have no access to any such core consciousness, no mysteries exist. Linguistic analysts aim to clear away all mysteries—alleged mysteries, they would say. Facts, however, must be respected, and the fact is that for reasons I can't explain, my own first consciousness has had a long unbroken history. I wouldn't know how to defend my faithful attachment to it. All I can say is that it is a fact and I wonder why anyone should feel it necessary to put its reality in doubt. But our meddling mental world puts all such realities in doubt. This world of truly modern, educated, advanced consciousness suspects the core consciousness that I take to be a fact of being inauthentic and probably delusive.

14. **BlizzardOfOz**
April 2, 2012

"The Large Hadron Collider has given tantalizing hints that the origin of mass, and therefore of all that we can see, is a kind of cosmic accident."

Yes, I'm sure the experiment "hints" "tantalizingly" at something he had already decided years ago. What a wanker.

15. **TB**
April 2, 2012

Peter said: “The multiverse philosophy is to sweep everything we don’t understand under the rug as a “cosmic accident”. You can do this if you want, but I don’t think you should claim experimental backing for this pseudo-scientific procedure.”

That’s interesting as that’s the same (valid) criticism of religion when they shrug their shoulders and say “god did it.” I suspect the rush to a multiverse has more political motivations than scientific.

16. **TB**
April 2, 2012

SC said: “It’s as bad when an atheist does it as it is when a creationist does it. Perhaps worse, since at least one can easily identify the creationist’s bias.”

Agreed. But that’s what seems to have changed in the past few years.

17. **Allan Rosenberg**
April 2, 2012

I’m a little disappointed by the four slash one post. I was hoping for some more NYC bakery recommendations or maybe a discussion of snide anti-string theory bumper stickers (“String Theorists Do It In Their Pants”). Maybe next year…

18. **Peter Woit**
April 2, 2012

Sorry Allan,

Not much news on the NYC bakery or biking fronts I fear. After extensive investigation, I can report though that an excellent Kouign Amann can be found in Paris at the boulangerie/patisserie on the square where Rue Monge and Boulevard St. Germain come together (i.e. at the Maubert-Mutualite Metro stop).

No one seems to have noticed this year’s much too subtle attempt at 4/1 humor, I guess no one reads the updates…

19. **Giotis**
April 2, 2012

Can’t you see why he is making this assertion Peter?

Currently in LHC we have light Higgs but no SUSY. If these results remain it means that extreme fine tuning is needed similar to CC. This means accident and this means multiverse.

20. **Peter Woit**
April 2, 2012

Giotis,

Yes, I understand that argument very well. I just don’t agree with it. That the ratio of the electroweak scale to the Planck scale is a very small number is an observed fact that we don’t understand. Saying that “the multiverse did it” just isn’t a scientific explanation unless you have a viable theory of the multiverse, testable in some way, even indirectly (which you don’t). At the moment, “the multiverse did it” is just a pseudo-scientific statement, being used to claim you have a scientific explanation, when you really just don’t know what is going on. This is a bad idea for lots of reasons, one of which is the one David Gross emphasizes: promoting a non-explanation for something you don’t understand discourages people from continuing to do the hard work of trying to find a real explanation. If you’re the sort who wants to argue religion, this doesn’t seem to me a good way to go: arguing against one non-explanation with another non-explanation is not going to convince anyone.

21. **Low Math, Meekly Interacting**
April 2, 2012

It’s not clear to me that the multiverse has any predictive value whatsoever, even in the complete absence of theoretical alternatives. If I read the history of the subject correctly, originally evidence of fine tuning in the value of the CC and phenomena at the electroweak scale, in combination with certain assumptions about what conditions were required to get flat universes with such-and-such matter content, complex chemistry, etc., left us with a stark choice between God or the multiverse. But those assumptions turned out to be far too narrow. Perhaps intelligent life and many other gross features of the universe we observe can be accommodated by a far greater range of constants, etc. than previously assumed. So it’s not even clear if we can make good estimates of probabilities of required conditions. Meanwhile, there’s probably no good way to estimate probabilities of finding some-or-other physical features in the Landscape. Apparently there are no solid constraints on, well, much of anything in the multiverse. You can simply posit its existence, twiddle the available knobs however you like, and satisfy yourself that what you get bears some resemblance to what we see.

If I’m totally or partially wrong about the above, I’m all ears. But, again, I haven’t the foggiest idea where the notion of “precision”, or anything remotely like a veritable “prediction” comes into any of this.

22. **Juan Ramón González Álvarez**
April 2, 2012

I think you missed this funny one: [First evidence for string theory at the Large Hadron Collider]

23. **Dan Winslow**
April 2, 2012

I’ve always wondered what ‘random’ means. People throw it around a lot in relation to quantum thingies and cosmology…Krauss uses it a lot. Lots of phrases like ‘…and then through random fluctuations of … ‘. But I’m not sure that the term random has any absolute meaning. I think it just means ‘for reasons unknown’…right? I think there’s a paradox about randomness, in that if you can define rules for deciding whats random then it’s no longer random, or something along those lines. Can any of the high powered folks here elucidate?

24. **paddy**
April 2, 2012

For my own April fools day exercize I attempted to calculate the transition probability from something to nothing and vice versa. That pesky density of states on the “nothing” side unfortunately kept coming up zero (e.g., nada, null, and–doh!–nothing). Not wishing to admit defeat, I am currently (a la a recent arxiv paper cited somewhere in this blog) attempting to sequentially approach “nothing” with diminishing state densities (as well as diminishing returns). Once again though I have a problem: trying to be careful about uniform convergence issues I keep losing track of my epsilons and deltas (physicist you see not a mathematician). Should someone find these characters (subscripted with “nothing”) I would be happy if they returned them.

25. **Peter Woit**
April 2, 2012

Dan,

The problem with current multiverse theories is that there is no viable underlying theory which would explain exactly what the different possible effective laws of physics would be, and allow computation of probability of any particular set of effective laws.

So, instead, people just talk about the “measure problem”, and say things are “random”, giving equal weight to all values of various parameters, for no reason other than that they don’t know what else to do. This has exactly the same implications as my “theory”, which is: I have no idea what determines the value of that parameter, so, a priori could be anything. This kind of “multiverse theory” is identical to complete ignorance. More honest if you ask me to just call it what it is.

26. **Don Murphy**
April 2, 2012

Peter

Nothing is wrong with your sense of humor.

Don

27. **Casey Leedom**
April 3, 2012

Okay, since you didn’t find that funny, try A Quantum Theory of Mitt Romney The New York Times author managed to find a way to very humorously integrate modern physics — including a multiverse reference — into the current year’s political landscape.

Note that I am explicitly **not** posting this as a “political” comment, simply as a humorous use of “physics speak” in the popular media. It would have been just as funny if it was about Obama, etc.

28. **N.**
April 3, 2012

@Christian Takacs:

You see, you get no funding for saying “I don’t know”…

It’s much wiser to say “I know almost everything about it, just need a little (better: a lot) more money”.

That’s it.

:))n.

29. **Adrian_H**
April 4, 2012

I’m not a great fan of Albert — his pugnacious style is off-putting to me, and he tends to weigh in too heavily on particular sides of debates. But I have to say that I completely agree with his review of Krauss. He nails it. OK there is still too much rhetoric, too much “this, and that, and tother, and your mother” rankling through the prose, but he is right about the way that Krauss is wrong.

Father of String Theory on LHC Funding

April 3, 2012
Categories: Uncategorized

A report from India:

> **'CERN need not spend so much on LHC experiment'**
>
> Father of String Theory and noted physics scientist Holger Bech Neilsen of Denmark has said that contributions from the Large Hadron Collider (LHC) at CERN are over-rated and that there is no need for spending so much on the experiment.
>
> Interacting with the students and faculty of National Institute of Technology (NIT), Warangal, here on Monday, Prof. Neilsen said that he discouraged spending huge funds on such research projects.
>
> When asked how he would justify the need for unification, considering the fact that individually theories such as quantum mechanics and gravitation have been showing good results, he said that there was no ardent need for a unified theory of everything but that such a theory would bring about new perspectives of understanding the world around us.
>
> Prof. Neilsen who was nominated twice for the Nobel Prize was here at NIT on a two-day visit at the invitation of the students.

The picture with the article show a blackboard where Nielsen has been explaining superstring theory to the students. The talk supposedly was on April 2, so presumably this wasn't an April 1 performance. I guess he's right: since string theory says nothing about LHC physics, the machine is kind of pointless.

Update: A commenter points to this video interview with Nielsen made during his trip to India.

Comments

1. **John Doe**
   April 3, 2012

   Somebody should tell them it's "Nielsen", not "Neilsen".

2. **SA**
   April 3, 2012

   This is embarrassing, disappointing, and I would claim also highly atypical. The LHC is the most crucial aspect of particle physics at the moment.

3. **Dan Winslow**
   April 3, 2012

   "he said that there was no ardent need for a unified theory of everything but that such a theory would bring about new perspectives of understanding the world around us."

   Wow, now *there's* an observation worth waiting for.

4. **Curious Wavefunction**
   April 3, 2012

   The article seems to have been deleted from the website.

5. **Zac**
   April 3, 2012

   @Curious Wavefunction

   No, Peter messed up the link. The article is here.

6. **Bernhard**
   April 3, 2012

   An how the heck do they know he was appointed twice for the Nobel prize? Do they really meant Nobel or was it the Oscar? Information about the Nobel nominations cannot be revealed until 50 years later.

7. **Peter Woit**
   April 3, 2012

   Link fixed.

8. **ComeOn**
   April 3, 2012

   Peter, this guy is a crank and he's been a crank for ages. The fact he did important work in the past is irrelevant. You shouldn't give publicity to this kind of stupidity.

9. **Arjun**
   April 3, 2012

   Didn't know there was a "father" of string theory. As to Bernhard's question about Nobel prizes, it is fashionable in Indian news media to mention Nobel prizes in various science related articles.

10. **Peter Woit**
    April 3, 2012

Arjun,

Nielsen doesn't actually have a Nobel prize (and this kind of thing won't help him get one). Being "nominated for a Nobel prize" is a rather low bar these days.

ComeOn,

Problem is that if I stop covering cranky behavior by theorists promoting string theory, there will be significantly fewer blog postings here. Hard to know where to draw the line…

11. **Student@NielsBohrInstitute**
April 3, 2012

I think I need to defend Holger Bech Nielsen here. I don't know what he has said in India, but I cannot recognize this picture of him. He is actually VERY excited about LHC, he has said that several times on danish television and radio shows and popular talks given to the public. People who have talked to him in person cannot recognize this attitude towards LHC, at least I can't.
I don't understand why Peter characterize him as a "cranky theorist, promoting string theory". Holger is famous for saying, during almost all popular talks, that he is one of the "fathers" of string theory (together with Nambu and Susskind) , but he is a bad father since he doesn't believe in his own child (meaning that he doesn't believe in string theory). I don't know why people think he is promoting string theory, nothing I have ever noticed.

He is an old guy now days, I think he is formally retired. So he works on more crazy ideas sometimes, nothing he is taking seriously himself. Sometime he is having fun and mentions for example "god" while explaining certain ideas, this has attracted some media attention and leading to people thinking that he is being serious. Talking to him it is clear that he is just having fun. Actually he is very bad at selling his crazy ideas since while giving talks and interviews about them, he usually emphasizes that they are probably all wrong and doesn't sincerely believe in them himself.

Finally, I don't know where they got any information about Nobel prize nominations since they are usually kept secret. Holger have many important contributions in theoretical physics (for example the Nielsen-Ninomiya no-go theorem and Niels-Olesen vortices), but I don't think any of them are Nobel prize worthy. I doubt he has been nominated twice.

I think this is more about bad and shallow journalism from "The Hindu", rather than about Holger's true beliefs.

12. **Peter Woit**
April 3, 2012

Student@NBI,

Thanks a lot for the information about Nielsen. It's probably true that the news report is a mangled version of whatever he was saying. As for whether he was promoting string theory at the talk, I was making assumptions based on the article and what little I could see of the board in the picture, but from what you say those assumptions are likely wrong.

As for whether he's a "cranky theorist" these days, I'm not sure he would disagree…

13. **Anonyrat**
April 3, 2012

Here is another report, with a little more than what the Hindu carried.
http://www.thehansindia.info/News/Article.asp?category=5&subCategory=5&ContentId=50228

14. **Anonyrat**
April 3, 2012

Nielsen is on a tour of India. Here is a 19:31 interview with Nielsen at IIT Kharagpur, by the college newspaper, Scholar's Avenue (scholarsavenue.org).

http://www.youtube.com/watch?v=h8LxN4fARU4

15. **Orwin O'Dowd**
April 4, 2012

No-go theorems are the critical experiments of the theory game, and any author deserves ba place in the Skeptics' Hall of Fame. Here's a view of what no-go theorems, and Nielsen's work in particular, meant for mainstream QCD: http://cerncourier.com/cws/article/cern/28271.

That was a decade ago, and at the physical limits of observation and computation, thoughts turn to pure logic and thus philosophy. Here's a no-go that takes out the whole Weyl/Wigner group theory stream: you can't make a universe of groups because the universe of groups is defined as the theory of groups (Lawere Theory)!

Time for theory of theory? But that's philosophy!

16. **emile**
April 4, 2012

I do not know any string theorists (or any particle theorists) who are not supportive of the LHC. There can be a big gap between what is written in the press and what someone actually thinks.

17. **somebody**
April 4, 2012

Holger is just having fun. He loves being crazy a bit, but he doesn't take himself too seriously.

His kind of personality is inevitable, and perhaps necessary, in a field like high energy theoretical physics. People who are outraged by this- sorry if I hurt your feelings, but yours is the imcomprehension that mediocrity has towards creativity. Theoretical physics is not accounting, it also has some poetry in it.

He has paid his dues by doing good science in his youth, and earned his right to think about interpretation of quantum mechanics or complex actions or whatever whimsical idea that he wants to think about these days.

Let him be.

18. **J**
April 4, 2012

Had some personal experience with him and agreed with some commenters that number 1 the journalist report could not be a good mirror image of him and number 2 Holger is a “far-from-equilibrium” person as compared with routine physicists you meet and talk with everyday, so whatever he said could not be taken as serious evidence for/against anything anyway…

19. **jg**
April 4, 2012

Holger Nielsen doesn’t need the lhc since he has pretty much worked out the structure of a theory of everything using pure thought with his random dynamics philosophy:

http://www.nbi.dk/~kleppe/random/trapp/u.html

(looks like a dodgy staircase)

Is it just me or does ‘fathers of string theory’ sound a bit feeble compared to ‘fathers of quantum mechanics’?

20. **Sadley**
April 4, 2012

Everyone very keen to discredit Nielsen, just because reportedly having said something that we do not like to hear.

s

21. **namenotfound**
April 5, 2012

You do a disservice to the field and to serious science in general by giving more publicity to this.

April Fools at the APS Meeting in Atlanta

April 4, 2012
Categories: This Week's Hype

From the latest Science News:

> **String theory weighs in on Higgs**
>
> **ATLANTA** – Physicists working on big experiments at particle colliders aren't the only ones who have something to say about the mass of the elusive Higgs boson. A theorist has now thrown his hat into the ring. Theoretical physicist Gordon Kane of the University of Michigan in Ann Arbor reported April 1 that he and colleagues have calculated the mass of the Higgs from the principles of string theory, with no additional inputs. In the standard model of particle physics, the Higgs boson is required for other particles to have mass. Kane's team, which also reported the calculation online last December at arXiv.org, put the mass at between 105 billion and 129 billion electron volts. The proposed mass is consistent with hints of a Higgs at around 125 billion electron volts, reported later that same month by both the Atlas and CMS teams at the Large Hadron Collider near Geneva. "This is the first string theory prediction for the mass of the Higgs — ever," Kane said.

For some background on this, see here.

Update: It seems that this joke is far more elaborate than I had realized. The APS this year awarded Kane the Julius Edgar Lilienfeld Prize, and then scheduled him to deliver the Prize speech on April Fools day. His speech abstract is:

> **The Higgs Boson, String Theory, and the Real World**
>
> In this talk I'll describe how string theory is exciting because it can address most, perhaps all, of the questions we hope to understand about our world: why quarks and leptons make up our world, what forces form our world, cosmology, parity violation, and much more. I'll explain why string theory is testable in basically the same ways as the rest of physics, and why much of what is written about that is misleading. String theory is already or soon being tested in several ways, including correctly predicting the recently observed Higgs boson properties and mass, and predictions for dark matter, LHC physics, cosmological history, and more, from work in the increasingly active subfield "string phenomenology."

His presentation advertises in large red letters:

> **First String/M-theory tested prediction for new physics — predicted 125 Gev (August)**

and claims that you shouldn't believe arguments that string theory is untestable, even when they come from string theorists:

> If your impression of string theory came from some popular books and articles and blogs (or from formal string theorists) you might be suspicious of taking string theory explanations seriously.

He has many slides explaining the supposed "125 GeV Higgs Mass Prediction", but I can't see an argument that gives 125 GeV, and it's a prediction that suspiciously comes without error bars. The closest thing to a bottom line seems to be page 30, where the "Blue dots are favored prediction", and these blue dots span a Higgs mass range of about 121-128 GeV, so maybe he means 125 +/- 4 or something like that. There are also a lot of red dots from 105 GeV to 121 GeV, which the theory "disfavors", "but doesn't yet rule out".

The other LHC predictions he makes are that the squarks are up around 30 TeV, so unobservable at the LHC, and that the gluino is light enough to be seen at the LHC. His "generic LHC predictions" plot has a gluino around 600 GeV, at a value that has already been ruled out by LHC results. Back in December, he was predicting "a few months" until he was vindicated by observation of a light gluino. If 4 is a "few", his time is up.

Comments

1. **Bernhard**
   April 4, 2012

   "with no additional inputs"

   Either then already knowing the results, of course.

   "reported later that same month"

   What a shameful campaign, what a big liar Kane is. The guy makes a postdiction and sell it as a prediction. Shameful, shameful.

2. **Peter Woit**
   April 4, 2012

   Bernhard,

   When, after decades of trying to find a string theory prediction for the Higgs mass, Kane came up with one just days before the number was publicly announced (although also days after it was described here…), I thought that was pretty strange and hard to understand. However, it is now clear what was going on: he was just setting up an April Fool's joke! It's definitely about the most successful one I've seen, had lots of people fooled.

3. **harryb**
   April 4, 2012

   It does show however the fine line that ST continues to run, and how it erodes away at science – its very obscurity makes it ever harder to discern ST from its own ironic counterpart

4. **Aspirin**
   April 4, 2012

   Kane is of course the King of String Theory Hype so this is hardly surprising. At this point he is just sullying the reputation of arXiv. I am surprised people like Witten haven't called him out as an embarrassment to the community.

5. **Mike**
April 4, 2012

Sadly, the April fool's joke is on the world, for being beguiled for many years by false predictions from string theorists. I think we laid some of this to rest last year with no evidence of SUSY and no gluinos. How long will people continue to ignore experimental evidence? If the excess at 125 GeV starts going down, all of the postdiction-prophets showing their theory's prediction at this energy should be looking for new jobs.

6. **P**
April 5, 2012

Groan groan groan groan groan. Some of the comments on this blog make people's biases extremely clear. Some of you are so anti-string-hype (I'm anti-string-hype as well, though not anti-string) that you haven't done your homework or even considered the fact that Kane et al did a field theory computation that had assumptions and consequences.

First, let me be clear: I'm not criticizing Peter on this issue, as he seems to have done some of his homework in the previous post on Kane's scenario, even though this post of his a bit of a rant. Second, I'm not a fan of hyping Kane's scenario as a unique prediction of string theory. It's not.

Criticisms:

@ Bernhard: Do your homework! You imply it's a "postdiction" because you think Kane only made these claims after the Higgs rumors came out. That's manifestly not the truth. Peter links to Kane's slides where he is clear that he was talking about this Higgs result at a conference in August. You can go to those slides from Madison in August and see that his 122-129 GeV range was discussed months before the Higgs rumors came out.

@Peter: Okay, one criticism of Peter. In these comments you seem to imply that Kane's claims were only made two weeks before, when (I think) you know he made these claims months before the Higgs rumors came out.

@ Aspirin: I don't disagree with you. He's overhyping and perhaps a big shot like Witten should make a clear statement about these things.

@Mike: Same comment as with Bernhard. Even though it's not a unique prediction of string theory, as he would like to hype, it's a bold-faced lie to say it came after the Higgs rumors came out.

Can we not talk honestly about science anymore? Are we really reduced to just attacking some person because he overhypes something without us really understanding the assumptions he made?

Make no mistake about it – Kane's scenario is not a "unique prediction" of string theory – but he and his collaborators actually make field theoretic assumptions and did a computation, and the consequences of the assumed field theoretic structure (that he claims is generic in string theory) is a 122-129 GeV SM-like Higgs if tan beta >= 7. Regardless of hype, this is a computation! In field theory! With a Lagrangian! They run coupling constants and impose cosmological constraints! And no one on here has even mentioned that yet. Particle physicists have taken SUGRA very seriously for thirty years and this is precisely the framework for Kane's paper. It just so happens that string theory gives rise to SUGRA, but SUGRA can be studied independently as well.

All of this is to say: regardless of claims about string theory, if a field theory calculation they did with some assumptions about moduli masses due to honest cosmological bounds (amongst other things) gave m_H in a given range, this is an interesting result.

Now I ask you all a question: Peter raised in the previous blog post that he doesn't know why Kane emphasizes tan beta > 7. I don't either, though Kane in his slides claims its phenomenologically preferred over low tan beta. Does anyone else know why this is?

Sorry for the rant. I just really hope we can raise the bar above blind criticism without understanding what he and collaborators did. That's not how we should discuss science.

Hype? Criticize away . . .

7. **Mark**
April 5, 2012

@P, if \tan\beta ~O(1) then the Higgsinos (the mu-term) are too heavy and the "little hierarchy" problem gets worse. So, having an intermediate range \tan\beta alleviates the little hierarchy problem in the split SUSY scenario of Kane et.al.

8. **Clara**
April 5, 2012

Peter,

who is on the Prize committee? Is it possible to find out?

9. **Bernhard**
April 5, 2012

P,

"@ Bernhard: ….
Peter links to Kane's slides where he is clear that he was talking about this Higgs result at a conference in August. You can go to those slides from Madison in August and see that his 122-129 GeV range was discussed months before the Higgs rumors came out."

I did. Here´s what is written "There's nothing in Kane's August talk about a 122-129 GeV range for the Higgs mass, but in the December 5 paper it appears explicitly three times"

In any case don´t worry about the Higgs, since the gluinos he predicted were not found , I now believe Kane 100%, I think "string theory is testable in basically the same ways as the rest of physics" and that because of it, is ruled out.

10. **Igor Khavkine**
April 5, 2012

Looking through the prize citations of past Lilienfeld Prize winners, it seems that what they mostly have in common is being active popularizers or science.

11. **Bernhard**
April 5, 2012

P,

sorry. What you mentioned was the slides themselves. I of course did look at the time, and it is exactly what Peter said.

One more thing, who took or takes SUGRA seriously? In my opinion, this is a framework experimentalists love for the low number of parameters, not that people were really taking it seriously.

12. **Ralph**
April 5, 2012

I predict that the Higg's mass is within 20% of the hints seen from LHC last year.
Please post the Nobel medal to me at my home address.
Ta.
R.
PS. I know what next weeks winning lottery numbers are. I'll prove that to you in May. wink. wink.

13. **P**
April 5, 2012

@ Mark: thanks! Simple enough answer . . . sounds good.

@Bernhard: I understand your objection now. For some reason, you're upset that he put error bars in his December paper, saying 122-129 GeV rather than "about 127 GeV". True, "about" is not a precise error bar, but are you really going to take issue with the fact that he said 127 GeV and "about", while the supposed observed value is 125.5GeV? I don't take issue with this. These were conference slides, and he was loose about it.

Regarding your remarks about gluinos: can show me the paper which makes the same assumptions as Kane's field theory model and rules out gluino? I just took at look at all ATLAS papers with the word gluino in the title and found nothing of that sort. Perhaps there is something from CMS or LHCb that definitively rules out light gluinos (below a TeV?), period. If so, show me. If not, we should still be very conservative about what we say about the LHC and SUSY. It's still in the early days of the experiment and they make very strong assumptions about their analyses that only apply to a fraction of SUSY parameter space. In my opinion, the joy of experiment is that it's not worth philosophizing too much now based on early analyses, but in a number of years we'll definitely know the answers.

Regarding SUGRA – I'm no supergravity expert, but I think you're mixing up SUGRA and mSUGRA. The latter has a small number of parameters and does some very interesting things, including the dynamic generation of an ESWB Higgs potential. SUGRA itself . . . I believe really anyone who takes SUSY seriously takes SUGRA seriously. And there are many, many non string-theorists who take SUSY seriously.

14. **P**
April 5, 2012

Also, for those that haven't looked back at the previous post on this subject, Mark's comments are particularly good and are worth a read. He seems to have really tried to understand what Kane et al actually did, as opposed to just getting angry at the hype.

http://www.math.columbia.edu/~woit/wordpress/?p=4262

15. **Peter Woit**
April 5, 2012

Aspirin,

Of course I think it would be a good idea if the elder statesmen of HEP thought it worth their while to speak up in cases like this. Pretty uniformly though, people seem to think that it's best to just try and ignore this behavior and hope it will go away on its own. Another example of someone who should weigh in on this is Matt Strassler, who claims to be serious about countering mis-information about HEP phenomenology. He's made a big point of going after people for taking too seriously the 3-sigma Higgs evidence, but my attempts to get him to do anything about Kane led nowhere. It is true here that Kane has had little success in getting science journalists to take him seriously and report his claims. I suspect that any journalist who thinks of writing a "string theorist predicts Higgs mass" story quickly finds after calling up a couple people that this is obviously a "phenomenologist makes unsupportable claim" story, about as worth covering as "dog bites man". From Kane's comments about "formal string theorists", I gather that he has heard from people like Witten and Gross what they think about this.

One place where authorities do weigh in is when Kane tries to publish this in a reputable journal. It seems likely that he would have immediately sent this to PRL at the beginning of December. As far as I can tell, it is still unpublished. When and if it is published somewhere, it may be interesting to compare the published version of the paper to the arXiv version, to see what changes the referees insist on. There's a history of string theorists (see the Distler et al story back in 2007) having referees refuse to let them publish their "string theory predictions", but then going ahead and issuing press releases about them anyway.

16. **Peter Woit**
April 5, 2012

Clara,

The prize committee is on the web-page I linked to. To be fair to them, they decided on Kane and announced the prize before he pulled this stunt in December. Maybe the later decision to schedule his talk for April 1 wasn't a coincidence…

17. **Bernhard**
April 5, 2012

P,

about SUGRA and mSUGRA, point taken, for some reason I assumed you were talking about mSUGRA since ATLAS and CMS are continuously using it. My mistake.

About gluinos, you should listen to what Kane himself said about it. According to his own predictions we should have seen some light gluinos already. If I believe parameters can be easily played with to adapt, sure, but that is the whole point with the non predictability of the theory.

About the hype. Well, this is my SINGLE problem. Papers like Kane´s that play with parameters and make Higgs predictions are many. In the old thread you can see many posted much older papers that make the same- I take it back, much better prediction about the Higgs mass but before a larger fraction of the parameter space being ruled out. Kane made a much stronger case about the exact mass value after the rumors and in any case even if we ignore this, and I´m willing to, there is absolutely no point in making the circus he is doing around this, otherwise every single phenomenologist that got the mass Higgs right should immediately get the Nobel, specially considering their predictions beat Kane´s in years.

All in all, I still think string theory says nothing, zip, nada, about the real world.

18. **Peter Woit**
April 5, 2012

P,

As I think I've made clear elsewhere, all I can see that Kane really has is a complicated calculation in a specific model implying the Higgs mass should be below about 130 GeV, something which was experimentally indicated already when he started making these claims last August. The "122-129" business just appears in the early December paper, after the 125 number was known. The public claims he has been making about having a prediction of "125" before the results were known are just outrageous.

Also in the August slides, there's some sort of "prediction" of a 600 GeV gluino, which I believe has been ruled out by now. Kane conveniently doesn't mention that.

He has been promoting "string theory predictions" of masses of new particles for 20 or more years (see his famous "supertestable" article in Physics Today back in 1997). These "predictions" keep changing, moving up as experimental results come in showing them to be wrong. I guess one easy prediction for anyone to make a few years ago would be that even if the LHC found no superpartners, for the one SM thing it would find (the Higgs), Kane would be there with string theory "predictions" covering the allowable range as it shrunk to the right value.

19. **P**
April 5, 2012

@ Bernhard:

Thanks for the thoughtful response. I think we see eye to eye on SUGRA vs mSUGRA now. Not to say that mSUGRA isn't interesting in it's own right.

Regarding gluinos: which Kane comments are you referring to? I'll take a look at whatever source you send me. Also, in the most conservative experimental sense, everything we can say about not having seen gluinos is in those papers, and the analyses seem to be in very limited frameworks, most of which don't apply to Kane's comments. (I haven't seen one, please show me if there is one!). Though rumors are exciting, I try to limit my thoughts about the existence or non-existence of hypothetical particles to what the experiments have actually said.

Regarding pheno papers: do you have examples from many years ago of serious phenomenologists who strongly pushed for 120-130 GeV SM-like Higgs in a SUSY framework? I'd be curious to see this. SUSY theorists like to talk about light Higgs, and I had really first heard about the stated m_H scenario in press releases (ugh) from Kane et al.

Regardless, hype – yes, it's an enormous disservice to both the string and the non-string community.

Regarding strings – depending on how nuanced you make your statement, our opinions probably differ. Saying that strings will definitely tell you something about scattering amplitudes at low energies (see: our experiments :)) that a field theory model COULDN'T is . . . well, a hell of a claim. There is good work, though, studying stringy scattering amplitudes at the string scale, and they consider M_s ~ O(TeV). It likely is much higher.

The reason for hope, I believe, is that compactified string theory DOES generically give rise to all of the ingredients we see in our world: non-abelian gauge theories, GR as a limit of quantum gravity, and scalar fields which could be of cosmological importance. True, your coming criticism that it hasn't yet singled out OUR gauge theory or OUR cosmology is a good one (and it may never), but of course field theory doesn't do this either . . . and moreover nothing in field theory requires the existence of gauge theories , GR, or scalar fields – they're input. In string theory, they're output. This compelling, and I think that if there were any other framework for physics that naturally gave rise to these three things as the output of fundamental principles, string theorists would take it seriously.

20. **Thomas Larsson**
April 5, 2012

Actually, it is possible to use string theory to make falsifiable predictions about the LHC. I made one back in 2007.

I'm especially proud that I already in 2007 could predict that poor Lubos would lose his experimental-susy-by-2006 bet, considering the he evidently hasn't realized it himself yet.

21. **Anon**
April 5, 2012

I know it sounds like a cliche, but "history will determine the truth".

You can't enforce truth by effective policing.

22. **Shantanu**
April 5, 2012

Peter, have you look at Susskind's talks at the KITP conference on bits/branes/black holes?

23. **Peter Woit**
April 5, 2012

Shantanu,

Not my kind of thing, but others might enjoy. Sounds like he's getting into the "philosophy of cosmology" business. If he'd stop saying mean things about religion, he'd be a natural for the Templeton Prize.

24. **P**
April 5, 2012

@ Peter:

Sorry, I didn't see your post from earlier in response to me. Clearly you're not a fan of Kane, and I'm also not a fan of the hype.

So I'm still not sure what you're really taking issue with regarding the slides from August. He clearly says 127GeV in those slides, and if you want to nitpick about 125.5 GeV and 127 GeV, that's fine, and you can take issue with that. In my mind, the thing that's interesting about the current location of the bump isn't that it's 125.5 and not 127 or 125 – it's that it's significantly about the 115-118 GeV often preferred by SUSY theorists (who might have told you SUSY like it below 100 pre-LEP).

25. **Peter Woit**
April 6, 2012

P.,

The "127" is not explained in the slides, and it doesn't appear in the paper. If "127" is the first actual prediction from string theory, it would be nice if Kane would explain the 127 in his paper. It would also be nice if he wouldn't call "127" "125". Again, the bottom line in his paper appears to me to be a graph of points covering the Higgs mass range from 105 to 128 GeV. If the LHC had found a signal at 118 GeV, I have no doubt Kane would have produced a paper about how that number was a "string theory prediction".

26. **P**
April 6, 2012

Peter,

Indeed, in his short talk he spends time explaining his setup and assumptions, discussing the masses of various particles that go into his RGE analysis. Then, at the end, he states the conclusions of the scenarios: heavy scalars, light gluinos, and a single light higgs boson with mass around 127 GeV. Now, if you want to be cynical and say the last number was complete lie and not the result of any analysis, that's fine. To me it seems more plausible that it is the result of an actual analysis, details not included in the paper because of time spent motivating the setup.

Do you think the "about 127" is actually a lie, not the result of an analysis that he didn't present in the slides?

Also, regarding your remarks about the gluinos of his scenario being ruled out: show me the paper that makes the same assumptions as his model. Some ATLAS papers clearly do not make the same assumptions. They may very well have ruled out his model, but I haven't seen it.

Cheers,
P

27. **P**
April 6, 2012

Also, sorry to be a stickler about this, but again, the surprising thing about "about 127" or the "125.5 +- error bars" is that it's a heavier Higgs than expected by most SUSY theorists.

For historical comparison: the ever useful Wikipedia (someone should check PDG) tells me that the error bars on the top quark mass are +- 1.5 GeV. Even if you want to ignore the "about" in "about 127", a 1.5 GeV discrepancy is not uncommon. In fact, though CMS was originally worried about being 2 GeV or so lower than ATLAS for m_H, this caused some worry but not enough to make strong statements. So I don't understand why you're harping on this.

Regarding claims that it is generic in string theory, I'm not sure, and in fact I'm skeptical and definitely think he shouldn't be hyping it. But I don't question the results of a field theory analysis.

28. **Peter Woit**
April 6, 2012

P,

I simply don't know what the argument for the 127 is. The situation here is that you are claiming that Kane had a good argument solving the biggest problem in particle theory, fixing the Higgs mass at 127 back in August using string theory, but didn't bother to give details of it in his talk or publish it. Then, several days after the 125 news came out, he puts out a paper with no 127 in it, but with an argument for 105-129, with above 122 "preferred". He then uses this to launch a publicity campaign claiming that he predicted from string theory the "125" long before it was announced. People can draw conclusions from those facts.

I also have no idea what his "string theory predictions" for gluinos are. He has a plot showing what appears to be about 600 GeV for the mass, was publicly claiming back in December that confirmation of his predictions was imminent, now acknowledges in his slides that "current limit for gluinos from string/M theory about 700 GeV" (page 33).

Yes, it's a heavier Higgs than you get from other popular string theory models. If the LHC had found a lower value, Kane would be giving talks about how string theory predicted the Higgs mass using those models.

I'm not arguing about what a reasonable size of error bars is here, either experimentally or theoretically, just pointing out that he never gives any error bars on his "string theory predictions".

29. **anon.**
April 6, 2012

CMS PAS SUS-11-020 excludes gluinos decaying through top quarks up to somewhat more than 800 GeV. ATLAS CONF 2012-004 sets ~ 700 GeV limits on gluinos decaying to stop/chargino, which is a similar topology to what you could get in the model under discussion. Standard jets + missing ET searches also set limits. Gluinos decaying to b+bbar+neutralino are excluded to ~900 GeV by 1203.6193 from ATLAS. Depending on branching ratios for gluino -> t+tbar+neutralino versus gluino -> t+bbar+chargino, you might not find an official CMS or ATLAS result excluding this scenario, but the gluino mass bound is probably ~ 800 GeV or higher, independent of all these details.

It would be a real stretch to say there's a sharp prediction of the gluino mass in these models, so you can't really say this rules them out. It's above what Kane was predicting a year or so ago, though.

Aside from the various overly strong claims, there are some basic facts that are worth bearing in mind:
* A Higgs mass of 125 GeV in the MSSM requires large mass parameters in the stop sector. This could be a very large A-term, with somewhat light stops. But it seems increasingly plausible that if the MSSM is right, some variation on split SUSY is the right model to be thinking about, with scalars in the range from ~ 10 TeV to 1000 TeV. The upper end of that range only fits a 125 GeV Higgs if tan beta is quite close to 1.
* The one input string theory really provides is that it suggests the existence of moduli, i.e. of scalar fields coupling with gravitational strength. With that ingredient,

standard effective field theory tells you that they probably have a mass near the gravitino mass and that this is a cosmological disaster unless the gravitino mass is ~ 30 TeV or higher.
* As observed by Randall & Sundrum in 1998, anomaly mediated SUSY breaking can make a 30 TeV gravitino consistent with ~ 1 TeV gauginos, and moduli decays can then produce dark matter (as explained by Moroi & Randall).
* And, as Giudice, Luty, Murayama, & Rattazzi noted in their simultaneous work on anomaly mediation, such a scenario can plausibly lead to scalars a loop factor heavier than gauginos. This kind of scenario was also studied by James Wells, and then Arkani-Hamed & Dimopoulos.

So, if we relax our idea that electroweak symmetry breaking should be completely natural, we have a supersymmetric scenario consistent with the measured Higgs mass and the observed fact that gauge couplings in the MSSM unify. The scalars are quite heavy but the gauginos may be in reach of the LHC. The moduli problem is solved, and flavor isn't quite as bad as in standard scenarios.

This basic idea was already around in 1998/99. Kane has essentially advocated a specific version of it, tied to a particular model of moduli stabilization. It's not quite identical to the preexisting split SUSY idea, since he has contributions to gaugino masses not coming from anomaly mediation, but of the same order. But it's basically a(n idiosyncratic, overhyped) variation on an idea that has been recognized as important for a decade.

30. **Peter Woit**
April 6, 2012

anon,

Thanks for the very helpful explanations.

31. **alsoanon**
April 6, 2012

An addition to anon. above. Even the large threshold corrections to the anomaly mediated gaugino masses is not a novel feature of the Kane model. Arkani-Hamed, Giudice and Delgado introduced the "simplest split susy" model in Jan 06, with one-loop splitting between scalars and gauginos, but also higgsinos around the same scale as the scalars, which completely changes the anomaly-mediated gaugino spectrum. Another point: as can be seen from the plots in Giudice and Strumia 's paper, http://arxiv.org/pdf/1108.6077.pdf, figure 3, stops at a few hundred TeV (as expected from the one-loop splitting) give a higgs near 125 GeV for a reasonable tan beta around 2-3. Taking tan beta close to 1 allows scalars nearer to 10,000 TeV.

32. **Mark**
April 6, 2012

I have studied the papers of Acharya et al and have heard several talks on the topic and I must say that to me the Higgs mass is the least interesting part of the whole story. To me, the most appealing feature of their construction is its simplicity and that it solves many problems simultaneously and in a natural way, the biggest of the problems addressed being the Hierarchy problem. Kane mentions some of those things in his slides so I'm not going to repeat them. However, I wanted to correct the previous poster that in these G2 vacua the gravitino mass scale is constrained to O(10-100) TeV *not* by the relation between the moduli masses and cosmology but instead by the requirement that the leading tree-level contribution to the vacuum energy is tuned to be of the same order of magnitude as the leading one-loop contributions so they could mutually cancel, combined with the constraint on the value of the seven-dimensional volume, which comes from the relation between \alpha_GUT, M_Planck and M_11. In these vacua, when one combines those two together one gets the above constraint on the gravitino mass. I think that it is quite non-trivial that the constraint on the cosmological constant plays a key role in constraining the gravitino mass and it should not be overlooked. Regarding the gaugino masses, just to be more precise, the anomaly mediated terms, which are typically discussed in the literature do not include the Konishi anomaly contribution since people always assumed some sort of sequestering. In the G2-MSSM there is no sequestering and the Konishi anomaly contribution to the gaugino masses is quite large and is directly proportional to the (large) tree-level reduced trilinear terms. So apart from the heavy scalars and trilinears, there is some non-trivial interplay between the trilinear couplings and the gaugino mass spectrum.

33. **anonymous**
April 6, 2012

Good science cares about explanation. Whether an explanation is a prediction or a "postdiction" is just a historical accident. There are plenty of postdictions that are good science, BCS theory of superconductivity being the first example that comes to my mind. The problem with Kane's paper isn't the timing (although that's maybe reason to be suspicious) as much as it is what Peter notes, that the paper pulls 127 GeV out of thin air, not really explaining anything.

By the way, Peter, I heard Erik Verlinde give a well-attended talk at Caltech yesterday. I know you've posted here about his entropic gravity before, so perhaps you would like an update. He said gravity as entropic force would come from string theory, but I took that to mean any underlying microscopic degrees of freedom from unknown physics. The more interesting new contribution was for dark matter. We know how Unruh temperature and Hawking temperature are proportional to accelerations and related to Rindler and black hole horizons, respectively. Verlinde applied the same logic to the cosmological horizon to get a temperature/acceleration. He didn't show all the details, but apparently the acceleration matched the a_0 of MOND. Someone asked how to cope with the Bullet Cluster, and he managed to brush it aside as not in thermal equilibrium. He also at the very end wrote on the board with no derivation a relation between baryonic matter and the inferred dark matter:
Omega_b=(pi/4)*Omega_DM^2
Someone else, Sean Carroll I think, asked how this relation could be time-independent. This question seemed to take Verlinde by surprise. The abstract for the talk advertised dark energy as well, but this was not really covered in the talk.

34. **Peter Woit**
April 6, 2012

anonymous,

Thanks for the update on Verlinde. I'm curious whether much of the audience found him convincing.

In a case where one has a completely clear argument, with assumptions stated explicitly and justification given for them, then of course even a postdiction can be completely convincing. Probably the main reason for being skeptical of string phenomenology models is not that they don't make solid predictions, but that they don't even make any convincing postdictions. If there was even one of the numbers characterizing the SM that had a convincing string theory explanation, that would carry a lot of weight.

Unfortunately, human minds being what they are, it's all too easy to come up with a bogus "explanation" of a number once you know the number. Thus the weight assigned to predictions over postdictions.

35. **Chris Austin**
April 6, 2012

Does anyone know how Kane et al propose to fit the small value of the cosmological constant, given that there are no fluxes in their G2-MSSM scenario?

36. **Peter Woit**
April 6, 2012

Chris,

Looking at page 39 of his APS presentation, the answer seems to be that he proposes to just set the CC to zero and ignore the problem.

37. **S**
April 6, 2012

Chris,
This exact question was brought up at the KITP String Phenomenology meeting back in 2010. A plausible mechanism, where the CC scan is due contributions from gauge degrees of freedom in multiple hidden sectors, was briefly discussed in this talk (watch from 41:50 to 43:30):
http://online.kitp.ucsb.edu/online/spheno_m10/bobkov/rm/flashtv.html

38. **Anonyrat**
April 7, 2012

Is the instability/"fine-tuning" problem in QFT an artifact of perturbation theory, or is it a genuine physical problem?

39. **Peter Woit**
April 7, 2012

Anonyrat,

The explanation of the "fine-tuning" problem in terms of quadratic perturbation theory divergences does look like it might be an artifact of perturbation theory. Another version of the problem though doesn't depend on perturbation theory: the ratio of the Higgs masss (or electroweak breaking scale) to either the GUT or Planck scale is a very small number, with no symmetry to explain it being almost zero. That's one motivation for SUSY, where SUSY is supposed to relate the Higgs to fermions with masses small because of chiral symmetry (this argument is potentially ruined by the SUSY breaking scale being too high).

My problem with this argument has always been that it's not clear why one should take it seriously: we don't know there even is a GUT, or a GUT scale for GUT symmetry breaking, and we have no idea what the relevance of the Planck scale or quantum gravity really is to the Higgs until we have a unified theory. Much of the argument for why the Higgs mass is "unnatural" seems to depend upon unification schemes for which there is no evidence.

40. **Shantanu**
April 7, 2012

Peter, interesting that string theory also predicts MOND. (I thought it predicted
supersymmetry and dark matter)

41. **Chris Austin**
April 7, 2012

Peter and S, thanks.

42. **Bernhard**
April 11, 2012

A bit old news, so perhaps already pointed out already. Sounds like a boring code problem somewhere, but who knows.

I noticed this on the arxiv today:
http://arxiv.org/abs/1204.2795
Compactified String Theories — Generic Predictions for Particle Physics
Bobby Samir Acharya, Gordon Kane, Piyush Kumar
(Submitted on 12 Apr 2012)
In recent years it has been realized that in string/M theories compactified to four dimensions which satisfy cosmological constraints, it is possible to make some generic predictions for particle physics and dark matter: a non-thermal cosmological history before primordial nucleosynthesis, a scale of supersymmetry breaking which is "high" as in gravity mediation, scalar superpartners too heavy to be produced at the LHC (although gluino production is expected in many cases), and a significant fraction of dark matter in the form of axions. When the matter and gauge spectrum below the compactification scale is that of the MSSM, a robust prediction of about 125 GeV for the Higgs boson mass, predictions for various aspects of dark matter physics, as well as predictions for future precision measurements, can be made. As a prototypical example, M theory compactified on a manifold of G_2 holonomy leads to a good candidate for our "string vacuum", with the TeV scale emerging from the Planck scale, a de Sitter vacuum, robust electroweak symmetry breaking, and solutions of the weak and strong CP problems. In this article we review how these and other results were derived, from the key theoretical ideas to the final phenomenological predictions.
Comments: 30 pages, 1 figure. Invited Review for International Journal of Modern Physics A

44. **Luke**
April 13, 2012

Thanks for the reference, Marcus! This is a very nice review article and contains a good summary of what's been known for some time about generic string vacua that result in N=1 D=4 supergravity. The main lesson being that the moduli masses and the gravitino mass are extremely hard to decouple, hence the non-thermal pre BBN cosmological history of the universe with moduli-domination at late times should take over after the radiation domination era, contrary to the standard cosmological picture, hence the axion overabundance problem for f_pq~M_GUT is naturally solved by the entropy dilution due to the moduli decays. Also, the absence of sequestering in string theory coupled with the limits on the gravitino mass from cosmology implies heavy scalars together with the Higgs mass somewhere above 120GeV, if one assumes the MSSM spectrum.

45. **Peter Woit**
April 13, 2012

Marcus,

I took a fairly close look at that last night. The Higgs mass “prediction” is based on the same plot as before, with, after various assumptions, masses between 105 and 129 GeV, with those above 121 GeV “favored”. According to Kane, string theory now predicts only one non-SM effect observable at the LHC, gluinos, and he’s cagey about them. In 1997 he was predicting 250 GeV gluinos based on string theory, last year they were supposed to be at 600 GeV, by December their observation was a “few months” away. Now they seem to be at “less than or about 1 GeV” and “should be observable with 2012 data”. Once the 2012 data is in, I’m sure an explanation will be found for why string theory “predicts” that their mass is above the LHC bounds.

46. **guest**
April 15, 2012

I really like how they simultaneously solved both strong CP and supersymmetric (weak) CP problems in one stoke. I was unaware of this connection before and I think it’s pretty neat that they found it.

47. **Vince**
April 17, 2012

Peter,

Jester has posted about a possible dark matter signal from FERMI. Lubos has posted about it as well, and claims that Gordon Kane can explain it with stringy physics. I wonder: If this does turn out to be a genuine dark matter signal, does this new particle show up in Kane’s earlier paper about how M-theory implies the right range for the Higgs mass (according to the LHC’s results)? If not, does this new particle imply that M-theory is wrong?

48. **Peter Woit**
April 17, 2012

Vince,

I recommend Jester’s (Resonaances blog) article for anyone interested in this. I’m not convinced by the signal, would be more convincing if this were coming from the experiment itself, will be interesting to see what they have to say.

About Gordon Kane’s claims to explain this with string theory, he can explain anything with string theory. You can’t falsify a theory that predicts anything you want.

Theory Bubbles

April 11, 2012
Categories: Uncategorized

In this week's *Nature*, Abraham Loeb, the chair of the Harvard astronomy department, has a column proposing the creation of a web-site that would act as a sort of "ratings agency", implementing some mathematical model that would measure the health of various subfields of physics. This would provide young scientists with more objective information about what subfields are doing well and worth getting involved with, as opposed to those which are lingering on despite a lack of progress. Guess what Loeb's main example is of the "lingering on" category?

> In physics, the value of a theory is measured by how well it agrees with experimental data. But how should the physics community gauge the value of an emerging theory that cannot yet be tested experimentally? With no reality check, a less than rigorous hypothesis such as string theory may linger on, even though physicists have been unable to work out its actual value in describing nature…
>
> **Theory bubbles**
>
> The study of the cosmic microwave background provides an example of how theory and data can generate opportunities for young scientists. As soon as NASA's Cosmic Background Explorer satellite reported conclusive evidence for the cosmic microwave background temperature fluctuations across the sky in 1992, the subsequent experimental work generated many opportunities for young theorists and observers who joined this field. By contrast, a hypothesis such as string theory, which attempts to unify quantum mechanics with Albert Einstein's general theory of relativity, has so far not been tested critically by experimental data, even over a time span equivalent to a physicist's career.

The problem of course is that of deciding who gets to make evaluations of what's a healthy field and what isn't. People with a lot invested in a dying or dead subject have strong incentives to misrepresent the situation (see, for example, the famous Monty Python Dead Parrot sketch). Loeb implicitly compares the current situation with string theory to that following the financial crisis, which was worsened by the ratings agencies assigning AAA ratings to debt not far from default.

> Senior scientists might seem the people best suited to rate the promise of research frontiers. But too many of these physicists are already invested in evaluating the promise of these speculative theories, implying that they could have a conflict of interest or be wishful thinkers. Having these senior scientists rate future promise would be akin to the 'AAA' rating that financial agencies gave to the very debt securities from which they benefited. This unseemly situation contributed to the last recession, and a long-lived bias of this type in the physics world could lead to similarly devastating consequences — such as an extended period of intellectual stagnation and a community of talented physicists investing time in research ventures unlikely to elucidate our understanding of nature — a theory 'bubble', to borrow from the financial world.

The problem of how to get scientists and academics to rigorously evaluate what works and what doesn't is a difficult one. In particle physics, success has led to making progress harder to come by, so just noticing a lack of progress at the rate of earlier times is not enough. String theorists are right to point out that developing ideas to the point that the theory can be compared usefully to experiment could be a difficult goal that may take a long time to get to. They're wrong though not to acknowledge the fact that they're not getting closer, but rather farther and farther away. And misrepresentations about the state of a subject can victimize young students and researchers, induced to devote crucial parts of their lives to something not worthwhile.

I'm rather skeptical about Loeb's faith in mathematical models to provide objective guidance. The AAA ratings assigned to dubious mortgate-backed securities were the product of mathematical models, defective ones. If you let me design the model, I can come up with one that will justify whatever conclusion I want. In the end, outcomes will depend on the quality of the judgment and decisions of those the community chooses as its leaders. Throughout academia, bad ideas live on, and good ones don't get the recognition they deserve. At the same time, in many fields those put in positions of responsibility live up to them and often do a remarkable job of countering the forces promoting stagnation as well as providing a positive vision that drives real progess.

As for Loeb's idea about a web-site where young scientists could go to get information about the health of a field, I remain skeptical about prospects for one that implements a mathematical model. However, a website devoted to honest and informed discussion about what is going on in a field and whether it is healthy, providing a place for students and others to listen to and participate in debate, helping them make up their own minds, seems to me an excellent idea…

Update: I just noticed that Loeb had a paper on the arXiv last year spelling out his proposal in more detail.

Comments

   April 11, 2012

   There is an interesting analogy here between analyzing stocks based on recent price movement (technical analysis), or based on earnings (fundamental analysis). In the long run fundamental analysis is what works, but in the short run in may not.

   It seems like funding and publications are like short term price movements while validation by experiment is more like earnings. I'm not sure about hiring and promotions!

2. **chris bolger**
   April 11, 2012

   Evaluating the health of a research field? I agree with you, how do you do that. It seems to me great advancements in history were made when some egg head told somebody else "This can't done." Indeed, the best advice might be to tell a young physicist to go into the field that such a website says is dying.

3. **piscator**
   April 11, 2012

   The Nature article is behind a paywall, but from your quotes and summary there seems to be not inconsiderable chutzpah for the chair of the Harvard astronomy department to say both that senior scientists are not the best judges of research frontiers and by the way string theory is overfunded.

4. **Peter Woit**
   April 11, 2012

   piscator,

   The "chutzpah" label has been previously applied to Loeb in this context:

http://www.bautforum.com/showthread.php/120202-Physics-Chutzpah

For another sort of argument from him, about encouraging people to also spend time on some riskier non-mainstream work, see

http://arxiv.org/abs/1008.1586

5. **abbyyorker**
April 11, 2012

I think it is ridiculous to think that young scientists need help in ranking fields of study. Typically, they're 20+ and have been thinking a long time on it. Grad students I have known, including future string theorists, know perfectly well the prospects. Many go into string theory anyway, for other reasons (one being that it interests them). Maybe a bad decision but I don't see a coverup of the truth.

6. **anton nymos**
April 12, 2012

"I advocate the need for a website operated by graduate students that will use various measures of publicly available data … to gauge the future dividends of various research frontiers. The analysis can … aim to alert the community of the risk from future theory bubbles. "

Peter, you are not a grad student but I think you have already implemented to some extent his proposal for string theory.

7. **Bee**
April 12, 2012

I've discussed the problem of bubbles of nothing in academia here and here for example. If Loeb had read what I wrote he might have understood that his proposal isn't going to solve the problem. The main problem is not that we need a better way to rate on the promise of a research field or project. The problem is that presently scientists have insufficient incentive to accurately rate it to begin with. I referred to this as "external pressures" that essentially prevent an accurate judgement. As a result, the system, as it is presently organized, doesn't optimize for "most promising research."

To see what I mean, consider the following example that I personally find the most troublesome, though there are other problems: It is hard if not impossible for a scientist to change fields after, say, the 2nd postdoc. At that time, you'll be desperately looking for a permanent position and trying to get in grants. Both will only work if you have a track-record in some field, and that field is in addition considered promising. Taken together, this means researchers will go around and advertise their research field because they're stuck on it. You can't sell your publication's keywords and buy new ones like you buy stocks. It's your history and the way the system presently operates it basically *forces* people to create bubbles of nothing because otherwise they'll end up unemployed!

You can find more details and other examples in my posts. More recently, in my post On the importance of being wrong. we discussed the problem that admitting on having misjudged the promise of a research project is not only not rewarded but actively punished in the community, and wishful thinking is one of the most common biases affecting science.

A "rating agency" isn't going to do anything about what's the actual origin of the problem. In fact, if people came to believe the ratings it would make the problem even worse, because it contributes to a rich-get-richer trend (if there are many people who work in a field there are many people who have all reasons to rate it up).

8. **Rhys**
April 12, 2012

I think Bee makes a very good point. New graduate students have the freedom to choose their field, but tend to be relatively naïve when they do so (I know I was; I couldn't possibly accurately evaluate the worth of, say, string theory, at the time). It's practically impossible to change fields after a year or two of graduate study, because one must write a thesis before running out of funding!

There may then be some freedom to wander during the first postdoc or two, but there are overheads in time and effort associated with branching out, and one is always concerned about writing enough papers, lest the next job not be offered.

9. **Steven Chan**
April 12, 2012

Speaking from a researcher from another field, I had my concerns who string theory develop. I think the comparison with an economic bubble is quite appropriate. One of the biggest problem faced by younger scientists are the need to publish and to be seen "doing"/"producing" something. The string theory "bubble" is self-reinforcing; the bigger the bubble gets, the urge to even make it bigger is even higher due to career pressure.

The biggest difference with an economic bubble is how the bubble could be burst. Real economic bubble burst as balance sheets and debt obligations implode, and people and institutions running out of money. I wonder what mechanism can burst an "academic bubble". I am not sure research grant cuts can actually burst an "academic bubble" – in the ends… it is experimental/field work that cost the most, not theoretical and computer model work. The folks inside the bubble field won't burst the bubble themselves, of course – for the interest of their own career.

What I think may burst the bubble is a major breakthrough in experimental physics that allow a highly competitive and creditable theoretical work to develop.

10. **Peter Woit**
April 12, 2012

Bee,

Thanks for the links to a lot of good discussions of this topic. I agree that young scientists are in their most vulnerable position, with a lot invested in a particular field, and leaving it very dangerous, at the time they don't yet have a permanent position, but need to get one soon. This is the time in people's career that they are least likely to be able to change research topic, so it's not surprising that few do.

What is more surprising is how few people are willing to give up on a failed research program and try something else AFTER they have a permanent position and (at least typically in the US), lifetime tenure. The whole point of the tenure system is to make it possible for people to make this kind of change, but few take advantage of this.

11. **Belizean**
April 12, 2012

> The whole point of the tenure system is to make it possible for people to make this kind of change, but few take advantage of this."

This shouldn't be too surprising. The tenure granting process actively selects those who are either not particularly curious about topics irrelevant to their immediate research or are sufficiently disciplined to suppress any such curiosity. A young condensed matter theorist who devotes a considerable fraction of her time to work on quantum gravity is unlikely to obtain tenure. If a newly tenured professor had in fact been suppressing a burning extracurricular curiosity for years, it is likely that this habit would have become permanently become ingrained.

12. **Jeff**
April 12, 2012

A better analogy IMO would be Technology Adoption and Meme Adoption. Both involve beliefs of what is true as well and they have many dynamics in common, specifically in term terms of human networks and in terms of nonlinear thresholds or tipping points of believe or "paradigm" acceptance.

Rather than "control" these, which generally isn't possible, it may be enough (or better) to simply characterize and comprehend where an idea or theory is in its adoption curve. Not all technologies are adopted and so too not a ideas are adopted. And also some technologies simply are "ready" adoption.

In technology there is the "20 year rule" which basically is the empirically observed time between discovery of an idea and its broad acceptance. When a technology isn't "ready" it typically takes a generational replacement to bring it up for consideration again so often technologies take 20, 40, 60, etc. adoption intervals.

I suspect theories in science follow a similar pattern for similar reasons.

13. **Shantanu**
April 12, 2012

Peter, Avi gave two talks one at KITP and another at CFA talking about these ideas in detail. Anyhow I know from personal experience that its very hard to work on independent ideas (without any sort of encouragement/feedback). I know someone who
has been working seven years tirelessly on a modification of GR, having refereed
publications and inspire of not getting paid a cent for his research, or getting
seminars/conference invitations

14. **Lucy-Lee de Cortez**
April 12, 2012

The irony is remarkable

Tenure is supposed to encourage independent thinking.
But anyone sould see what would happen.
That it would coerce people to think the way the tenure granters tell them to.

Was it always thus?
And was that the purpose all along?
And now, how do you get rid of a system that is so corrupting?

15. **N.**
April 12, 2012

Most researchers do not recognise the simple fact that to admit "I was wrong" means that other fellows might not follow the same path, thus lots of funds, energy, time, etc. could be spared.

I was even considering setting up a "Wrong Nobel" fundation – rewarding those who have the courage and honesty to say aloud "I was WRONG"!!

Unfortunately, the EGO is stronger than any award… (especially with matematicians – sorry Peter :)))

16. **arjun**
April 13, 2012

Bee said: "It is hard if not impossible for a scientist to change fields after, say, the 2nd postdoc. "

I think it is hard to change fields even after a PhD (and this includes subfields of physics), unless one is going into the industry (then one can do whatever one wants to). For one, there is a steep learning curve, and two, there are already many PhDs in the new field who will be in the queue for post-docs.
The only way I can think of someone changing fields (or a subfield) is by getting a second PhD and this time in an area chosen with better judgement—born-again academic.

17. **srp**
April 16, 2012

The obvious answer is that science must go back to recruiting the independently wealthy types like Boyle, Darwin, Noyes, etc. who have little need for external funding. Theorizing is cheap, so someone with a good inheritance could do good work without any need to deal with these institutional problems. Selection from such a narrow group would of course restrict the talent available, but a) you could keep the existing system alongside it and b) those wealthy pseudo-amateurs did a pretty remarkable job over a long period of time.

The implementation barrier is that being an independent scientific theorist is no longer a "cool" thing for the idle rich to aspire to.

Emerging Grant Opportunity

April 12, 2012
Categories: Uncategorized

I just noticed that the Templeton Foundation has a competition for $5 million in grants in the area of "strong emergence", submission deadline very soon (April 16). I'm not sure I understand their distinction between "weak emergence" and "strong emergence" (classical phase transitions are weakly emergent, quantum ones strongly emergent), but they seem to intend to support real physics research, and they're inspired by Philip Anderson's wonderful paper More is Different. This is a refreshing contrast to some of their other ventures I've written about here that tend towards encouraging pseudo-science, so I hope this one is a success and they do more things like it.

Their other current funding opportunity, also with a deadline of April 16, is Breaking New Ground in Science and Religion, which is more the usual kind of thing for them. They don't give a total number for what they intend to spend in this area, but it appears to be much less than the $5 million going to emergence.

Comments

   April 13, 2012

   Peter

   Thank you for the reference: More is Different. Indeed one of the best papers ever written on the subject.

   Don

2. **Chris Austin**
   April 13, 2012

   Thanks for pointing out the Physics of Emergence competition. I've just submitted an entry; I thought the submission procedure was very well designed and organized.

Testing the Holographic Principle

April 12, 2012
Categories: Uncategorized

Adrian Cho at Science magazine this week has an article about Craig Hogan's project to build a "holometer" and somehow test the "holographic principle". Since this promises some sort of experimental test of fashionable ideas about quantum gravity, it has gotten a lot of attention, including a cover story in the February Scientific American (also available here and maybe elsewhere).

This kind of thing often gets promoted as a "test of string theory", but in this case, at least from certain quarters, that definitely isn't happening. Cho quotes Raphael Bousso:

> But some experts on the holographic principle think the experiment is completely off-target. "There is no relationship between the argument is making and the holographic principle," Bousso says. "None whatsoever. Zero." The problem lies not in Hogan's interpretation of the uncertainty relationship, but rather in "the first step of his analysis," Bousso contends.
>
> Bousso notes that a premise of special relativity called Lorentz invariance says the rules of physics should be the same for all observers, regardless of how they are moving relative to one another. The holographic principle maintains Lorentz invariance, Bousso says. But Hogan's uncertainty formula does not, he argues: An observer standing in the lab and another zipping past would not agree on how much an interferometer's beam splitter jitters. So Hogan's uncertainty relationship cannot follow from the holographic principle, Bousso argues.
>
> The experiment can do no good in testing the holographic principle, Bousso says, but running it could do plenty of harm. The holometer has garnered an inordinate amount of attention in the blogosphere and in press accounts, he says, raising unrealistic expectations. "They're not going to have a signal and then there is going to be a backlash saying that the holographic principle isn't valid, and we'll look like we're on the defensive," Bousso says. "That's why I'm trying to get the word out without appearing to make excuses."

There's also the following from Lenny Susskind:

> Not everyone cheers the effort, however. In fact, Leonard Susskind, a theorist at Stanford University in Palo Alto, California, and co-inventor of the holographic principle, says the experiment has nothing to do with his brainchild. "The idea that this tests anything of interest is silly," he says, before refusing to elaborate and abruptly hanging up the phone.

Comments

1. **Shantanu**
   April 12, 2012

   Peter, two swallows don't make a summer. am sure you will find some string theorists who will claim this as evidence for string theory.
   Over the years I have found that string theory agrees with even contradictory facts.
   o string theory is consistent with both equivalence principle and violations of equivalence principle
   o string theory predicts supersymmetric dark matter as well as MOND.
   o string theory agrees with superluminal neutrino as well as neutrinos moving at c.
   someone should add more such examples.

2. **Dan Winslow**
   April 12, 2012

   Well, hype aside; whether it tests the holographic principle or not it does seem to me (as a layman) to be an interesting test. Wouldn't having some quantization of space time affect things like renormalization and other infinity-plagued calculations? Forgive me in advance if I;m not making sense.

3. **Peter Woit**
   April 12, 2012

   Shantanu,

   If Hogan's experiment actually sees something, I have no doubt it will be claimed as "evidence for string theory".

   Dan,
   A quantization of space/time is a holy grail for many theorists, with the fact that it would provide a natural cut-off for QFT calculations just one of many reasons to be interested. The argument here is over whether Hogan's experiment actually is sensitive to such a quantization. It seems overwhelmingly likely that it won't see anything, so Bousso/Susskind are sensibly trying to distance themselves from having their favorite theoretical idea associated with it.

4. **Low Math, Meekly Interacting**
   April 12, 2012

5. **Bee**
   April 13, 2012

   I explained the issue with Lorentz-invariance years ago here. One has to be grateful, I think, to Bousso and Susskind to speak at least a few clear words before hanging up the phone.

6. **Sesh**
   April 13, 2012

   Peter, your first link is missing a semicolon.

7. **Sesh**
   April 13, 2012

Sorry, I meant a colon.

8. **Rhys**
April 13, 2012

I think it's important to emphasise that the holographic principle is independent of string theory; AdS/CFT (of the 'hard' variety) is just the most concrete realisation that has been found. If there is one thing which is thought to be 'known' about quantum gravity, it is the relationship between horizons and entropy.

But as Bousso said, there doesn't appear to be any link between what Hogan is doing and the holographic principle. The "Scientific Bibliography" on the holometer website is extraordinary, by the way:
http://holometer.fnal.gov/scientific-bibliography.html

9. **Peter Woit**
April 13, 2012

Sesh,

Thanks, fixed.

10. **Visitor**
April 13, 2012

"In fact, Leonard Susskind, a theorist at Stanford University in Palo Alto, California, and co-inventor of the holographic principle, says the experiment has nothing to do with his brainchild. 'The idea that this tests anything of interest is silly,' he says, before refusing to elaborate and abruptly hanging up the phone. "

Considering how much of his time and effort is spent in creating and proselytizing for baseless speculations that masquerade as theory, and his appeals to their utility as a philosophical foundation of atheism as a reason to support those speculations, Susskind seems to me to be pretty nearly the last person to be making such a criticism, and this would have severely diminished my opinion of him, had I any positive opinion of him in the first place.

11. **Owen Patterson**
April 17, 2012

While I am sure that Dr. Susskind is a very busy and important man, perhaps if he had taken a few moments to explain things a bit to the interested pleibians huddled outside his door, perhaps we would all be better enlightened and then would not bother the great man with so many such puny questions and theories in the future.

Short Items

April 13, 2012
Categories: Experimental HEP News, Multiverse Mania

- The LHC is back in business, with the experiments collecting data at 4 TeV/beam, marginally higher than last year's 3.5 TeV/beam. They are ramping up the number of bunches in each beam, already this afternoon achieving a higher initial luminosity than the best of late last year. This should be a record luminosity for a collider. One place to follow the amount of data being accumulated is this CMS page.
- Also in Switzerland, another hard to comprehend publicly funded experiment is going on, see details here.

> The Swiss boson is a hypothetical condition which is supposed to account for why the Swiss franc has 'mass' when all other neighbouring currencies don't.
>
> A multi billion-euro experiment, operated by BERN (but funded outright by tax payers), is currently under way on the borders of Switzerland and the Eurozone to try and stamp out the asymmetries, ideally by creating something known as the 'anti-franc'.
>
> As part of the experiment, highly skilled practitioners smash billions of Swiss francs against the euro currency daily, with the explicit aim of blowing apart the franc.
>
> Experiments to date suggest the boson is probably hiding somewhere in the 1.20-1.22 field. Though some say there's a chance of finding it at the 1.25 mark.
>
> Yet as the experiment continues, fears grow that a black hole could unwittingly be created in the current account of the nation — a singularity known as the "ever depreciating euro asset" phenomenon.

- Jean-Pierre Serre has a web-page at the Collège de France where one can download copies of many of his recent manuscripts. There's also a wonderful interview with him here.
- Michio Kaku, the "co-founder of the superstring version of string theory", gave a talk about the future recently in Yakima, Washington. Clifford Johnson reports on a recent phone conversation he had:

> *Michio Kaku says that the universe is full of many things and all you have to do is ask for something and you'll get it. How do you go about doing that?*
>
> Well… I am not sure what he had in mind. It might be…. might be best to ask him…. But maybe what he meant is that the universe is a very big place, with lots of things going on, and maybe he meant that there are all sorts of things you could find out there because it is so big and diverse… But perhaps he did not have in mind that a particular person could go out and get any of those things… but you might want to ask him. I can't say for sure.

Perhaps Clifford should have clarified things for his caller by explaining that it's only string theorists for whom "the universe is full of many things and all you have to do is ask for something and you'll get it".

   The "Swiss boson" article seems to be satirical in nature, Peter. Possibly a belated April Fools' item.

2. **Peter Woit**
   April 13, 2012

   Visitor,

   It's not an April Fool's joke, but yes, it's a satirical comparison of what is going on with the Swiss franc and stories about the Higgs boson. I thought it interesting to see that discussion of the Higgs has gotten so much attention that financial journalists find it a worthwhile topic to use in a satire. Unless you're pretty well informed about the Higgs, you're not going to get the joke and find it funny. That the Financial Times thinks much of its readership will get the joke is kind of remarkable.

3. **MathPhys**
   April 13, 2012

   I usually have negative things to say about M Kaku, but I have just watched the video clip that Peter linked and I must say that he spoke very well in favor of supporting science. He gave a level-headed impression, used the right words and metaphors (no matter how oversimplified) that can make sense to the layman and, hopefully, make a difference.

4. **anonymoo**
   April 14, 2012

   Peter,

   Read the FT piece through to the comments and you'll see that pulling strings behind the facade of "reality" is taken to be the prerogative of the policy wonk. The text-book is Thomas Hobbes' and that should not surprise Ye denizens of Ecclesiastical Polity. This is Scientific Materialism as also preached by Galileo from Tertullian.

5. **Shantanu**
   April 14, 2012

   Peter, see Rabi Mohapatra's talk at PI. e believes SO(10) has to be right.
   http://pirsa.org/12040080/

6. **Joel Rice**
   April 14, 2012

   I have not seen anything so funny on a physics blog in … well, ever.

7. **Joy**
   April 15, 2012

Ok, so electrons collectively interacting in condensed matter can function on a quantum level as a sort of virtual “Majorana particle” (not the public’s idea of a particle, but never mind that)
Prediction: This 1930s concept will be said to be evidence for string theory by midweek

8. **luminosity**
April 17, 2012

It is curious that almost all the posts are to laugh at Kaku/string theory but nobody has anything to say about the LHC and the outstanding work at CERN. When claiming a record luminosity, be careful to restrict to hadron colliders. Or else check what the e+e- colliders achieved, for example at the B factories (including CESR). It’s so easy to laugh at or put down other people. It’s so much harder to come up with a positive contribution of one’s own.

9. **Peter Woit**
April 17, 2012

luminosity,

Thanks for the correction. You’re right, the LHC has not yet quite reached the luminosity levels achieved at the e+/e- B-factories (they are above CESR, but not PEP-II). I agree with your comment that the progress at the LHC is remarkable and this deserves to be noted and appreciated. Unfortunately, as long as things are going well, the LHC likely won’t produce dramatic news until early July. So, to keep people entertained, the continuing antics of Kaku and the string theorists are one of the few possibilities here.

Quantum Gravity at Scientific American

Scientific American is doing a good job this month of putting out stories related to quantum gravity that actually make sense, steering clear of the multiverse and other pseudo-science. This month's magazine has a very nice article by Steven Carlip about quantum gravity in 2+1 dimensions. For a more technical introduction to the subject, Carlip's book and review article are good places to start.

I haven't seen the new May issue yet, but from their web-site, it seems that their cover story on new ideas about "A Unified Physics" is what looks to be an interesting article from Zvi Bern, Lance Dixon and David Kosower: Quantum "Graviton" Particles May Resemble Ordinary Particles of Force, summarized as

> Maybe unifying the forces of nature isn't quite as hard as physicists thought it would be.

I'm curious to see the full article, but I assume it's about the intriguing work on amplitudes of recent years that has shown that supergravity theories have fewer divergences than people thought, for reasons that are still unclear. There's presumably some new symmetry structure here, and understanding it may offer a way around the old argument that "you can't put quantum mechanics and general relativity together, the quantum fluctuations at short distances are just too violent." Maybe you don't need strings, M-theory, the multiverse, and all the other baggage theorists have been weighed down by for the last quarter-century. There has been quite a bit of discussion about this topic here, the earliest posting is this one from 2005. For another take on how these ideas might lead to a new way to handle quantum gravity, the latest visionary talk by Nima Arkani-Hamed from last week at the Simons Center is available here.

Also at Scientific American, George Musser has been producing some interesting blog entries on these topics. There's a video here about the Carlip piece, a story about Darth Vader and the Emperor Palpatine that was discussed here, and a recent nice explanation of work on higher spin theories here.

Update: Also in the May issue, from Davide Castelvecchi, there is a shorter article, *Is Supersymmetry Dead?* with summary

> The grand scheme, a stepping-stone to string theory, is still high on physicists' wish lists. But if no solid evidence surfaces soon, it could begin to have a serious PR problem.

Peskin is still a believer though:

> "It is the next step up toward the ultimate view of the world, where we make everything symmetric and beautiful," says Michael Peskin, a theorist at SLAC National Accelerator Laboratory…
>
> Many are still hopeful. "There are still very viable ways of building supersymmetry models," Peskin says. Expecting to see new physics after just a year of data taking was unrealistic, says Joseph Lykken, a theorist on the CMS team.

   April 17, 2012

   I'm not, by any stretch of the imagination, an expert at any of this, but I heard it said that supergravity still needs a "UV completion" even if it is finite/renormalizable. And string theory is supposed to provide that UV completion. Is this necessary?

   Also, is this allegedly finite supergravity theory a supergravity theory that may describe our universe? That is, is this supergravity theory based on 4D spacetime, etc.?

2. **Proudmemberofthecult**
   April 17, 2012

   @ Vince

   There are two issues here:

   – does N=8 supergravity make sense as a perturbative quantum field theory? (is it finite or renormalizable)
   – what is the complete non-perturbative structure of this theory?

   Bern et.al. have something to say about the first question. The second question is very interesting as it has relevance for black hole physics and many other things. If your interest is in question 2, then it seems at present you need superstring theory to give a well-defined answer. However, we do not know the (full) answer to the second question even for Yang-Mills theories! As far as *perturbative* finiteness is concerned superstring theory is irrelevant.

   Moreover, if N=8 would make sense perturbatively (be finite or renormalizable), there's no reason why it shouldn't make sense also non-perturbatively. This however is very much a handwaving argument.

3. **Peter Woit**
   April 17, 2012

   Vince,

   Yes, this is 4d supergravity. In principle it could describe our universe. It doesn't obviously provide an interesting unified theory though (in the sense that it doesn't explain the standard model or make solid LHC predictions). What's interesting about this though is that it raises the possibility that there are new ways of dealing with QG and making unified theories, you don't need completely new, different degrees of freedom.

   I've repeatedly seen the argument made that "OK, maybe supergravity is alright perturbatively, but there's problem X non-perturbatively, which is solved by string theory". But we know little about supergravity non-perturbatively, and definitely don't have a viable non-perturbative string theory, so any arguments of this kind seem to me less than solid. But, again, even if N=8 supergravity has some problem as a viable unified theory non-perturbatively, the interesting thing is that its unexpected perturbative consistency raises all sorts of new possibilities, opening back up an area of research that had been considered closed off.

4. **Speculative**
   April 18, 2012

I'm no expert so I'm only speaking from a standpoint of analyzing possible reactions, but if N=8 Supergravity is finite, it probably won't dampen string theory research. In my opinion it will probably be a boon to ST because supergravity is a low energy limit of ST. Correct me if I'm wrong, but if a supergravity theory is finite, wouldn't the ST UV completion also be finite? Besides string theory does still hold the promise of a unified theory in a way that sugra doesn't.

I'm not making any judgements on the merits of the theories themselves, I just think this will be a more likely reaction among the HET/String community.

5. **Peter Woit**
April 18, 2012

Speculative,

If N=8 supergravity is finite, that doesn't fix any problem with string theory that anyone was worried about, quite the opposite. It removes the whole "ultraviolet completion" motivation for string theory, since it says that N=8 supergravity already is "ultraviolet complete". Yes, N=8 supergravity does not now provide a viable unified model, but the interesting thing here is that we may be learning something new which could affect our understanding of the possibilities for such models. I go on far too much about this, but I think it has been clear for a while that string theory is a failure on the unification front. The possibilities inherent in string theory for unification have been investigated to death for more than a quarter century, leading to the dismal current state of affairs.

At this point though, having the main motivation for string theory removed isn't likely to convince many string theorists to head for the lifeboats. If the landscape didn't do that for someone, there's no reason not to believe they're not willing to go down with the ship.

6. **Giotis**
April 19, 2012

Peter,

I didn't know that you are promoting N=8 supergravity these days. This is a pleasant surprise from someone who don't believe in SUSY.

7. **Peter Woit**
April 19, 2012

Giotis,

I "don't believe in SUSY" in the sense that I don't believe that the standard version of SUSY is a symmetry that appears in nature. It's not completely mathematically compelling, one doesn't see it explicitly, and breaking it, even spontaneously, leads to a useless mess. However, there are some very interesting mathematical structures involved in SUSY, which likely do have something to do with the real world. An example of the kind of thing I have in mind is Witten's use of "twisted N=2 SUSY" to produce topological quantum theories. Maybe there's some other way of "twisting" SUSY to get something more interesting.

N=8 supergravity doesn't give a viable unified theory, but, if it shows that there is a class of QFT's which give quantized gravity without non-renormalizability problems, I'd love to know why this happens, and how large the class of such QFTs is.

8. **SA**
April 19, 2012

I am surprised that you have not discussed the recent article from Kane, attempting to shift the perception of string theory towards it being a theoretical framework, like vanilla QFT and not necessarily a theory of particle physics.

9. **Peter Woit**
April 19, 2012

SA,

I've discussed Kane's claims quite a lot here, probably more than is a good idea since no one takes them seriously. The "string theory is just a framework, like QFT" excuse for failure has been around a long time, also often discussed here.

10. **Giotis**
April 20, 2012

OK Peter but the thing is that you are facing a contradiction here. All these novel approaches (like those in Musser's posts) which apparently you find very interesting are more or less related to String theory research. They are investigated and promoted by String theorists working within the general context of String theory and become important due to that.

Amazingly String theory incorporates every promising idea in high energy theoretical physics and soon you won't be able to talk about anything without referring to the general String theoretic framework.

In fact this general framework would become so large that practically would be synonymous to high energy theoretical physics.

This ship is unsinkable…

11. **Peter Woit**
April 20, 2012

Giotis,

"This ship is unsinkable…"

I don't doubt that whatever idea has some success, string theorists will insist it is "string theory", since there will be some connection of some sort between it and at least one of the tens of thousands of "string theory" papers written over the last 30 years. At this point, Strings 20XX mostly has nothing much to do with string theory. Where this was going was clear back at the time of the following quote, way back in 2005

"Most string theorists are very arrogant," says Seiberg with a smile. "If there is something [beyond string theory], we will call it string theory."

Whatever. If a great discovery is made that gets us beyond the SM that will be wonderful, no matter how many string theorists will insist on saying it is "string theory" to make themselves feel better about the wasted last quarter-century.

12. **Aleksandar Mikovic**
April 21, 2012

String theory is not the only known theory which provides an UV completion of quantum General Relativity. Spin foam models of quantum gravity are another example, and it has been recently shown that the EPRL-FK class of spin foam models has representatives whose classical limit is General Relativity, see
arXiv:1104.1384, Effective action and semiclassical limit of spin foam models,
A. Mikovic and M. Vojinovic,
Journal-ref: Class. Quant. Grav. 28, 225004 (2011).

Adventures in Peer Review

April 18, 2012
Categories: Uncategorized

Yesterday's New York Times had an article by Carl Zimmer about increasing numbers of retracted papers in the biological sciences. Physics and Mathematics weren't part of the story and I don't know of any evidence of retractions increasing in these fields (although maybe they should, given the Bogdanov and other scandals).

There's a blog called Retraction Watch where they follow these things, and they have come upon a mathematics example. A couple years ago the Elsevier publication *Computers and Mathematics with Applications* published the article "A computer application in mathematics". It's less than a page long, one author has a yahoo.com e-mail address, the other a budweiser.com address. Last week Elsevier finally got around to acknowledging that something was up, publishing a retraction notice that explained:

> This article has been retracted at the request of the Publisher, as the article contains no scientific content and was accepted because of an administrative error. Apologies are offered to readers of the journal that this was not detected during the submission process.

I gather that this is behind a paywall, so you need to be at a place like Columbia that pays Elsevier a lot of money, otherwise you can't read the retraction. That's also true of the original paper, but if you want to violate all sorts of intellectual property laws, you could click here.

Comments

1. **Mean and Anomalous**
   April 18, 2012

   Thanks. Sean Carrol at Cosmic Variance is exploring this same topic, but he did not mention the Bogdanov affair (last I checked).

2. **Rhys**
   April 19, 2012

   My favourite bit have to be this:

   "In brief an impossible proposition was proved as possible. This is a problematic problem."

   Yes, it is!
   Obviously something went badly wrong here, but the whole peer-review system is a bit shaky, as it depends on referees being conscientious, with no tangible rewards if they are so, or serious repercussions if they are not.

3. **DaniH**
   April 19, 2012

   Dear Peter,

   In relation to the Elsevier paper, the "bad habits" of Elsevier are well known in part of the physics community and most of the mathematical community. It is well-known, for example, the case of the journal Chaos, Solitons and Fractals where the editor-in-chief, El Naschie, published tens of papers without any peer review.
   Some more cases in mathematics can be found at Math2.0
   The peer review model has serious problems and some are discussing alternatives there.

   Offtopic: I am still astonished to see that most of the physics blogs have not said a word about the ongoing Elsevier boycott. I invite everybody interested to visit The Cost of Knowledge

4. **Cesar Laia**
   April 19, 2012

   That paper is a funny (and extreme) example of how things go wrong, but I think it is impossible to avoid these sort of things. I wonder how many papers are being overlooked or hyped, and how to many papers are being ignored or refused because they don't meet certain obscure criteria of editors, readers or reviewers… it's a sociological pain.

5. **Aidyan**
   April 20, 2012

   A quite natural consequence of the "publish or die" and "impact factor" philosophy of our actual academic system. Goedel published only a handful of papers. De Broglie did not much other significant work beyond his particle wave relation paper. A giant like Feynman published about 120 papers but half of it were reviews, reflections, philosophical commentaries. While I find those who boast about their "more than 200 papers in peer reviewed journals" (and are perhaps only 40 years old…) as laughable little midgets on stilts. Most of these are at best good science managers, politicians, academic barons who have under their feet several little soldiers who work for them and sign their papers. A system where a Sadi Carnot or a Gregor Mendel would have no chance, as they in fact didn't have, or a new semi-autistic Dirac would be discarded from the outset because of his scarce PR qualities (or because being a former engineer…). A system so obsessed by presenting to the audience its "renowned physicist" being 'brilliant' in talking and joking during their PPT presentation, instead of looking for new ideas. A system obsessed by deadlines and of "over secrecy, and rushing out their papers to beat their competitors" that it obviously had to produce 'faster than light neutrinos'. Papers retracted? Maybe, to understand what really stands behind it, it would be worth to take a look also at some of the papers rejected.

Spring in the Virgin Islands

April 19, 2012
Categories: Uncategorized

One thing that a career in math or physics research can get you, courtesy of financial industry wealth, is a nice trip to the Virgin Islands. A couple current possibilities are:

- The Simons Foundation funds week-long Simons Symposia, at Caneel Bay, on St. John. The next one is next week, on Knot Homologies and BPS States. These are serious, invitation only, family members discouraged, events. To get this trip you better be a top expert in a specific field of the Symposium. The Simons Foundation plans to accept proposals for next years Symposia in the fall, see here.
- If you're a "renowned physicist", preferably one with a Nobel prize, then you're eligible for a trip to financier Jeffrey Epstein's own Virgin Island, Little Saint James. Epstein (described by Wikipedia as "an American financier and science philanthropist, and convicted sex offender") a couple weeks ago "Convened a Conference of Nobel Laureates to Define Gravity", according to this press release from his foundation. The event was organized by Lawrence Krauss, who is quoted as describing the situation as follows:

  > "Right now we're floundering," Krauss admits. "We're floundering, in a lot of different areas."

Comments

1. **jpd**
   April 19, 2012

   "an American financier and science philanthropist, and convicted sex offender"
   i am not sure which is most disgusting

2. **Yatima**
   April 20, 2012

   Financier – Provides jobs and shifts resources where they are needed
   Science philanthropist – Provides money for people to perform tasks that do not need to show a ROI next quarter
   Convicted sex offender – For all we know, bonged a slightly underage beauty early in his life to the great horror of the "no fun allowed" puritanicals around

   À priori, I see nothing to be disgusted about.

3. **Peter Woit**
   April 20, 2012

   I think the two comments above more than enough cover the range of reactions to Epstein's sexual behavior. Please, that's enough on that topic.

4. **Tim Duckley**
   April 20, 2012

   How should we construe the lack of Witten at the conference? Did he refuse to go or was he refused an invitation? Were you invited Peter and if so why did you refuse to attend?

5. **Peter Woit**
   April 20, 2012

   Tim Duckley,

   Since attendees at Epstein's symposium are supposed to be physicists with Nobel prizes or equivalent scientific achievements, it would be absurd to invite me. If instead of "renowned physicists", he decides to have a symposium of "renowned physics bloggers", maybe I'll get invited. I have no objection as a matter of principle to helping wealthy financiers spend their money.

   I have no idea if Witten was invited, his achievements certainly qualify him for an invitation. Unlike me though, Witten is a very serious person, I suspect not much interested in the entertainment value of a week of hob-nobbing and snorkeling with illustrious people. So, I wouldn't be surprised if he turned down this travel opportunity (and many of the others he gets offered). For a somewhat related story, I was amused to read in David Kaiser's "How the Hippies Saved Physics" about how a yearly series of Werner Erhard-funded theoretical physics conferences came to an end once string theory took off, so Witten's presence would be expected, but Witten (quite sensibly…) wanted nothing to do with that sort of thing. See my review of the book here:

   http://www.math.columbia.edu/~woit/wordpress/?p=3785

6. **Shantanu**
   April 22, 2012

   Peter or anyone else, is there a website for this conference? Note that there was a similar one in 2006 http://www.phys.cwru.edu/events/grav_ws.php

7. **Don Murphy**
   April 24, 2012

   Shantanu:

   I sent Krauss and email asking if there is a website for the conference and if there will be any results published. I am awaiting a reply. I found nothing on his website.

   Don

8. **Wojciech Langer**
   May 9, 2012

   It is hard to reply to this very well 'camouflaged' information – so many restrictions placed by the author 🙂

I found this site looking desperately for any reviews or comments by scientific community, regarding recent Krauss' book "A Universe from Nothing".

I read Krauss books 7 years ago: "Quintessence" and "Hiding in the Mirror", both quite good. Man , oh man, how he has 'evolved' since then!
Epstein's recent 'conference' info can be found googling 'Epstein Foundation'.
The conference was IMO essentially meaningless to the scientific world (as per Krauss quote), but snorkeling must have been nice! What money can do!

Weinberg on the Crisis of Big Science

April 21, 2012
Categories: Uncategorized

Steven Weinberg has a new article in *The New York Review of Books* on The Crisis of Big Science, which is based on a talk he gave this past January at the American Astronomical Society meeting in Austin (for some discussion of this, see here and here).

Weinberg is rather gloomy about prospects for particle physics, seeing dim prospects for a new generation of particle accelerators, especially in the US. He goes over the sorry story of the SSC, which he was deeply involved in, and worries that the same thing is happening to the James Webb Space Telescope project. He argues that progress is particle physics will be difficult without going to higher energies:

> The discovery of the Higgs boson would be a gratifying verification of present theory, but it will not point the way to a more comprehensive future theory. We can hope, as was the case with the Bevatron, that the most exciting thing to be discovered at the LHC will be something quite unexpected. Whatever it is, it's hard to see how it could take us all the way to a final theory, including gravitation. So in the next decade, physicists are probably going to ask their governments for support for whatever new and more powerful accelerator we then think will be needed…
>
> That is going to be a very hard sell. My pessimism comes partly from my experience in the 1980s and 1990s in trying to get funding for another large accelerator….
>
> During the debate over the SSC, I was on the Larry King radio show with a congressman who opposed it. He said that he wasn't against spending on science, but that we had to set priorities. I explained that the SSC was going to help us learn the laws of nature, and I asked if that didn't deserve a high priority. I remember every word of his answer. It was "No."…
>
> All these problems will emerge again when physicists go to their governments for the next accelerator beyond the LHC. But it will be worse, because the next accelerator will probably have to be an international collaboration. We saw recently how a project to build a laboratory for the development of controlled thermonuclear power, ITER, was nearly killed by the competition between France and Japan to be the laboratory's site.
>
> There are things that can be done in fundamental physics without building a new generation of accelerators. We will go on looking for rare processes, like an extremely slow conjectured radioactive decay of protons. There is much to do in studying the properties of neutrinos. We get some useful information from astronomers. But I do not believe that we can make significant progress without also pushing back the frontier of high energy. So in the next decade we may see the search for the laws of nature slow to a halt, not to be resumed again in our lifetimes.

He has similar worries about cosmology:

> But cosmology is in danger of becoming stuck, in much the same sense as elementary particle physics has been stuck for decades. The discovery in 1998 that the expansion of the universe is now accelerating can be accommodated in various theories, but we don't have observations that would point to the right theory. The observations of microwave radiation left over from the early universe have confirmed the general idea of an early era of inflation, but do not give detailed information about the physical processes involved in the expansion. New satellite observatories will be needed, but will they be funded?

I'm not well-informed about what is going on with large projects in astronomy like the JWST, but do see news reports about cancellation or possible cancellation of important and valuable instruments which people have been working on for years. It's likely Weinberg's arguments are highly relevant in these cases. About particle physics though, I fear he neglects to mention the underlying scientific and technological difficulties of going to higher energies. A major reason why things look gloomy for another generation of colliders is that it's not clear what to build. Electron-positron colliders like ILC/CLIC would be very expensive, and not necessarily get to energy levels above those reached by the LHC. They would be excellent tools for studying TeV-scale physics, but if the LHC has shown there's no new physics there, the case for building them will be hard to make. Probably the best bet for going to higher energy is the HE-LHC, an LHC upgraded with higher field magnets. The technological limits on such magnets though will make it hard to go to dramatically higher energies. If no new physics besides the Higgs shows up at the LHC, there won't be a good reason to expect it at HE-LHC energies. The case for the LHC was a slam-dunk, because we knew that the Higgs or something doing the same job had to be accessible at LHC energies. What there will be for an HE-LHC to study is less clear.

An HE-LHC would of course be built in Europe, so prospects for a new collider in the US are very dim indeed. Weinberg attributes the problem to a failure of the US to support scientific research, and the public good in general (please, take discussion of his political arguments elsewhere, I'm sick of this already, and November is a long ways away…). About support for science I think he's a bit disingenuous though, arguing:

> Funding is a problem for all fields of science. In the past decade, the National Science Foundation has seen the fraction of grant proposals that it can fund drop from 33 percent to 23 percent.

without noting that the NSF has seen sizable budget increases over the past decade. The fact that the number of Ph.Ds in the subject is increasing much faster than funding for them to do research is another problem…

Comments

1. **uair01**
   April 21, 2012

   I hate to be obnoxious but isn't there some truth in what the congressman says? At least something to take seriously? I'm not a scientist so for me the fundamental research into neutrinos and Higgs bosons is a beautiful cultural enterprise, akin with art and poetry, beautiful, inspiring and life-value-adding but not something that "puts bread on the table". And if I have to spend my tax money on fundamental research then I would prefer to invest it in research on nuclear fusion – that scientists have been promising us for 50 years already – because that would solve a lot of our energy and climate problems. I don't see deep particle physics or cosmology doing that – let alone all the money that is spent on string theory.

2. **Peter Woit**
   April 21, 2012

   uair01,

   Money spent on string theory is negligible compared to everything else being discussed. Similarly, funding for deep particle physics and cosmology research is small compared to energy and climate research. The usual argument that we can't do particle physics because we need the money for X isn't very compelling since typically money already spent on X is 1-2 orders of magnitude higher.

   To me, the question is whether the particle physics community can come up with a compelling plan that can be funded at a level around the historical budget fractions devoted to fundamental research of this sort. You're always going to have people with different views on what society should fund, and maybe things will shift and those opposed to spending even a small fraction of the budget on fundamental research will impose their will. But no one should be under any illusion that eliminating particle physics funding is going to make a dent in overall budget problems.

3. **SteveM**
   April 21, 2012

   Increasing vision is increasingly expensive: peering deeper into space or the structure of matter takes bigger telescopes and accelerators, which simply cost more and more until there is a cut off. If the LHC finds nothing except the Higgs then it will probably be a last big accelerator project. But the congressman was flat wrong. The status of the US as a superpower depends in part on it being able and willing to pursue projects like the SSC. The purpose of fundamental research is that we don't know what the long-term potential applications could be. I guess in the 20s the emerging field of quantum mechanics must have looked pretty useless but it eventually spawned the transistor, laser and microchip, leading to vast new industries and sources of wealth. The problem the US is facing in big science right now is that it is not losing out in just one area but that it is losing its edge, to Europe and Asia, right across the board: in particle physics, space/aerospace, fusion, biology etc. The space shuttle is now in a museum and pretty soon Fermilab will probably become a science museum. Some of these issues are also discussed in this video featuring a distinguished panel with James Simons, Michio Kaku, biologist Craig Ventor and others..

   http://www.youtube.com/watch?v=i8lKGdDsHfg

4. **Anonyrat**
   April 21, 2012

   In a country where about 40% of the electorate subscribes to the notion that taxation is theft, it is hard to gain support for large government-funded science projects. This is true even if overall spending on science is rising. The big ticket item still serves as a lightning rod.

5. **sam coleridge**
   April 21, 2012

   By far the most important system for in situ (under water) observation of the ocean for climate is NOAA's fantastic TAO array which spans the entire tropical Pacific.

   http://www.pmel.noaa.gov/tao/

   Its annual running cost is of the order of $10m (that's m for million) yet the lead scientists are endlessly defending it. The array should be extended into the subtropical N and S Pacific, at the cost of a few more $10m. Fat chance. Folks should not blame the shortage of funds for HEP on climate research.

   By The Way whenever I have told taxi drivers about the TAO array they would go totally ape. They always said: "THAT is what we should be spending tax dollars on".

   BTW(2) I am not funded by TAO nor NOAA.

6. **Peter Woit**
   April 21, 2012

   sam coleridge,

   No one is blaming the shortage of funds for HEP (to the extent there is one; as I tried to make clear, a big problem is that HEP is facing difficulties no amount of money can solve) on climate research. It's a good idea to keep in mind though that if there's a fight over funding for some particular HEP project and it gets canceled, I'm quite sure that the money is not going to be redirected to the TAO.

7. **Thomas Larsson**
   April 21, 2012

   SteveM. Physics discoveries like EM or QM may have been esoteric in their days, but they were esoteric on terrestial energy scales. TeV physics is relevant in supernovas or in the Big Bang, but will never be relevant on earth. You cannot build a nifty gadget if you need to carry around an LHC to create the relevant state of matter.

8. **Peter Woit**
   April 21, 2012

   Thomas,

   Please avoid the unpleasant use of ad hominem arguments, they're really unhelpful, so I've edited your comment to remove them.

   I actually agree that it seems unlikely that better understanding of TeV scale physics will lead to practical applications. However, in the early part of the last century it might have seemed obvious that nuclear energy scales could never be practically relevant. Probably a lot of people believed this up until the day Hiroshima was annihilated.

   The interesting discoveries at the LHC will be the ones that tell us about the Higgs mechanism. It is not inconceivable (although I agree, not likely) that understanding the Higgs mechanism could in the distant future have some sort of application.

9. **Trulo**
   April 21, 2012

   Thomas, I agree with you on general grounds, but with one important caveat. If in 1980, say, I'd have asked you what use is GR on human or even terrestrial scale, I'm sure you'd have told me no use at all. Yet, today you probably have a GPS device in your car.

   The moral of all this is that natural laws must be there at our disposal when we need them. Much like books in a library, most of which hardly anyone ever reads. But still they must be there in case we need them. For that to be possible we need to discover them in the first place.

10. **SteveM**
    April 21, 2012

    Thomas, not sure what I said to merit an ad hominem response. (Now edited, before I read it.) But I really meant fundamental research in general, across the board in all areas, and not just in TeV-scale particle physics, which I strongly support nonetheless. Maybe I'm an idealist but I think fundamental big science research and the quest for pure knowledge–whether it can ultimately be applied or not–is the best investment there is, esp. for the US. Certainly money better spent than the trillions wasted on wars, "wars on terror", and bailing out certain dysfunctional and dated financial firms.

11. **Z**
April 21, 2012

What are the prospects for a muon collier in the next 20-30 years? There was a lot of talk about such an idea a few years ago, with the principal reason being much higher energies, or lower cost compared to the ILC.

But I haven't heard much of this idea recently. What are the technical or economical problems with it?

12. **ChuckO**
April 21, 2012

If physicists would really like the government to fund the next-generation collider in the US, all they would have to do is convince Congress and the Pentagon that it would lead to the development of some sort of super weapon.

13. **uair01**
April 21, 2012

The discussion raises interesting questions for me (as an outsider). I'm convinced by Peter Woit that the amount of money spent on "esoteric" physics is negligible compared to the rest of the research budget. But what about the intellectual energy? Would it be possible to redirect it in a fruitful way? For example, could people switch fruitfully from deep particle physics to nuclear fusion? And could young scientists be motivated to choose one field over another? And should we meddle with the mechanism or should we leave it to the "free scientific market" and could a "scientific plan economy" work at all? Thinking about all the serendipitous discoveries we should probably not try to steer the process, but then Woit & Smolin have already demonstrated that the process is not fruitfully self-regulating.

14. **Tony Smith**
April 21, 2012

Steven Weinberg said (New York Review of Books 2012) about The Crisis of Big Science:
"… What really motivates elementary particle physicists is a sense of how the world is ordered – it is, they believe, a world governed by simple universal principles that we are capable of discovering.
…
But not everyone feels the importance of this.
…
What does motivate legislators is the immediate economic interests of their constituents
…
Perhaps if the SSC had cost more, it would not have been canceled. …".

What if the USA physics community (prominent figures like Steven Weinberg, and associations such as APS)
proposed a $1 trillion project to understand more about fundamental high-energy physics
and
to create jobs for subcontractors which jobs would be required to be USA jobs spread out over the entire USA
?
The $1 trillion would allow for at least 3 projects:
1 – reconstruct the Texas SSC and raise its energy to 100 TeV
2 – a Linear Collider (maybe on a midwest site)
3 – a Muon Collider (maybe in the Pacific area on a site far from cities to minimize radiation hazard, say in eastern Oregon or Washington)
Subcontractor jobs could be spread all over the USA.
The projects should be built to a gold-standard with no cost cutting
in order to guarantee spending all of the $1 trillion and maximize job creation.

The $1 trillion could be directly funded by the USA government as part of the Quantitative Easing (effectively money-printing without raising any specific tax rates) program
that has already put multi-trillion dollar amounts into propping up the Derivative Casino of the Big 5 Banks.

Maybe the APS and prominent physicists might make a clear and loud case
that understanding fundamental physics is more important to human civilization than any Derivative Banking Casino
and
that a revived SSC will give more jobs/money to the bulk of the population
than does putting trillions in the pockets of Derivative Casino Bankers
and
will at $1 trillion actually cost LESS than the multi-trillion dollar QE bailouts already spent on the Big Bank Derivative Casino.

Tony

PS – I would like to add another Steven Weinberg quote, from a 28 June 2011 Bloomberg article by Zinta Lundborg:
"… the students who really are so good that they can feel they are going to be part of the effort of discovering the fundamental principles of nature … stay in the field.
It's the students who are not so sure of that who migrate into Wall Street.
I don't know of any cases where a student was doing really first-rate work who then moved into Wall Street. …".

That seems to me to be yet another reason for the projects of the first-rate students to get at least $1 trillion from the Quantitative Easing program that has already given multi-trillion to the Wall Street of the second-raters.

PPS – To those faint-hearted souls who might say that such a project might not succeed in the political climate of today's USA, I say that
you will never find out unless you try: I CAN'T NEVER DID.

15. **Roger**
April 21, 2012

No amount of money is going to "take us all the way to a final theory", as Weinberg advocates. As long as he states his goals in terms of these unachievable fantasies, the congressman is right to say "No".

16. **Steven C**
April 21, 2012

Given current political environment, very expensive and high profile science projects are going to be hard political sell. Even overall science spending is relatively small in US budget, science bearing part of the cost of US fiscal problems is expected. I do have to agree that under current political environment, prioritizing projects are definitely necessary.

If there is one thing I am against the tone of Dr Weinberg, what science folks should do is to sell/market/talk to the public the coolness, applications, and benefits of science. That would probably manage the expected science funding cut. I dislike the gloomy and negative tone (especially when some of the gloominess is not based on current physics possibilities as some poster stated already – you don't build a particle collider for its own sake – one does need to show possibility of new physics from whatever new collider). Instead of talking about fear that we may fall behind, we may better off selling projects that we know it may work, and make the projects sexy to the public.

17. **Peter Woit**
April 21, 2012

Tony,

The only problem with this plan is that if the Fed could be convinced that helicopter drops of cash should be directed elsewhere than the large banks, HEP physicists wouldn't be the only ones with their hands out. We could however possibly convince Simons and Epstein to stop wasting their money on directly supporting science, and instead start pouring their billions into electing officials who would make sure HEP gets the lion's share of any further QE. After all, that's what other interest groups are doing…

18. **Aidyan**
April 21, 2012

People are getting more and more skeptical of the so called 'big science'. And rightly so. The genome project promised us miraculous cures for genetic diseases, but now we know that it miserably failed. The ISS was advertised as a great revolution for material science, but so far not much came out of it. It is now half a century that they are telling us that controlled nuclear fusion would save us from future energy crises, but it is still unclear if it is possible even in principle to build the plasma containing walls. Astronauts were send to the moon but today everyone realizes that it was only about the cold war and politics, certainly not about science (and where is the 'giant leap for humankind.'..?). The Space Shuttle was supposed to become cheap and reusable, instead it turned out to be a bottomless pit. Another half of a century on cancer research produced equally very partial and disappointing results. It is now at least three decades that I hear about the coming bio-engineering revolution that should save the world. And we are still waiting…. And responsible of this state of affairs are to a good extent not only politicians but also men of science (I remember Carl Sagan lobbying for sending men on Mars… oh, no please not….).

But, what about funding several small science projects instead of a single big science one? Does it really make sense to divert all the funds, efforts and skills of people into the n-th mammoth project? It has become easier to get mi-bi-tri-zillions for conventionally accepted lines of research than for small and cheap original projects. I saw how it is sometimes almost impossible to get only 50.000 dollars for a post-doc working on a little but novel and original non-mainstream line of research just because it is new (i.e. risky), original (i.e. of uncertain effectiveness), and non-mainstream (read: who will take responsibility if the 'black sheep' will not bleat with the flock?). Of course, I know, I know…. some discoveries will never come from little projects, and the times of the lonely genius working in the patent office are over. But maybe we should reconsider this obsession for stratospheric projects. It is not about abolishing big science, it is about rediscovering the potentiality of the small scale one.

19. **Peter Orland**
April 21, 2012

Much of what I am seeing here has little to do with Weinberg's original points about high-energy physics. Most of science, including most of physics (but perhaps excluding particle and h-e nuclear physics), has a bright present and a bright future. For every example above of a failure there is also a success.

Some programs have not lived up to their technological promise – ventures always bring risks. People often conflate discoveries (or non-discoveries) hyped through the media with real progress- then become cynical when their expectations aren't realized. So what?

Who said science and engineering were easy?

20. **armin**
April 21, 2012

Nowadays, any big science project that spans several election cycles severely risks falling victim to the vagaries of politics.

Why can't we invest at least some resources to try to find entirely new and different answers to the technical question of how to precisely deliver a large amount of energy to single elementary particles? Sure, this will require going back to the drawing board, possibly even revisiting some 80-90 year old engineering concepts that underlie modern particle accelerators, but, given (1) the staggering costs of any future particle accelerators, (2) the enormous risk that they will not be completed and (3) the absence of exotic discoveries with the LHC so far that would further motivate the construction of such projects, this seems to me a worthwhile line of research to invest in. Arguing against this strikes me a little like arguing against modes of personal transportation that are entirely new and different from the latest high-end model horse carriage.

BTW I don't know of nor advocate any particular "alternative" approach to accelerating particles, but I do believe in out-of-the-box thinking.

21. **Ben**
April 21, 2012

Re: Tony Smith's idea is naive. Also, in regard to Weinberg quote "I don't know of any cases where a student was doing really first-rate work who then moved into Wall Street" We have a high profile example in Jim Simons, of Cern-Simons fame

22. **Clara**
April 22, 2012

Weinberg hides a failure. The failure of big science is first of all a failure of theoretical physics. We lack a good theoretical model. One that is so compelling that it excites everybody to test it with a big experiment. If somebody came up with a great theory, a theory that would get everybody excited in the style of "yes, now we really have a candidate of a TOE" and "Finally a TOE without nonsense, without strings and without a multiverse" and "Finally a TOE that is not obviously not even wrong" THEN the trillion dollar experiment would be no problem.

Nobody will spend huge amounts of money if the chances for result are so low.

The failure is one of theoreticians. They do not need big money. But they have produced only "Not even wrong" models since 40 years. They have focused on supersymmetry – because Weinberg promoted it for 40 years, among others – and now are finding out that they were chasing a fantasy.

The real failure is people like Weinberg, who drove most theoreticians and experimentalists to search for supersymmetry. And this was a mistake. It was, first of all, Weinberg's personal mistake. If Weinberg had not created such a "lemming climate" in theoretical physics, we all would have had a much better chance to have his "final theory" already on the table.

The whole article is that of an old bitter man who tries to divert from the fact that he is one of the main culprits for the present sad situation.

23. **harryb**
April 22, 2012

Some authors claim up to 30% of current US GDP can be directly linked to applications of QM – transistors, lasers etc and their technological offshoots. A century earlier than that you could make the same argument I guess re Maxwell's Equations.

The cheapness of theoretical physics, chalk and PCs, suggests its economic leverage is potentially vast, and sad to see it come under such cost scrutiny.

But, when taken down dead-ends, that credibility is undermined. The over-focus on ST has surely contributed to the lack of options now open to HEP.

Its a crisis of ideology and theory as much as Big Science.

24. **David Bailey**
April 22, 2012

If nobody had known about General Relativity, I somehow doubt that this would have prevented satellite navigation. I think the engineers would have discovered the discrepancy and added an ad hoc correction to fix the error. Anyway, developing and testing GR had a much lower cost than anything being discussed here.

I think Aiden makes a very strong point that (sadly) big science has not delivered in recent years.

The problem seems to be that science just blurs into politics at this exalted level!

More generally, unless the human race can expand into space and command much more enery than it can on earth, the quest for larger accelerators must end sometime – politics is just bringing that day forward!

25. **emile**
April 22, 2012

Clara: as you probably know, Weinberg came up with the theory that is currently being put to the test at the LHC (A model of leptons). To blame him for the current situation just sounds strange: he came up with a theory that we can test. Second, searching for Supersymmetry on the experimental is not a waste of time: it covers such a vast amount of final states that it is essentially a generic search for physics beyond the Standard Model.

26. **jpd**
April 22, 2012

this claim:
"The genome project promised us miraculous cures for genetic diseases, but now we know that it miserably failed."
is wildly ignorant

27. **Anonyrat**
April 22, 2012

It may be interesting to plot for each year from 1890-2010, the age of the chief mover/shaker in theoretical physics that year. If there were several, include them all.

Such a plot might show that physics is becoming more and more a field where long-established authority reigns.

One data point is below
{1905, 26}
🙂

28. **SteveM**
April 22, 2012

There are often useful technological spin offs and side applications that arise from big science projects not necessarily directly connected with the science itself: for example, advances in computing, engineering, supercomputing, software engineering, data mining/analysis etc., developed for particle physics and genome research; indeed the WWW originated at CERN. There were many technological advances and spin offs and new industries in the 70s, arising from the Apollo moon program. Cancer has not been cured as such but there have been considerable strides in treating and managing it, in everything from nuclear medicine to new drugs. Science and engineering are also difficult and often progress slowly but they do progress because ultimately the scientific method works; and some things just have to be done on a large scale and require huge effort. Clara: Weinberg predicted weak neutral currents and the W, Z bosons and these things turned up just like he described them. Supersymmetry was (and is) a compelling and powerful idea, compatible with both particle physics and Einstein gravity–it made total sense to pursue it, along with superstring theory, even if ultimately they do not describe nature as it really is. The jury is still out on susy and evidence of it could still turn up–a scientific discovery as significant as finding life elsewhere in the universe. (Personal opinion.) One should not describe this great physicist as a "bitter old man" but I suspect he is expressing a certain amount of frustration in that he would really like to know certain things within his life time.

29. **Aidyan**
April 22, 2012

Clara: "If Weinberg had not created such a "lemming climate" in theoretical physics, we all would have had a much better chance to have his "final theory" already on the table."

Agreed. But I don't think we can make only Weinberg responsible for this. If few central figures like him could create a flock-like mentality among theoretical physicists it is only because they found a large number of them willing to behave like sheep in the first place.

30. **cormac**
April 22, 2012

Re "The observations of microwave radiation left over from the early universe have confirmed the general idea of an early era of inflation, but do not give detailed information about the physical processes involved in the expansion "
it seems a pity not to mention that we may currently be on the cusp of a breakthrough; E-mode polarization has already been detected in the CMB, and if the PLANCK

satellite resolves B-modes, that will surely go some way towards pointing us in the right direction

31. **Neto**
April 22, 2012

I'm not a physicist, and I don't want to get in a political talk, but the fact is that humanity (and governments) have limited resources. I think we are getting in a time where HE experiments are very expensive. It's not about being pro or against science, but we can't make all the Science at the same time. Of course, particle physicist – and myself, and I'm not a scientist – want to know the real truth about the nature, but the question should be, the billions and billions that would be used to build a new particle accelerator could be used in another science areas that could bring more sooner and direct benefits to humanity? I mean, we need to think like a business and make ROI analyses to decide what the priority is in science. We have some real problems getting closer, water polution, food to feed billions and billions of people, etc. We need to be reasonable.

32. **Peter Woit**
April 22, 2012

Neto,

Since humanity is not a business,there's no reason this question should be addressed by "thinking like a business". It may be that understanding the fundamental nature of the physical universe is not something that ever is going to make anyone a buck (other than popular science writers, and that's not a very well-paid profession…) or solve any social or environmental problem. Historically though, many human beings are interested in such understanding and society has devoted (a small fraction of its) resources to pursuing this understanding. To me, wanting the answers to such questions is a part of being human, and to decide we're no longer interested enough to put any effort into this search would be a change in human nature, not necessarily one for the better.

I think anyone proposing to change the historical fraction of society's resources devoted to this research needs to either claim that it was a mistake to do this in the past, or explain what has changed. Weinberg is arguing I think that since the problems have gotten harder, physicists and astronomers need even more than in the past. I'm not sure this argument is going to convince people, and the lack of a very scientifically compelling argument for a higher energy collider is a huge problem for HEP. On the other hand, those who argue for cutting HEP funding also need to explain what has changed. The GDP or major nations is as big as ever, it's just not true that all of a sudden they can't afford this small fraction of their resources.

33. **Neto**
April 22, 2012

Peter,

It's not about the humanity being a business, but about rational use of the resources.

I'm as curious about the our nature as you are, that's why I keep visiting your blog and a lot others even without being a physicist. Actually, I spend a lot of my time looking for answers about the big questions, and I really would like to see great improvements in my lifetime.

But, I live in a third world country, and maybe because of this I can see that there are some really urgent areas that we should be investing into now, not only enviromental ones, I don't wanna look like an enviromentalist, but health, energy, and so on.

I'm not favorable to cut any resource that is being used in HEP physics today, I have a moderated view, I just think that before making new huge investiments in the big questions now, we should look for some big problems first.

If I could choose, I would give up being alive when the big questions get answered by sooner improvements in peoples lives around the world, I wouldn't hesitate.

Maybe if my life was dependent of HE physics, if I was a physicist myself, my view would be different.

If what you're saying is that the next HE particle accelerator would consume relatively as much as LHC, then I think it's justifiable.

34. **Anon**
April 22, 2012

@Neto, what is so wrong with looking like an environmentalist? Indeed, if I had had the opportunity to answer that congressman, I would have said that a century or two from now only two things about our era are going to truly matter to our descendants. The first is how we treat the environment, and the second is what we have achieved in fundamental research. Unfortunately, experience has shown that our political system is not remotely able to address either of these issues, and that makes me deeply pessimistic about the future.

35. **Mike**
April 22, 2012

Sounds like a good time to get into molecular biology or bioinformatics – it doesn't require a lot of capital expenses (like large machines) and the results are applicable to the human condition (= more funding). That being said, there is a surplus of PhDs in the life sciences as well.

36. **Neto**
April 22, 2012

@Anon,

Nothing wrong about it. I just didn't want to look like a radical, maybe I was not clear.

I think that there are more things that will matter to our descendants. A more equal, more safe world, for example.

Fundamental answers are… Fundamental. But I don't think it's the only way to measure humanity evolution. At least not this time in history.

37. **Einstein_kid**
April 23, 2012

Hi everyone!
I'm new to posting but not to the blog itself. I feel this debate is a good one for me to start contributing because it does not deal with high energy physics details (of which I am not an expert) but with the public face of sciences in general and physics in particular, where I think I may have my 2 cents to share (I am indeed a physicist).
Discussing about public money calls for addressing public needs: the very first one among those, I believe, is accurate information. The public is curious: just look at all the "LHC will create a black hole" thing! And the public is reactive and powerful: take the mobilization behind the last servicing mission of the Hubble Space Telescope

in 2009. It might sound too simple and obvious but if there is no public engagement toward theoretical physics, there is not going to be much funding for it in the future, which to me means not only no HE-LHC or NASA satellites but also no students, no professors and no universities. "Engagement toward theoretical physics? are you crazy" no, I'm not: there is a lot of things that can be told (and done), starting from emphasizing the word "Hadron" in the LHC acronym, which goes hand-in-hand with hadron-therapy, a technique that might have cured some listeners' friends/relatives' tumor.
For these reasons I think that public engagement has to become a funding priority for every scientific project or collaboration. I like to think of this problem "quantum-mechanically": if there is no efficient scientific communication, your project's case does not exist; same holds true for the results already achieved by an experiment: if these results only live inside the ivory towers of universities and research institutions, they do not exist for the public.
I truly believe that the scientific community has to become more actively involved in scientific communication in order to stay alive.

38. **william c wesley**
April 23, 2012

Ahh….reality check time. We spend 10 times more on sports than on science. Think about that. Bet we spend more on pornography than on science, ditto fashion and entertainment . Our military budget is the largest expenditure in history and I'm sure what is spent on religion is incalculable, like what the Egyptians spent on pyramids. No one EVER questions these other expenditures, why? So lets see, how many economic spin offs have come from ALL these other expenditures combined….ahhh, near Z E R O!
Now how many industries and jobs have spun off from scientific investments? NEARLY ALL OF THEM. Most of us virtually owe our existence to scientific investment. People who don't think shouldn't control investment nor should they be given a platform on which to offer opinions about investment ether.

39. **Serge**
April 23, 2012

@Peter Woit
Couldn't TeV energy physics become practically relevant in unpleasant sense if something heavy hit nearby black hole in 1600 ly from us? Or more remote black hole which happen to point axis on us, or would point as result of collision? Does gamma ray burst modelling not require any new physics?

40. **Peter Woit**
April 23, 2012

Serge,

TeV energy scales are so high that there aren't known astrophysical objects that probe them. The things that we still don't understand about possible TeV scale physics are typically very weakly-interacting phenomena, such as the Higgs or possible WIMPs. Such phenomena would be responsible for a vanishingly small fraction of whatever potentially dangerous radiation would be coming from some nearby astrophysical object.

41. **Satan Claws**
April 23, 2012

"One day sir, you may tax it."

> Michael Faraday's reply to William Gladstone, then British Chancellor of the Exchequer (Minister of Finance), when asked of the **practical value of electricity** (1850), as quoted in "The Harvest of a Quiet Eye: A Selection of Scientific Quotations" (1977), p. 56

Can you use something like that?

42. **Zathras**
April 23, 2012

The issue with funding particle physics is that there is not much left to do. It's been slow for 40 years, and there is no indication that this is going to change. The next energy gap to predictions is just too big. The only argument for a bigger collider is maybe we will see something new, but selling predictions of null results will be very, very difficult. There is no point in even trying to sell a next generation collider unless the LHC finds something unexpected.

43. **science rules**
April 23, 2012

uair01, fundamental research can do more than put bread on your table. It already put the web on your hands, so that you can discuss here and do much more with it. This has changed the way we live and on top it was given to the world for free. There are countless examples of money badly spent by governments everywhere everyday. There are few enterprises more useful, rewarding and honorable than fundamental research.

44. **Another Peter**
April 23, 2012

It seems a bit strange to me to take as granted that the general public will constantly support fundamental research. We do what we do mainly because we are interested in it. Most of the time we don't think of applications and many regard questions of "applicability" as being close to insulting. Unless we teach, we are satisfying our curiousity using tax money. The general public will support this if it makes people **feel** great (or superior) and if they can afford the luxury to pay for this feeling. I think we have to understand that we are being lucky that we are paid at all (again, teaching excluded). Financially speaking, it is natural at a time of crisis to restructure your "investment portfolio" by shrinking the high-risk component (and gambling) and by getting rid of the "little indulgencies" that you may otherwise have.

45. **Peter Woit**
April 23, 2012

All,

Please, repetitive, tendentious argumentation not carrying any new information is not appreciated here. This is not Slashdot, which now has a new posting about this, so take such arguments there:

http://news.slashdot.org/story/12/04/23/1235202/the-crisis-of-government-funded-science

46. **vorpal**
April 23, 2012

It would seem to me that in the 21st century, China would be the appropriate place to build a next generation high energy exploration instrument. They are a big country, with lots of money and hightly motivated to establish themselves among the technologically elite nations.

The U.S. is a nation in decline, mostly because it's interests have become synonymous with the interests of large corporations. I just don't see a lot of corporate lobbyists pleading U.S. representatives for a new facility so they can get some supercollider contracts.

Besides, even as a theoretical physicist, I would rather see the money go to the NIH for basic research into aging, cancer, stem cells etc.

47. **Noah Smith**
April 23, 2012

Only tangentially related, but:
http://noahpinionblog.blogspot.com/2012/04/down-with-particle-physics-up-with-big.html

48. **Owen Patterson**
April 25, 2012

Does every thing that humanity delves into have to have some immediately tangible benefit? I can think of a lot of wasteful junk that people spend lots of money and time on that does little more than immediate, temporary pleasure and is even often harmful. Our "souls" need nourishment too, otherwise let's just go back to the caves and grunt around the fire.

As for ignorant lawyer-trained politicians – to heck with them.

49. **Art Brown**
April 25, 2012

Dear Physicists and Rocket Engineers,
In case you didn't notice, we won the cold war. Congrats and our deepest gratitude for your contributions: we got to the moon first, and while you didn't develop any bigger bombs since the '50s, you showed convincingly that the other side wouldn't either. As a bonus, the Standard Model looks quite serviceable for all our future conceivable needs.

So again, hurrah for you: we contemplated a ticker-tape parade, but after Feynman passed, there just wouldn't be much star power there, would there? Going forward, the obvious new threats are biological in nature, so we'll be directing our resources that way. We hope the graduated reduction in your funding gives you all a chance to adapt.
Best regards,
America

50. **markob**
April 26, 2012

Why spend the money searching for the ultimate laws of nature when, according to Weinberg and many others, that ultimate description of nature, string theory, has already been discovered out of considerations for beauty and elegance alone? Why not just wait until more accessible means of experimental verification of the ultimate theory become available? When mathematical elegance becomes the true arbiter of a theory it really does become that much harder for the HEP community to make the case for bigger and bigger machines. I think, also, Jeff Hughes had a book on the Manhattan Project and Big Science where he argued that science has slowly evolved away from "big science" and that big science is, in his words, "pathological science."

51. **arjun**
April 26, 2012

Given the current economic climate where India and China are growing rapidly, I wouldn't be surprised if India or China might end up building the next generation of colliders. Already India has pledged an estimated $250 million for the INO project:

http://en.wikipedia.org/wiki/India-based_Neutrino_Observatory

52. **Shantanu**
April 27, 2012

So Weinberg is not excited by non-0 evidence for theta_13?

53. **Craig**
April 27, 2012

It's all comes down to cost and (likely) benefit. I'm sorry, but there you have it. If a new generation of accelerators cost 19.95 plus shipping, and you could run them with a couple of grad students, then we'd do it. When you hit twelve billion dollars, we've got to have a serious conversation about making choices.

Dr. Woit gets it exactly right here–it's not quite clear what we would be doing with a big new collider. On the other hand, astronomy in general is working on a thousand fascinating problems, from dark matter to extrasolar planets. Frankly, I'd much rather have a big new telescope. I'd probably much rather have a _lot_ of different things. Let's sit down and make a list of scientific projects we could spend twelve billion dollars on. Now, show of hands: who gets the feel that some fantastic new advance is "just out of reach" of the LHC?

If all this means that a certain kind of high-energy physics has run its course, then that's what it means. This is not about the Seekers of Truth versus the philistines, and I'm tired of seeing arguments framed that way. It is about priorities, and making limited resourses count.

Something and Nothing

April 23, 2012
Categories: Multiverse Mania, Uncategorized

- In the something of interest category, last week at Columbia there was a panel discussion held as part of the World Leader's Forum, introduced by our president Lee Bollinger, on the topic What If We Find the Higgs Particle and What if We Don't.

  Columbia's Michael Tuts and Brian Greene gave an excellent discussion of the topic, to a large and attentive audience. Probably nothing new to readers of this blog, but I think they did a great job of it, and was interested to notice that Brian expressed skepticism about Kane's claims to derive the Higgs mass from string theory. Dennis Overbye of the New York Times seemed rather wary of hype about HEP, since he's a veteran of seeing the Times burned by this sort of thing. It's now been quite a while since they've made the mistake of putting up LHC headlines like Physicists Finally Find a Way to Test Superstring Theory.

  Maybe there's a better source for the video linked above, in the version I'm looking at, everyone is blue…

  In other "something" news, Brian's World Science Festival has just announced its schedule, available here.

- On the Krauss/Albert debate over nothingness front, yesterday there was a piece on the Huffington Post by Victor Stenger taking up the fight on Krauss's side. Over at Scientific American today, John Horgan comes into the ring on Albert's side.

  Like Horgan, I've recently got ahold of a copy of a pre-publication copy of a much more interesting take on the something/nothing business, Jim Holt's Why Does the World Exist?. I look forward to writing something about it here soon.

Update: Thanks to commenter Zathras for pointing to the latest punches returned by Krauss (see here):

> Well, I read a moronic philosopher who did a review of my book in the New York Times who somehow said that having particles and no particles is the same thing, and it's not.

Update: When checking out John Horgan's SciAm piece on this, don't miss the comment section, where he and Krauss are going at it.

Update: Via commenter Billy Hudson, Krauss's fighting words about philosophers and philosophy seem to have brought the philosophy community into the fight on Albert's side, see Massimo Pigliucci's latest.

Comments

   April 24, 2012

   the 'blue people' problem I think is a recent flash bug.

   if you have html5 enabled browser there are no visual problems.

   try opting in to the html5 trial at youtube and restarting your browser.

   http://www.youtube.com/html5

   (you have to select a link at the bottom of the page to opt in to the trial)

5. **CarlN**
   April 24, 2012

   Yes, this nothing business is a lot ado about nothing..as it should 🙂

   Regarding where reality ultimately comes from, we cannot base any explanation on anything that needs further explanation of course. In particular we cannot base any explanation on any eternal "things" as there would be questions on why this eternal thing (a law of physics or a god) have a particular form or particular properties (that would explain everything else) instead of other conceivable properties. Thus no real explanation can be obtained. Of course the concept of eternal things has other logical problems as well.

We need to start with absolute Nothing (no spacetime, no laws, no gods etc) as this point of departure does not need any explanation at all.

Fortunately this is simple 🙂

There are no laws “when” there is Nothing, hence there is no law of causation (“things” may happen without causation, Big Bang anyone?) , no laws of conservation (of energy,charge etc).

In short, “when” there is Nothing there exist no “things” (since a true Nothing contains no “things” like laws) that can prevent the creation of (self-consistent) “things” from Nothing.

So logically the “road” is totally open for creation from absolute Nothing. But only for things that are self-consistent of course.

CarlN

Massimo Pigliucci has a post about the Kraus/Albert dust-up:
http://rationallyspeaking.blogspot.com/2012/04/lawrence-krauss-another-physicist-with.html

9. **Peter Woit**
April 25, 2012

Thanks billy,

I’ll add a link to the main posting. Looks like Krauss picked a fight with the entire philosophy community…

10. **JC**
April 25, 2012

This book is really nothing new. It is just a re-package of all these unsubstantiated craps (landscape, multiverse, … etc) under the new hype of “something from nothing”.

This generation of “particle” physicists is really pathetic. They might be good as second-class mathematicians (since really good ones could just work on hard-core mathematical problems). They achieve nothing comparable to the those of the great minds in the past. At the same time, they are trying very hard to make themselves look good and smart.

11. **abbyyorker**
April 25, 2012

I’m with the philosophers on this one, if only because I don’t like mediocrities running around calling people they disagree with morons. And the pointless “muscular atheism” of Dawkins et al disgusts me (though I am atheist myself). But I sure like Dawkins books!

12. **David Kordahl**
April 25, 2012

Has anyone else here actually read the works of David Z Albert? I read his books while a physics undergraduate, and I found them to be very worthwhile, especially “Quantum Mechanics and Experience,” which is a simple but cogent introduction to the measurement problem. Krauss’s behaviour of late seems to be embarrassing at best, and not quite the sort of thing that makes one proud to be either atheist or physicist. For Krauss to write a book of philosophical claims and yet to say that philosophers of science have nothing of interest to say to anyone but themselves is quite the whiplash display of specious logic. The desire to attack things as unimportant simply because one does not and does not wish to understand them seems to me as good a definition of a “nerd” (in the pejorative sense) as any, and as this squabble continues my respect for Albert has only increased–regardless of the Templeton thing.

13. **Dan D.**
April 25, 2012

As a theist (and scientist) myself, I’m heartened to see that not every atheist is against us on this point at least: namely that science does not get to determine what “progress” and “knowledge” means for every other field of inquiry, and that mere dismissals of entire fields of inquiry that have existed for thousands of years do not count as arguments.

14. **MathPhys**
April 26, 2012

As a theist (and a scientist) myself, I never understood what the fight is about. Anyone who has 1. solved an algebraic equation, and 2. fell in love, must realize that the fully-rational and the totally-irrational compartments of our brains coexist, perfectly peacefully, right next to each other, and that they often operate at the same time.

15. **hdz**
April 26, 2012

Let me quote a passage from the Kraus interview in The Atlantic on which you provide a link:

“Is there an empirical frontier for this? How do we observe a multiverse?

Krauss: Right. How do you tell that there's a multiverse if the rest of the universes are outside your causal horizon? It sounds like philosophy. At best. But imagine that we had a fundamental particle theory that explained why there are three generations of fundamental particles, and why the proton is two thousand times heavier than the electron, and why there are four forces of nature, etc. And it also predicted a period of inflation in the early universe, and it predicts everything that we see and you can follow it through the entire evolution of the early universe to see how we got here. Such a theory might, in addition to predicting everything we see, also predict a host of universes that we don't see. If we had such a theory, the accurate predictions it makes about what we can see would also make its predictions about what we can't see extremely likely. And so I could see empirical evidence internal to this universe validating the existence of a multiverse, even if we could never see it directly."

Well – as yet it requires some imagination to have such a theory that would convince us of the existence of these multiverses on empirical grounds.

But would it? Imagine further there were then a bunch of influential conservative physicists who insist that "… this theory is not made for the universe, but only a tool to calculate certain laboratory data." And that "we cannot say anything about physical reality but only about our knowledge."

This is in fact what permanently happens to Everett's interpretation, since here we do have a perfect and extremely well confirmed theory for more than 80 years on which his multiverse is built: the Schroedinger equation.

16. **PS**
April 26, 2012

JC: many of "this generation" of particle physicists are really very, very smart people. The question of why they haven't accomplished that much really has to be answered not by dismissing them all as second-class mathematicians, but by looking at the sociology of the field of string theory and particle physics. I think something really wrong has happened in the culture of this field. However, I can't quite put my finger on what and I don't know whether it'll correct itself if the LHC starts producing interesting data.

17. **cormac**
April 26, 2012

I don't understand all the hostility to the Krauss book. I found it a clear and enetertaining read, intorducing the public to a simple concept that has been known to physicists for many years; that a universe does not necessarily need a cause, according to quantum physics.
He does not say this is what happened, he simply explains the possibility with admirable clarity. I found both the review by Albert quite poor and rather biased; and Horgan doesn't really engage with the material at all

18. **Foster Boondoggle**
April 26, 2012

Albert has earned a certain amount of skepticism for his views on physics by lending his academic credentials to the cult pseudo-science of "What the Bleep…" a few years back. That might go some way towards accounting for the level of vitriol from Krauss. It's a bit harder to understand the tone of Albert's review of Krauss. Albert seems to be saying that you can never make a philosopher stop asking "why" at the end of a chain of explanation. But so what? Krauss' point is that, where 40 years ago we had no idea how the Big Bang got going (we couldn't go back before Weinberg's "First 3 Minutes"), now we have speculations (admittedly) that are at least grounded in models based on currently viable fundamental theories, and that explain the emergence of "everything" – i.e., the observable universe – from "nothing", i.e., the physicist's vacuum. Yeah, the philosopher can keep asking "why this, why that", but that seems ultimately sterile, and a losing battle for mindshare. (It's the "god-of-the-gaps" all over again.) More explanatory power is better than less.

19. **Bernhard**
April 26, 2012

@cormac
"I don't understand all the hostility to the Krauss book. I found it a clear and enetertaining read, intorducing the public to a simple concept that has been known to physicists for many years; that a universe does not necessarily need a cause, according to quantum physics"

The problem begins with Krauss and his unnecessary hostility towards philosophy. If that was Krauss´s only point he could probably have sold it to some people, but not satisfied with that, he began a silly debate about nothingness. He is even backed up by incredibly silly comments from Dawkins (who probably got more impressed then he should because he is himself not a physicist and because it fits his anti-religion agenda).

When Peter first said this debate over nothingness was silly I complained, but I regret, this debate is not only silly but pointless and the blame is on Krauss´s side. He wanted to make the headlines by basically saying physics has the answer to the philosophical nothingness question. When confronted with the problem of quantum laws themselves being something he used "brilliant" arguments like "if the 'nothing' of reality is full of stuff, then I'll go with that." Really, what is he talking about? He should have made an argument of physics and stayed there and not gotten into stuff he clearly demonstrates he is ignorant about (philosophy). He wrote a popular book, not a philosophical essay nor a physics article. That he wants to use it to attack philosophy is simply ridiculous.

In the end I think he is trying to promote the book by making this cretinous noise and is being successful.

20. **JC**
April 26, 2012

Here is the first sentence from the preface of the "nothing" book:

"In the interests of full disclosure right at the outset I must admit that I am not sympathetic to the conviction that creation requires a creator, which is at the basis of all of the world's religions. "

This arrogant clown claims that "a creator" is at the basis of ALL of the world's religions. First, take Papua New Guinea for example, there are roughly 840 indigenous languages. I guess probably there are more than 500 indigenous religions too. Did this clown check all of them before he made this claim ?
Not to mention that many branches of Buddhism do not proclaim the need of an omnipotent creator deity.

This is just another example that Krauss should just shut up about those things that he is ignorant.

21. **Aidyan**
April 27, 2012

As a theist (and scientist) myself, who found Dawkins, Hawking, Krauss et al. atheistic arguments always quite primitive and unreflective, I must however say that if the debate has fallen to these lows it is also because of the incompetence of the other side, that of the minority of theist scientists and philosophers who could not offer serious alternatives, or worst aligned with the new-age pseudo-science. Most of us are still stuck in even more untenable conceptions which refuse to give up anti-Darwinian semi-creationists biblical interpretations and more or less implicit anthropocentric views of our place in the Universe. Obviously, a viewpoint that is easy to disprove first and ridicule then. This forced theist intellectuals to silence especially in the last years (where are they?), and gave ample space to a 'scientistic' militant atheist movement which, once it believed it has won its crusade, now targets what it considers the last remanent of ‘time-wasters’: all philosophers, theists and atheists without distinctions. But I think that, if the former would once and forever accept Darwin, acknowledge homo sapiens as a species as others, reconsider the unwarranted ontological meaning assigned to categories as ‘chance’ and ‘randomness’ in biology and physics, and drop their religious dogmatic interpretations of reality, it would become easy to debunk the naive arguments of the latter.

22. **BDennehy**
April 27, 2012

I’m not sure if I speak for anyone else here but Peter could you please put a stop to yet more people mouthing off about their particular take on religion and spirituality!

23. **Peter Woit**
April 27, 2012

BDennehy,

I agree completely. Been planning to take action, but spent the morning bike-riding along the Hudson river, saw the Space Shuttle fly by three times on its way to landing at JFK.

All,

Please help keep this blog free of religion, both pro and anti, of any stripe. There’s plenty of other places to debate such issues, and rarely is such debate interesting.

Off to lunch, then some more updates to this posting…

24. **Allan Rosenberg**
April 27, 2012

I think Krause is being totally irresponsible in his attacks on philosophers. If you physicists aren’t careful, the philosophers of physics will go on strike, and then you’ll really be screwed.

25. **cormac**
April 27, 2012

Peter: I agree, and Bernhard also has a point. I think it was a great pity to have an endorsement from Dawkins at the end of the book, it introduced a completely unnecessary religious/anti-religious element to the book

26. **SpearMarktheSecond**
April 28, 2012

The great part about the forum is getting Michael Tuts, a real scientist and not a pettifogging fop, up on stage. He is worth 10 or 100 of the Krauses and the Greenes.

27. **OMF**
April 29, 2012

What an embarrassingly public waste of time and effort.

If I was a public representative, I can’t say I’d be inclined to fund an SSC or other projects after reading the likes of this.

28. **Bob Levine**
April 29, 2012

@OMF:

Sorry, but I cannot see the logic behind your comment. The SSC represented the best chance the world ever had to probe energy scales at a range likely to yield robust data that could have shed light on BSM physics; the chance for a real, empirically robust breakthrough was there, and was lost. The comments in this thread reflect pseudoscientific issue that reflect the lack of any new findings to drive responsible, creative theorizing—nothingness and multiverse studies are what we have, arguably, *because* the SSC wasn’t built.

There were some interesting sensory deprivation experiments in the sixties that showed that people deprive of all stimuli (total darkness, deadened sound, aqueous suspension etc.) start to hallucinate after being left in that state long enough. What we’re see now, on a variety of ‘not even wrong’ fronts, seems like a different version of the same thing. Canceling projects designed to gather new data is a good chunk of what lead us to this state—not the whole story, certainly. Given the problem, how would your prescription be a constructive response?

29. **Peter Woit**
April 29, 2012

Bob Levine,

The standard argument for tolerating multiverse/pre-big-bang nonsense by prominent theorists is that it may not be science, but it gets the public interested in and excited about science, and hopefully they’ll then go on to the real thing. The problem is that if the nonsense goes too far, people will realize this and the field will get discredited. I think OMF is pointing to that danger. I have no idea how serious it really is, but physicists in general might want to think about the desirability of speaking up against nonsense promoted by their colleagues. There are now a lot of prominent physicists out there spouting nonsense about the multiverse, very few speaking up with a more sensible viewpoint.

30. **OMF**
April 29, 2012

> The problem is that if the nonsense goes too far, people will realize this and the field will get discredited. I think OMF is pointing to that danger.

I think this danger has long since been realised. Frankly, given the state of the field, I don’t think big physics projects should get any funding, or at least, not before big astronomy, or chemical, or engineering projects, etc.

I wouldn’t give funding to a field whose top representatives spend most of their time in cat fights with creationists, and giving interviews for CGI-ridden cable documentaries. It might sound harsh, but giving these people funding is actually part of the problem.

31. **Peter Woit**
April 29, 2012

OMF,

This might be a good argument for defunding some subfields of theoretical physics, but the experimentalists building and using tools like the LHC really have nothing at all to do with the multiverse-maniacs. If you take away funding for things like the LHC, you won't affect multiverse-mania, since those engaged in it aren't funded from there. Worse, if you got rid of LHC funding, you'd get rid of the people in the field doing actual science, leaving only the pseudo-science in place.

32. **OMF**
April 29, 2012

In that case, I think it is time for experimental(and other) physicists to begin disassociating their fields from the practices exemplified by this particular scandal.

33. **srp**
May 2, 2012

The pity is that Krauss could have been almost as provocative without overreaching. Proposed re-titling of his book: "You Ain't Seen Nothin' Yet."

The argument is that modern physics makes the constraints on "nothing" a lot more stringent than the casual thinker (and possibly the uninformed philosopher) realize. In the interview, Krauss claims to go beyond saying that empty space in our universe is unstable and will spawn particles and such. He claims to show that space and time themselves will emerge from quantum fields, so that a no-space, no-time, no-stuff field is unstable, too.

So Albert is correct–you can't stop asking "where did that come from?" because the fields' existence is taken as given–but Krauss has a point (assuming he's got the physics right) that logically banning creation ex nihilo requires a much more nihilistic nihilo than it used to.

Much Ado About Nothing

April 27, 2012
Categories: Favorite Old Posts, Multiverse Mania

I suppose I'm posting too much about this, but the ongoing fight over nothing between prominent physicists and philosophers strikes me as perhaps marking some kind of end-point in the multiverse-mania-driven decline of part of theoretical physics from a difficult, serious subject to a trivial and kind of ludicrous undertaking. How can you get any sillier than arguing over nothing? Will this be the end of it, or is there somewhere lower to go that I can't yet imagine? There's also a *Three Stooges* sort of entertainment value to following this fighting. It's kind of like a segment of Dumb (a multiverse explains everything!) vs. Dumber (bringing religion into it, "pale, small, silly, nerdy").

If you haven't been following the story so far, to start see links here, here, and here. Lots of gems there, one I just noticed is the moderated discussion at the Templeton-funded "Philosophy of Cosmology" blog, where the proprietor writes that:

> Krauss is a crybaby.

and then goes on to complain that Krauss hasn't taken him up on his request that he explain himself at the Templeton blog.

In this morning's developments, we have prominent skeptic Michael Shermer, in Much Ado About Nothing, making the case that the Multiverse finishes off that "God" business, using "multiverse hypotheses predicted from mathematics and physics". His authority here is the Hawking/Mlodinow popular book, but he's also convinced that WMAP and LIGO are somehow going to provide evidence for multiverses, something that even the most far-out theorists in this field aren't claiming. In addition:

> Maybe gravity is such a relatively weak force (compared with electromagnetism and the nuclear forces) because some of it "leaks" out to other universes.

Nobody seems to have told Shermer that this is not an idea taken seriously by a significant number of theorists, or that LHC data has shot down the hopes of the one or two such theorists.

Also this morning, with The Consolation of Philosophy, Krauss tries to extract himself from the trouble he got himself into with philosophers with his recent comments about them and their profession. He sticks to his criticism that it's physicists who have interesting things to say about fundamental issues of physics, not philosophers, but admits that at least they're not as bad as theologians:

> To be fair, I regret sometimes lumping all philosophers in with theologians because theology, aside from those parts that involve true historical or linguistic scholarship, is not credible field of modern scholarship.

Will now go get some popcorn to await further episodes of this comedy…

Update: Two more links. Sean Carroll has a long posting about this, with bottom line that he thinks Krauss is right, but shouldn't have said mean things about philosophers. David Albert responds to being called "moronic" by accusing Krauss (whose name he has trouble spelling) of being incompetent:

> …the business of pontificating about why there is something rather than nothing without bothering to get crucial pieces of the physics right, or to think about them carefully, or to present them honestly, strikes me as something of a scandal.

Update: Brian Leiter, at the well-known philosophy blog Leiter Reports, joins the fight, of course on the philosopher's side. In response to the Krauss attack on philosophers in general, he has this to say about physicists:

> Of course, it was not always so with physicists, but the current generation (at least those who try to speak to the broader public) does seem remarkably inept in logical and rational thought, and unembarrassed to display that to the world. Which raises the question: why? My best guess is that the culture so celebrates physics, that physicists have come to believe the "PR" about them.

Update: The fist-fight between Krauss and the philosophers continues in various venues. Surprisingly, today Leiter's blog has a philosopher (Justin Fisher) throwing punches on Krauss's side:

> …Albert is clearly just being snide for the sake of being snide.
>
> So Albert published a review that was needlessly uncharitable and snide, berating a good work in popularizing science for not solving philosophical puzzles that it openly acknowledges it doesn't solve. Albert was a jerk and then (as we all know) Krauss was a jerk back. It's all very entertaining drama. But why have you picked sides?
>
> My own view is that Albert's review was an embarrassment to our profession, and a setback for all philosophers of science who want our work to be taken seriously by scientists. When a prominent philosopher publishes a careless snide review like this – and in the NYT, no less! – it should be no surprise that many scientists react as Krauss did, by suspecting that philosophers generally behave as Albert did in this review: shedding much noise and little light. And, you're not helping when you, as a prominent philosophical opinion-shaper, uncritically take Albert's side. So I urge you to consider at least staking a more moderate stance, if not actively admonishing Albert for publishing a pointlessly snide review that reflected poorly on all of us.

Comments

1. **Deane**
   April 27, 2012

   I also liked "if God were to have existed she would have sent Lawrence Krauss to earth to give atheism a bad name"

2. **Thingumbob**
   April 27, 2012

   "Will this be the end of it, or is there somewhere lower to go that I can't yet imagine?"

   I think the next step in this Plutonic dialog about nothing must needs be whether there will be a big end of nothing or a little end of nothing.

3. **Don Murphy**
   April 27, 2012

   Peter Wrote:

Will now go get some popcorn to await further episodes of this comedy…

Don says:
Let's not give comedy a bad name as well.

4. **Bob Levine**
April 27, 2012

Krauss' problems with the philosophers seem to be fairly straightforward. He's written a popular science book taking some well-established ideas from QFT,about the vacuum state and the sources of vacuum fluctuations, which have some very speculative applications to quantum cosmology, and (in my view, somewhat disingenuously) titled the book so that it appears to have a bearing on the hoary (and possibly incoherent) metaphysical question of what motivates existence, as vs . nonexistence, thereby tapping into people's curiosity about Ultimate Things. The philosophers have been pointing out that what he's writing about has nothing to do with the latter point, which jeopardizes some of the marketing appeal of the book. So LK is pissed off, and responses with abusive nonsequiturs. He's close to admitted as much in the interview, in the parts that Massimo Pigliucci discusses at

http://rationallyspeaking.blogspot.com/2012/04/lawrence-krauss-another-physicist-with.html

Follow the (scent of) money, and you won't go far wrong, sums it up, I think.

5. **JC**
April 27, 2012

I think much more rectifying work has to be done by people like Peter. It is difficult for laypeople to understand that the "nothingness" of quantum vacuum is not really nothing at all.

I guess because of this, Krauss might continue to have some success in selling his crap and fooling the general populace.

6. **Peter Woit**
April 27, 2012

JC,

You really mistake my point of view on this. I've nothing against Krauss's definition of nothing. The problem here isn't the general populace getting fooled, since they almost all have enough common sense to see that there's nothing interesting at stake in this argument.

With the entertainment value a positive, the only negatives I see here are skeptics like Shermer discrediting their whole endeavor by swallowing whole nonsense they've read from Multiverse-maniacs, and physicists and philosophers turning their profession into a laughing-stock.

7. **Julian English**
April 27, 2012

I'm not sure if Krauss ever did good physics but I'm sure he doesn't have time to do any of it now; he's too busy promoting his book and being a public intellectual. Pop science is valuable but should be written by seasoned grad students unable to get tenure track jobs, not professors paid to do research.

8. **Peter Woit**
April 27, 2012

Julian English,

I'm not sure that the problem of tenured researchers not having time for research since they have taken up public debate is any larger than that of tenured researchers not having time for research since they have, say, taken up yoga, a new love affair, or decided to renovate their basement. The problem is what they do in this public debate, which may be valuable, neutral or damaging.

9. **Bernhard**
April 27, 2012

Now let´s hope some theologians get in the circus and take offense so this gets even more laughable.

10. **CWJ**
April 27, 2012

I wonder if Krauss could even name a modern theologian, such as Borg or Moltmann.

11. **Nex**
April 27, 2012

I agree its time to end multiverse-mania, we should instead focus on a more general and beautiful entity – hyperverse – a grand collection which besides all the mundane members of the multiverse (ie universes with different physical laws, or realizing different branches of wavefunction, or causally separated, etc) also contains all the really exotic universes like those to which no laws of physics can be applied at all (every hypothetical law one might propose in such an exotic universe has infinitely many exceptions violating it) and those in which mathematics is completely useless as a description of reality (whether those two classes are separate is the fist important question that needs to be answered).

12. **Sean the Mystic**
April 27, 2012

Don't you think New Atheist ideologues like Shermer and Krauss have become as hubristic as many theologians? The idea that the latest fashionable theories of cosmology and physics have *just now* rendered age-old questions about the cosmos null and void seems rather presumptuous, does it not? Where is humility and skepticism? Aren't these so-called skeptics trying a little too hard to find "just so" stories from the most speculative areas of modern science to discredit their theistic foes? I'm really struck by the ideologically-charged nature of science these days, and wonder how intellectual integrity will be maintained if science is reduced to a bludgeon in a war of worldviews.

13. **Dan Winslow**
April 27, 2012

Nex – Not to mention the hyperverse universe in which multiverses (multiversi?) are impossible….

14. **paddy**
April 27, 2012

Peter: Unfortunately, many*–even here–disappoint in not seeing the humor. This is funny in and of itself.

*exception for Don Murphy to whom I might paraphrasically whisper: "Apparently physics has become easy while comedy yet remains hard."

15. **Friend**
April 27, 2012

It might be that this argument about nothing is being fuled by equivocation of terms. What is nothing? Even according to GR the Big Bang started from a singularity, a single point. Yet, what dynamics can occur in a single point? None! For all practical purposes a singularity is equal to nothing. And we're all talking about the same thing.

16. **Avattoir**
April 27, 2012

Julian English: "I'm not sure if Krauss ever did good physics …"

Do you write that after or before having reviewing the first 101 publications on this list?

http://genesis1.asu.edu/Publications.htm

I'm not judging; I have no idea whether "Krauss ever did good physics". But he sure seems to have had lots & lots of peer-reviewed articles published in credible journals that are associated with good physics standards. I suspect our host tried to express a view in his response, but it's not exactly direct.

I think our host was a bit unfair on Schermer. Yes, that bit about gravity leakage is cringe-worthy; but it only pops up in the context of his attempt at a sketchy sketch on various ideas in the area, & in any event doesn't, as our host more than merely implies, purport to squash theology with the multiverse stick. Instead, Schermer consistently uses phrases like "may have been" & "may be just" in referring to the multiverse; nor does he stray from that standard on any of the other ideas; nor even does any part of his sketchy sketch detract from his point:

"… why turn to the supernatural when our understanding of the natural is still in its incipient stages? We would be wise to heed this skeptical principle: before you say something is out of this world, first make sure that it is not in this world."

Also, it seems to me Krauss is learning that semantics is a tricky game to play with semanticists.

17. **Peter Woit**
April 27, 2012

Avattoir,

Krauss is a perfectly respectable theorist. I don't think his research has led to any dramatic progress in recent years, but then again this is true for virtually everyone in this business. My dismay about him and Schermer is based on my belief that they're both smart, well-informed, and not easily bamboozled people who should know better than to get involved with multiverse-mania. They're careful to add lots of "maybe" caveats, but they should realize that people tend to not hear those, and that in any case, better to steer clear of dubious speculation than to engage in it while trying to protect oneself with weasel-word clauses.

18. **Neto**
April 27, 2012

To me it's very clear, you just have to look who is in Krauss side. Some people just don't care about religion, some feel they have to show religion is wrong at all costs, and will eventually give up good skepticism just to please their egos. Krauss, Dawkings and Shermer are really insterested in debunk religion, and debunk now. But they need some possible explanations to our reality that we don't have at this time. So they will accept a lot more easily some dubious possibilities because, you know, they are just like every other animal and they need to satisfy their egos. We do that all the time. Maybe we're more moderated in this subject because we don't really care about religion, and we can keep our skepticism while we wait for some new evidences.

19. **Anonyrat**
April 27, 2012

People grinding their ideological axes with highly speculative theories that superficially resemble physics – and some respectable physicists are aiding them, (inadvertently?) – either weep or break out the popcorn.

20. **Lee Smolin**
April 27, 2012

Dear Peter,

Krauss's hostility to philosophy is hardly new, it is the perspective within which our generation of physicists was educated. It is the defining polemic of a tradition of pragmatically oriented theoretical physicists whose dominance began with the generation of Feynman and Dyson. They took over leadership of science from the previous generation, who were heavily influenced by, and respectful of the tradition of philosophy, led by Einstein, Poincare, Bohr etc. The transition was marked by Dyson who noted that he was part of a generation of young conservatives who took over from a generation of old revolutionaries, who were seen as having exhausted themselves on fruitless philosophical quests such as the interpretation of quantum theory.

The triumph of that generation was quantum field theory and it is certainly ironic that the exhaustion of their pragmatic style is marked by the over-extension of quantum field theory to address questions it can't possibly answer such as the origin of the universe. Only someone whose understanding of the world comes entirely from within the pragmatic tradition could imagine that the description of a phase transition from one quantum field theoretic vacuum to another-both existing in a background spacetime-addresses the metaphysical-and probably unsolvable-question of why something exists rather than nothing.

And sadly, among the things you throw out when you discard philosophy is the work of Popper and others who established the demarcation between science and metaphysical nonsense.

I believe that the pendulum is swinging back because many of us have learned that an engagement with philosophy does greatly aid a serious assault on the key questions physics faces such as quantum gravity, the foundations of quantum theory and questions as to the choice of laws and cosmological initial conditions. Krauss wouldn't know it because he hangs out in the wrong circles, but there is a healthy dialogue between physicists and philosophers about these issues, which has greatly stimulated both sides. This engagement has been fruitful to a large extent because of a new generation of philosophers, such as David Albert, who are very well educated in physics. And as we see from Albert's review, they can certainly hold up their side of a debate because they understand contemporary physics far better than Krauss understands contemporary philosophy.

It is also disturbing to see that this fake issue is taken as somehow proxy for the conflict between science and religion. For one thing, it is hardly the case that Albert or other contemporary philosophers of physics defend the claims of religion or the medieval arguments about the why something rather than nothing query. Quite the opposite, they tend to employ the same piercing logic Albert used to puncture Krauss's arguments to destroy the claims of theologians and metaphysicians. Among the several ironies of this story is that the people Krauss is attacking are able to more powerful arguments against the claims of religion because they have a sophisticated education in the history of science and philosophy. To see how effectively a philosophically sophisticated physicist with a good classical education can make a case against religion that goes far deeper than Krauss's into the historical roots of the conflict with science, you might look at Carlo Rovelli's The First Scientist: Anaximander and his Legacy.

21. **Visitor**
April 27, 2012

Well I am not a scientist or mathematician, but I was struck by Krauss' claim that "science is meant to make people uncomfortable" because I have never heard this particular claim before. Being, it seems, very naive, *I* would have thought that, very loosely speaking, "science is meant" to make falsifiable statements describing observable facts. His statement is not an uncommon one, though, among attention seekers who think it excuses any kind of public or intellectual dishonesty. To me, it looks very much as though Krauss is saying that being a scientist gives him a license to lie. (Which is out-and-out Schneiderism but that's another subject.)

The antics of the current crop of loudmouth atheists brings to mind some of the more depressing and bleak sections of Ortega y Gasset's "The Revolt Of The Masses" because, in spite of their academic credentials, these people seem to be profoundly ignorant, and such people – very highly educated in certain narrow areas and completely lacking any knowledge of other areas – occupied a significant amount of Ortega's reflections.

22. **Roger**
April 27, 2012

Part of the confusion here is to equate nothing = aether = quantum vacuum state. Krauss's title says "Why There Is Something Rather Than Nothing", but there are always complicated quantum states present. He cannot say what happens when there is truly nothing.

23. **Peter Woit**
April 27, 2012

Hi Lee,

Thanks for writing. I agree that Krauss's broad-brush dismissal of philosophy is unfortunate. When Feynman, Gell-Mann and others were making great strides in understanding particle theory, one could understand their hard-nosed lack of interest in philosophy. These days I don't think theorists can afford to be so arrogant, since their track record of the last few decades is rather poor. Perhaps they need some help from another quarter.

I don't however think Albert's review was an impressive example of the power of philosophy. That there's other "nothings" than the vacuum state is rather obvious and didn't require a long bombastic argument. The "nerdy" business seemed to me just unprofessional and embarrassing. It came off as, well, something Feynman or Gell-Mann might pull.

If "philosophy of cosmology" would help keep straight the difference between science and metaphysical nonsense, that would be great. I haven't seen much of this though, and being funded by an organization devoted to blurring that line isn't really confidence inspiring.

24. **Anna**
April 28, 2012

Has science ever gained any insights from the musings of philosophy? The whole'nothing' debate is reminiscent of the 'how many angels on the head of a pin' discussions. If it is not measurable, who cares? Personally, I think that if the LHC confirms the Higgs and finds no hints of new physics, we will be left in a very uncomfortable place – two mutually inconsistant theories (QFT and GR), a swathe of apparently arbitrary parameters, some unknown symmetry breaking potential (the Higgs) … at least a null result or new physics would mean we need to rethink our models.

25. **Bugsy**
April 28, 2012

The easiest (and laziest) approach to something you haven't really studied is to belittle it. I see this tendency in myself concerning mathematicians- an analyst may privately
think set theory or category theory is a waste of time, a probabilist may feel that way about algebraic geometry and vice versa. Observing these tendencies in myself, the only thing I know is that when I really look into a new area, I am invariably surprised to find
something really interesting there. Don't know much about philosophy, for instance, but
I found Carlo-Rota's musings in his book "Indisrete Thoughts" very readable and interesting. Philosophy should not be mistaken for physics, however, nor vice-versa. For one thing, the general erudition and ability to use the language to express thoughts is expected to be higher in the humanities.

Where we get into trouble is when people in any area are motivated by personal greed, whether for money, power or fame, to over-hype low-quality work, and when intellectually lazy and arrogant people criticize what they do not want to try to understand.

On a lighter note, following Nex, I suggest the multiverse be expanded to something called the merriverse, which would bring the poets and real comedians (not unintentional ones) into the fray…

26. **theoreticalminimum**
April 28, 2012

Peter,
Have you read the latest news about *l'affaire Bogdanov*? Probably something you'd like to write about in a post?

27. **Lee Smolin**
April 28, 2012

Dear Peter,

I am normally a big fan of Krauss's writing defending science and I should say I haven't read the book. But if he said what Albert indicated he said then this time he over-reached.

The reason to prefer science to religion is not that science offers the better story to explain enigmas like why the world exists or consciousness. To the contrary, science offers nothing to compete with the certainties of religious dogmas on such questions. The reason is that science has a far higher standard for belief and this standard results in knowledge that is limited in scope and always provisional. But it is the best knowledge we can have, if by knowledge we mean provisional understanding that can be established and defended by rational argument from public evidence. Therefor it is a mistake to compete with religion on explaining how or why the universe began because it is a fight we can only contest by giving up the methodologies and standards to which we owe our entire success.

Anna asks for examples of contributions from philosophy to progress in physics. Here are a few that come quickly to mind:

-Leibniz's thinking on the need for space and time to be relational, a consequence of his principle of sufficient reason, inspired Mach to invent Mach's principle, which in turn inspired Einstein in his invention of general relativity.

-'t Hoofts work on foundational problems in quantum theory led to his postulation of the holographic principle which led to AdS/CFT.

-Turing and Godel's work on foundations of mathematics and logic directly inspired von Neumann and his colleagues in his invention of the standard architecture of computers. (as detailed in George Dyson's recent book.)

-David Deutch's thoughts on foundational problems in mathematics led him to invent quantum computation. The field of quantum information remains a lively point of interchange among physicists, computer scientists, and philosophers.

-Julian Barbour's extensions of Leibniz's and Mach's critiques led him to a deeper understanding of the role of active diffeomorphisms as the gauge symmetry of general relativity. This was a formative influence on the invention of background independent models of quantum gravity including loop quantum gravity. This also led him and younger colleagues to a reformulation of general relativity called shape dynamics, which in turn appears to explain the AdS/CFT correspondence as a property of general relativity.

-The best work on the many worlds interpretation of quantum theory is by philosophers of physics in Oxford, Simon Saunders, Hillary Greaves and David Wallace. I must say I am not convinced, for reasons best argued by David Albert, but they made a far better case for the cogency of the interpretation than had been given by physicists.

28. **Emanuel Derman**
April 28, 2012

I was present at a cosmology seminar at Columbia in the late Sixties in Pupin when Ed Tryon http://en.wikipedia.org/wiki/Edward_Tryon, in the audience, an assistant prof there, asked the speaker whether the universe might be a vacuum fluctuation. IT sounded like a joke at the time. He eventually published his idea as a paper: http://www.nature.com/nature/journal/v246/n5433/abs/246396a0.html. He once years later asked me to corroborate that I heard him ask that question, and I did.
—–
Science/physics is about studying details and deducing generalities: "To see the world in a grain of sand." I'm not a practicing anything, but I'm always struck by how narrowly Krauss and some of the new atheists interpret "the world."

29. **Jeff M**
April 28, 2012

Nice to see that Lee Smolin still thinks like a Hampshire student 🙂 Also nice to know that all those times Herb Bernstein told me "you'll never be as good as Lee if you don't get your act together" he knew what he was saying. Of course I decided I liked the math better anyway…
. I certainly agree that physics has no business discussing origins, since it just cheapens everything. My own intuition is that fundamentally the issue is "Godelian," in that I think there are things you can't say about a system unless you go outside that system, which in this case of course we can't do. From my experience there are very few philosophers who discuss origins for pretty much exactly this reason. You would think obviously intelligent people might realize how stupid they look when they're arguing about the existence of god or the concept of "nothing."

Then again, you can get some great jokes out of it. My favorite will always be from the Hitchhiker's Guide to the Galaxy, when Adams mentions Oolong Kaluphid's latest blockbuster, "Well That About Wraps it up for God." 🙂

30. **Peter Shor**
April 28, 2012

Peter: I believe Feynman was actually quite interested in philosophy. His work on the physics of computation owes something to philosophy in its nature, and he thought very hard about getting around Bell's proof of non-locality by using negative probabilities (an effort which ultimately was unsuccessful; I heard a talk he gave about it while I was at Caltech around 1980—see his article in *Quantum Implications: Essays in Honour of David Bohm*). There is a famous quote where he advises students not to pursue the philosophy of quantum mechanics—I think this was (and is) excellent advice, but I also think that it should not be taken to reflect his own opinion of the subject.

31. **Anonyrat**
April 28, 2012

I don't think Feynman would have any better opinion of some modern what-passes–for-physics than he had of some what-passes-for-philosophy.

32. **Peter Woit**
April 28, 2012

theoreticalminimum,

Thanks I hadn't seen that. Maybe I'll write about it here if I can learn more about what has been going on. Seems very odd that someone was taken to court for publicizing what I would have assumed was a public document (Igor Bogdanoff's thesis).

Given the recent trend towards nothingness/pre-big-bang/God studies in theoretical physics, perhaps the Bogdanovs should be recognized as true visionaries. They were pioneers in this field more than a decade ago. Their "zero-point" origin of the universe is true nothingness beyond Krauss's feeble attempt at nothingness, and might even satisfy Albert as really being nothing.

33. **pah**
April 28, 2012

It's weird… I am a theoretical particle physicist, and I never hear about studies on nothingness, pre-Big-Bang, multiverse etc, except through blogs such as this one. Guess I'm too busy working on LHC physics. Readers of this blog must have a pretty skewed idea of what people are working on in the field.

34. **Peter Woit**
April 28, 2012

pah,

You must also not watch TV (probably a good idea), not frequent bookstores (increasingly easy as they all go out of business), and avoid a segment of the hep-th arXiv. It's a valid point though that the high public profile of multiverse-mania does not at all correspond to the fact that most physicists think it is best ignored and act accordingly.

35. **Giotis**
April 28, 2012

"I am a theoretical particle physicist, and I never hear about studies on nothingness, pre-Big-Bang, multiverse etc, except through blogs such as this one. Guess I'm too busy working on LHC physics."

Good for you but not all people have to roll in the mud of the Standard model and of LHC physics. There are other issues of high theoretical importance which need to be explored. The fact that you are ignorant about these topics doesn't give you the right to belittle the people who are working on these fields.

36. **Peter Woit**
April 28, 2012

Giotis,

I find it wonderful that sometimes I can't tell whether you're serious or parodying a point of view…

37. **Mitchell Porter**
April 29, 2012

Nothing should be left to chance in this discussion. We can take nothing for granted.

38. **rshaw**
April 29, 2012

This entire discussion is wholly vacuous.

39. **pah**
April 29, 2012

Giotis, I meant no disrespect to anyone. There are indeed issues of high theoretical importance. However, I believe the only way to address them is by raking through the mud.

40. **Sebastian Thaler**
April 29, 2012

Lubos Motl has just chimed in as well on his blog.

41. **Marcus**
April 29, 2012

The logician R. Smullyan has considered the question "Which is better: eternal happiness or a ham sandwich?" and has argued as follows.
*
Well, nothing is better than eternal happiness.
And a ham sandwich is better than nothing.
Therefore a ham sandwich is better than eternal happiness.

42. **Peter Woit**
April 29, 2012

Sebastian,

In the Krauss/Albert case the insults flying everywhere are better than Lubos can muster (best he can do is describe Krauss as a "jerk"). He does however give an accurate account of a recent preprint by Lenny Susskind, the father of string theory:

"It's a philosophical ideology with a few equations remotely resembling elementary science that is being promoted by folks who found out that they feel very happy if they're sloppy and if they have a big mouth. Some of them are on crack."

43. **Thomas**
April 29, 2012

For those who can understand french (can't find an english version, sorry), here is the link to Carlo Rovelli's talk.

44. **The Lone Haranguer**
April 30, 2012

*Krauss (whose name he has trouble spelling) *

Maybe he's confusing him with someone else:
http://www.hellshaw.com/flann/deselby.html

45. **Marcus**
April 30, 2012

Thomas, in Lee's 8PM post on 27 April he mentioned this new book:
"… you might look at Carlo Rovelli's The First Scientist: Anaximander and his Legacy."

And then you kindly posted a link which according to the title is to a talk by Rovelli on Anaximander and the roots of the scientific tradition (in French).

However this link may contain an error. When I try it I get a lecture by a French astrophysicist named Kunth about some distant galaxies which he has observed.
Is the link to a two-part lecture, with the second half by Rovelli? I tried, but was unable, to fast-forward.

Rovelli gave a talk last week at Princeton about Anaximander and the scientific tradition–seminar in the Philosophy department organized by Halvorson, but AFAIK there is no recording online.

46. **Peter Woit**
April 30, 2012

Marcus,

The link works correctly for me, giving Rovelli's talk. Check to see that you're correctly following the link.

47. **Allan Rosenberg**
April 30, 2012

Before we get too comfortable with the idea of there being something rather than nothing, don't we need to define nothing more precisely? For example, can we say that nothing could have had an actual existence in its own right, or would nothing have been defined only relationally, as the absence of everything other than nothing? Had there been nothing, would there have been just a single nothing, or might we have had an entire multinullity in which–perhaps–every thing that could have existed would have had an independent nonexistence? As much as I wish I could come out on Krauss's side in this, I think philosphers are much better equipped to explore these kinds of empty questions than are scientists.

48. **paddy**
April 30, 2012

Allan R.: Yup, philosophers are much better equipped to deal with questions which are meaningless in science/physics.

49. **Thomas**
April 30, 2012

Marcus, Indeed Kunth rambled on for ages before Rovelli – I should have mentioned that.

I thought that was a deep and fascinating talk about a lesser known paradigm shift, the earth/sky vs up/down paradigm shift.

But particularly enjoyable is the argument Rovelli makes, that this paradigm shift was also some kind of a meta-paradigm shift: the birth of the "constructive criticism" that is essential to science. Brilliant.

I would like to put two questions, then, to this sophisticated readership (sorry if this brings us somewhat out of the Krauss thing):

1. is there a learnable method to accelerate the findings of paradigm shifts? (not just more budget)
2. is there a meta-paradigm shift that will be to science what science was to previous modes of thoughts? (found by a new Anaximander, in a move that would superseed science itself?)

50. **Neto**
April 30, 2012

@paddy

Actually, I could argue that physicists are much better to given the "meaningless" status to a question they can't answer.

Every question that is correctly formulated is meaningful, the question "why there's something rather than nothing" is perfectly meaningful, and it can have a lot of possible answers, between then the simplest "just because".

In fact, all this aggression between Krauss and philosophers is very naive, silly. Even this kind of post. As I'm not a physicist myself and have no reputation to lose, I can give me the please of commenting.

Of course philosophy is very important to our understanding and lead our thinking to new frontiers. Just because it sometimes can discuss topics that we cannot answer, or even give the wrong direction, it don't make it less useful. Indeed, that poor philosofical basis that some physicists may have makes them not even understand philosophical assumptions and propositions that themself made, what is embarassing.

I think the concept of nothing that sometimes philosophers are refering to is very conceivable and even is part of current models. As far as we know, this universe is expanding from a point the size of an atom to a finit size that it have now. What is inside this universe, despite being "something" (matter, stuff), is the Krauss' nothing, that is, vacuum full of properties and interactions between photons and so on. What is outside the boundaries of this finit universe is – possibly – the philosophers' nothing, the "meaningless no-existence". So, the meaningless no-existence is perfectly conceivable with our current theories, there's no reason to think the only no-existence that can exist is the Krauss' one.

Even this "existence of no-existence" talk is sometimes tricky and people want to use it to fuzzy the discution. But the questions still, and maybe, just maybe, sometime in the future we may have answers that will address them a lot better than now. But this questions should work as motivators, not as insult.

People like Krauss should note that being doubtful and intellectually honest won't make them looks any dumber, but the opposite. The most respectable and smart people that I know have no fear to say they don't have a clue about anything they don't know. It's all about intellectual honesty.

51. **Anonyrat**
April 30, 2012

"Every question that is correctly formulated is meaningful…"

The test of a question being correctly formulated is, is it meaningful?

52. **Aidyan**
May 1, 2012

"As much as I wish I could come out on Krauss's side in this, I think philosphers are much better equipped to explore these kinds of empty questions than are scientists."

Empty questions because the simple attempt to grasp 'nothingness' amounts to objectification. But objectifying is a cognitive act that refers always more or less implicitly to 'existence', and the very notion of 'existence' is rooted in some form of experiential conscious state of 'being', and which is 'something', leading to contradiction. Therefore the whole argument becomes circular and undecidable, at least for human mind. Taking second quantization's ground state levels or any definitions of quantum vacuum state (or 'quantum fluctuations' mixed up with or without 'virtual particles', an already doubtful fiction of our classical physics mind interpreting the math of QFT) as 'nothingness', can be a convenient physical mathematical working tool, but has no future as an ontological and universally accepted definition of nothingness, and even less can lead to any theological interpretations.

53. **Neto**
May 1, 2012

@Anonyrat

English is not my first language, so I can sound confusing. What I'm trying to say is that any question that respects language constructions and coherent semantics have a meaning. The "Why there's something rather than nothing" (WTISRTN) question have a perfectly clear and have meaning, but it may not have an perfectly clear answer, yet. Maybe someday we'll get in the time where one answer will be just "it is because it is", but that don't make the question meaningless, and I really hope this is not the case for the WTISRTN question.

Give the meaningless status to an reasonable question sounds a lot more like an Ostrich tactic than a real reflection about it.

If we consider that science is not about the truth, but about the facts that can be reach trough the scientific method, the question WTISRTN may not be a scientific question right now, but it don't make it meaningless. It may be someday.

54. **Peter Woit**
May 1, 2012

All,

Enough discussion of nothing, please. Please restrain your philosophical impulses. This is neither interesting nor entertaining.

55. **jg**
May 1, 2012

I meant to post this comment here (accidentally posted it on the other thread)

I'm not sure Einstein was so respectful of philosophical tradition as Lee Smolin (for example) suggests, in fact on page 2 of his 1922 'The Meaning of Relativity' he writes:

> ……………………………………………………. I am convinced that the philosophers have had a harmful effect upon the progress of scientific thinking in removing certain fundamental concepts from the domain of empiricism, where they are under our control, to the intangible heights of the a priori. For even if it should appear that the universe of ideas cannot be deduced from experience by logical means, but is, in a sense, a creation of the human mind, without which no science is possible, nevertheless this universe of ideas is just as little independent of the nature of our experiences as clothes are of the form of the human body.

http://www.gutenberg.org/files/36276/36276-pdf.pdf

56. **D R Lunsford**
May 3, 2012

Odd – Penrose had a "something from nothing" idea a while back that was actually interesting. As the universe empties out in the heat death of expansion, the world goes over into conformal invariance (nothing but free radiation) and the time scale becomes undefined. In this world without a clock, a vacuum fluctuation could be seen as a new Big Bang. The current discussion seems to have forgotten or ignored this relatively recent work.

-drl

57. **Nige Cook**
May 4, 2012

You've modified Penrose's "cycles of time" very slightly: he argued that the instant when blackholes have converted all matter into radiation which is redshifted so much it *cannot* cause any quantum event (wavefunction collapse), time ceases to exist and – with it – space (space can't exist without time). So at the precise instant that photons cease to be able to do work, space disappears and universe becomes a singularity, a new big bang. The big bang arises not because of a quantum fluctuation, but because such any fluctuation is impossible. Very Zen.

58. **Allan Rosenberg**
May 7, 2012

"Enough discussion of nothing, please. Please restrain your philosophical impulses. This is neither interesting nor entertaining."

So I guess you don't want to speculate on whether, had there been nothing rather than something, this blog would have been called Not Even There?

A Prediction About a Prediction

May 1, 2012
Categories: Uncategorized

In the years leading up to the LHC, string phenomenologists were vocal about their hopes to use string theory to make predictions about what the LHC would see, despite a history of a quarter-century of failure on the prediction front. For example, in late 2007 Michael Dine was writing in Physics Today:

> A few years ago, there seemed little hope that string theory could make definitive statements about the physics of the LHC. The development of the landscape has radically altered that situation. An optimist can hope that theorists will soon understand enough about the landscape and its statistics to say that supersymmetry or large extra dimensions or technicolor will emerge as a prediction and to specify some detailed features.

The main target for a landscape prediction has always been what appears to be the simplest possible question about BSM physics that the landscape could hope to address: is the supersymmetry breaking scale likely to be high (GUT/Planck scale) or low (electroweak scale)? By the time the LHC data started to arrive (showing no supersymmetry), these hopes for a landscape prediction had failed, as it became clear there was no way to get a clear answer about this (or any other question…) out of landscapeology. Landscape proponents have still not given up though, with Michael Douglas yesterday putting out a survey of work on the SUSY question, The string landscape and low energy supersymmetry. He has no string theory predictions, but he has a (very tentative) prediction about a (sort of) prediction:

> I am going to go out on a limb and argue that
>
> *String/M theory will predict that our universe has supersymmetry, broken at the 30 – 100 TeV scale. If at the lower values, we may see gluinos at LHC, while if at the higher values, it will be very hard to see any evidence for supersymmetry.*
>
> This is a somewhat pessimistic claim which far outruns our ability to actually make predictions from string theory. Nevertheless I am going to set out the argument, fully realizing that many of the assumptions as well as the supporting evidence might not stand the test of time.

As for the time scale and reliability of this prediction of a prediction, he writes:

> My guess at present is that twenty years or more will be needed, taking us beyond the LHC era. Even then, it is likely that such predictions would depend on hypotheses about quantum cosmology which could not be directly tested and might admit alternatives. It is entirely reasonable that sceptics of the landscape should reject this entire direction and look for other ways to understand string theory, or for other theories of quantum gravity. At present we do not know enough to be confident that they are wrong. Nevertheless the evidence at hand leads me to think that they are wrong and that this difficult path must be explored.

So, optimistically, if all goes well, long after the LHC is shut down, maybe we'll see a landscape prediction about whether the LHC should have seen SUSY. This prediction will depend upon assumptions about quantum cosmology that can't be tested, so if it disagrees with what the LHC saw, that won't falsify the landscape anyway.

Meanwhile, Gordy Kane is promoting the idea that string theory already has made a prediction: a 125 GeV Higgs mass, spectacularly in agreement with the latest data, and gluinos detected "by summer", "with masses around a TeV, maybe less" (see here). He's giving a talk today at the Simons Center with the title "String theory, the real world, and the prediction of the Higgs boson mass". As far as I can tell though, no one except possibly his collaborators believes him. At a public talk on the Higgs recently here at Columbia, Brian Greene was very skeptical, joking that if the LHC had seen something at 142 GeV, that would be Kane's "prediction" (for more about this, see Lubos's outraged coverage here).

Matt Strassler recently weighed in on the Kane prediction, which so outraged him that he has stripped Kane of his professional title. Matt is careful to put "Professor" before his own name and those of others who deserve the title, but Kane is now "Mr. Kane":

> The level of garbage and propaganda surrounding the Higgs is getting pretty ridiculous.
>
> You realize, yes, that by August 2011 the window for the Standard Model Higgs was down to 115 to 140 GeV, right? So your chances of getting within 5 GeV of the right answer is 15%. Many theories before Mr. Kane predicted a range that included 125 also. I'm completely unimpressed both by the science and the propaganda. Most of my friends who are experts in compactification (which Kane is not — he relies on one of his collaborators — and I am not an expert either) are not convinced of the assumptions on which they base their arguments. It all sounds good. But is it really? I've heard lots of arguments that sounded good over the years… and most of them are now known to be wrong. None of them are known to be right.
>
> Do not judge science on the ability of the scientist (who wants his or her Nobel prize and is trying his or her best to convince you) to present a compelling argument. A great salesperson can create a terrific argument; a great physicist does not need one.

So, Kane seems to be finding that his "string theory prediction of the Higgs mass" is being met with scorn, from all segments of the particle theory community. I'm curious what has happened to his paper from early December, which I'd guess was intended for PRL, but has yet to appear. He has about a month and a half for the gluinos to show up "before summer" and vindicate his "prediction".

The Strassler comment was at a useful posting about the state of SUSY searches (see here). Matt's time estimate for how long it will take the LHC to rule out SUSY: "This will take a while, probably a decade." A more mainstream time estimate might be that it has already happened. For Tommaso Dorigo's take on this, see SUSY and the Silence of the (Roasted) Lamb.

Starting tomorrow Brookhaven will host a workshop on the state of SUSY topic. For latest developments, look at the slides as they appear here.

Update: The video for Kane's talk at the Simons Center is now available. Instead of gluinos "by summer", he's now changed his tune, and he expects "discovery during 2012" (if the expected luminosity goals are met). The mass of the things has moved up from less than about 1 TeV to less than about 1.3 TeV.

Update: The Kane et al. paper with the Higgs mass "prediction" has just appeared at Phys. Rev. D. The preprint went to the arXiv on December 5, the Phys. Rev. D submission date is February 13. One guess would be that this more than two month delay might be due to the paper being rejected (or a referee insisting on the "string theory prediction" nonsense being removed) wherever it was first submitted, perhaps PRL.

Comments

1. **Shantanu**
   May 1, 2012

   Great article, Peter. Btw what's the status of models like Randall-Sundrum or ADD?
   From what I understand there is no evidence for these in LHC data. But some people such as Cliff Burgess(from his talk at PI) still seems sanguine. I asked this question

to L. Randall when had a post on cosmic variance, but didn't get a reply.

2. **Peter Woit**
   May 1, 2012

   Shantanu,

   LHC data has ruled out RS and ADD models at currently accessible energy scales at the LHC. Despite the huge publicity campaign for these things pre-LHC, hardly anyone ever seriously thought they would show up at the LHC. Now no one does, and it's thought best to just try and forget the publicity campaign. In principle in a few years when the LHC goes to near design energy, there's a new energy range to check. I seriously doubt though that even the biggest enthusiasts for these things would bet any money that something will show up, even with 10-1 odds in their favor.

3. **Allan Rosenberg**
   May 1, 2012

   "You realize, yes, that by August 2011 the window for the Standard Model Higgs was down to 115 to 140 GeV, right? So your chances of getting within 5 GeV of the right answer is 15%."

   Last time I checked, 10/(140-115) = 40%.

4. **Bernhard**
   May 1, 2012

   Wow, so lots of people putting Gordy Kane in a tight corner. I think Witten should speak up too, that would probably put and end on his infamous campaign.

5. **P**
   May 1, 2012

   Hi Peter,

   Two questions, but first a comment.

   Mike Douglas is better situated to say things about the landscape than just about anyone, including predictions of individual vacua (they exist!) but also whether or not the landscape as a whole prefers certain types of physics over others (which would be interesting if it did, because quantum field theory doesn't.) You make it seem that no one who is serious takes Kane seriously, but Douglas directly quotes Kane's work as having influenced his thoughts on the subject.

   Which leads to my questions:

   Did you actually read the Douglas article or did you just cherry-pick the first section regarding "predictions", bringing up the sorts of issues you usually do? That's a fine approach to some articles, though still unfair, but Douglas is a real expert and he wouldn't put his name on it without serious thought. There are very few people on the world that have his level of knowledge on string vacua and the landscape.

   And a more playful question:

   It seems you're not a fan of low energy SUSY. Do you believe that Higgs boson exists, and if so, what is your favorite mechanism for solving the hierarchy problem and why? Many theorists would invoke SUSY for precisely that reason.

   Cheers,
   P

6. **Slacker**
   May 1, 2012

   The paper of Kane et al clearly states all the assumptions and caveats, e.g. the MSSM spectrum below the GUT scale, N=1 D=4 supergravity framework, etc, so I see no reason for Mr. Strassler to belittle this work and refer to is as 'garbage'. Btw, both Acharya and Kane were twice acknowledged in the Douglas paper, so string phenomenologists do pay close attention to what they have to say. If you read their most recent review and compare it to the Douglas paper you'll notice a common thread. The set of arguments presented in their review, which also includes the Higgs mass discussion, are not at all controversial and pretty much agreed upon by most string phenomenologists who understand the details of moduli stabilization and SUSY breaking in N=1 D=4 supergravity.

7. **Peter Woit**
   May 1, 2012

   Slacker,

   Perhaps you can take up Strassler's and Greene's evaluation of Kane's claim with them. I'd be curious to know if you can find a single prominent theorist (not a collaborator of Kane) willing to say publicly that he thinks Kane really has done what he claims: predict a Higgs mass of 125 GeV from string theory.

   Slacker and P,

   I don't doubt that Douglas has paid attention to what Kane is trying to do, and, as he says, that line of thought has influenced his hopes of getting predictions out of string theory. I also note that he doesn't reference Kane's December paper claiming the 125 GeV prediction, or mention this prediction. He's quite explicit about what he sees as prospects for getting predictions out of string theory, and what he says about this is completely inconsistent with Kane's claims. He is clearly implicitly saying he doesn't believe that Kane has a string theory prediction of the Higgs mass.

   Slacker,

   I read parts of the paper carefully, skimmed others enough to see what arguments Douglas was making. Note that I've attended several talks by him on this topic, read the slides of others, as well as several of his previous papers. With this background, I looked at his paper to see what was new. The most striking new thing to me was the much more pessimistic evaluation of prospects for this program, so that's what I wrote about. I've never heard him before say that it would be at least twenty years before this led to any sort of prediction, and that even then it wouldn't be a real one (i.e. you would always have to put in assumptions about string cosmology).

   Kane I think is really out of his mind, making absurd and outrageous claims. Strassler's "garbage" quote is apt. Douglas is quite different. He's not claiming to have solved any problems or to have something he doesn't have. He even acknowledges that others looking at the same set of facts as him will quite reasonably conclude this is a doomed project.

I've repeatedly written about the "hierarchy" problem here. My basic point of view is that I'm unconvinced that it's a problem. One way of stating the problem is to say that we have no explanation for why the electroweak scale is so small compared to the GUT or Planck scale. Here I think it's a good idea to keep in mind that we don't even know if there is a GUT scale, and don't know enough about quantum gravity to understand the significance of the Planck scale. Put differently, the hierarchy problem is largely a problem set inside the GUT/string scenario of what a unified theory looks like. Such scenarios seem to so far be failures, so why worry about a "problem" that comes with them?

The Higgs field does pose serious problems, but they seem to me different than the "hierarchy" problem. Matter and gauge fields have a geometrical structure that tightly constrains their behavior. A scalar Higgs doesn't, introducing for instance the highly undesirable feature of completely unconstrained Yukawa couplings and thus arbitrary fermion masses and mixing angles. This to me is what really cries out for explanation, not the fact that the Higgs mass is small compared to the Planck scale. If SUSY had anything interesting to say about that, then I'd be a fan.

8. **Shantanu**
May 2, 2012

Peter or others, I think someone mentioned on physicsforums that Wetterich and Shaposhnikov had a paper on Higgs mass of 125 Gev 2 years before CERN result (see http://arxiv.org/abs/0912.0208). What do you think of this
Why doesn't anyone refer to this or mention it as a prediction of "string theory"?

9. **Peter Woit**
May 2, 2012

Shantanu,

I know nothing about that particular calculation, but it is remarkable that the Higgs is in the range where the SM holds out to very high energies. But, since this has nothing to do with string theory, it doesn't get that much publicity.

10. **theoreticalminimum**
May 2, 2012

I think it might be somehow interesting to some to read some of the other articles to figure in the memorial volume, which are linked to here.

11. **Andy**
May 2, 2012

Higgs-mass predictions, by Thomas Schucker
http://arxiv.org/pdf/0708.3344v8
gives a list of 96 Higgs-mass predictions, with references.

12. **M**
May 2, 2012

It is beautiful to see how well these pre-dictions change when new data arrive.
We should admire how flexible is string theory in adapting to whatever experimental result, improving from old-fashioned Heterotic Strings to modern Elastic Strings.

13. **theoreticalminimum**
May 3, 2012

I am currently watching the linked Kane talk. First of all, I am very surprised that Kane spent so much time painfully elaborating so much on what would be considered very elementary to a SCGP audience. Did he realise he was talking to experts in theoretical physics? Just something that caught me off-guard: I'm not sure I understand what Kane meant by F=ma not being testable. He used the word "tested" many times in his talk, but didn't seem to be bothered to define what he understands by something being testable or not. Can anyone enlighten me?

14. **piscator**
May 3, 2012

The simplest objection to the Kane etc work is that G2 manifolds are not, unlike Calabi-Yaus, actually constructed. The `G2-MSSM' does not involve an actual construction of the MSSM and does not involve an actual G2 manifold.

So given that in the UV you don't have the manifold and you don't have the model, many (including myself) think a little humility is needed on the the extent to which any of this work represents string theory predictions for the Higgs mass.

15. **Bernhard**
May 3, 2012

Peter,

you mean "about 1 *TeV* to less than about 1.3 *TeV*".

16. **Peter Woit**
May 3, 2012

Thanks Bernhard, fixed.

17. **Bernhard**
May 3, 2012

theoreticalminimum,

I also don´t get it. Kane say other strange things like "the Standard Model is the most theoretical theory that´s ever been, maybe that ever will be", but none of them is more nonsense than

"last summer we did a string theory, a honest string theory calculation of predicting the Higgs boson mass and the one they reported in December was the one we predicted they should report".

18. **Peter Woit**
May 3, 2012

theoreticalminimum,

This is now standard issue string theory ideology: string theory (which predicts absolutely nothing) is just as good as the quantum field theory (which gives us the Standard Model, the most successful theory in the history of science). The argument is that both are just "frameworks", just like "F=ma" is a "framework" (you need to pick a QFT, and pick an F, just like you need to pick a "string theory vacuum").

Arguing that the biggest failure in history of science is the same as the biggest success is obviously sophistry, but rather popular sophistry these days.

19. **Mark**
May 3, 2012

piscator, indeed, the G2-MSSM does not involve a specific singular G2 "manifold" (explicit smooth examples have been constructed by Joyce and Kovalev and the singular ones should exist by the arguments involving dualities) but instead, it uses the most general *known* properties of G2 manifolds. The scaling dimension of the 7-dim volume wrt to the moduli is known, the form of the moduli Kahler potential is known from dim reduction, likewise, the general functional form of the gauge kinetic function in terms of the moduli and the general dependence of the Yukawa couplings on the moduli are known, and the general scaling properties the Kahler metric for bifundamental chiral matter is also known from locality. It turns out that one can robustly demonstrate how to stabilise the moduli in this very general case without referring to a specific G2 construction, for instance, without knowing the precise moduli dependence of the volume in the Kahler potential but only its scaling property. Also, surprisingly, it turns out that the soft breaking terms in these vacua "forget" about most of these microscopic details as these computations involve a bunch of contractions, so the explicit moduli vevs drop out of the final result. In the end, the only moduli dependence appears through the 7-dim volume, which is considered a parameter, but which becomes fixed from bottom-up by the relation between alpha_GUT and m_planck. The specific properties of G2 manifolds that directly affect the numerical coefficients in the final results for the soft terms are the scaling dimensions, which are known. Be assured that Bobby Acharya, who is a world expert in these matters, would not be putting his name on these papers if there was something dodgy.

20. **Mark**
May 3, 2012

piscator, here is the G2-MSSM reference I found to be the most useful: http://www.springerlink.com/content/g6288v55tj184588/?MUD=MP

21. **P**
May 3, 2012

Peter,

Forget the F=ma stuff.

You state that you don't the like argument but you don't actually argue against it, which particularly frustrates me because I've espoused this view multiple times.

String theory and quantum field theory make predictions about the sorts of objects that exist in those frameworks. Neither, as frameworks, makes precise predictions about precise structures.

A string vacuum or a particular quantum field theory require introducing more input. Each makes precise predictions (matter content / gauge symmetry and scattering amplitudes, e.g.) that either are like the world or are not like the world. Most string vacua look nothing like the standard model. Most field theories look nothing like the standard model.

It is dishonest and an outright lie to pretend like an individual string vacuum doesn't make precise predictions about things like gauge symmetry and matter content. The ST FT and string vacuum particular QFT analogy is a good one for the reasons just mentioned. The issue, as I say over and over, is whether or not with LOW ENERGY EXPERIMENTS we can tell the difference. After all, at low energies, string vacua just look like effective field theories.

It's not that there aren't issues – there are – but pick the right ones, please. The landscape and the vacuum selection problem are the issues, not whether individual vacua make predictions.

P

P.S. Your previously comment about the Higgs mass hierarchy problem misses the point that it doesn't require GUTs or strings. The problem is the fine-tuning associated with the quadratic divergence of the Higgs boson mass, which has nothing to do with WHAT the UV completion is.

22. **P**
May 3, 2012

I second what Mark says.

Agreed, the big drawback of the G2-MSSM scenario is that no one has constructed an actual global MSSM model of M-theory on a G2 manifold.

Their scenario takes a very different approach, as discussed by Mark.

23. **P**
May 3, 2012

Sorry to harp, Peter, and sorry for three postings in five minutes.

Just to remind everyone, by the "biggest failure in the history of science", Peter is referring to string theory for the purposes of unification and a theory of everything.

Though I find his arguments flawed, there, as do many, I think that he and I would both agree that string theory as a subject has made tremendous contributions to pure mathematics and our understanding of quantum field theory, regardless of any statement about unification of fundamental physics.

Cheers,
P

24. **Peter Woit**
May 3, 2012

P,

I've repeatedly, many time, here explained what I see as the difference between the Standard Model situation and the string theory vacuum situation. In one case, among the simplest possible choices leads to an extremely restrictive and predictive model, one that makes absurdly precise predictions, which agree exactly with experiment. In the other case, all you are doing is cooking up more and more complicated models, carefully designed to avoid falsification.

Trying to argue that the QFT/SM situation is "the same" as the string theory/string vacuum situation is like trying to claim that black=white, since they're both shades of grey. It's a waste of time to try and have a discussion with someone who wants to tell you why black=white.

About the hierarchy problem: the quadratic divergence may just be an artifact of perturbation theory. I state it the way I did (which is quite conventional) because it makes sense non-perturbatively.

25. **Bernhard**
May 3, 2012

    P,

    I think the problem is in in the framework itself. To put differently, what do you need to construct a realistic theory of nature starting from QFT and starting from string theory? Peter made some interesting comments e.g. here: http://www.math.columbia.edu/~woit/wordpress/?p=4065&cpage=1#comment-98564

    And after we deal with this very ugly construction, what does it predicts? At low energies you say it looks like QFT, so I certainly don´t need it.

    At high energies (GUT scale? Planck?) what does it say? Would one be able to compare string theory with experiment in the same way the standard model is, even if we had a galactic accelerator?

    I don´t think so, put please correct me if I´m wrong.

26. **piscator**
May 3, 2012

    Mark, P

    Thanks for the comments. I do know this model and these papers (in fact I was the referee for the paper Mark referred to).

    It is a perfectly well-defined and honest task to take a 4d supergravity model, with assumptions that are more or less inspired by string theory, and study its properties and analyse its phenomenology. The model considered has some interesting features and it is perfectly reasonable to study it.

    However this gives absolutely no justification for saying this is a string theory prediction of the Higgs mass. I haven't watched the video, so I don't know whether the quote is accurate, but it is indefensible to call this an `honest string theory calculation'.
    This is not string theory. At best it is a 4d supergravity theory with properties inspired by string theory – which is fine, but is not string theory.

    String theory is special because of its ultraviolet behaviour. Look at the ultraviolet for these models – there is no actual manifold there, there is no actual construction of the MSSM, there is not even the worldsheet picture as you are in the M-theory regime.
    I'm not that down on this, because the subject is hard and you have to do what you can and not what you can't. But let us be honest about the difference between computing something and postulating it.

27. **P**
May 3, 2012

    Peter,

    Simplest possible choices!? The representation theory and couplings of the standard model are far from simple.

    And remember, I'm not comparing vacua with the SM, i.e. a single field theory. I'm comparing vacua with particular QFTs. The point is, given a particular quantum field theory or a particular string vacuum, in each case we can ask "does this match what we see in the world?". We have a particular quantum field theory, the standard model, that experiment tells us correctly describes particle interactions below the TeV scale or so. It has a tremendous amount of unpredicted, empirically determined input. Tell me, now, what predicts the tremendously detailed, complicated structure of the standard model? What predicts the gauge symmetry, matter content, and chiral structure? Because string vacua predict these things, remember . . .

    Re the hierachy: okay, I'll agree with that, but it's still not a GUT / string issue. It's a "high scale" issue. Any non-perturbative physics which would solve the hierarchy problem would have to kick in at a very low scale (TeV), though. And your point is that it would alleviate the quadratic divergences and cut off the running?

    Bernhard,

    Thanks for the comment. Your question "why do I need it?" depends on your taste. If you're just interested in modeling nature at low energies and are fine with unexplained mass hiearchies (note: different from previously discussed hierarchy problem), e.g., then effective field theory will model it just fine. String vacua give many mechanisms for explaining detailed structure and also predict things that QFTs don't (as far as I know): gauge symmetry, matter content, and chiral structure.

    At high energies, there definitely are stringy signatures that are clearly distinguishable from field theory. Technically this occurs at the string scale, but this is typically a high scale near the Planck scale. There, it is possible to excite very massive string modes which form an infinite tower, and there are papers on how the collider signatures could determine that it is a string mode and not some other type of tower of modes, such as a KK mode. It's worth pointing out that, along with gauge symmetry (almost always spontaneously broken) and general relativity at long distances, such modes are generic predictions of all string compactifications (that I know of). It is on the details where particular vacua differ, such as the precise structure of the gauge theory, and these are very important.

28. **P**
May 3, 2012

    Piscator,

    The one addendum is that their "string-inspiredness" regarding moduli masses really is applicable to all string compactifications. How broadly their claim about m_3/2 holds in M-theory, I don't know.

    I couldn't agree more. Very well said. Thanks for the comment.

P

29. **Peter Woit**
May 3, 2012

P,
In the case of string theory you're invoking a non-existent fairy land, where all the many problems of string theory and string theory "vacua" have vanished. In the case of the SM, you're describing a theory that can be written on a t-shirt as "tremendously detailed, complicated structure", and the trivial and defining representations of SU(3) and SU(2) as "far from simple". This kind of argument allows you to equate black and white, but it's kind of absurd.

Again, I'm not convinced there is a hierarchy problem that needs to be solved. The quadratic divergences are not obviously relevant. Until you have some specific kind of new physics at a higher scale, you just don't know whether the fact that the electroweak scale is much smaller than that scale is something that requires any explanation.

30. **Mark**
May 4, 2012

piscator, I agree, these are effective N=1 D=4 sugra computations where W, K and f are dictated by the known properties of G2 manifolds/compactifications. I'd also add that apart from toroidal orbifolds where explicit worldsheet computations have been done to compute, e.g the moduli dependence of the Yukawa couplings, Kahler metric etc, a lot of string phenomenology comes down to an effective field theory analysis combined with methods from algebraic geometry. I'm convinced that a lot more progress would be possible if explicit global G2 examples were constructed, independent of whether we have a complete formulation of M-theory. So yes, I think that for Gordy Kane to claim that they did explicit string theory computations is very misleading but. having seen his talk, I'd say go easy on him, he is not a string theorist so maybe he just does not know the difference, but his enthusiasm is certainly inspiring.

31. **P**
May 5, 2012

@ Peter:

Name a particle in the standard model that is only in the fundamental of SU(3) or SU(2) and transforms trivially under all other groups. Give me an example of some trivial structure of couplings or mixing angles that appears in the standard model.

The only reason we have identified the standard model as a good description of nature is because low energy experiments are good at distinguishing between particular quantum fields theories in the continuously infinite class of theories. The real problem with string vacua isn't that they don't make predictions. The problem is the landscape, and the fact that at TeV scale energies string vacua almost always look like standard quantum field theories. Sufficiently high energy experiments would be able to not only distinguish between the effective theories of different vacua, but also differentiate between whether nature is described by a string theory or a quantum field theory which is UV completed in a different way.

You're not really even responding to my arguments and instead are just saying the names of colors and invoking fairies. Please, please, please: just acknowledge the real problem. A string vacuum makes predictions, e.g. a low energy gauge theory. Almost none of them look like the standard model, but some do. With low energy experiments, it may be impossible to decipher which UV completion gives rise to the effective theory that describes nature. That is the problem, not that a string vacuum doesn't make predictions. If you acknowledge this, I'm happy to stop harassing you, but I feel the need to respond as long as there are false things stated in these comments!

You are not a string theory expert and have written a popular book and gained a voice in the community – and there should be dissenting voices, including yours – but progress of science requires honest dialogue about what the problems actually are in any given field. You seem to miss the actual problems, sometimes. Notice that I'm not one of those string zealots who is trying to say there aren't problems. I'm just trying to be clear about what they are . . . and I've stated them here.

Q: Do you acknowledge that a given string vacuum predicts the low energy gauge group and matter content? You continually avoid this question and imply that a string vacuum makes no predictions. Maybe you're just not aware, but I'm curious.

Regarding the hierarchy, I'm confused by what you're saying. Are you arguing that there isn't a fine-tuning problem between the bare mass and the lambda^2 contribution? Surely that must not be it – I've never heard a physicist take this viewpoint – but if so, please explain. The fine-tuning problem is independent of what new physics might come in at the cutoff.

@ Mark: right on.

32. **Peter Woit**
May 5, 2012

P,

Yes, there are 3 couplings in the standard model we don't understand the origin of, as well as an interesting, simple, pattern of representations of SU(2), SU(3) and U(1), involving nothing more complicated than the fundamental representations in the case of SU(2) and SU(3). This is a very small amount of basic data we don't understand and have no idea what explains it (best effort is the SO(10) GUT). There's also a matrix of masses and mixing angles, and two couplings, all due to the Higgs field. That's a huge problem we have no idea about.

For the case of string theory: we don't even know what string theory=M-theory is, and we can get almost anything we want out of it. No one has any way of even saying what a "generic" string theory/M-theory vacuum would be, or, given best guesses of such a thing, no way to reliably calculate what it predicts. The one "M-theory vacuum" that has been extensively studied outside of perturbation theory (AdS5) looks nothing at all like the real world: wrong dimension, none of the SM at all). All "string theory vacuum predictions" are based upon going to some extreme limit of parameters where you hope string perturbation theory will be reliable and various assumptions about branes will work out, and engineering something to fit the simple data that define the SM. When you do this, all you ever get is what you put into it.

I have no idea who you are and whether you have any idea what you are going on about. The description I gave above of the situation of string theory is not just my opinion (based on 30 years in this business), but now conventional wisdom among particle theorists. Even most string theorists these days agree that string theory can't be used to predict anything and think activity like Kane's is a bad joke (see the Strominger talk linked to in the next posting for example).

Answers to your questions: as explained above, you only get reliable calculations of the low energy field content when you drive the theory to a corner of its parameter space, and make some optimistic assumptions. As for the hierarchy problem, for the N'th time, the problems with the perturbation expansion is not obviously a physical problem. I don't have time to find a good reference that explains the standard lore about this, but 5 seconds of Googling turned up this paper

http://arxiv.org/pdf/1201.0857.pdf

which explains the issue from the point of view I've been talking about, one which is completely conventional.

33. **P**
May 5, 2012

Peter,

We're in complete agreement, then, about how the standard model is complicated, particularly at the level of Yukawa couplings which all involve the Higgs field, and how the matter content representations fit nicely into the 16 of SO(10). We're also in agreement that this is a huge problem, and you would probably agree with me that it would be tremendous progress in particle physics if one were able to derive them from some more fundamental consideration.

Since you mentioned how SO(10), for example, can nicely explain the standard model representations, I'll mention how this might arise in one type of string vacuum, though similar considerations hold elsewhere. Consider heterotic M-theory on CY3 x interval. This is not simply a "region" of "parameter" space (which doesn't even make sense, we should be talking about moduli space). A stable holomorphic bundle with structure group SU(4) will break the E8 (which must exist at 1 end of the interval for anomaly cancellation) directly to SO(10). Simple discrete choices of bundle-defining parameters can give rise to 16's of SO(10). As you implied by your mention of SO(10), all of the standard model fermions can fit into this representation. Furthermore, a good deal is known about non-perturbative effects in heterotic M-theory (worldsheet instantons and the like), contrary to what you implied. So getting things something like the standard model reps are definitely NOT just in miniscule regions of parameter space where all we have is perturbation theory and we don't know anything else.

Rest assured that I am well educated in both particle physics and string compactification and am familiar with the pitfalls and subtleties in both subjects. I am someone who sometimes feels the need to correct misinformation about these subjects on the web, regardless of where it may be. Often times I see it on this blog. Regarding particle theorists, many dislike string theory for the sake of unification. Sometimes that dislike is out of knowledge (as I've said, there are good criticisms!), and sometimes out of ignorance. Then there are also serious particle physicists who like string unification and have worked on it or related topics.

Regarding string theorists themselves, many would probably be wary (as would I) of the ability of low energy experiments to determine the UV completion of the effective theory we see at low energies – i.e. to test the stringiness of string theory that is not present in QFT. But 95% of string theorists would tell you 1) that string vacua predict certain things at low energies such as gauge symmetry and matter content (as evidenced by quality of people in the last ten years who have worked on these things) and 2) at high energies (string scale) there are clear stringy signatures that would allow one to distinguish between string theory and quantum field theory. This is a limitation of our experiments, not of our theory.

Regarding hype, we're in total agreement. It has no place in any science of any kind, and honest dialogue about science is the only proper thing to replace it.

Regarding the hierarchy – perhaps there is something I'm missing and I should look at this paper closely. But as an expert it worries me that I've never heard of the people who wrote that paper, and moreover I've never heard any particle theorist try to dismiss the hierarchy problem in the way you are. An alternative Google search "why the hierarchy problem is a problem" returns two Wikipedia articles first, and then some slides by Joe Lykken on solving the hierarchy problem. He, a very very well known particle theorist, as you know, seems to take it quite seriously.

34. **P**
May 5, 2012

clarification: on the last paragraph, I mean that as an expert in high energy theory (not the hierarchy problem) who very often talks to people who focus solely on particle physics, I've never heard anyone try to dismiss the hierarchy problem in the way you are. Humbly, I haven't thought about it too seriously beyond the common objections stated by particle theorists. There may be more things to take into account that I'm missing, but my point is that very very good people take the problem very seriously and don't just talk it away. I'll take a look at the paper you posted this week, though.

35. **Peter Woit**
May 5, 2012

P.

Yes, I know you can get SO(10) and the spinor rep (as well as just about anything else…). The big problem though with an SO(10) GUT (besides proton decay, or course…) is that you don't have a good idea about how to break it down to the SM. Adding more Higgs fields just adds a new set of parameters you don't understand in addition to the SM ones. If string theory provided any insight into these problems it would be interesting, but it doesn't. The problem with string theory, right back to 1984-5, is that it doesn't tell you anything about the SM you didn't already know. This was the reason I (and many others) were skeptical about the whole idea from the beginning. Nearly 30 years of effort hasn't improved the situation, quite the opposite.

The paper I linked to was randomly chosen, I don't know the authors. Their introductory text though makes clear that they are just repeating conventional wisdom you can find anywhere. This is the way the "hierarchy problem" looks if you try and state it non-perturbatively. As for my point of view on the "hierarchy problem", maybe it is a minority one, but I think if you ask around you won't have trouble finding theorists who were never impressed by the "hierarchy problem" argument, or see it as a relatively weak one, tied to our flimsy ideas about GUT-scale physics. The idea that there is a GUT/Planck scale and that you should worry about it is certainly part of the standard lore of how to think about BSM physics, but this lore has been highly unsuccessful in terms of leading to anything.

Much of the attention to the "hierarchy problem" was always because of its use as an argument for why the LHC should see BSM physics. Now that this physics is not showing up, the "hierarchy problem" argument will start to get ignored.

36. **Anonyrat**
May 5, 2012

1. If String Theory cannot tell me anything about how the effective QFT GUT (e.g., SO(10)) that it yields further flows down to the Standard Model, then the solution of the mystery of the Yukawa couplings and of the hierarchy problem (if there is one) cannot lie in String Theory.

2. For String Theory to be convincing as a lead I would want to follow, at a minimum, I would expect the stringy SO(10) GUT to be very strongly theoretically constrained. It should pick a very tiny part of the space of SO(10) GUTs that can plausibly flow down to a low energy theory that looks like the Standard Model. If it does that, even if I can't practically calculate anything, I'd be strongly inclined to take another serious look at String Theory.

37. **P**
May 9, 2012

Hi Peter,

Sorry for the delay in writing back, it's been a busy week.

Regarding your SO(10) comments – I don't disagree *quite* as much with these, though I'm certainly no expert on Higgsing it to the SM (126-dim rep, right?). There has been some talk of whether these reps are even possible in string vacua. A rough argument against them is that in many types of string vacua, a 248 of E8 is the highest rep, so you're not going to get a 126 of SO(10).

A string vacuum can and does predict things that QFT does not, e.g. particular matter reps, etc. If one vacuum was uniquely selected by some mechanism (hopeful), this would be a prediction (or postdiction, you might say) of something that is input in the standard model. But barring that, it is likely very difficult or impossible at the TeV scale to differentiate whether the effective field theory we observe is lying in a string vacuum or some other UV completion. Though you might not be happy with the first two sentences, I bet you'd happily agree with the last.

Anonyrat,

Certain it is well known that string vacua do give mechanisms for accounting for Yukawa hierarchies and the like. Small Yukawas can be generated radiatively from bulk effects or from any of the myriad of instanton effects, for example. There are also various rank arguments in F-theory.

The space of SO(10) GUTs is enormous, but gauge theories in string compactifications are typically more constrained than the space of all gauge theories due to something known as tadpole cancellation. For example, in QFT you could take SO(10) GUT with N 16 dim spinor reps. Quantities like N are typically bounded in string compactifications. In QFT they are not. Of course, from data observed below a TeV, N=3 seems like the right number, but we do not know for sure.

Cheers,
P

Neutrinos to Give High-Frequency Traders the Millisecond Edge

May 1, 2012
Categories: Experimental HEP News

Recently US plans for the LBNE next-generation neutrino experiment have run into trouble finding room in projected HEP budgets. Today (via Emanuel Derman's twitter feed), I learn of a promising new source of funding. A Forbes columnist reports here on prospects for using neutrino-based communication through the earth to do high-frequency trading, arbitraging prices in markets on opposite sides of the globe.

To actually do this, I'd guess that financial firms would have to site machines like Fermilab's proposed Project X and detectors like the LBNE one close to the servers running the markets. When they do this, maybe they'll let physicists use them on weekends to do physics. It has been unclear whether the US government could afford to build Project X/LBNE, but surely Goldman Sachs and other major investment firms would have no problem coming up with the billions needed. Yes, I'm well aware that this is a completely insane and ridiculous idea, but that hasn't been an obstruction to Wall Street innovations in recent years.

Update: For the latest on LBNE, see this from Nature, out today.

   May 1, 2012

   Was this article posted exactly one month late by accident?

2. **Peter Woit**
   May 1, 2012

   Michael Hutchings,

   No, but it shows the problem one has trying to come up with April 1 postings. Truth is stranger than fiction. Actually, in this case I'm pretty sure this idea is unrealistic. But, I may be wrong…

3. **Edward**
   May 1, 2012

   Markets on the opposite side of the world are typically not open at the same time, which makes this less useful than it might be.

4. **paddy**
   May 1, 2012

   Let us calculate the bit rate available per Watt…..oops..never mind.

5. **Yatima**
   May 1, 2012

   I don't understand. Why would the computers (seller or buyer and the exchange) be on opposite sides of the globe so that the need to communicate with each other with low latency becomes a concern? Typically, one would set up seller and buyer computers in the same housing company building as the exchange computer. No other communication would be needed or useful, so there will just be a couple of routers and firewalls and a few metre of twisted pair cabling to pass. Maybe I'm being naive.

   Off-topic, but there recently was this fun article on HFT.

6. **Peter Woit**
   May 1, 2012

   Yatima,

   I think the point is that you want to be making a decision to buy or sell based on information that is 44 milliseconds ahead of your competitors trying to make the same decision (since your information channel goes straight at the speed of light, theirs goes around the globe). Of course, once everybody installs an accelerator, neutrino beam and neutrino detector in their office building, the things would kind of become worthless…

7. **Anonyrat**
   May 1, 2012

   The time to modulate a neutrino signal (even just on-off) is probably longer than the difference between the light travel time around the globe and through the globe.

8. **anonymous**
   May 1, 2012

   Maybe a few physicists who work on the project will get royalty contracts and become extremely wealthy (another quant bubble? Sign me up!). Wall Street could use some scientific involvement, though – maybe they could even learn the real calculus instead of that watered-down version they have to take.

9. **Z**
   May 2, 2012

   There was a March Physics World article on neutrino communication: http://physicsworld.com/cws/article/news/2012/mar/19/neutrino-based-communication-is-a-first

   There is also another, military application, for covert communication to submarines.

   The gist of it is that with current detector design and error correction techniques, the bit rate is about 0.1 bits/sec for a neutrino beam. This is a far cry from even the 160 bit/s that Voyager had, which is a celebrated example in information theory.

10. **S**
May 2, 2012

I think it's pretty clear they're hoping FTL neutrinos were true. Think of the money they could make then!

11. **M. Wang**
May 2, 2012

Two years ago, when a new firm raised $300m to dig a STRAIGHT-line trench for a new fibre optics line between Chicago and New York, I had joked with a colleague that the next step would be neutrino beams, which was the only thing capable of avoiding the earth's curvature. I guess someone else has now come up with the same idea, but not as a joke.
–
The reason why these investment makes sense (to varying degrees) is the physical separation of trading activities in two sets of financial assets: stocks and the stock-index-based futures. The former trades in New York, but the latter trades in Chicago. Usually, the big pension funds or mutual funds find it cheaper to enter/exit a big position by buying/selling futures than the corresponding stocks. Therefore, the futures price would move first. The competition to use this information to make money on the slower stock markets is intense. The aforementioned new fibre line saves 2ms in communication time, for which the firm charges $1m per month. Only the leading arbitrageurs in the country, typically with $500m or more in annual revenue can justify the expense.
–

It is important to stop this senseless race of shaving off another nano-second; there is no increased productivity once the refresh lag drops below human reaction time, roughly 200ms, a milestone that was passed in 2004. On the contrary, there is actually tremendous downside in this crazy speed race, as witnessed two years ago in the "flash crash". Actually, there are plenty of simple and natural remedies, such as charging for rapid cancellations of orders on the book for less time than human can react to, but the US equity market is "self-regulated", i.e. the SEC does not set the detailed rules; the exchanges do. The root cause to all this silliness can therefore be traced to the fragmentation of the equity (i.e. stocks) markets in the US. As each of the four major exchanges compete for order flows, they become beholden to the largest traders, and nobody can do more volumes than high-frequency firms.
–

Finally, just two weeks, the NASDAQ (in my opinion, the most professional and sensible exchange in the US) decided to take a small step in the right direction. A small fee will be charged on frivolous order placements/cancellations. So, maybe speed will lose its allure and no one will be funding the neutrino idea…

12. **Chris Oakley**
May 2, 2012

In 1994, when I worked on the Swaps Desk at UBS in London we planned to set up a neutrino communication link with with Sydney office. Originally protons were to be accelerated to 99.99% of the speed of light and smashed into a Nazi gold target, but to cut costs, it was decided to use Argentinian government bonds instead of protons. Unfortunately, this did not work as the bonds would default before reaching the target.

13. **Anon**
May 3, 2012

Well, if neutrinos are FTL, that could provide a whole new mechanism of shorting a stock. 🙂

14. **Ted Baxter**
May 4, 2012

Dare I ask what a Nazi gold target is?

15. **Chris Oakley**
May 4, 2012

Ted,

I don't wish to labour this but UBS = Union Bank of Switzerland. A lot of gold is stored in vaults in Zurich by Swiss banks including, allegedly, that originally stolen by the Nazis. I doubt whether, in reality, they would allow it to be used in a scientific experiment, especially if it ends up being radioactive. The chiefs would often play lip service to globalization but the reality was that the various centres (London, Zurich, New York, Tokyo and Sydney) would do their own thing. The only time that fast communication would have made a difference for our group was when Zurich & London had a video conference with New York – we actually had to fly to Zurich to join it and as well as a huge delay, the picture quality was poor (this was 1994/5).

Going back to the original topic, I doubt that program traders would benefit from a few tens of milliseconds speed advantage, and if they did, it is questionable whether such trades should be allowed as it would almost certainly be because someone was trying to game the system.

16. **Owen Patterson**
May 4, 2012

Let Wall Street and its global coven think they need neutrino communications. They will pay for all of it and then the science community can take it off their hands and get some real work done.

17. **AnonToo**
May 5, 2012

M.Wang, although your comment is well-informed (which I very much appreciate given all the misinformation out there on finance), and I agree with much of what you say, I'll have to disagree with this:

> It is important to stop this senseless race of shaving off another nano-second; there is no increased productivity once the refresh lag drops below human reaction time, roughly 200ms, a milestone that was passed in 2004. On the contrary, there is actually tremendous downside in this crazy speed race, as witnessed two years ago in the "flash crash"

First, the flash crash was a confluence of many causes, including an extremely large price-insensitive sell order, and I've never seen a report (speculation, sure, but nothing formal) that indicated HFTs were to blame. Of course HFT behavior is important, since it's a huge fraction of the market. But I don't know of a theory that says HFT caused the crash. If anything, it was HFT pulling out that caused the liquidity to disappear. In fact, the SEC was even considering adding rules that HFT can't "turn off" like they did!

Second, the flash crash was not a "tremendous downside". It was something like 20 minutes. It had no consequence to most investors, and errorneous trades were busted.

A few people learned that stop-loss orders with no limit are a bad idea (which was true before the flash crash, too), but overall there were few stories of real pain and there was no domino effect.

Third, I think you are vastly underestimating the benefits of HFT. There most certainly are benefits to sub-200ms trading. The liquidity in stocks with HFT participants is tremendous–as measured by bid-ask spread and cost of executing large orders–compared to stocks without HFT participants or stocks 30 years ago. We've replaced a large number of slow humans taking huge bid-ask spreads with a smaller number of very fast computers fighting for a few pennies. Needless to say, the latter is much more efficient (in the sense of market efficiency AND use of human talent) and is a better deal for investors.

Sure, it's silly people can make a lot of money reducing their network ping. But it's diminishing returns, so it won't last forever. Over the next 20 years (uneducated guess) things will stabilize as traders pull out the last bits of arbitrage that are still left.

We might as well accept the silliness for now, and be happy there are people investing in communication technology, no?

18. **Bugsy**
May 8, 2012

Z:
Interesting about the submarine communications. So, you need 1o seconds to transmit the one bit "fire missiles" and a bit more to transmit the more complicated "Oops-scratch that!!!"

Correction

A while ago I wrote here about a recent "conference of Nobel Laureates" convened by Jeffrey Epstein in the Virgin Islands. This was based upon stories in boston.com (Boston Globe) and marketwatch.com (Wall Street Journal), which were based upon this press release from Epstein's foundation. The foundation also has stories about this on their web-site (see for instance here).

Looking into it more carefully, it appears that everything in the press release refers to something that happened not this spring, but back in 2006. More details about the 2006 event are in a piece by Lawrence Krauss at Edge.org. The pictures and quotes are the same as in the 2012 press release. Still available on-line here is a schedule of talks from the 2006 conference.

When I saw this I was wondering why it didn't give a specific date for the conference, and how Epstein had gotten the same prominent people as in 2006 to return this year, despite his well-known problems with the law in the interim. I have no idea why the Epstein Foundation recently issued this peculiar press release.

Epstein is a rather curious story, for some background, see this New York Magazine profile from 2002, and this Harvard Crimson piece about him when he donated $30 million to establish a Program for Evolutionary Dynamics in the Harvard math department. At the time of the 2006 conference, Epstein was under investigation by the police for having hired under-aged women for sex, and he ended up serving 13 months in prison as a result. He was arrested soon after the conference. Some recipients of donations from Epstein returned the money, but not Harvard.

Update: About the Program in Evolutionary Dynamics, I should point out that after losing Epstein to the penal system, it has landed on its feet, with a $10.5 million grant from Templeton.

For another article about Epstein, from 2003, see this at Vanity Fair.

Update: Another strange Epstein press release has appeared: Jeffrey Epstein's Involvement With the Edge Foundation. It's an endorsement of John Brockman and his Edge Foundation, with text that was also posted on all sorts of odd internet sites back in 2010. Very strange…

   May 3, 2012

   And I thought quantum mechanics was strange and unexplainable . . .

2. **Mike**
   May 3, 2012

   Stay away from gossip Peter, it will only get you in trouble . . .

3. **Peter Woit**
   May 3, 2012

   Mike,

   No gossip here, just what's in the public record. The intersection of moneyed individuals and math/physics research is a legitimate topic of interest, one that may be becoming more and more significant for how this research is funded and conducted.

4. **Shantanu**
   May 5, 2012

   Peter, this is probably OT, but couldn't find a place for it.
   anyhow wanted to point you to Andy Strominger's colloquium at
   Berkeley (which was almost same as the Harvard talk you blogged about a year ago).
   See his reply when someone asked him about loop quantum gravity.
   http://physics.berkeley.edu/events/Colloquia/movies/col.streaming.3-12-12.mov

5. **Peter Woit**
   May 5, 2012

   Thanks Shantanu,

   I took a look at the talk, interesting to see what Strominger's point of view is, but there seemed to be nothing new. The hype level was rather high (the way the failure of "string theory is the physics of the 21st century" has been morphed into "this idea from string theory is the harmonic oscillator of the 21st century" is idiotic. People should have learned to dial back the unsupportable hype, not recycle it). The message seems to be that string theory failed at what it was supposed to do, but we should all keep doing it anyway. As for the string theory/LQG fight, again, nothing new.

   Anyone who wants to argue these old tired issues, please resist the temptation.

6. **Wojciech Langer**
   May 9, 2012

   If not recent Krauss' book "A Universe from Nothing" I would not have a clue about Epstein. It is definitely easier to make "A $ from Nothing" 🙂
   BTW: do you have any opinion about this book?

7. **Peter Woit**
   May 9, 2012

   Wojciech,

I haven't read the book, just flipped through it in a book store. I'm just not very interested in that sort of speculative cosmology. That Krauss seemed to be discussing multiverse scenarios as an answer to the idea of God as starting it all didn't look very wise to me. But, again, I haven't read the book. Life is short, I'm way behind on other things, including writing my next posting, about a better book on the same question…

Half Hour to Midnight

May 5, 2012
Categories: Uncategorized

Matt Strassler posts here about a recent panel discussion of phenomenologists talking about the implications of the latest results from the LHC. You can listen to the thing for yourself, and see what Matt has to say at his blog, but here are some things that I noticed from watching the discussion:

- I don't recall string theory even getting mentioned once. The extent to which string theory is now agreed to be thoroughly irrelevant to LHC physics is kind of striking. The few people like Kane claiming otherwise are being ignored as an embarrassment. If evidence for SUSY or extra dimensions had shown up, this would be very, very different.
- Arkani-Hamed is probably the dominant personality in this field, and as Matt mentions, he embodies the conventional wisdom of the subject, expressing it at length and with brio. Back in 2005 he was claiming we would know whether SUSY solves the hierarchy problem within a year of LHC turn-on. Somewhat more than a year after LHC turn-on, in February 2011, he was saying that we'd have to wait until 2020. Now he's putting it differently: it's the "eleven and a halfth hour" for the idea of SUSY solving the hierarchy problem.

  The only remaining hope for this is that there's a light stop, which has so far escaped detection, and gluinos just above the current bounds. He sounds willing to bet against this, and is arguing that the idea may soon be toast, to be finally put to bed as results from better stop searches come in over the next few months. If there's no sign of SUSY in the 2012 data set, it sounds like he's willing to concede that SUSY can't be what stabilized the weak scale.

- On the other hand, he argues that a 125 GeV mass for the Higgs is evidence for SUSY. Here the argument is that such a low-mass Higgs must be an elementary scalar, not the sort of thing you get in technicolor or extra-dimensional models. "SUSY" is here equated with the SM, without comment. I'm not sure what the reason for this is other than the sociological reason that it's the dominant remaining paradigm for BSM physics, I don't see a positive scientific argument.

  The 125 GeV value is also described as uncomfortably inconclusive for the idea of SUSY explaining the hierarchy. It's somewhat too high for this, but not so high as to make it impossible.

- If the SM continues unvanquished at LHC energies, it sounds like conventional wisdom will move to "it still has to be SUSY, even though our main motivation for SUSY is gone, since we don't have any better ideas." Best guess for the SUSY breaking scale will move up to be just high enough to be unobservable at the LHC.
- Clearly a lot of theorists are looking at the failure of the last quarter century of BSM ideas and trying to figure out what else they can work on. The idea of "back to working on QCD" was repeatedly mentioned. Arkani-Hamed has over the past few years dropped BSM work and moved to a radical speculative program about new ideas for QFT based on a different point of view about amplitudes. One of the speakers jokingly accused him of becoming a mathematician. Maybe that's where things are going…

Comments

1. **Interested Observer**
   May 5, 2012

   There are still several SUSY scenarios that have not been explored at the LHC. These include violations of R-parity, spectra where the NLSP decays predominantly to the top quark, degradation of the "missing energy" signals through longer cascades etc. These require more data and effort before anything conclusive can be said about them.

   Of course, these models are not the "simplest" avatars of SUSY – but I doubt anyone would write down the standard model with its hideous yukawa structure if they were only motivated by "beauty" and unknown "top-down" philosophy. BSM physics may well exhibit similar complexity and if so, it would require effort to extract it from the dirty hadron environment.

   The important thing is that the LHC, as a machine, is performing very well and with time and effort, it should be able to probe several of these scenarios. And if anything, the first year of the LHC is a stern reminder of the importance of experiments in physics. For much of the past 30 years, we have unfortunately spent way too much time pursuing ideas solely on the basis of mathematical beauty and consistency. The LHC tells us that this armchair philosophy has not been useful in guiding us to describe physics at 1 TeV, a paltry order of magnitude above the 100 GeV scale explored at LEP. And yet, there are those who insist on extending these philosophies all the way to physics at the Planck scale, without the guidance of experiment. God be with them.

2. **Peter Woit**
   May 5, 2012

   Interested Observer,

   Fine to pursue searches for things like R-parity violating SUSY, as long as one acknowledges there's no good motivation for such things (such models are hideously ugly and explain nothing), and this doesn't interfere with actually important and well-motivated searches. I didn't mention the obvious point repeatedly made by everyone on the panel: anything at all about the Higgs and its decays, as well as anything probing electroweak symmetry breaking in new ways, is incredibly important and should be the highest priority.

   At this point, I fear the best argument for obscure SUSY searches is just that no one has better ideas about where to look for something unexpected. If there are such ideas out there, I hope they're not languishing because of higher priority being given to SUSY searches.

3. **Interested Observer**
   May 6, 2012

   I am not sure what you mean by stating that R-parity violation is "hideously ugly" or that "it explains nothing". R-parity itself isnt particularly natural – it was imposed as a way to protect the proton. At low energies, this is guaranteed as long as either baryon number or lepton number is conserved. There are very reasonable, straightforward ways of breaking lepton number at low energies. Breaking baryon number is harder, but again, not impossible.

   Indeed, R-parity preserving models have the virtue of stable dark matter candidates etc. But, it may well be that dark matter has nothing to do with the hierarchy problem (could easily be axions), in which case R breaking models would be natural and dedicated searches should be done in their aid.

   I am not particularly trying to defend R-parity breaking, but I just want to reiterate that it is now time for people to do the broadest possible searches since the governing theology of the past 30 years ie: the package of the MSSM + dark matter is very much at odds with experiment.

4. **Garbage**
   May 6, 2012

CMB fluctuations were detected five seconds before midnight. There also a theory: inflation, was proposed to solve a 'naturalness' problem (e.g. flatness), and we're waiting for PLANCK to give us some hints to nail it. Perhaps the LHC is like COBE, if the branching ratios stay (believable) away from SM; and like Nima says, we'll need ILC, etc (WMAP…PLANCK) to be able to probe SUSY at the high scale.

SUSY at the 100TeV scale won't be fully natural, neither is inflation for that matter (ask Steinhardt). But truly is the *only game (left) in town*. Yes, this smells like string theory as a theory of QG. Perhaps the universe is fine tuned and that's about it (read CC), or perhaps there's some aspects of tuning we yet don't understand.

I'm not sure I buy Nima's argument that m_H ~ m_Z = SUSY-like. The Higgs was designed to break EW symmetry. We knew G_F, hence the vev. One could have naively guessed: m^2_H ~ 1/G_F, which is obviously too high, so toss in some weak-coupling constant (\lambda) and voila, 100-ish GeV. (In fact, that's a very educated guess, considering e~0.3) It is true SUSY gives us a 'natural' mechanism for m_H at~ m_Z (or smaller, ahem…) but the Higgs still is where we expected it to be, SUSY hasn't 'predicted' anything here so far… All we hope for now is a confirmation the Higgs was found and significant departures from SM-like decay rates. Even a 300-ish GeV 2HDM could do at this point, so there's perhaps *new physics* to be found…

By the way, I'm not sure what you think of Matt S. attitude: "let's try everything". That's not how physics works…

5. **Peter Woit**
May 6, 2012

Garbage,

I just don't see any serious motivation at all for 100 TeV scale SUSY, from string theory or anything else, other than that a large group of theorists have careers invested in SUSY phenomenology and don't want to acknowledge that this hasn't worked out.

Matt S. seems to me obsessed with making sure to be extremely cautious and not acknowledge what has almost surely happened until it is 99.999% all locked up. For instance, he was paying attention to the OPERA FTL neutrinos long after it was clear there was no point to this. I suspect he'll also be working hard on obscure SUSY searches long after this is also a waste of time. The real question is whether there's something more promising the LHC experiments could be looking for. To my mind, the sooner phenomenologists admit that SUSY is a failed idea and devote their energies to other things, the better.

6. **john McAllison**
May 7, 2012

Peter, great that you've posted the link to the audio talk of Arkani-Hamed in 2005, but I'm sure there's an important public talk he gave before 2010 on the expected LHC milestones. It's fascinating because I'm sure he talks about susy being discovered within two years – maybe even before the Higgs. I'd love to be able to see it again.

7. **Peter Woit**
May 7, 2012

John McAllison,

I'm not sure what talk you're referring to, Arkani-Hamed is a favorite invited speaker for talks of this sort, so there have been lots of them, although most not available on-line. The idea that SUSY would be an early discovery, the Higgs much harder and later was always conventional wisdom. The simple reason is that SUSY was supposed to be visible via strongly-interacting partners (gluinos and squarks), which would be copiously produced, even at low luminosities, whereas Higgs production is a weak process. This was borne out, as even the earliest LHC results at low luminosity provided impressive limits on SUSY, nothing about the Higgs until later.

8. **MathPhys**
May 7, 2012

Well, look on the bright side. We surely have quite a bit to learn over the next 5 years. Exciting times in high energy physics.

9. **Kevin Lahey**
May 7, 2012

I just wanted to say I appreciate the summation and straight talk about latest results from the LHC data. Keep up the good work.

10. **Cesar Uliana**
May 7, 2012

Peter,

Could you comment on why Peskin said that the Higgs implies BSM? The talk seemed to me that if the Higgs is at 125 GeV then SUSY is not much of a help.

On a side note, could you explain why the Physical Review Letters has published an article saying that Lorentz force is wrong? It's on the arxiv http://arxiv.org/abs/1205.0096 as well as the PRl page. Really amusing.

Thank you

11. **Peter Woit**
May 7, 2012

Cesar,

I don't remember exactly what Peskin said, and I don't know what he had in mind. Not having a Higgs would definitely be BSM physics, having one is just the SM (if it behaves like an SM Higgs should, that's what everyone wants to find out from the LHC).

I heard about the Lorentz force controversy, but I confess to a lack of either expertise or interest in the subject. There's a nice story about it here

http://www.sciencemag.org/content/336/6080/404.full

but you need another site for an informed discussion.

12. **neo**
May 7, 2012

"MathPhys says:

May 7, 2012 at 10:56 am

Well, look on the bright side. We surely have quite a bit to learn over the next 5 years. Exciting times in high energy physics."

What that be true if the SM holds with no deviations?

13. **Peter Woit**
May 7, 2012

neo,

Even in the nightmare scenario of no SM deviations, we'll learn something. I think that one thing the field is already starting to learn is that the whole SUSY scenario that so much effort and attention went into was a mistake. The LHC's big accomplishments may be confirming the Higgs sector and shooting down some bad ideas which have dominated the subject for too long. Of course, will be even better if it provides hints for where to look for better ideas.

14. **MathPhys**
May 7, 2012

If SM holds with no corrections, then we'll learn that ideas such as naturalness, and our views about radiative corrections, what is large and what is small in perturbative renormalization theory, etc, are too simple minded.

On the other hand, rejecting supersymmetry altogether is too radical to contemplate at this stage (too many papers on the subject, too many good names on the line), and anyone who advocates that viewpoint puts himself in the same position as those who advocate supersymmetry since the late 1970's.

15. **God**
May 7, 2012

The Standard Model works and is fantastic. Its *main* problem is the hierarchy problem (followed by no dark matter, no baryogenesis, inflaton, no grand unification, or including gravity), so if nothing is found at LHC, theorists will have to scratch their heads as to what is going on to keep the EW scale so low. If no low energy SUSY is found (and I agree with Peter, its just about dead already), then I think we have 2 possibilities:
i) anthropics to explain the smallness of EW scale
ii) dynamical explanation that no-one has come up with after all these decades of trying
I think its a little too easy for Peter to just say that theorists should try other ideas…they do all the time…only SUSY seems to fit together nicely. But nature doesn't care about that. thank goodness experiment is pointing the way forward by killing it. so maybe we are left with i)…yikes…

16. **HypeWatch**
May 7, 2012

Oh Lord: hunt is on for 5 God particles
Jonathan Leake, Science Editor
The Sunday Times, 6 May 2012

Rolf-Dieter Heuer, director of the laboratory, has admitted there could be a family of Higgs particles and this could keep his team in work for 20 more years: "There could actually be a number of Higgs particles. In fact there could be up to five."

After smashing 640 trillion protons together, the Large Hadron Collider, Cern's giant particle accelerator, has generated 80-100 possible Higgs bosons. But the number of candidates is slightly more than predicted.

"One possible reason is that there is more than one Higgs," said Heuer. "And if there is more than one, then theory suggests there could be up to five."

This hypothesis is known as "supersymmetry", which predicts each known sub-atomic particle could be partnered by another "superparticle", although these remain undetected.

Heuer remains confident that Cern scientists will soon confirm at least one Higgs. "We will know if the Higgs exists at all by the end of this year. That I can pledge," he said.

17. **Peter Woit**
May 7, 2012

God,

I'm still not convinced that the big problem of the SM is "what keeps the electroweak scale so low?". Low compared to what? It's actually a high-moderate scale compared to any energy scale we actually understand. Without seeing a proton decay, there's no evidence for GUTs and a high GUT scale, and about quantum gravity we know even less.

The Higgs field and the Higgs mechanism for EW symmetry breaking is the most dubious part of the standard model, crying for someone to find a better alternative (and yes, I know people have been trying, hard, for a long time..). But I'm not convinced that the supposed hierarchy problem is the key to anything. It's going to get used by anthropicists as an argument for giving up, but it's not a good one.

18. **Peter Woit**
May 7, 2012

Hypewatch,

Thanks. But why stop at 5? Surely one can find SUSY models consistent with experiment with more than 5 Higgs particles…

19. **God**
May 7, 2012

I don't get your answer. I can only take from your answer that you don't really understand what the problem is; the problem is that the EW scale is sensitive to quadratically divergent corrections. So the SM taken at face value, assumed to be valid up to arbitrarily high energies requires infinite fine tuning. If it is taken to be valid up to, say, the Planck scale, then it has 1 part in 10^30 fine tuning, etc. So it indicates that something should intervene to keep the scale low.
Your point that we don't know much about the GUT or quantum gravity scale doesn't alleviate the problem at all. If the GUT scale is 10^15 GeV or so, as is usually assumed, then we have a 1 part in 10^26 fine tuning if the SM is valid up to this scale. If you are alternatively suggesting that we know so little about GUT physics that the

"true" GUT scale might turn out to be a TeV or so, well great; so that is the wild new physics that we are hunting for! Either way, the existence of the hierarchy problem tells us that crazy fine tuning is required or new dynamics is present. What about this do you not understand?

20. **Peter Woit**
May 7, 2012

God,

My point is that we not only don't know what the right GUT is, we don't even know if there is a GUT or a GUT scale. We really know nothing much for scales above 1 TeV or so. Describing the hierarchy problem as not knowing how to keep the EW scale very small compared to the GUT or Planck scale seems to me a robust way of characterizing the hierarchy problem, but it requires a high GUT or Planck scale, and these things are huge mysteries in themselves.

The quadratic divergence problem comes from applying perturbation theory and a momentum cutoff to the dynamics of the Higgs field at energy scales one knows nothing about. This kind of behavior of elementary scalar fields does look like an indication of something pathological about them at short distances, but there are other reasons anyway to be unhappy with elementary scalars.

Maybe one way to explain my point of view is that I see the bad high energy behavior and sensitivity to the cutoff of elementary scalar fields as maybe part of the problem, but that's not the same as "why is the EW scale so low?" unless you postulate some unknown BSM physics at a scale that acts as an effective momentum cutoff for the perturbative Higgs calculations. We're just barely starting to be able to observe the effects of tree-level physical Higgs field processes. Is there really any indication that Higgs loop processes are there and behaving like elementary scalars? I'm no expert on higher-order SM calculations, and I'd be curious to hear from someone who is, but I'd assume that if these calculations were significantly sensitive to physical Higgs loops, we'd have had a much better fix on the Higgs mass than we did pre-LHC.

21. **Wilson's ghost**
May 7, 2012

I think a lot of the discussion has to come down to understanding renormalization. The SM is renormalizable in the "old" sense and in principle none of this matters as long as the Higgs mass resides within a certain window. On the other hand from the Wilsonian point of view, clearly a Higgs behaves differently. Peter, I'm not clear as to what you mean about higher-order SM calculations. The problem arises from the mass renormalization of the Higgs, not the effect of the Higgs entering into other calculations (e.g. unitarity of WW scattering in the SM). One last thing to point out is there isn't any vodoo associated with the modern view of wilsonian renormalization and effective field theories, we use it all the time often to describe pretty difficult situations in QCD that are naively strongly coupled.

Now if there were no other scales beyond the TeV scale, we could just throw our hands up and say sure, there is no problem with fine tuning. Ironically this is akin to the original prescription for large extra dimensions which bring the Planck scale down to the TeV scale. However, this of course has consequences experimentally which we have seen none of. To do so without a model (more along the lines of what Petr is suggesting) means we should have an infinite set of higher dimension operators suppressed by the TeV scale. Of course we've searched for these things and found nothing of the kind. Now of course one can claim there is no higher scale, but the point is then there are a whole host of OTHER problems that become more pressing. This is also similar to the field theoretic understanding of the fact that if the Higgs weren't elementary there should be a whole host of higher dimensional operators at the TeV scale associated with strong dynamics that we don't see. This really isn't a matter of understanding perturbation theory, it's understanding if there is some pink unicorn theory that solves all the outstanding problems of the SM and leaves no traces elsewhere. There are certainly methods to understanding the implications of strong dynamics, and they all tell us we should be seeing something more if it's not an elementary Higgs. Additionally there definitely are much higher scales associated with the problems in the SM (listed by God) otherwise we would have seen experimental effects associated with flavor and CP violation popping up all over the place.

22. **Ravi K**
May 7, 2012

Hi Peter,

Considering that neutrino masses define a new mass scale we naturally now have high mass scales such as M_W (M_W/m_nu) in the theory. I don't think the argument that we don't know whether large mass scales exist or not in the quantum field theory can be made.

However whether the hierarchy problem needs a solution or not may still be a relevant issue, even if there are large mass scales. If nothing new other than the std. model Higgs is discovered at LHC, I guess we would have to conclude that it does not need one.

23. **MathPhys**
May 8, 2012

Peter Woit writes "The quadratic divergence problem comes from applying perturbation theory and a momentum cutoff to the dynamics of the Higgs field at energy scales one knows nothing about. This kind of behavior of elementary scalar fields does look like an indication of something pathological about them at short distances."

Or maybe there is something pathological about using a perturbative expansion where terms diverge one by one, we know that there are no divergences (the electron has finite mass and charge) so we subtract the divergences, then we complain that the subtracted terms must be finely tuned.

Maybe it is this way of doing things that is pathological in the presence of elementary scalars.

24. **Peter Woit**
May 8, 2012

Ravi K,

The problem of neutrino masses you mention is "why is the electroweak scale so large?, a different one (if you get neutrino masses by a see-saw mechanism you do get a new large scale, but there's no evidence that you need to get them that way). I agree that the problem of fermion masses, with their widely different scales, is about the biggest mystery around. By the way, there's something about this that has always bothered me that maybe someone can explain: supposedly the Yukawa coupling to the top is very close to 1 (an accident or a hint?). Doesn't this ruin one's ability to compute Higgs physics in perturbation theory (since the coupling is not small)?.

25. **Peter Woit**
May 8, 2012

Wilson's ghost,

My point was just that the significance of a one-loop perturbative mass renormalization calculation by itself is unclear: is this just a technical problem with perturbation theory? I'd be more inclined to take it seriously if we were in the situation of QED, where you can physically measure effects (g-2, for instance) that show that loop calculations are correctly giving you something physically observable.

I agree that getting the Higgs out of unknown strong dynamics at the TeV scale introduces its own problems, and certainly don't claim to have any good idea about how to resolve the problems introduced by the Higgs. It just seems like a good idea though to stay clear on exactly what the problems are and whether one comes from something you have solid knowledge of, or from some speculative framework that you understand even less (e.g. I'm not going to worry so much that the properties of the inflaton cause this problem with the Higgs).

26. **Ravi K**
May 8, 2012

Peter,

The neutrino masses break B-L symmetry and there is a fundamental new mass scale associated with this breaking — I think whether it is larger or smaller than M_W is immaterial as the hierarchy argument can always be made for the Higgs sector of the smallest scale.

If the B-L breaking scale is around the weak scale then it would have observable consequences at the LHC….for example a B-L breaking Higgs.

27. **YBM**
May 8, 2012

Some (unrelated to the article) news on the Bodanov Affair:

[Researchers and the threat Bogdanov]

The french scientific community reacted strongly:

[Affaire Bogdanov : lettre ouverte de 170 scientifiques]

By the way, as you know, their main "protection" in the political world has just lost his job.

28. **Ravi K**
May 8, 2012

Is there a renormalizable theory for the observed neutrino masses without having either a high mass scale (like see-saw) or a new light Higgs particle?

29. **Peter Woit**
May 8, 2012

Ravi K.,

I don't know, maybe someone more expert on neutrino masses can comment. But if you do this with a right-handed neutrino and another Higgs field, I don't see why the new Higgs can't be at the electroweak scale. Yes, you wouldn't know why Yukawa couplings were so small, but we already have that problem in the rest of the SM.

I guess that to me it's the Yukawas that are the huge mystery here, it's a huge array of numbers we understand not at all, even though we can measure them precisely.

30. **Ravi K**
May 8, 2012

The new Higgs can be at the electroweak scale — thats what I meant by the light Higgs — EW or lighter — but then it would have observable consequences at LHC and at some point will be ruled out.

The Yukawas hierarchy can be at least understood as being due to chiral symmetries that get restored as the fermion masses go to zero. For example if the electron mass is zero then there is an additional chiral symmetry that will explain this.

This is the 'tHooft criterion for naturalness (electron, up and down quark masses satisfy it) : At any energy scale mu, a physical parameter or set of physical parameters alphai(mu) is allowed to be very small only if the replacement alphai(mu)=0 would increase the symmetry of the system.

31. **God**
May 8, 2012

Peter you still seem confused about basic QFT of scalars. Scalars suffer quadratic corrections to their mass, unless protected by a symmetry. Hence the SM, which does not carry any such symmetry, by itself has infinite fine-tuning. One either accepts this, OR there must be new physics at some scale of the order of a TeV or so. That's what the realization that scalars have quadratic divergences leads to. Its a profound conclusion, and by itself has nothing to do with GUTs, etc. Hence, we should see all sorts of new physics at < 1 TeV, or there is fine tuning. What is it you don't get?

32. **Peter Woit**
May 8, 2012

God,
You seem to just ignore everything I write, in favor of the idea that I must not understand the conventional calculation and the conventional arguments about what it means. For your benefit:

I DO KNOW HOW TO COMPUTE ONE-LOOP FEYNMAN DIAGRAMS AND THAT YOU GET A CONTRIBUTION TO THE HIGGS MASS QUADRATICALLY DIVERGENT IN THE MOMENTUM CUT-OFF.

OK? The question is what to make of this. Is it (and the necessity of "fine-tuning") just an artifact of perturbation theory? This kind of sensitivity to short distances is one of several legitimate reasons to be suspicious that something funny we don't understand is going on with the idea of the Higgs as an elementary scalar. We're just starting to probe the behavior of the physical Higgs field at its lowest excitation energy. I don't see that it's useful to formulate the main problem of the Higgs as "fine-tuning is necessary to keep the Higgs mass small compared to some speculative physics at some high energy scale we know nothing about". That certainly hasn't been a fruitful avenue to pursue so far.

33. **JR**
May 8, 2012

Not an expert but: If you do the one loop calculation with dimensional regularization you get a 1/epsilon pole instead of the quadratic divergence. Is that not a hint that the fine tuning argument is a red herring?

34. **Florian**
May 8, 2012

Hello,

tomorrow's Sueddeutsche Zeitung, a German, high quality newspaper based in Munich is running an interview with Lisa Randall in its Wednesday issue. The occasion is some book of hers (knockin on heaven's door) appearing in German. I'd like to share the highlights of the interview. Since I am translating back something somebody has translated from English this will probably not be literal. Here goes.
[…]
SZ: You are trying to find pictures for these invisible worlds and you have developed a theory after which the universe has 4 space dimensions. Accordingly there could be parallel universes, which are very close to us.
LR: They are probably only 10-31 cm away. But these extra dimensions cannot be observed directly, because they are very small and rolled up.[…]
[…]
SZ: You attach a great importance to the fact, that your theories can be experimentally tested. Your calculations may be tested at the LHC. Can we expect new discoveries?
LR: After initial difficulties the LHC works now incredibly well, so I hope so.
SZ: I would have expected a clear "Yes" here.
LR: The reason why I am not sure is connected to the energies the LHC is able to reach. They might not be high enough to find the particles we are looking for. The once planned American supercollider (SSC) would have reached energies 3 times as high as the LHC, that would have made me more confident. At least we are now seeing clues of the Higgs Boson. But there are a few fascinating theories, like extra-dimensions or Super-Symmetry, in which heavy particles play a role. We could be lucky and see these particles at the LHC. But it could also be that we nearly miss these energies, which can give us the right answers.
[…]
There is other stuff, which is amusing, but I'm too lazy to translate that. The 10-31cm and the almost caught particles are the best part anyway. It would be amusing, if it wasn't so sad. Sorry for being slightly off-topic, Peter.

35. **JustDisWonce**
May 8, 2012

@God,

you are parroting the standard story used to sell SUSY for decades. That this story is so ingrained in the community may reflect great marketing more than great physics. While this story may turn out to be correct, the data thus far suggests otherwise. If nothing is found to stabilize the weak scale, "the community" is presumably thinking incorrectly about the matter. Time will tell. (These last statements are not controversial.)

From your comments, my guess is that you have not studied the corrections to the Higgs mass in detail (as I find with a number of my "expert" colleagues), as the matter is not as trivial as you imply. Study and figure out your own answers to questions like the following: How does this "problem" manifest itself in different regularization schemes? What is the physical meaning/origin of this difference (if any)? Which regularization scheme is "better" — does it even matter? Why are some schemes better in eg SUSY models; ie why do we choose regularization schemes in SUSY models that preserve the SUSY (an obvious one)? Does the answer to this question have any implications for the regularization of the SM (or implementation thereof)? What about if you send the bare Higgs mass to zero — does the way in which scales manifest via the trace anomaly alter your answer (see Bardeen's work)? Does the answer to these questions depend on whether there is a UV scale describing QFT-able physics like M_GUT? If there is no M_GUT, does the answer depend on the nature of quantum gravity (this one is harder)?

If you can answer these (except the last one, of course), you will understand what Peter is saying —- if not it would take more time to explain than any self-respecting person would have to spare.

An aside: if more people spent time pursuing original research directions in the '90s, rather than telling everyone else that SUSY was the only solution to the hierarchy problem, there is no apriori reason why things like ADD, RS and Little Higgs could not have been discovered earlier (no offense meant to the very insightful folks who eventually did make these discoveries). These statements alone are a good reason to be wary of anyone who tells you string theory/SUSY is the only hope, rather than encouraging diverse research programs to explore as many possibilities as are conceivable.

@Peter,

I congratulate your efforts and applaud your patience in responding to these same comments over and over again. Though no doubt tiresome, it is a valuable service.

@Ravi

There are a number of eg radiative models that generate nu mass without invoking high (beyond ~ TeV) scales; these are renormalizable and easily accommodate the data. The problem with neutrino mass is not that its hard to explain (nor that the existence of the scale m_nu implies a hierarchy problem), rather it's just too easy to write a renormalizable theory that explains the data, is completely natural, and has new physics at (almost) any scale you care to mention. This is what makes nu theory somewhat boring (along the lines of Jester's recent post); only experiment can shed light on the matter, but the scales may or may not be accessible and the couplings may or may not be large enough to allow detection. Also note that nonzero m_nu does not imply that B-L is broken; neutrinos can just as easily be Dirac particles and nu mass will be competely natural.

If one adopts the view that the SM Higgs mass is tuned, then this, at least, is a much more difficult problem to solve (thus the high number of original nu-mass-models compared to the number of original solutions to the hierarchy problem).

36. **pah**
May 8, 2012

I'd also be interested to hear an answer to JR's question above.

37. **Anonyrat**
May 8, 2012

pah, JR,

My memory is failing – I was sure I had a copy of this 1975 book: "Dimensional Regularization and the Renormalization of Quantum Field Theory", John C. Collins, but I can't find it. I'm about just as sure that in this book J.C. Collins worked out an example of a toy model with two scalars, one light and one heavy, and showed that even with dimensional regulation, the light mass was inexorably drawn to the heavy scale unless there was fine-tuning. But my memory is suspect.

38. **Anonyrat**
May 8, 2012

I'd appreciate being reassured that my memory is fine. 🙂 Anyway, if there is a GUT, then we have a hierarchy problem.

http://arxiv.org/pdf/0708.3550v1.pdf

"In fact, the structure of divergences does depend on
the regularisation scheme. One can use also the scale- independent regularisation, such as the dimensional reg- ularisation of 't Hooft and Veltman [48]. In this scheme the renormalization of parameters is the multiplicative one and thus there is no difference in removing the divergences from dimensionless parameters such as gauge coupling or dimensionfull parameters such as the mass of the Higgs boson. However, inspite of these specific features of the dimensional regularisation the conclusion about fine tunings remains intact [49]: even in this scheme to have a field theory GUT with two or more well separated scales one has to tune a number (varying from 1 in SUSY GUTs to 14 in non-SUSY GUTs) of terms to achieve the hierarchy of masses."

Reference 49 is:
[49] S. Weinberg, Phys. Lett. B 91 (1980) 51.

39. **God**
May 8, 2012

@JusDisWonce,
I am not parroting anything about SUSY, etc. Personally, I doubt low energy SUSY is right – i said that in my first post, see above, so your discussion is off target.

@Peter,
Sorry, but what you are saying doesn't make sense. The basic principles of effective field theory guarantees that the SM extrapolated to high energies is highly fine-tuned. If you are disputing this, you are disputing the core principles of EFT. If so, then please state so. You will be wrong, but you should at least state so clearly, so I understand the claim you are making. The alternative to this fine tuning is some form of new physics; I do not know what form the new physics will take. These arguments are completely general, they have nothing to do with GUT theories, etc.

40. **MathPhys**
May 8, 2012

Anonyrat,

Your memory is okay.

In fact, the first paper that gives an explicit computation in which the 'technical fune tuning problem' shows up is by E Gildner (a PhD student of S Coleman) from the late 70's, and there he uses dimensional regularization.

41. **MathPhys**
May 8, 2012

On a different matter, can an expert confirm or deny that one can compute scattering amplitudes, even for massive scalars, and that the results are finite and no divergences show up anywhere in the intermediate steps?

42. **Garbage**
May 9, 2012

"I think that one thing the field is already starting to learn is that the whole SUSY scenario that so much effort and attention went into was a mistake."

I'm not a big fun of susy at the EW scale myself either; I do believe though susy is too pretty for nature to pass on it at the GUT scale. However, susy at 100TeV is still partially motivated. Nature may have a split spectrum whether we like it or not. If the departures form the SM decay rates withstand further scrutiny, then high-scale susy will be by far one of the most natural options to look for an explanation. Now, if we find *just* the Higgs with 1-2 sigma-ish deviations from SM here and there, then is another story… Nima will tell you we need to measure the electron's dipole moment, gotta get down to 10^{-31} (current bounds at 10^{-28}). The cool thing is that there's still a lot of physics to be done and understand before we accept the universe is fine tuned for good…. (we have almost done it with lambda…)

43. **SpearMarktheSecond**
May 10, 2012

How about mentioning the theorists who long ago (even prior to, say, 1997) became disenchanted with SUSY at accessible energies, and sort of moved on? I can think of two easily. It would kind of compensate the negative undertones.

One of the two is Tini Veltman…. although the quote is from 2004, I can remember him saying this stuff through the 1990's….

http://www.timeshighereducation.co.uk/story.asp?storyCode=187373&sectioncode=1

"Anyone who thinks that string theory has, in the meantime, shown the way that particle physics is going gets short shrift from Veltman. Supersymmetry and string theory are "figments of the theoretical mind", he writes."

44. **MathPhys**
May 11, 2012

SpearMarktheSecond,

Veltman says these things, and in stronger terms, since the early 80's.

45. **Anonyrat**
May 11, 2012

MathPhys,
What were Veltman's stated reasons in the early 80s for giving short shrift to supersymmetry?
Thanks in advance!

46. **Peter Woit**
May 11, 2012

Veltman was far from the only one to be skeptical about supersymmetry. Among the other Nobelists I can think of who never showed much interest would be Glashow and 't Hooft. Actually I suspect that faith in SUSY has always been a minority viewpoint among theorists (although the minority has been much louder than the majority). For some evidence about this, see how people lined up back in 2000:

http://www.staff.science.uu.nl/~hooft101/susy_wager_2000.gif

47. **MathPhys**
May 11, 2012

Anonyrat,

I didn't hear him give any reasons. I only heard him say

"Gordy, if they discover supersymmetry, I'll eat my hat",

then he mimicked eating his hat.

48. **MathPhys**
May 11, 2012

That's a significant historical document you've linked to above, Peter. I haven't seen that before.

49. **Ravi K**
May 11, 2012

@JustDisWonce

I will try and give a more general argument than what I gave before. For masses of charged leptons such as the electron you just need the Yukawa couplings and no new term in the Lagrangian of mass dimensions (need only the usual std model Higgs mass term). However for the neutrino mass you can't get from Yukawa terms alone and the std model Higgs — you need to introduce some other term with mass dimensions no matter what the model. If this mass term is much more than the electro-weak scale then even in Peter's sense there would be a hierarchy problem as his artifact argument crucially depends on there being only one mass scale in the QFT. On the other hand if it is at the weak or TeV scale or lower then it would inevitably lead to new physics that the LHC or a future generation of colliders should see. If there is no new physics and only a std model Higgs then you will essentially end up with two different mass scales in the QFT — one to explain the neutrino masses and the other the weak scale. Even as theories like SUSY getting constrained so are all other new physics theories at or near the weak/TeV scale. If nothing new is found then fine-tuning must exist even in the sense Peter is talking about where you regard the cut-off as an artifact.

50. **Trulo**
May 12, 2012

Peter, the document you link to says that "The party of winners organizes a meeting of all involved in this wager not later than in June 2011" in which the cognac bought by the losers of the bet will be drank. I'm curious to know if that meeting has already taken place, or if it has at least been announced.

51. **Peter Woit**
May 13, 2012

Trulo,

The LHC turn-on ended up being several years later than expected back in 2000, so I think this bet may have been renegotiated to extend the time-line. No cognac purchased by losers yet as far as I know.

Phenomenology 2012

May 8, 2012
Categories: Uncategorized

This week at the University of Pittsburgh the Phenomenology 2012 Symposium has talks reviewing the current situation in particle physics phenomenology. Not much new, but there is one plenary talk on string phenomenology, Cumrun Vafa's Stringy Predictions for Particle Physics. Mostly this deals with Vafa's ideas about F-theory "predictions" for the fermion mass and mixing matrices. Quite a few assumptions and rather little string theory (the predictions are "stringy") goes into this, and except for the one recently measured neutrino mixing angle, these are all postdictions, not predictions. I suspect that most string theorists are no more sold on these as predictions of string theory than they are on Kane's Higgs mass prediction. For example, Vafa's colleague Andy Strominger in recent talks (and not so recent ones) gives string theory an "F" in the area of making unambiguous testable predictions, and I assume he's well aware of Vafa's work.

Pre-LHC, Vafa had been claiming F-theory predictions for SUSY at the LHC (see for example here, here and here). The most dramatic one, the focus of the Harvard Gazette story, was for a stable stau. One of the papers linked to has various detailed calculations for what such an stau would look like, with typical masses around 200 GeV.

At the conference on Monday, this talk gives recent CMS results relevant to such an stau, listing new mass limits of 314 GeV for a "cascade-decay" scenario, 223 GeV for a "pair-produced" one. Vafa only briefly mentions SUSY at the end of his talk, with his final slide "We will wait to see if SUSY plays any role at the weak scale!" I'm guessing he's getting resigned to the idea that the answer is probably No.

Update: Also on the No SUSY news front this evening, there's a preprint entitled Should we still believe in constrained supersymmetry? analyzing the current situation with one popular version of SUSY, the CMSSM, which concludes:

> We find that LEP and the LHC strongly shatter our trust in the CMSSM (with M_0 and M_{1/2} below 2 TeV) reducing its posterior odds by a factor of approximately three orders of magnitude.

Comments

1. **M**
   May 9, 2012

   Similar statements about the naturalness problem of CMSSM SUSY had been made already after LEP, see

   http://arxiv.org/abs/hep-ph/9904247
   "The Bayes theorem says how much one must reduce its confidence in SUSY after knowing the LEP2 results"

   After LEP the confidence dropped to 5%. Now down to 0.1%.

   Nowadays pointing out that SUSY & strings have problems is like shooting on the red cross.

2. **paddy**
   May 9, 2012

   a)Theorists putting such effort into a Bayesian analysis to quantify what we "know" may be quite a sign of the times–and not a good one.
   b)After reviewing the C. Vafa cartoonical slides, I must say that I prefer xkcd.
   c)In some other universe there is an S. Glashow who is not quite as nice as the one in this bubble (who decades ago taught stupid me Group Theory without making me feel stupid). This not-so-nice Glashow multiverse-twin is rolling his eyes and saying I told you so.

Why Does the World Exist?

May 9, 2012
Categories: Book Reviews

With a lot of attention these days (see here for instance) going to an argument between philosophers and physicists about the "Why is there Something rather than Nothing?" question, this is the perfect time for Jim Holt's new book Why Does the World Exist? An Existential Detective Story. While the argument between Krauss, Albert and their fellow combatants was mind-numbingly dumb, boring, narrow, petty and ill-mannered, Holt's discussion of the topic is brilliant, entertaining, and wide-ranging as well as generous in spirit to all points of view. The only unfortunate thing here is that the book won't be out until July. I've checked with him though, and he doesn't mind if I write about it now, since I just read an advance copy. In July I'll try to remember to repost this.

Holt first sets the stage by explaining some of the history of the question "Why is there Something rather than Nothing?" and why it's one he finds compelling (as well as explaining why one might reasonably think otherwise…). He first ran across the question as a high school student fascinated by Existentialism and trying to read Heidegger's *Introduction to Metaphysics*.

(Personal digression:

Around the same time I was also trying to read that book as a college freshman. I just found my old copy, where I underlined lots of things that seemed of significance at the time, as well as putting exclamation points around the paranoid nationalist ravings that appear at one point. I soon decided Heidegger wasn't for me, and some years later learned of a personal reason to dislike him, see this from the Wikipedia entry on Heidegger and Nazism:

> *Heidegger also denounced or demoted several colleagues for being insufficiently committed to the Nazi cause.*
>
> *On September 29, 1933, Heidegger leaked information to the local minister of education that the chemist Hermann Staudinger had been a pacifist during World War I. Heidegger knew this would cost Staudinger his job. The Gestapo investigated the matter and confirmed Heidegger's tip. Asked for his recommendation as rector of the university, Heidegger secretly urged the ministry to fire Staudinger without a pension.*

Hermann Staudinger was my great-uncle (on my father's side of the family). Despite Heidegger's efforts, he managed to keep his job, survived the war, and went on to win a Nobel prize. I never really got to know him since he died when I was rather young, but got to know very well his widow, my great-aunt Magda. Decades later, she was still quite upset by the Heidegger business.

End of personal digression.)

Holt then moves on to contemporary thinker's takes on the subject, including entertaining descriptions of his trips to visit some of them, starting with some philosophers. These include Adolf Grünbaum who takes the position (to which I'm sympathetic…) that this is a pseudo-problem, and derisively refers to worries about Nothingness as the "ontopathological syndrome". Another visit is to Richard Swinburne at Oxford, who goes for the "God did it" explanation.

The first physicist he visits is David Deutsch, also at Oxford, and Holt's description of the experience and account of their conversation is quite wonderful. As you might expect, lots about the deep significance of quantum physics and Many-Worlds. After a discussion of Robert Nozick and his principle of fecundity ("all possible worlds are real"), it's on to Alexander Vilenkin and the cosmological multiverse mania that has gotten so much attention from physicists in recent years. Here the sort of "something from nothing" that Krauss was discussing in his recent book comes into play.

The most intellectually powerful figure Holt talks to might be Steven Weinberg, who has this to say about the multiverse:

> "Vilenkin is a really clever guy, and these are fascinating conjectures," Weinberg said. "The problem is that we have no way, at present, of deciding whether they're *true* or not. It's not just that we don't have the observational data – we don't even have the *theory*."

and this about string theory:

> When I brought up string theory, a melancholy strain became detectable in Weinberg's voice.
> "I was hoping that with string theory things would fall into place much more rapidly than they have," he said. "But it's been rather disappointing. I'm not one of those people who bad-mouth string theory. I still think it's the best effort we've made to step beyond what we already know, but it hasn't worked out the way we were expecting it would."

About Susskind's claims that the Many-Worlds and string theory multiverses may be one and the same, Weinberg is having none of it, describing the two ideas as "completely perpendicular" and saying:

> "I found it puzzling too," he said. "I've spoken to other people about it, and they don't understand it either"… "I don't agree with Susskind on that," Weinberg told me, "and I don't know why he said it."

The discussion with Weinberg brings up the whole question of a "Final theory", a truly unified fundamental theory of physics, and what its significance for the question of existence might be. After Weinberg, Holt describes a meeting with Sir Roger Penrose, and explains Penrose's "Platonism", the philosophical point of view that mathematical objects actually are real things that exist (in some sense…). Penrose attempts to also bring the question of consciousness into this, which seems to me a mistake, but the questions raised here about the relation of mathematics and our fundamental ideas about the physical world are dear to my heart. To the extent that to me there's a sensible question behind "Why is there Something rather than Nothing?", it's bound up with this great mystery of the origin of the fundamental laws of physics. Mathematics and physics have a completely unexpected and still not understood congruence at their deepest levels, and this mystery seems to me not only a very real one, but one that we can hope to further elucidate. I realized from Holt's discussion that maybe my own mystical views on this subject are best described as "Pythagorean". While he does a reasonable job of raising some of these issues, to me he dismisses them too quickly in favor of moving on to other topics much less worth taking seriously. But I would think that, wouldn't I?

The later part of the book reverts to the philosophers. For his discussion with John Leslie about "axiarchism", you can watch the two of them here on Bloggingheads. His final philosophical encounter is with Derek Parfit, in the imposing venue of All Souls at Oxford. Novelist John Updike is his last interviewee, and Updike also isn't so happy with string theory:

> "But this whole string theory business… There's never any evidence, just mathematical formulas, right? There are men spending their whole careers working on a theory of something that might not even exist."

Holt ends the book on a personal note, telling the story of the death of his mother and his return to the place he grew up. Throughout the book, he weaves in accounts of time spent in Paris, reading at Sartre's Cafe de Flore, and wandering the city contemplating aspects of his great philosophical question, as well as life in general. Some might find this distracting and not so serious, but I enjoyed those parts of the book a lot. Of course, this may largely be due to the fact that I'm a sucker for Paris and know well and love the locations he was describing.

If you have even the slightest interest in the "Why is there Something rather than Nothing?" question, be sure to get yourself of a copy of this wonderful book when it comes out.

My interest in the question has always been rather minimal (I got grief from some of my commenters recently for my dismissive attitude on the topic), but this didn't keep me from getting a lot out of the book. It's philosophy of a high level, pursued in an unusual and personal manner, and it's a pleasure to follow along with the author as he tells a fascinating and thought-provoking story.

Comments

1. **pakri**
   May 9, 2012

   I believe this is nothing but a word-play. None of the writers,
   including Sartre, has had deep insight. Great physicists and
   mathematicians should shun the subject.

2. **Peter Woit**
   May 9, 2012

   pakri,

   That's a reasonable take on the question, but I'll just point out that Weinberg and Penrose disagree with you and thought the subject worth discussing.

3. **Bobito**
   May 10, 2012

   "Why Does the World Exist?"

   Bad question because it suppose an ill-defined alternative.

4. **anton ymous**
   May 10, 2012

   >> Heidegger knew this would cost Staudinger his job.
   >> [..]
   >> Despite Heidegger's efforts, he managed to keep his job

   This does not really fit together?

5. **Neto**
   May 10, 2012

   "Mathematics and physics have a completely unexpected and still not understood congruence at their deepest levels"

   You can use math to model anything that is scientific reachable. How the use of math to describe natural physics can be "completely unexpected"?

6. **Aidyan**
   May 10, 2012

   Everyone asks why things 'exist' taking for granted that we know what 'existence' is. But a honest thought about it would reveal that we really don't know.

7. **Peter Woit**
   May 10, 2012

   anton ymous,

   I forget the details, but from what I remember Staudinger was forced to resign his position because Heidegger denounced him to the Gestapo and suggested he be forced out of his job and have his pension taken away. Staudinger did manage to get reinstated, after Heidegger and others in power realized that this would make the university look very bad internationally.

   Neto,

   This is just the usual "unreasonable effectiveness" argument of Wigner, which has accumulated much more evidence for it since his time.

8. **Jeff McGowan**
   May 10, 2012

   I must say I find it amusing that this is what physicists are busy talking about. Nothing wrong with philosophical discussions, or literary ones, but physics? Perhaps it comes from some deep seated desire for a theory of everything, which unfortunately (or maybe fortunately) Godel proved was clearly impossible quite some time ago. You would think that someone as seemingly smart as Weinberg would understand something that basic. And Peter, gotta say I think you're wrong and Penrose is right, consciousness is at the heart of it somehow. Check out Newcomb's paradox.

9. **Igor Khavkine**
   May 10, 2012

   About this "unreasonable effectiveness". Some time ago, I watched this video lecture by cognitive scientist (and apparently ex-logician) George Lakoff, recorded at the Fields Institute. In it, he briefly addresses this observation in the question period. His take on it was interesting enough for me to get a copy of his book on the cognitive science of mathematical thought, which is unfortunately still collecting dust in my to-read book pile.

   In my imperfect recollection and rendition of his position, they key to taking the mystery out of this question is the observation that mathematical thought is carried out by the brain, which resides in the body, both of which are physical systems following physical laws. The application of the "(unreasonable) effectiveness" to particular physical process then simply corresponds to the existence of a translation from this process to the physical processes of mathematical thought. These translations Lakoff calls *metaphors*, I believe. And they are supposed to be documented in detail in his book.

   The above argument would answer a "how" question. "Why" questions are always trickier. However, I think some light could be shed on the corresponding "why" question by answering a related one: When is it possible for any part of a physical system (the universe) to be mapped to (be simulated by) another part of the same physical system (the brain)? Personally, I have no idea what the answer to this question would be, but it seems to me already somewhat better defined than Wigner's original remark. It even has shades of Turing universality, which has been studied in some detail.

10. **Peter Woit**
May 10, 2012

Jeff and Igor,

I don't think either Godel's or Lakoff's arguments are relevant. We're actually very close to a unified theory, with the questions we don't understand seeming to have no connection to the problems Godel's theorem raises. The fact that a very non-obvious to the human mind structure (the Dirac equation) explains so much of reality, at the same time that it appears non-obviously in the deepest parts of mathematics (e.g. it's the fundamental class in K-homology) seems to me to show that something mysterious is going on, and it's something that has nothing to do with the structure of the human brain, for which both parts of the story are quite alien. This stuff is very difficult for the human mind to understand, it takes quite an effort, and only is successful due to the high adaptability of human thought processes. It's quite possible, and Holt mentions this possibility, that there is some deep structure going on here, that is as incomprehensible to our minds as calculus is to the mind of a dog. But we have somewhat better abilities than the dog to learn new things.

This is getting kind of off-topic though…

11. **Jeff McGowan**
May 10, 2012

Peter,

No question one might get a "unified" theory, my point was that a "complete" theory won't ever happen. "Theory of everything" implies complete, at least to me. Now I'll stop…

12. **billy hudson**
May 10, 2012

@JeffMcGowan

If you haven't already seen it, you may be interested in the book "Godel's Theorem: An Incomplete Guide to Its Use and Abuse" by the late Torkel Franzén.

13. **Igor Khavkine**
May 10, 2012

@Jeff, I'll second billy's suggestion.

@Peter: The question you seem to be posing is I think different from the original one posed by Wigner. In that case, I agree that Lakoff's argument is not particularly relevant.

14. **Jeff**
May 10, 2012

Billy and Igor,

While I'm sure the book is enjoyable, if I want to revisit Godel I'll dig out my notes on Turing's proof, which I always thought was one of the prettiest things in mathematics (despite being a geometric analyst myself…) And Lakoff was never a logician, his Ph.D. is in Linguistics.

15. **Allan Rosenberg**
May 10, 2012

I'm not so sure that the philosphers are entirely convinced that there is something rather than nothing. True, Descartes did argue, cogiter ergo sum, but that leaves open the precise definition of the following words: cogito, ergo, and sum, all disputations subjects in contemporary philosophy. Until those definitional issues are resolved, it's hard to see how we'll reach a philosophical consensus as to whether anything exists.

16. **Christian Takacs**
May 10, 2012

"Why does the world (universe) exist?" is begging the question. Kinda like, When did you stop beating your wife? The question presupposes that the universe didn't exist before it did, and unless you can prove former first, you have no latter 'creation ex nihilo' to debate. This is a good argument for why philosophy matters, if physicists would employ basic philosophy and logic before running off with silly 'interpretations' of limited data, (e.g. Copenhagen intrepretation) fewer such houses of cards would be assembled… and have so much prestigious math piled upon them. Heisenberg himself was actually very philosophical (not in a good way)… and a Nazi, as well as working for the German's on the atomic bomb. His colleague and friend Niels Bohr went to some effort to hide this glaring little truth, probably so his own career wouldn't be tarnished. So much for the glory of quantum mechanics.

17. **billy hudson**
May 10, 2012

Jeff,

Do your notes analyze the applicability of the Incompleteness Theorem to "The Theory of Everything"? Section 4.4 of has a nice analysis. From page 88: "The basic equations of physics, whatever they may be, cannot indeed decide every arithmetical statement, but whether or not they are complete considered as a description of the physical world, and what completeness might mean in such a case, is not something that the incompleteness theorem tells us anything about."

18. **Yatima**
May 10, 2012

> silly 'interpretations' of limited data, (e.g. Copenhagen intrepretation)

What am I reading. It just becomes silly if esoteric weirdos start to confuse "observer" (which can be an LHC detector) with "conscious observer" (an ill-defined, slightly icky concept if there ever was one). Other than that, it apparently remains the only one that makes consistent sense. For people who accept that probability theory can be extended, that is. Others write endless philosophical drivel on this, which may be necessary to bring in the bacon, granted.

http://arxiv.org/abs/math-ph/0002049 "It took some time before it was understood that quantum theory is a generalisation of probability, rather than a modification of the laws of mechanics. This was not helped by the term quantum mechanics; more, the Copenhagen interpretation is given in terms of probability, meaning as understood at the time. Bohr has said that the interpretation of microscopic measurements must be done in classical terms, because the measuring instruments are large, and are therefore described by classical laws. It is true, that the springs and cogs making up a measuring instrument themselves obey classical laws; but this does not mean that the information held on the instrument, in the numbers indicated by the dials, obey classical statistics. If the instrument faithfully measures an atomic observable, then the numbers indicated by
the dials should be analysed by quantum probability, however large the instrument
is."

19. **Jeff M**
May 10, 2012

Billy,

That statement strikes me as a bit of a cop out. "What completeness might mean in such a case" allows for pretty much anything, no? Not saying he's wrong, since I have no doubt that different people might mean very different things by "completeness" in relation to a physical theory, but to a mathematician completeness is very clear. Perhaps that was really my point – when people start talking about "final theories" it isn't at all clear what they mean. Then again, perhaps I'm just being a nit-picky mathematician 🙂

20. **paddy**
May 10, 2012

And perhaps I am being a nit-picky physicist: "shut up and calculate".

21. **Anonyrat**
May 10, 2012

"Why is there something instead of nothing?" is an existential question that is meaningful only in the context of religion. This can be seen by thinking about what would constitute an acceptable answer. The prototypical answer to an existential question requires a God that is outside of and independent of the universe, and then "there is nothing" has meaning. Religion seems to have faded away, but it still lingers on powerfully. This shown by the number of people who think "why is there something instead of nothing?" is still meaningful.

22. **billy hudson**
May 10, 2012

Jeff,

I'm sympathetic with paddy's statement. In my experience, mathematicians (outside of the field of logic) are no more concerned with completeness than physicists. All of our calculations take place in an incomplete theory, but this doesn't affect anyone's practice of mathematics/physics (I'm of the camp that has a hard time distinguishing between the two). In any case, we've strayed off topic so I'll leave it there. Cheers . . . 🙂

23. **Friend**
May 10, 2012

"Why is there something rather than nothing?" Perhaps this is just another way to ask what is the purpose of the universe? Or, what is the most general principle that it displays as a whole? Then the answer to those question might answer the "why" of its existence. For example, one might venture to say that the most general thing that the universe does is display a set of consistent facts. Then that could be "why" it exists… to display a consistent set of facts.

24. **Bourgeois Nerd**
May 10, 2012

Thank you, Peter, for the review. The book sounds as great as I'd hoped! Can't wait for July!

25. **Fabien Besnard**
May 11, 2012

Thanks for the very interesting review, Peter.

26. **Peter Burnett**
May 12, 2012

Consider the intellectual distance between the knowledge you possess and the problem you're trying to solve. 'Why is there anything rather than nothing' is the question with the greatest distance. But let's not give up or ignore it just because it's a long trip. There must be a rational answer to this problem, if not, we might as well give up physics and spend the rest of our lives with our hands down our shorts.
The best comment I've come across is that there are three possibilities: either there is something, or there is nothing, or they are both the same.

27. **Tony Smith**
May 12, 2012

Since I do not have an advance copy of the Jim Holt book,
my question is whether/how the book might differ with respect to a couple of points in his November 1994 Harper's article "Nothing Ventured – A bold leap into the ontological void" in which he said:

1 – about Hegelian dialectic:
"… At the beginning of Hegel's famous dialectic is the assumption that
the Absolute is Pure Being.
But Pre Being is totally indefinite; it has no qualities; it is utterly empty. It is the same as Pure Nothing.
You can't have one without the other; they are dialectical twins.
And yet, inasmuch as they are also contraries, they can't coexist very happily.
Something new must be found that reconciles and supersedes them.
And that turns out to be: Becoming!
Becoming is what happens when Being is on the verge of passing into Nothing–or vice versa.
Thus does the Hegelian dialectic get merrily underway, eventually yielding up human history and culture in all their variegated splendor. …".

2 – Jim Holt's personal argument, thought of while shaving:
"… If the laws of physics come into being along with the universe, then they can't explain it.
If they exist prior to the universe, then there is nothing to account for their existence …
That is the dilemma of the nothing theorists.
… there is no need to get impaled on its horns …
a … way of showing why there is something rather than nothing … goes like this. Suppose, for the sake of argument, that nothing existed.
Then, in particular, there would be no laws. …
If there were no laws, then everything would be permitted.
If everything were permitted, then nothing would be forbidden.
Therefore, if nothing existed, nothing would be forbidden.
Therefore, nothing, if it existed, would forbid itself.
Therefore there must be something. …".

Tony

28. **Peter Woit**
May 12, 2012

Tony,

Sounds like the sort of thing that is in the book, in similar form. Holt is no fan of Hegel, but write a bit about him, along the lines of what you quote.

29. **Friend**
May 12, 2012

Peter,

Since you have an advanced copy, are you allowed to write a review on amazon.com?

30. **Tony Smith**
May 12, 2012

Just for fun, here is a silly thought about the Hegel quote:
Absolute Something = PURE BEING
Nothing = PRE BEING
Absolute Something – Nothing = PURE BEING – PRE BEING = U
So, U = YOU are what distinguishes Something from Nothing.
(?a version of cogito ergo sum?)

Tony

31. **Peter Woit**
May 13, 2012

Friend,

I think Amazon has a program to get people advance copies of books in exchange for writing reviews. I'm not part of that, my copy didn't come from them. Whether or not I could post a review there, I think I'll stick to just doing this on the blog.

32. **arjun**
May 13, 2012

Dear Peter,

Could you please expand on this statement that you make:

"The fact that a very non-obvious to the human mind structure (the Dirac equation) explains so much of reality, at the same time that it appears non-obviously in the deepest parts of mathematics (e.g. it's the fundamental class in K-homology) seems to me to show that something mysterious is going on …"

33. **Peter Woit**
May 13, 2012

arjun,

This is a very long story. I think there is quite a bit about it in my book.

An oversimplified way of stating it is that the most powerful theorem telling you about the relation of analysis, geometry and topology is the Atiyah-Singer index theorem (and you can abstractly express it using K-theory). In some sense it says that the Dirac equation is a "generator", everything else can be written in terms of that. Atiyah and Singer actually rediscovered the Dirac equation for themselves in the course of their work on the index theorem.

34. **Tom Whicker**
May 14, 2012

I think we have a strong aversion to the contemplation of non-existence, because
contained there-in must be the admission of our own personal non-existence. It is
very real and soon to happen to each of us. We try to laugh or to say it is uninteresting, to say there is no useful math or physics there, which is true. But
the topic itself is deeply disturbing.

35. **Anonyrat**
May 14, 2012

Luboš Motl:

"We use the term string theory for everything that is connected by equations to what we previously called string theory. That's why we will simply use the term "string theory" for every consistent corner of quantum gravity we may discover in the future. With this convention – which was adopted in recent decades – the uniqueness of string theory as a consistent theory of quantum gravity is a tautology. "

Elevated from the comments [here.](#)

36. **Peter Woit**
May 14, 2012

Anonyrat,

Thanks, but the philosophical issues raised by the existence of Lubos Motl and the fact that prominent string theorists guest post on his blog and put his endorsement on their books are greater mysteries than that of existence in general, and best left for another time…

37. **paddy**
May 14, 2012

PW:
Your LM post left me laughing til I went into a coughing fit. 'Twould be indeed better if LM were capable of seeing the humour.

38. **prianikoff**
May 15, 2012

Hegel was an idealist.
A materialist would define nothing as the anwer to the question.
"What's a Greek urn?"

39. **clauderains**
May 15, 2012

Why does anything exist? Because it's easier than not existing. And we exist within it to satisfy a statistical outlier on the universe's ability to 'spontaneously' create toasters…

40. **tulpoeid**
May 16, 2012

A little bit off-topic (but only a little bit), this is a chance for a comment I've meant to leave here for some time now. In case you (or any readers) enjoy good science-fiction, you might want to have a try at Neal Stephenson's Anathem. You'll find it touches on issues related to this blog!

41. **Dave Miller in Sacramento**
May 18, 2012

Peter,

Can you suggest any readable but mathematically detailed discussions of your point about the Atiyah-Singer Index Theorem?

I managed to figure out for myself (maybe "guessed by myself" would be more accurate!) this idea that the Dirac equation is at the base of the Index Theorem.

But, I cannot find a discussion of the theorem that actually explains this clearly and in detail. I am in the frustrating position that I understand (I think) the details of various proofs (Sobolev spaces, Chern characters, etc.) without really understanding the proofs.

And, thanks for the book review. Unlike you, I suspect the question is meaningful, but I must admit to a sneaking suspicion that it is not. Needless to say, I found Weinberg's comments the most sensible among those you quoted.

Dave

42. **Peter Woit**
May 18, 2012

Dave,

One good reference is these lectures by Nigel Higson and John Roe
http://folk.uio.no/rognes/higson/Book.pdf

Something much more general is this

http://web.me.com/ndh2/math/Papers_files/Higson,%20Roe%20-%202006%20-%20The%20Atiyah-Singer%20index%20theorem.pdf

43. **Dan**
May 18, 2012

The idea of origin brings with it a simple but profound bit of baggage: causality. Simply put, "something" must exist, and be transformable into "something else". In this context, the problem arises because we must now substitute "nothing" for "something" with the absurd transformation of "nothing" into "something else". How is "nothing" transformable? It is simply not logical.

There are various ways to try to beat this problem:

1. There never was a state of "nothing". The universe (as a transformable substrate) has unbroken temporal existence. It is either "temporally closed" (going in circles) or "infinite" (going going going …..)
2. The transformation of "nothing" into "something" is a false dilemma because you just ain't smart enough to understand such an abstract transformation. Now shut up and calculate.
3. God did it. And he needs some money. (of course, don't ask where God came from as this might invalidate the solution)

Please add to this list if you can think of any other options.

On a much lighter note, this SMBC comic is apropos.

Igor Frenkel 60th Birthday Conference

May 14, 2012
Categories: Uncategorized

This week Yale is hosting a conference on Perspectives in Representation Theory, in honor of Igor Frenkel's 60th birthday. I'm planning to take the train up there and attend some of the talks tomorrow and Wednesday. Frenkel has been a pioneer in the field of representation theory, especially in the area of infinite-dimensional algebras whose representations are significant for understanding low-dimensional QFT, string theory and topological QFT. He started his career in the early 1980s, with many important results relevant to understanding affine Lie algebras. These became central in the explosion of interest among physicists in 2d conformal QFTs after 1984 due to their importance in string theory. Frenkel's later work has covered a wide variety of topics, with one theme that of trying to understand higher-dimensional generalizations of affine Lie algebras and their potential application to QFTs in higher space-time dimensions than 2. He has also promoted the themes of "categorification" and geometric incarnation of representations that are now central to much research in this area.

Pavel Etingof and other students and collaborators of Frenkel have put together a wonderful document, On the work of Igor Frenkel, which gives much more detail about the many topics of his mathematical research.

Update: Videos of the talks are now available here.

Comments

   May 20, 2012

   Sigh! I had a look at Pavel Etingof's paper, and I got seriously depressed, due the following quote:

   "In spite of this progress, however, it is still not clear what the representation theory of central extensions of double loop groups should be like. Perhaps we don't yet have enough imagination to understand what kind of representations (or maybe analogous but more sophisticated objects) we should consider, and this is a problem for future generations of mathematicians."

   On the Lie algebra level, the answer has been around for 15 years or more. Geometrically, the off-shell representations of the multi-dimensional affine algebra (the MF extension is not central) act on trajectories in the space of g-valued p-jets, where g is the finite Lie algebra. The representations of the multi-dimensional Virasoro algebra are completely analogous.

   OK, I understand if people ignore an crackpot amateur physicist, but perhaps one should bother to have a look at the work of professional mathematicians, like Billig, Rao or Moody.

The Smell of SUSY

May 16, 2012
Categories: This Week's Hype

The implications of the failure to find SUSY at the LHC are beginning to sink into the particle physics community: the paradigm that dominated the subject for the past 30 years has collapsed in the face of experimental (non)-evidence, threatening to take down the life's work of hundreds if not thousands of theorists. For some recent attempts to quantify what is going on, from some people with much more statistical expertise than me, see Philip Gibbs and Tommaso Dorigo. By now a significant number of SUSY analyses of the full 2011 dataset have been completed, with negative results. By the end of the year there will be more data, but just a factor of 2-3 more, at about 14% higher energy. To believe that these sorts of increases will turn no signal into a signal requires a willingness to engage in a rather large amount of wishful thinking. The 62% jump in 2014 to 6.5 TeV/beam is more significant, but it's hard to see an argument for why this should do the trick, and the wait for these results will be discouragingly long, probably until 2015. How many SUSY enthusiasts will keep the faith?

A small number of theorists though still claim all is well, with one group producing a new paper claiming the full 5 inverse femtobarn results show Chanel No5 (fb^-1): The Sweet Fragrance of SUSY. Last year the same authors were claiming to detect Profumo di SUSY in the first inverse femtobarn, and argued that 5 times more data would be conclusive. To quantify the SUSY smells they are advertising, one can plot as a function of time their published predictions for the parameter $M_{1/2}$ which determines the gluino mass.

arXiv:1007.5100 455 GeV ("Golden Point")
arXiv:1009.2981 455-481 GeV ("Golden Strip")
arXiv:1111.0236 512 GeV ("Universe F-U2")
arXiv:1111.4204 518 GeV ("Profumo di SUSY")
arXiv:1203.1918 610 GeV ("Aroma of Stops and Gluinos")
arXiv:1205.3052 708 GeV ("The Sweet Fragrance of SUSY")

It's rather easy to extrapolate to the future what these authors will be claiming the SUSY masses are, harder to extrapolate how they'll be describing the smell. The rest of the particle physics community I suspect is already using very different terms for this.

Update: According to this report from Pheno 2012

> As pointed out by Rahmat Rahmat (yes, that's his name—in my notes I list him as Rahmat^2) and Csaba Csaki, respectively from University of Mississippi and Cornell University, the LHC should have detected some signature of SUSY by now, especially if the MSSM is correct. As Csaki said, "SUSY is a wonderful woman who does not return my letters. It makes you wonder if she even exists!"

   Maybe you should have titled it:
   "The Smell of Dead Susy"

3. **Frank**
   May 17, 2012

   Peter, some people are starting to play a well-known game with supersymmetry: whatever negative result comes in, they answer that it does not refute supersymmetry. This behavior begs the following question, which you know well enough from a similar field: is there any definite, testable prediction of supersymmetry at all? Or even more precisely: is there any definite, testable prediction of *broken* supersymmetry?

   To interested people it seems that none of the concepts introduced by supersymmetry, from sparticles to super-gauge fields, has any evidence to back it up. This begs a second question: Why have people been so convinced about supersymmetry to start with?

4. **Speculative**
   May 17, 2012

   Frank,

   1) Unlike String Theory, SUSY is certainly testable. The problem with discovering or ruling out SUSY is not its testability but its parameter space. That is there it will take a lot of experimental work to really rule it out. It is probably impossible to rule it out completely, rather if a large enough parameter space is ruled out theorists and experimentalists may just move on. Theories usually not outright disproven, but rather proven untenable.

   2) SUSY is (or was) appealing because it seemed to solve so many problems at once. It makes working with the math nicer, it fixes the gauge coupling at higher energies (so they all converge at the hoped for GUT scale), and it gave possible candidates for Dark Matter. Of course this doesn't matter if it doesn't actually exist but the search for it is certainly not without merit.

   My feelings coincide with Professor Strassler. We need to wait and see and not jump into any conclusions. Science is a slow process and there's no need to rush it or jump to conclusions. That being said, the results coming out of the LHC aren't encouraging, but you never know how things can change.

5. **Hun Hunahpu, PhD**
   May 17, 2012

   This accelerating increase in the gluino mass indicates that one of the hidden dimensions is rapidly decompactifying. My calculations indicate that the transition to a genuinely five-dimensional macroscopic world should occur a little over seven months from now.

6. **don**
May 17, 2012

I think both sides of the SUSY debate have jumped to conclusions too quickly. Those who worked on it believed it would be found soon after the LHC started up and now those who were skeptical of the idea believe SUSY is dead. What is happening now reminds me of the state of the Higgs search about nine months ago when nothing had been found yet and people were declaring the Higgs dead. SUSY might be right or it might be wrong, let's wait until we have more data before we jump to conclusions. This search is, after all, one of the reasons the LHC was built, let's let it do its job. And let us not forget this point: we will not have evidence of something until we have evidence of something. This is what science is all about: we have a problem, we come up with an explanation that attempts to solve the problem, then we test it.

7. **Peter Woit**
May 17, 2012

don,

I don't think there's much parallel to the Higgs case, where I don't remember anyone declaring it dead, just some speculation about what it would mean if it were ruled out.

In the SM Higgs case the predictions are very solid, with one free parameter, so it has always been very clear exactly what is ruled out (some range of the one parameter at various confidence levels). For SUSY, there are vast numbers of parameters to describe even the simplest SUSY extension of the SM, and it will never be possible to say "SUSY is ruled out at X confidence level". So, it's worth getting clear on exactly what the case for SUSY is, what exactly you expect to see at the LHC if that case is valid, and exactly what the analyses show. I'd argue that pre-LHC the case for SUSY was weak, with many arguments for it leading to the conclusion that it should have already shown up. The only remaining hopes for those arguments required SUSY to show up early in the LHC data, and it didn't. We've now seen quite a few analyses of the full 2011 data set, and there's no good reason to believe the 2012 data set will make large increases in the exclusions already available. So, now is a good time to start drawing conclusions. You can try and argue to wait for 2015-6 and higher energies, but I don't think there's a good argument there, just an attempt to stall for a few more years.

8. **don**
May 17, 2012

I think I am being fair when I say that while SUSY may not be true it is at least a reasonable theory that very well could be true. I think it is also fair to say that we are nowhere close to having excluded over 95% of the possible reasonably likely iterations of SUSY. Let's search and then draw conclusions after we have at least a year of full power LHC. It's not as if we are wasting our time on a crackpot theory that has almost no chance of being correct or that we even have very many other sensible theories at this time that could possibly go beyond the Standard Model. Perhaps you will argue that we should move on now, cut our losses, and try to come up with something new. I'm all for alternatives to SUSY, but I also believe that we can multitask.

9. **Peter Woit**
May 17, 2012

don,

My point was more about what theorists should do, not what the LHC experiments should do. It's long past the time that theorists should admit that things like the MSSM are a failed idea. I see no argument for waiting until 2015-6 for this.

As far as the LHC experiments are concerned, they certainly shouldn't stop SUSY analyses, and in any case there's no danger of that. It would however be a good idea for the people making decisions about which analyses to do (or how to design triggers) to have a realistic point of view about the prospects for SUSY, not an overhyped one.

10. **Visitor**
May 18, 2012

"As Csaki said, 'SUSY is a wonderful woman who does not return my letters. It makes you wonder if she even exists!'"

Beware non-existent women! Heed the troubles of Paul Frampton, and let it be a cautionary tale for you!

PW,

How does the failure to find SUSY in 2011 data set @ 7TEV energies translate to not likely finding evidence for SUSY at 14TEV (or 13TEV)

do you think there will be new physics, such as SUSY, in a proposed future upgrade to a higher-energy LHC ("HE-LHC") with about 16.5 TeV beam energy (33TEV)?

12. **Peter Woit**
May 19, 2012

neo,

The main argument for SUSY at LHC energies has always been that it would solve the hierarchy problem and stabilize the weak scale. The problem with this argument was always that if so, you should have already seen evidence for SUSY pre-LHC. One could argue though, that it was just beyond the pre-LHC range. That argument is now dead. I don't see a good argument for expecting SUSY either at 13 TeV or 33 TeV. Hopefully the LHC will see something non-SM, which will justify building an HE-LHC to investigate. Otherwise, the main argument for the HE-LHC will just be to check the SM at higher energies. That would be enough for me, but it will make selling the machine harder.

13. **neo**
May 20, 2012

A certain string partisan, whose name I won't mention, debated this with Tommaso Dorigo on his blog, that in his view, the situation is similar to the hunt for the Higgs –

Higher energies + enough data takes time to collect and analyze, and there are many versions which have not been ruled out.

14. **Peter Woit**
May 21, 2012

    neo,

    The MSSM adds more than 100 parameters to the SM, you will always be able to find corners of parameter space that the LHC can't rule out, or just push the SUSY breaking scale high enough. Some fraction of SUSY diehards will never give up on the idea, no matter what. If you look at Lubos's long posting about this, it boils down to his accurate argument that if your prior probability is 99.99% that SUSY exists, the LHC exclusions don't change your beliefs by much. Or, less technically, if you're a fanatic, experimental evidence is pretty much irrelevant. Most people however are not fanatics, and opinions about SUSY in the mainstream are definitely changing substantially in response to the LHC results.

    Interestingly, even Lubos doesn't believe the "Smell of SUSY" argument of Nanopoulos et al., which is remarkable.

    Why the SUSY search with its vast number of free parameters is just like the Higgs search, with its one parameter, escapes me.

15. **neo**
May 21, 2012

    I didn't mention the name yet you correctly guess. Haha. His claim "Your analogy with the Higgs allowed intervals is very appropriate. When we're approaching a discovery, we're inevitably able to eliminate increasingly large portions of the regions that were possibilities just a year ago. This just means we're learning something about the details of the model. For Higgs, the discovery could actually take place well before the exclusions of the most of the parameter space because its signals are sharp as a function of the Higgs mass. But this didn't occur. For SUSY, the signals are much more widespread as functions of the superpartner masses so we must clearly expect to exclude an even higher fraction of the parameter space before the discovery – at least one able to find out the masses of the new particles – can actually be made."

    In his opinion, the current LHC bounds only exclude a small fraction of the SUSY parameter space, MSSM and still resolve the hierarchy problem and stabilize the weak scale.

16. **Peter Woit**
May 21, 2012

    neo,

    In Lubos-land, it doesn't matter how much parameter space the LHC rules out, or how much fine-tuning is required for the MSSM to "resolve the hierarchy problem and stabilize the weak scale". 5 years from now when the LHC has gone to higher energies and luminosities, he'll be saying the same thing, although by then he'll have gone from being in a minority of theorists (the situation today) to being in a very small minority of true-believers.

17. **neo**
May 22, 2012

    –PW Possible, but that's assuming continued null result, which is entirely plausible. If the LHC continues to provide null results even at 13-14TEV design energies and sufficient fb-1 & data analysis, what do you predict will happen to string theory research and interest? Do you think Witten, Susskind, Greene, Kaku, Hawking, et al will continue to work on it and promote it to a popular lay audience?

18. **Peter Woit**
May 22, 2012

    neo,

    Most of those you mention already have stopped working on string theory, and have likely already given up on the LHC vindicating string theory. On the other hand, people who have devoted 20-30 years to promoting something rarely publicly admit this was a mistake. I'd guess what will see will be a continuing refusal to publicly admit failure, coupled with half-hearted endorsements of string theory unification, while working on other things. Kind of like the situation now…

Latest from the Rumor Mill

May 16, 2012
Categories: Uncategorized

There's at least one thing about string theory that has changed dramatically since my book was written back in 2002 or so. At the time I accumulated various numbers showing the way hiring in particle theory at leading institutions in the US had been dominated by string theory hires. Overall, at that time about 20 people/year were getting tenure-track positions, roughly half in string theory half in phenomenology. This data came from the [Theoretical Particle Physics Jobs Rumor Mill](), and Erich Poppitz has done an excellent job of putting some statistics together based on this data (see [here]()). In recent years Erich's data shows a much lower number of such positions (10-15/year), due to some combination of the bad economy and lack of enthusiasm for particle theory by other physicists. The number of string theorists getting positions had come down to about 2/year, then down to only one last year.

The hiring season is not yet over and not all the data is in, but so far the Rumor Mill shows no job offers to string theorists at all. Job offers are going pretty exclusively to phenomenologists and cosmologists, with phenomenologists allowed to stray into formal theory if they work on topics related to N=4 SYM and its superconformal invariance (including the hot topic of amplitudes). Marcus at [PhysicsForums]() has patched some of the Rumor Mill links for better accuracy.

One thing hasn't changed though since 2002: there's a much larger number of talented and accomplished candidates than there are jobs, and departments are playing it safe, offering the few jobs available only to people working in a small number of areas that are conventionally agreed to be "hot". As always, if you're working on some idea that's not in the narrow mainstream, there's no chance you'll get hired into a permanent position at a US institution.

Update: There is one string theorist now with a job offer it seems, with Princeton making an offer to Simone Giombi, who works on the hot topic of higher spins. So, at least Princeton has not given up….

   "One thing hasn't changed though since 2002: there's a much larger number of talented and accomplished candidates than there are jobs, and departments are playing it safe, offering the few jobs available only to people working in a small number of areas that are conventionally agreed to be "hot". As always, if you're working on some idea that's not in the narrow mainstream, there's no chance you'll get hired into a permanent position at a US institution."

   Agreed, and the last sentence is particularly sad. In the absence of earth-shattering theoretical papers (compared to papers in the 1990's, e.g.), departments seem to be hiring purely based on what is "hot" (as you point out), but this is usually defined in a given 2-3 year time span.

   What do you think happens to faculty hires in HEP theory in five years if we have Higgs + nothing at LHC, no tensor modes from Planck, and no direct dark matter? The phenomenology of these fields are "hot" now, and rightfully so, but it will be interesting to see what happens in the next few years.

2. **Peter Woit**
   May 16, 2012

   P.,

   That's the "nightmare scenario" as far as business as usual in particle theory is concerned, and I don't know what will happen, although I suspect it will involve physics departments hiring fewer theorists overall.

   One thing one can be sure of: if Planck/LHC/direct dark matter experiments actually see something unexpected, if you want a job you're going to have to be working on that…

3. **Christian Takacs**
   May 17, 2012

   Peter,
   For quite some time now you have been speaking out about how physics should not have put all it's eggs in one basket, particularly a basket woven of superstrings and multiverses stuck together with supersymmetry glue. Ok. Given. How far back are you expecting the wayback machine to be set before physics has something it can testibly prove again? Pre superstring? Pre QED?? Pre SM??? Pre General/Special Relativity???? When things don't work out, you usually have to start questioning your assumptions, as logically this means some unrecognized error has taken place. This rethinking of a field of science has happened before, it's reality's way of saying "you're looking the wrong direction", and If you could even suggest such a place where the physics community might start looking for where they went wrong, as opposed to Not Even Wrong, a great service will have been rendered.
   I wouldn't worry so much about how many phsyicists get tenured, as sheer quantity isn't going to solve the trouble with physics as long physicists are looking to follow someone elses lead. I would be more concerned about how any physicist who could actually find a working solution could get any traction in your community to put things back on track, as the past history of physics has shown quite clearly, its not the group thinkers looking for approval from their peers or seekers of job security or conformity that makes for discovery. It's usually someone willing to challange the status quo, pecking order, or established assumptions, usually at personal cost to themselves.

4. **Peter Woit**
   May 17, 2012

   Christian Takacs,

   The experimental evidence is clear that the SM is a fantastically successful idea, supersymmetric and extra dimensional extensions of it are failures, which makes it clear where you want to roll-back to. There are aspects of the SM that remain poorly understood, for instance: confinement of QCD, non-perturbative behavior of chiral gauge theory, BRST treatment of gauge symmetry (outside of the perturbation expansion). These are difficult problems, and no one is likely to solve them quickly. If an ambitious young theorist in the US devoted their post-doc years to working on one of them, making some modest progress, what would their chances be of appearing on the Rumor Mill with a job offer? Perhaps the biggest obstruction to progress is the ingrained attitude in the theory community that only someone stuck in the past and too stupid to understand the standard textbooks would worry about such issues. Real men quickly learn the trivial SM and move on to the cutting edge of SUSY models, extra dimensions, strings and branes.

   What I'm wondering is how long you can keep claiming to be the "cutting edge" when your ideas have failed and you aren't coming up with new ones.

5. **Bernhard**
May 17, 2012

Peter,

this is not restricted to the US, in Europe too, you have no chances at all of working on your own ideas and get tenure. I would say the situation in some European countries is even worse, as one depends on grants for the rest of his life. In the US as far as I understand, after tenure you could in principle work on whatever you want. European funding is strongly driven to competition with the US and if you write a proposal on something that is not hot enough, be prepared for comments like "excellent proposal, but focused on rather exotic theoretical models" (as you may suspect I´m talking about my own experience). An "exotic model" is by definition almost exclusively something that is not SUSY, although with stronger limits I have no idea how is this going to be evaluated. If you look at the highly prestigious ERC grants from 2011 (PE2 is where HEP competes):

http://erc.europa.eu/sites/default/files/document/file/erc_2011_stg_results_all_domains.pdf

you see that the few HEP project granted are either dark-matter or more very down-to-earth experimental projects like using diboson final states or measuring the W mass. There is not a single project that (at least the subject) is not something that smells awfully traditional or mainstream. Oh yes, from the starting grants for 2011 you see no string theory projects, in 2010 two were granted. No idea what will happen for 2012 but this will be out in the middle of the year.

The way out I found in the past, was to find a way to include SUSY (in whatever way I could) in all projects I was writing. I always got grant this way. Now the new trick is to include "Higgs" in whatever you write and so we (sadly) go.

6. **Mike**
May 17, 2012

One thing I always wonder is that given universities seem to hire tenure-track people annually, does this mean a significant fraction never get tenure and are kicked out after 4 or 5 years? I can't believe departments are expanding indefinitely, and I suspect not many people leave the academic world voluntarily.

7. **Peter Woit**
May 17, 2012

Bernhard,

Too bad to hear about how similar things are all over the world. It used to be that the existence of local cultures of particle theory with different points of view allowed for a variety of viewpoints. Now we have a not necessarily good form of globalization.

Mike,

At least in the US, most tenure-track jobs carry a fairly high probability of leading to tenure and a permanent position (with a small number of exceptions, e.g. Harvard). The main source of new positions in the system is retirements these days, as the large number of people who got tenure in the 60s retire. When someone retires though, for budgetary reasons the university may not allow the department to replace them. The department may also decide to change fields, replacing a particle theorist with someone from a different field that they see as more promising.

There are also a small number of new institutions that are hiring all new staff. Main examples are Perimeter and the Simons Center.

8. **Marcus**
May 17, 2012

Mike,
"One thing I always wonder is that given universities seem to hire tenure-track people annually, does this mean a significant fraction never get tenure and are kicked out after 4 or 5 years? I can't believe departments are expanding indefinitely, and I suspect not many people leave the academic world voluntarily."

I imagine that someone hired tenure-track at a first-rate Ivy who then does NOT win tenure after 4 or 5 years is likely to make faculty or find a secure research position somewhere less celebrated to the south or west. So such folks do not necessarily leave academia.

9. **Aidyan**
May 18, 2012

"As always, if you're working on some idea that's not in the narrow mainstream, there's no chance you'll get hired into a permanent position at a US institution."

Indeed. But it is not only in the US but also in Europe (and i suspect a worldwide trend), and not only in theoretical physics. When you propose something which is not mainstream, say also in down to earth applied physics like nanophotonics (my stuff), it is usually something people don't know about precisely, which means also that those who have to take up responsibility (for funding, or mentoring, or represent the research group, etc.) begin too panic. The reptile brain "what if" reaction that begins to foresee possible dangers in case of failure (and that will always find some) dominates and mesmerizes every thought pattern. And at that point the typical response you get is "I'm afraid this is too far afield from…". The problem is that we lack of people who have e bit of spine. Most of these people are managers, politicians, bureaucrats who have a degree in science, but not scientists who manage any more.

10. **lun**
May 18, 2012

With a few exceptions, senior theoretical physicists, even senior ones, are in my experience open-minded to mainstream ideas being wrong, so the picture of an inquisition keeping down modern-day Galileos is simply not true.
The exclusion of non-mainstream ideas happens in a rather more subtle way: Physicists are ranked according to how good they are at solving "useful" and "timely" problems. These, by definition, are mainstream problems.
Hence, a physicist who is developing non-mainstream ideas, BY THAT DEFINITION, is not a good physicist.

This effect is systemic, not particular to string theory or any other mainstream idea.
And it seems much more efficient, at stamping out non-mainstream ideas,than outward hostility.

11. **srp**
May 18, 2012

There seems to be a general malaise across a broad range of natural sciences (for example, in biomedical research as well as particle physics) emanating from

1. Funding mechanisms that require a) endless grant-writing at the expense of doing actual research, b) conservative, closed-ended proposals rather than innovative, open-

ended proposals (sometimes to the extent of "promising" results that have already been obtained but not yet published), c) overproduction of new grant-seekers, leading to declining success rates over time, thereby exacerbating a).

2. A surge of questionable publications that make it hard to find actual nuggets of useful stuff in the literature. Said surge being induced by the funder and institutional pressure for lots of "high-impact" papers.

3. Strangling of new ideas by peer review abuses and by the need for junior faculty to placate senior colleagues.

Scientists are very institutionally conservative, so no matter how much they complain about 1-3 they will never support fundamental reforms out of fear that what comes after will be even worse. And since most incumbent scientists succeeded in an earlier, more functional, incarnation of the system, they are emotionally comfortable with its basic contours.

I am led to the conclusion that only alternative institutions, funded and governed independently of the existing system, will be able to remedy these problems. The original scientific revolution in Europe entailed just such a movement away from traditional institutional structures, so at least there's precedent.

12. **Peter Woit**
May 18, 2012

srp,

There are generic problems with modern academic scientific research, but it strikes me that the situation in mathematics is quite different than in particle theory. Math is a very similar style of research to theoretical physics, no labs, but the results are very different. Math has its problems, but in general it's a pretty healthy subject. It's an interesting question why the results are so different than in particle theory.

13. **DB**
May 19, 2012

Peter,

As an outsider with physics degree, which I haven't used for around 15 years I would hazard a guess that the difference between physics and mathematics is that maths has no requirement to meet the real world. So long as it is rigorous it is pretty much all good and any future application is a bonus.

Once you add the requirement that your mathematics has to model a universe then you add whole new ways for elegant, self consistent, rigorous work to be wrong.

In other words it is a lot easier for perfectly competent physicists to waste their careers, which makes the stakes somewhat higher.

14. **Peter Woit**
May 19, 2012

DB,

That's one difference, but that has always been a difference, and it didn't stop particle theory from being healthy pre-1970s. One thing that change around 1970 is that the job market in particle theory got awful and has stayed awful since then, in a way that is very different than mathematics and other sciences. I suspect that having a job market where you only have 1 in 10 chance of getting a permanent job, and that chance requires that you work on the most fashionable topic, is a big part of the story.

15. **Peter Shor**
May 19, 2012

It seems to me that one difference between math and theoretical physics is that there is a lot more unsubstantiated dogma in physics. There are a few leaders in the field, and everybody tends to believe what they say. For example, I've heard comments to the effect "if there's something to this non-commutative geometry stuff, why isn't Witten working on it?" and "Susskind showed that if the universe wasn't unitary, experiments would have detected it by now, so we know it must be unitary (this without having any idea of what was in Susskind's paper, and whether it was invalidated by the discovery of topological error correction)."

In math, if the leaders in a field have a proof, they are generally believed (sometimes incorrectly), but if they have a conjecture, it's not taken as solid evidence for anything.

16. **Shantanu**
May 20, 2012

Peter, do you have any data on the trends in topics covered in HEP or particle seminar series at various universities (over the years). That may give another idea of what's hot (or not) or how trends have changed over the years.
shantanu

17. **Peter Woit**
May 20, 2012

Peter Shor,

Interesting comment. One major difference between math and theoretical physics is that mathematicians are very focused on precisely drawing the boundary between what they completely understand (thus have a "proof"), and what they don't. This provides for a fruitful research environment, where people can try to push the boundary, even if only a little bit. In QFT, the distinction between what is completely understood and what isn't often is lost or highly obscure. People rely on the best minds of the subject (e.g. Witten) to make the distinction, but even Witten is not infallible (and relying on someone like Susskind for this is really kind of nuts).

This also leads to an environment where people assume that everything about QFT is basically understood, so anyone who works on a range of topics must be a second-rate intellect, unable to handle thinking about the acknowledged areas where we don't know what is going on.

Shantanu,

I have no such data, nor any good idea even how one would put it together. An interesting idea though, looking at seminar topics at major research institutions does give a good idea of what the current "hot" topics are.

18. **Maynard Handley**
May 20, 2012

(a) Regarding supposed malaise in science in general: do we have any real evidence of this. To an outsider, it certainly looks like we're discovering more faster than at any point in human history.
People seem to have a desire to claim to be living in the worst of all possible worlds (cf the on-going nonsense we hear about how violent our society, or our world, currently is — claims confidently made by people with absolutely zero knowledge of history or anthropology). Discussion of a general malaise in science strikes me as very much in that vein.

(b) Regarding particle theoretical physics in particular, my humble suggestion is that it is long past time that we throughly revise the curriculum and the textbooks. We have a situation right now where the amount of material that must be learned to reach competence is so large that it is way beyond the capabilities of most mortals.

That's fine if your goal is to be a very exclusive club of Sheldon Coopers; but as a general principle keeping out large swathes of the population is not conducive to intellectual progress. You can argue that progress in this field will only be made by those dedicated enough and smart enough to walk this trail — but we've been running the experiment for about thirty years and the results have not been positive, which suggests that perhaps we need to cast a wider net.

What would I suggest? In order of, perhaps, controversiality
(a) theoretical physicists should learn much more probability (and not bother with the little statistics that they do learn). Mathematicians have a robust and powerful vocabulary of probabilistic ideas culminating in stochastic processes, while physicists think of probability using the ideas of vocabulary of someone like Bernoulli.

(b) perhaps we need to split into theoretical and experimental physics tracks even at the undergrad level. The theoretical track could omit, for example electronics and much of optics. Also, as an undergrad, I did not (could not) take only physics courses, so I filled in the time with, for example, chemistry, which, IMHO, was a waste of time. (Not a slight against chemists — my point is that there is a LOT of physics to learn, and I would have been better off if I'd been able to take more physics courses, if the way the curriculum was sliced and ordered allowed for that.)

(c) we have to get realistic and sensible about how we teach the math. Yes, in an ideal world every student would work through, understand, be able to perform, every proof of every theorem of every branch of mathematics that is required. But we don't live in that world. IMHO we spend too much time teaching what is easily taught (or at least easily written down, easily tested, easily claimed to be rigorous) and too little time teaching an understanding of why this stuff matters.

Similar to "Physics for poets" type courses, I'd like to see the construction (and especially the accompanying textbook) of a "Math for scientists" type course. This would be a survey course of the whole shebang — analysis up to at least Measure and Integral, algebra up to at least Lie groups+algebras, Riemannian geometry, probability up to Stochastic Processes.

But here's the catch — no rigorous proofs. This is not meant to be a trivial course. I want to see rigorous definitions, the rigorous statement of theorems, and reasonable "explanations" for why the theorems are true. But we have a lot to cover, which means the point is to show you the sweep of what's available and how it all fits together, at a rather higher level than you can get from the popular science books at your local bookstore.

This book is a reasonable very first stab at what I have in mind
http://www.amazon.com/All-Mathematics-You-Missed-Graduate/dp/0521792851
but it's too biased in the direction of what the mathematicians need rather than physicists, and it doesn't go as far as I would like in a number of directions.

(d) the physics community has got to get its act together and improve the teaching of QM and the QFT. What is being today is a freaking travesty. We don't teach mechanics using Newton's original methods, and we don't teach EM as Maxwell's mechanical models, but we teach modern physics by its history. We use a set of ideas and language that were outdated by 1940.

My particular bete noire is that we not only insist on using Hamiltonian vocabulary to teach QM, we insist on wasting a semester teaching classical mechanics so that this Hamiltonian vocabulary is vaguely familiar. This is so ass-backwards it isn't funny — we might as well be teaching fluxions and quaternions.
Then, after insisting on forcing QM into the Hamiltonian procrustrean bed, we make learning QFT far harder than it has to be by trying to fit IT into Hamiltonian vocabulary until, eventually, we give up and admit there is a better way. WTF is all this achieving apart from wasting a year and a half of precious learning time?

And this is not even to mention minor idiocies like the handling of negative frequency solutions for the Dirac equation. For crying out loud — it is 2012. And still, most textbooks begin with weeping and wailing about how these are "negative energy" solutions and how will we interpret them, followed by some nonsense about holes and filled vacuums. Then we get the same thing all over again when it's time to calculate densities and currents and now the weeping and wailing is over how we can generate negative "probability densities". We need textbooks that spend ZERO time rehashing the surprises (and obsolete vocabulary and ideas) of the past and that, on every page, tell us how things ARE and how they fit together, not how things might have could have been if we interpret them using ideas from 1920 and how the results are then so puzzling.

To give another example of — not as egregious, but still a grievous waste of time. Why is time spent "deriving" the Pauli version of the Schrodinger equation? What on earth is the value of this exercise? Why not start by saying "this is the way the world is — this is the Dirac equation" as soon as you want to introduce spin, and deriving the Pauli equation from that. Follow logic, not history.

19. **David Nataf**
May 20, 2012

Maynard Handley,

Your post reminds me of a discussion I had with friends when taking a freshman-level undergraduate physics course, several years ago. The physics textbook we had for that course would not just discuss the physical concepts, but would include numerous blurbs about the physicists responsible for those concepts, and the intellectual and sociological conditions in which they worked. As you are against "history", you would have been one of the ones against the historical anecdotes.

I however, was for them, I thought they improved understanding, and in general I think it's valid and useful, for every scientist, to know the history of why some ideas took a long time to develop even though they were just around the corner, since scientific mini-revolutions are taking place all the time in many fields of science. It's 100% relevant, imo, that Boltzmann, as brilliant as he was, could not crack quantum mechanics. It's also interesting that Einstein took 10 years to put he equations of GR together, and the failed starts he had in between.

You also confuse the mathematics you need in your own work with the mathematics scientists need. Mathematical education should be broad, as you can't predict what type of work a first-year undergraduate will encounter. Further, good luck predicting, with any accuracy, whether a first-year undergrad will be a theorist or an experimentalist. I'm sure 90% of physics majors think they're going to be theorists when they're starting out, just like 90% of first-year law students think they're going to be human rights lawyers.

With that said, there is a lot of specialization in later years. In my program, particle physics, nuclear physics, general relativity, string theory, various labs, optics, advanced statistical mechanics, astrophysics, et cetera were all available electives for senior-year undergraduates. I suspect this is standard, and consider that optimal.

20. **Maynard Handley**
May 20, 2012

David, I am not against history. Most of my pleasure reading is history.

What I am against is teaching physics as it was historically discovered. Look at the list of examples I gave in my comment for precisely my point. We don't teach chemistry by starting with caloric, explaining why that doesn't work, then going on phlogiston, explaining why that sucks, THEN arriving at oxygen.

Look, the problem I am describing — too much physics, not enough time — is REAL. All the pretense, all the complaining about how things would be in a perfect world, won't change that. We can admit the problem and deal with it, or we can have another thirty years as oh-so-fruitful for theoretical particle physics as the past thirty.

21. **David Nataf**
May 20, 2012

Maynard,

Even though I think we started off physics with the same goals, I am now an astronomer, and from what I gather you are a theoretical physicist. You say your education was missing: Point set topology, complex analysis, differential forms, the curvature of surfaces, the axiom of choice, Lebesgue integration, Fourier analysis, algorithms, and differential equations (from the Amazon link you posted), whereas I'd say mine was missing numerical methods, fluids, tensor algebra, and computer science. It's very hard to envision a modified curriculum that would have been ideally suited to both of us. Can you?

It is true that it is bad for science if people can't push the boundaries until their late 20s. However, I'll point out that many intelligent individuals are never challenged by our education system until their early to mid 20s. I do think this waste of talent is bad for science, though I don't know that it ties in to any of Peter's specific points.

22. **Peter Woit**
May 20, 2012

Maynard Handley and David Nataf,

The discussion about teaching physics is interesting, but off-topic. Soon I will be writing about something related to this, maybe best to resume it then.

In an environment where ten times more people are getting phds in particle theory than there are jobs, I don't believe the solution to the problems of the subject is to figure out how to change the educational system so one can expand the population trained in particle theory.

23. **thomas**
May 20, 2012

I think the difference between the job market in math and physics is just a numbers game. At large US universities math departments do more service teaching than physics departments, and the number of faculty is larger. Grants are smaller, and there are no research projects that consume a lot of manpower, so the number of graduate students is smaller than in physics (even in absolute terms). This makes for a much better job market. I grew up in Germany, where Math departments don't do a lot of service teaching. Math departments are smaller than Physics departments, and the job market is just as tight.

We are worried about physics at the smallest and the largest scales, but most of physics is somewhere in the middle, and doing just fine. We hear about progress in math when difficult theorems are proved, but most successful math nowadays lives at the interface with computer science, finance, statistics, and biology.

24. **Jeff McGowan**
May 21, 2012

As a mathematician I thought I should weigh in. I think there is truth on both sides, leaning towards the "math is healthier" side, but with caveats. My caveats are that there is some of the "gods of math" thing which goes on, but it is seriously tempered by the fact that even the gods have to eventually come up with a proof. Peer review can also be a serious issue, but there are enough good outlets that there are ways around it. And while it is certainly true that the job market in math is much much better than the particle physics market, it's not that it's good or anything….

25. **Shantanu**
May 21, 2012

Peter to answer my own question, I have some data at my own alma-mater, BU (which has
no string theorists BTW) Between 2000-03, most of the talks were on braneworlds, RS,ADD models, deconstruction models, little higgs models etc. Then next few years, the trend shifted towards dark matter
searches (both direct and indirect) and I think last few years most of the talks were about dark matter. In fact I was surprised by the large no of talks on DAMA
expt, even though I myself don't believe it. (OTOH around 1999, many particle physicists didn't even know/believe about the "WIMP miracle" or that solution to galactic rotation
curves has something to with EW symmetry breaking).
Maybe others can chime in about the trend in their univs. (Probably someone shoud

26. **Henry Bolden**
May 25, 2012

Peter: Is there any data to suggest that the string theorists from that hiring wave have to turned to other kinds of physics?

Higgs Update

May 21, 2012
Categories: Experimental HEP News

The announcement of new Higgs results from the LHC is now scheduled for about a month and a half from now, July 7th, 9:30 and 10am Melbourne time, at ICHEP2012. The LHC is performing well, with nearly 2.5 fb^{-1} of integrated luminosity/experiment. With only 2-3 weeks more of data collection before the cutoff for what can be analyzed in time to be made public July 7, one can expect the July announcements to be based on perhaps 4-5 fb^{-1} per experiment. Rough estimates show that, combining last year's 5 fb^{-1} at 7 TeV and this year's expected data, if the SM Higgs really is there at 125 GeV, each experiment should see a signal of 4 sigma significance. This is not quite the 5 sigma significance traditionally set for a discovery claim, but very close.

It thus looks possible that a discovery claim will require combining the results from CMS and ATLAS. The LHC Higgs Combination Group has been hard at work for the last couple years, developing methods for combining results from the two experiments. This time, they will be ready to quickly combine all the data from the two experiments, and maybe this will be what gives the 5 sigma needed for CERN to claim discovery. I don't know what the plan is for when they will be provided with the CMS/ATLAS data, or when they plan to announce a result.

The LHC-HCG is competing with Philip Gibbs, who today released a Higgs Combination Java Applet which allows anyone to produce their own data combinations. If the LHC-HCG can't produce a combination by 10:30am July 7, CERN should perhaps consider getting Philip's applet properly set up and having DG Heuer publicly press the right button, allowing CERN to claim the Higgs discovery before Philip does.

Comments

1. **Rob R.**
   May 21, 2012

   > This is not quite the 5 sigma significance traditionally set for a discovery claim, but very close.

   [re: "very close"]Forgive the noob question, but, I thought, statistically speaking, there was a big difference between 4 and 5. As a layman, I thought it was akin to the (logarithmic) Richter scale (i.e., while 5 sigma is a somewhat arbitrary cut-off it was still much larger than a 4 sigma.) Is a 4 sigma really a big deal? Dumb question? Not Even Wrong, even?

2. **Peter Woit**
   May 21, 2012

   Rob R.,

   My "very close" maybe is overly optimistic, but Not Even Wrong, since I haven't specified the metric. To give some more numbers to justify it though, the same calculation I've seen that has an expected significance of 4 sigma at 125 GeV gives an expected significance of 5 sigma at 130 GeV. Also, this is just the expected significance: if they get lucky and get a statistical fluctuation of more events than expected, say of size 1 sigma (where the sigma now is a different one…), they would get to 5 sigma.

3. **HHG**
   May 21, 2012

   There will be no official combination until each experiment will have reached 5 sigma alone – for "political" reasons.

4. **Peter Woit**
   May 21, 2012

   HHG,

   Thanks! But if CERN in early July is looking at CMS and ATLAS 4 sigma announcements, do they have a plan for dealing with the "political" problem of the Higgs discovery being announced not by them, but on viXra log?

5. **Bernhard**
   May 21, 2012

   HHG,

   that´s a bit strange statement. Two experiments getting 4 sigma, would be more than enough to claim a discovery. Not so time ago one the the spokespersons of one experiment was actually claiming that ATLAS and CMS getting a bit more than 3 sigma would allow them to claim. 5-sigma alone EACH is overkill.

6. **Peter Woit**
   May 21, 2012

   Bernhard,

   Maybe CERN would just go ahead and announce "discovery", on the grounds that it really doesn't matter how you do the combination, the conventional standard has clearly been met. Pretty odd though if the only quantitative combination result available is that from Philip.

7. **Anonyrat**
   May 21, 2012

   Since CERN has no competition, in my opinion, there is no need to hurry up the claim of discovery of the Higgs. Whether two months or six months from now, it will be the CERN collaborations that discovered the Higgs. So let them do it as carefully and properly as they can.

8. **emile**
   May 21, 2012

   I think it could be a mistake for CERN and the experiments not to combine their results. **IF** the two experiments had over 4 sigma each at ICHEP, everyone would consider the Higgs discovered, and unofficial combinations would provide the "discovery threshold" of 5 sigmas. When CERN did eventually release results of one or both experiments with more than 5 sigmas, the cat would already be out of the bag, and the level of interest will just not be there: people will say that they have not announced anything they did not already know. They (CERN) should be prepared to go public with an official combination **IF** the two experiments together meet the discovery threshold or they will lose control of the PR game. This kind of event happens very, very rarely. You have to milk this for all it's worth. You can't mess things up because of "political reasons".

9. **BJM**
   May 21, 2012

   It seems to me that announcing discovery while both experiments are at 4 sigma alone but together reach 5 sigma is ideal from the standpoint of equal sharing of credit. If the announcement awaits both experiments to reach 5 sigma, one will inevitably reach it first and claim (and perhaps be due) sole credit. Is that desirable?

10. **strong field physicist**
    May 22, 2012

    BJM,

    In my opinion not. Scientifically, its good to have two independent experiments which may eventually confirm a discovery. But there is no valid reason why official combinations would detract from experimental independence. This political rubbish, though perhaps inevitable, is not justified. I dont think any particular experiment should see this as "their" discovery. Since funding is in a vast part from the public purse, its more correct to see it as *humanity's* discovery.

    I'm all for Phil's efforts (and his applet). It plays an important part in bringing science to the people – so to speak. Its just a bit sad that we are reduced to digitising data from webpages

11. **Nex**
    May 22, 2012

    I played with the applet and it looks to me that there is only a distinctive bump in the gamma gamma channel at ATLAS and CMS, while other experiments and channels are also above expectations there they are very flat and very broad and look to me like an underestimation of the background in the 110 – 140 GeV/c2 region.

    Isn't the fact that the bump is only in one channel a reason for skepticism?

    Personally I doubt the Higgs boson is real and the data as presented by the applet doesn't look convincing at all. The most likely explanation of the data IMHO is the underestimation of background in the 110-140 range combined with 3 upward fluctuations (CMS actually sees 2 similar bumps one at 125 and one at 135) in the gamma gamma channels, two of which happened to overlap.

12. **Bernhard**
    May 22, 2012

    Nex,

    you have to remember that the Tevatron results (2.2 sigma) are also consistent with the interpretation of a signal there. I agree one should be careful and has the right to be skeptical, but things are looking more and more in the direction of a signal rather than a statistical fluctuation.

13. **David Derbes**
    May 29, 2012

    There is one sort of political reason for announcing the discovery in July (if they have the data from both ATLAS and CMS that, responsibly combined, give 5 sigma): the age of the theorists involved. There are a lot of individuals whose work contributed to this; the Sakurai Prize was split six ways. But it was done circa 1964, nearly fifty years ago. Robert Brout has died. Peter Higgs whose health, as far as I know is fine, is 82. I don't know how the Nobel committee will assign credit, but you can't win it posthumously. It would not in my opinion reflect well on anyone if Englert or Higgs or any of the other four survivors died between, say, July and late September, when the evidence will presumably be more definitive. (Disclaimer: Peter Higgs was my thesis supervisor, and I admit to wanting to see him win. Who else additionally wins is fine by me. :-))

Welcome to the Multiverse

May 21, 2012
Categories: Multiverse Mania

Multiverse Mania makes the big time this week, with a cover story Welcome to the Multiverse by Brian Greene in Newsweek. While the title indicates that the Multiverse is here and part of our scientific world-view, the subtitle is a bit cagier: "The latest developments in cosmology point toward the possibility that our universe is merely one of billions."

The article is pretty uniformly a promotional piece for multiverse mania, although buried fairly deep in the piece is something a bit more skeptical:

> because the proposal is unquestionably tentative, we must approach it with healthy skepticism and invoke its explanatory framework judiciously.
>
> Imagine that when the apple fell on Newton's head, he wasn't inspired to develop the law of gravity, but instead reasoned that some apples fall down, others fall up, and we observe the downward variety simply because the upward ones have long since departed for outer space. The example is facetious but the point serious: used indiscriminately, the multiverse can be a cop-out that diverts scientists from seeking deeper explanations. On the other hand, failure to consider the multiverse can place scientists on a Keplerian treadmill in which they furiously chase answers to unanswerable questions.
>
> Which is all just to say that the multiverse falls squarely in the domain of high-risk science. There are numerous developments that could weaken the motivation for considering it, from scientists finally calculating the correct dark-energy value, or confirming a version of inflationary cosmology that only yields a single universe, or discovering that string theory no longer supports a cornucopia of possible universes. And so on.

I don't see how we're anywhere near finding such a version of inflation or getting rid of the string theory landscape, so the only hope of getting any evidence against the multiverse seems to be to calculate the cosmological constant. The multiverse thus looks to be pretty much impregnable and immune to any conceivable scientific challenge. A few years ago, pieces like this would hold out hope that the LHC would discover something encouraging for the multiverse, but now the LHC isn't even mentioned. The only possible positive evidence suggested is seeing remnants of bubble collisions in the CMB, but the very likely eventuality of not seeing such a thing doesn't count as evidence against the multiverse idea.

So, I fear Brian is right: Welcome to the Multiverse, physics is going to be stuck with it for a very long time…

Comments

1. **Anonyrat**
   May 21, 2012

   On the other hand, failure to consider the multiverse can place scientists on a Keplerian treadmill in which they furiously chase answers to unanswerable questions.

   Kepler to Vincenzo Bianchi, 17 February 1619: 'Don't sentence me completely to the treadmill of mathematical calculations,…leave me time for philosophical speculations, my sole delight". (from "Music and Science in the Age of Galileo, by Victor Coelho).

   The book then goes on to describe Kepler's attempt to relate musical scales to the fastest and slowest speeds of planetary motions.

   So **that** is the Keplerian treadmill! I fail to see how the multiverse rescues scientists from the Keplerian treadmill. The multiverse sounds to me more like the music of the spheres…

2. **Bernhard**
   May 21, 2012

   The only purpose of the multiverse seems again to sell books and make headlines. I never went to a conference where I saw a speaker talking seriously about it. It does not explain anything and is completely shielded from experiment. Brian Greene used to promote string theory, but with no advances, no chances of telling if the theory is write or wrong, and the cherry on top: no signs of SUSY, the multiverse is what is left. The only thing I am amazed is how long are these guys going to repeat the same story again and again and still find suckers that are "fascinated" with it.

3. **Chris Austin**
   May 21, 2012

   According to Kleban and Schillo and Guth and Nomura, observation of positive spatial curvature at \Omega_k < -10^{-4} would falsify the eternally inflating multiverse.

   Moreover, if we live inside a bubble, we would not in general expect to be exactly at the centre of the bubble, so there would be a cosmically preferred direction pointing towards the centre of the bubble. Thus searches of this type can also favor or disfavor the multiverse.

4. **Spencer Tracy Jr.**
   May 21, 2012

   I wonder if in any of the other universes their scientists realize how ridiculous this whole multiverse thing is?

5. **Peter Woit**
   May 21, 2012

   Chris,

   Somehow, I suspect that if spatial curvature of that magnitude and sign is found, some version of eternal inflation can be found to deal with the problem.

   As for whether searches of the type you point to can "favor or disfavor" the multiverse, I gather they've already been done, with negative results, so the multiverse is already disfavored, no?

6. **Aspirin**
   May 21, 2012

   I think Brian Greene has reached the apogee of bad science popularization. His recent TED talk with the gratuitous use of multimedia makes him look less like a scientist and more like the pastor of a mega-church pitching the most fashionable current faith-based doctrine with slick animation and rock-star gimmicks but little to no substance.

7. **Peter Woit**
May 21, 2012

Aspirin,

To be fair to Brian, I don't know about TED, but my experience at TEDx was that "gratuitous use of multimedia" was part of the whole concept of the thing, and strongly encouraged. Personally I don't have anything against him or others using gimmicks, multimedia or otherwise, to get people's attention, but I do think it would be better to stick to topics with more solid content.

8. **srp**
May 21, 2012

There really is a difficult question about what can be explained according to a broad covering law (e.g. Kepler's phenomenological laws of planetary orbits being derived from Newtonian gravitation) and what is "accidental" (or "environmental" or "path dependent"), such as the particular spacing of planetary orbits in the solar system. Up until very recently, we had no ability to observe other star systems and detect their planets, yet scientists were still convinced that the particular size distribution and spacing of the planets in our system was an accident of history. Hence Kepler's attempt to derive these spacings using Platonic solids was perceived to be wrong-headed. (Although everyone hasn't given up: http://arxiv.org/abs/0903.1732)

I haven't seen anyone trumpeting observations of extra-solar planets as verifying this conviction–it's long been taken as an article of faith or common sense rather than a point of controversy that the particular configuration of our solar system is a unique combination of historical circumstance. It isn't clear why a similar type of judgment could not be applied to, say, the masses of the fundamental particles, similarly without needing justification by empirical observation of other universes.

Solar systems are taken to be individuals rather than what philosophers call "natural kinds." In biology, there was a significant change when Michael Ghiselin argued that species are best thought of as individuals rather than natural kinds–his argument has made considerable headway there. A minimal multiverse "theory" would simply claim that some physical constants, based on internal logical and observational grounds, don't look to be derivable from more-fundamental laws but are brute facts that "could have been different." That's not obviously crazy, although it may be massively premature.

9. **Peter Woit**
May 21, 2012

srp,

The problem with current string/multiverse "theory"(i.e. we're in some random "string vacuum", no way to figure out how we got there) is that it's not a theory at all, just an excuse. In particular, it doesn't tell you which things "could have been different" and which "couldn't have been different".

10. **srp**
May 21, 2012

Peter:

I could really use clarification on what you believe is the methodological difference between a) the string theory "excuse" for not having a unique solution to our universe and b) the conviction that you can't explain the solar system's configuration without reference to historical accidents. I suspect I am not alone in this lack of clear understanding, at least among your lay readers.

It may well be premature surrender to say that, for example, we can't derive the relative masses of the various particles from general principles just because string theory looks like it can't do it. There might well be alternatives that could do the job. But someone who doesn't care about string theory at all might still agree with the intuition that particle masses, say, are "arbitrary" parameters, and that people working on trying to derive them from higher symmetry principles are as misguided as Kepler was in trying to fit planetary distances to the Platonic solids.

Not sure if I'm missing your point or just communicating my point badly.

11. **Beelzebud**
May 21, 2012

As an outsider looking in, I'm simply astounded that something as unscientific as this, is being taken seriously. If we had even a shred of evidence to think this way, that would be one thing, but as far as I can tell we don't.

I hope the data from the LHC will return physics to a more reality-based science, because it's going to be hard to fund something like that again, if the public thinks the money is going to nonsense.

12. **lun**
May 21, 2012

srp: Dont know about Peter, but for us two accept the "anthropic" explanation for solar system dynamics two things had to happen:

a) A clear understanding of the theory of gravity. In particular, that it really has a continuum of solutions and no fundamental way of choosing between them
b) An quantitative experimental validation of the theory of gravity, both for problems independent of the planetary one and for the "phenomenology" of planets (deriving Kepler's laws and such).

Once (a) and (b) were satisfied, we could confortably accept an anthropic explanation for planetary motion, and this explanation became fully scientific.
Any chance of anything remotely comparable happening with the multiverse, both w.r.t. (a) and (b)?

13. **Peter Woit**
May 21, 2012

srp,

It's possible some of particle masses, mixing angles, coupling constants, theta-angles, gauge groups, gauge group representations are "environmental", but to have evidence for this you need (as lun points out in the analogy) a well-defined theory which comes with a testable explanation of which ones are "environmental" and which ones aren't. String theory doesn't have that, it basically is being used to "explain" that everything we don't understand can't be understood, and this "explanation" can't be tested.

To make the Keplerian analogy, it's as if Kepler was being told there was no point to investigating planetary motion at all, since whatever laws governed it were "enviromental", and different everywhere. No point in trying to relate Jupiter's behavior to Saturn's since they were operating under mysteriously different physical principles, due to the unknown different ways they came into being.

The problem with the string theory multiverse is circularity, string theory predicts the multiverse and the multiverse predicts that string theory can't predict anything you can test. What's being put together here is not a scientific theory, but a bunch of excuses for failure, carefully constructed to be untestable and immune to challenge.

14. **srp**
May 21, 2012

lun:

Thanks for your response. Here's my problem:

Could we not say the SM gives us a good understanding of all the observable interactions and so all the remaining parameters are plausibly environmental? My point is not that I believe this (I'm not qualified to have much of an opinion, for one thing), but that these things are judgment calls. In the solar system case, there are people playing around with the Bode-Titius law for example, but most people seem not to take this very seriously. Is the community giving up too quickly? Or are the enthusiasts on a wild goose chase?

Peter,

I totally get your complaint about using the concept of a string theory multiverse to "explain" the purportedly environmental nature of all the stuff that's still not derivable from more basic principles. It smacks of special pleading. But my question is more basic and would hold even if there were no string/multiverse idea to swat at:

Kepler practically killed himself teasing out his three kinematic laws from Brahe's data, but it worked. He also tried very hard to deduce mathematical principles for the spacing of the orbits, which most people now think was a wild goose chase. What was the a priori difference? If you could go back in time, could you advise Kepler, based on principles of theoretical methodology (NOT on the basis of knowing by hindsight how the science later developed), which of these two endeavors would be fruitful? And if so, is the argument you would make to Kepler also applicable to today's high-energy particle theorists?

My guess is that that kind of question cannot be systematically answered. In the end, judgment or guessing is required and there is not way to be sure about who is right. But perhaps I'm missing some canon of method that can distinguish these cases.

15. **Peter Woit**
May 21, 2012

srp,

I don't think there's any way to know in advance what will be fruitful things to look at because they have a simple, fundamental explanation, and which things will turn out to have a complicated, possibly "environmental" explanation. We have no idea what sort of explanation is needed to understand what determines particle masses. But whatever explanation one suggests, one has to come up with some way to test it, some way to show it's not just something one cooked up to make the problem go away.

16. **Bugsy**
May 22, 2012

First: I recall hearing a math lecture where the speaker gave a very convincing dynamical argument for the spacing of asteroid belts; sorry I don't have the reference, but basically if the rocks are in the wrong place resonances cause them to eventually be ejected from the solar system. So
sometimes weird numerical "coincidences" do have an explanation.

Second: If I understand part of srp's point, it is that just because there is a valid stochastic model for something (for instance evolution of the species) it doesn't mean that worlds actually exist where all the other paths were taken. On the face of it, that is ridiculous. Nevertheless, there is a stupid anthropomorphic argument that
I am here because I happen to be here. The only reason I am writing these lines is because my parents' DNA happened to have met up in just that way. Similarly,
any small change way back when and the humans might have been wiped out, leaving only Neanderthals left to attempt to have this discussion. But so what?
We are lucky to be here. That could increase our sense of marvel. But the universe could care less, and will wipe us out in the near or distant future anyway. What makes us think we are so important? Only the fact that we are we, the ants don't care either, unless we leave crumbs for them to eat.

But this evolution conversation happens within a given, fixed system (ours) and what seems ridiculous on the face of it is to postulate that: (1) changing the basic laws or constants can be treated in the same way; (2) we can then jump to saying that all sample paths actually "occur".

17. **Peter Shor**
May 22, 2012

Even an "anthropic" origin of the solar system should be able to explain some facts: why do all the planets orbit the sun in the same direction, and roughly in the same plane?

Similarly, there are some facts about the Standard Model that any good "anthropic" theory should explain: why are there several different generations of particles, that are identical except for their masses? If we had a truly random theory of physics, it seems very unlikely that the fermions would be organized into three generations the way they are. How does the multiverse theory explain that?

18. **D R Lunsford**
May 22, 2012

I really wish you would stay away from these depressing topics and stick to things that are interesting. Write something about K-theory. You should change the direction of this blog away from the war you've already won, and just ignore these idiotic articles. Even lay people I talk to now with interest in science have realized that all this nonsense is passe'.

-drl

19. **Chris Oakley**
May 22, 2012

I have to concur with DRL – in the sinking Titanic of theoretical physics, the Multiversers are the third-class passengers.

<aside>I notice that your book has appeared in Czech but not, for example, German or Spanish. Indirectly, you probably have Lubos to thank for that. I hope that you are sharing some of the royalties.</aside>

20. **ScentOfViolets**
May 22, 2012

There's what, 19 parameters in the Standard Model? What's wrong with that number, and why would 5 be better than 19 and 1 better than 5? In the absence of any other compelling motivation, this seems to come down to some sort of numerological argument. Is this really the present case, or am I being unfair?

Same thing with the actual values of those parameters – given that they exist, why are people so uncomfortable with those particular values? After all, they have to be some particular number; indeed, given the range of numbers available, one could just as well express bemusement at how close they are to each other – within a factor of 10^50!

Finally, is there some sort of test or principle that would tell you where the regression stops? E8 has been a contender for the algebraic structure that ties everything together. Assume for the sake of argument that this is true and a complete theory of everything emerges which gives predictions in accord with reality down to the limits of testability. Wouldn't you then have to ask why E8 and not, say F4 or G2? Or would you be able to supply compelling reasons for why these sorts of questions need not be pursued any further?

21. **vmarko**
May 22, 2012

why do all the planets orbit the sun in the same direction, and roughly in the same plane?

Ignoring all the complexities of the models dealing with solar system formation, this can basically be explained via the angular momentum conservation. Think like this: the whole solar system started out as a big lump of gas, which gradually collapsed under its own weight to become coarser and eventually create the Sun and the planets. The initial lump had some nonzero total angular momentum, and since it is a conserved quantity, the solar system as we know it today still has it. This angular momentum determines both the plane and the direction of the rotation of planets.

In fact, it would be very weird if one of the planets were rotating in the opposite direction or in a different plane. I'm not even sure that this could be a stable configuration in the long term, given the attractive gravitational force among the planets themselves.

HTH, 🙂

22. **vmarko**
May 22, 2012

There's what, 19 parameters in the Standard Model? What's wrong with that number, and why would 5 be better than 19 and 1 better than 5? In the absence of any other compelling motivation, this seems to come down to some sort of numerological argument. Is this really the present case, or am I being unfair?

Having 19 or so parameters is considered too complicated. By your argument, one could have stopped at the periodic table of elements and be content that there are cca 110 (or so) "elementary atoms", without ever asking if they have any structure or not. Today, we have cca 100 "elementary particles" which can be arranged into a similar "periodic table", so it stands to reason to ask about some deeper explanation for that as well.

The number of experimental parameters in a given physical theory is just a measure of our theoretical ignorance about the physics in question. The less experimental parameters, the better the theory, and thus the greater the understanding.

The multiverse idea is a premise that denies us the ability to ask this sort of question. And furthermore, that premise is even untestable. By some definitions, such a framework can be called a religion, rather than science.

23. **Thomas Larsson**
May 22, 2012

The anthropic explanation of the Michelson-Morley experiment: a non-zero ether wind is incompatible with human life.

24. **ScentOfViolets**
May 22, 2012

Having 19 or so parameters is considered too complicated. By your argument, one could have stopped at the periodic table of elements and be content that there are cca 110 (or so) "elementary atoms", without ever asking if they have any structure or not.

By my argument? Well, no, I'm perfectly happy with having 19 parameters if that's what it takes to have the explanatory power of the Standard Model. Less than 19 doesn't give enough freedom to satisfactorily explain observable phenomena and more than 19 is unnecessary.

Contrariwise, the motivation for finding a deeper structure to atoms wasn't because there were "too many" of them; it was because the theory of indivisible atoms did not accord with observable reality (iirc, J. J. Thomson's discovery of the electron.)

By all means, speculate on why there are three spacial dimensions instead of four or four hundred, or why we live in a world based on the L2-norm instead of the L1-norm. But istm that if your only reason for doing so is that three and two are unsatisfactory numbers then your motivation seems to be more numerology than science.

25. **Peter Woit**
May 22, 2012

ScentofViolets,

Actually, 19 is just the number if all neutrinos were massless, so you need a few more for neutrino masses and mixing angles.

One can happily decide to just accept the SM as is, and have no interest in attempts to improve it. But, it's a structure that sure looks like something we don't completely understand, so (some) people are motivated to try and do better. Such a better understanding may lead to the possibility of computing some of these parameters, or just to knowing why one can't.

26. **ScentOfViolets**
May 22, 2012

The multiverse idea is a premise that denies us the ability to ask this sort of question. And furthermore, that premise is even untestable. By some definitions, such a framework can be called a religion, rather than science.

In that case, why stop at the multiverse? Why not extend the scope to include a class of universes whose basic structure is an infinite-dimensional Hilbert space, for example? One could even populate it with hypothetical beings who use anthropic arguments to reason that *of course* since life needs an infinite number of dimensions to exist, that must be why the universe is observed to have an infinite number of dimensions.

Iow, the Landscape idea seems to be little more Tegmark's notion that all mathematical structures are realized "somewhere" and throwing in a few restrictions to make it less ridiculous as a scientific theory.

27. **uair01**
May 22, 2012

Funny to mention Brian Greene. As a layperson I read his "The Fabric of the Cosmos" and I still remember vividly how my feelings about the book changed at the break between part 3 and 4:
Part 1: Reality's Arena
Part 2: Time and Experience
Part 3: Spacetime and Cosmology
========= break =======
Part 4: Origins and Unification
Part 5: Reality and Imagination
Before the break it was an inspiring description of exciting (thought and real) experiments and weird surprising outcomes. It taught me a lot about modern physics.
After the break the whole atmosphere changed and somehow I found the whole thing depressing.
Much later I realized that it was the lack of "feet on the ground" in parts 4 and 5 that made this part of the book so unappealing.

28. **ScentOfViolets**
May 22, 2012

Actually, 19 is just the number if all neutrinos were massless, so you need a few more for neutrino masses and mixing angles.

One can happily decide to just accept the SM as is, and have no interest in attempts to improve it.

But isn't this just how science proceeds? Up to the point where neutrinos were found to have mass, 19 was enough. It is the updating of the facts that changes the number from 19 to whatever, not that 19 is an unsatisfactory number, therefore there must be something like a nonzero mass for the neutrino. imho.

But now I'm repeating myself.

29. **harryb**
May 22, 2012

I share Peter's worry about the strength of the Multiverse attractiveness. Feynman noted in the The Character of Physical Laws "you cannot prove a vague theory wrong". He preferred imagination "in a terrible strait-jacket" to derive new laws.
But in the final section of the book he goes very bleak: "some of my colleagues say that this fundamental aspect of our science will go on: but I think there will certainly not be perpetual novelty for a thousand years. This thing cannot keep going on so that we are always going to discover more and more new laws."
Ultimately he foresaw " the philosophers who are always on the outside making stupid remarks will be able to close in"
If we run out of testable new laws the stupid remarks may win.
Very precise carbon energy levels may suggest billions of other universes, or sheer luck in the only one that exists that creates self-aware neurons.
But I think Peter's blog continues to raise a key point – fundamental physics has entered a strange phase of dual impenetrability – String Theory's increasing esoteric nonsense, and the Multiverse's low science but 1960s-sci-fi appeal.
The latter will be ascendant for a while. Feynman's outlook doesn't give too much optimism it will be usurped soon. New testable laws required.

30. **Tammie Lurleen Sandoval**
May 22, 2012

This is not a joke. It is a disaster.

And its NOT about discrediting science.with the public. Horrid as that is.
Its about science destroying itself.

With nothing to show for 40 years, the big names like Greene have just left physics behind. So when the top guys spout fantasy, and the mainstream press promotes it, how do you stop this train wreck. Who has the prestige to stop them before they ruin the whole scientific endeavor?

31. **Anonyrat**
May 22, 2012

No, not nothing to show for 40 years – I disagree – we have a whole set of approaches that had to be tried in order to be ruled out, there was no a priori way of knowing that these ideas would not work (I'm assuming of course that the current trend of these ideas not working continues.) It is on the shoulders of the unsung giants who cleared away all the unworkable underbrush that the future Newton might stand.

32. **Tammie Lurleen Sandoval**
May 22, 2012

Please accept my applogy.
I didn't mean to imply that physicists have not been working or learning for 40 years.

But it is my understanding that that the results of their work is negative. In other words they have shown what wont work rather than what does. If I'm wrong on this I'd be grateful to be told.

I have the highest respect for science. CP Snow said that science must be ruthless in surpressing those who state a aflsehood, even innocently. Otherwise the public has no rational basis to trust what it cant understand. This multiverse fantasy stikes me as far worse than what Snow feared. And it appears there is no will, either among individuals or institutions, to condemn those who advance it.
If so, this wont have a happy ending

33. **David Nataf**
May 22, 2012

srp,

The specific masses of the planets in the solar can't be predicted from theory, but you can predict probability distributions for these planets, derive them from reasonable rigorous theories (eventually), and compare these to planetary distributions in other star systems, and even to unbound planets in free space.

For example, note that the Jupiter mass is a characteristic mass for masses of the largest planets around stars with planets… the largest planet is typically 0.5-2.0 jupiter masses. Thus, while the exact value can't be derived from any specific model, good models of the probability distribution can be derived from gas and accretion physics, and are testable with real-world observations.

34. **CPV**
May 22, 2012

The less inherent quality a product has, the more important the advertising campaign. I think theoretical physics tolerates the Brian Greene's of the world to help perpetuate funding in times when the cupboard is plainly bare.

35. **Mitchell Porter**
May 23, 2012

Tammie, the standard model – the 40-year-old theory which explains almost everything we know about – has a lot of properties which in turn demand to be explained. Physicists have accumulated numerous ideas about how to explain them – e.g. grand unification to explain the patterns of fermions, and weak-scale supersymmetry to explain the "hierarchy problem". Model-building in physics draws on these ideas but isn't defined by them. It's the difference between saying "Let's have a simple symmetry group that incorporates all the separate symmetries" and "Let's use SO(10) symmetry with the following superfields in the specified representations". The true advance beyond the standard model will come when someone hits upon exactly the right combination – or when the LHC or some other experiment forces decisive new data upon us. Until then it's trial and error, and we *are* learning, both by the accumulation of ideas and by the accumulation of models that are still consistent with the data, as well as by the falsification of those models which do become incompatible with experiment. Anthropic multiverse reasoning is a *very* small part of what goes on. Try the PDF at http://arxiv.org/abs/hep-ph/0207124 for a glimpse of what has actually been happening. It's a technical account, but hopefully you will at least see that it still looks like science.

36. **vmarko**
May 23, 2012

I'm perfectly happy with having 19 parameters if that's what it takes to have the explanatory power of the Standard Model. Less than 19 doesn't give enough freedom to satisfactorily explain observable phenomena and more than 19 is unnecessary.

How can you be sure that 19 is the minimal number of parameters that one needs in order to build the Standard Model? Maybe the same SM can be worked out as an effective model of some other theory containing only 2 or 3 parameters. In that case, 19 would be totally unnecessary. And in addition, this theory would provide us with deeper understanding of the mathematical structure of particles and interactions we observe in experiments. If all coupling constants and particle masses could be calculated out of some first principles and a couple of experimental parameters, it would be a massive gain in terms of "describe more by using less".

That is the idea behind the program of unification of interactions. Of course, you are welcome to be content with the SM as it is today and its 19 parameters, and free to not look for a more profound theory. But claiming that people who do look for it are numerologists is a bit too much. Seeking out a more powerful model with less parameters is IMO a perfectly valid scientific question.

The fact that so far we have no experiments to force us into looking for a stronger theory is no excuse to claim that there isn't one. Maybe the experimental data is just inaccessible for our current technological level. Imagine that Thompson did not find the electron (for example, if all subatomic particles were in principle harder to find experimentally). Would you be content with the periodic table of atoms as basic structures in Nature, given no experimental evidence to the contrary? The very fact that the periodic table is actually *periodic* is a hint that there is some simpler underlying structure. People who are (and were) looking for this strucure are certainly not numerologists.

Patterns do not emerge randomly. If your experimental data shows a pattern, it is quite reasonable and scientific to look for a rule that explains the pattern.

HTH, 🙂

37. **Trevor Turton**
May 23, 2012

I love Chris Oakley's view, "in the sinking Titanic of theoretical physics, the Multiversers are the third-class passengers." Very timely.
vmarko says: "The multiverse idea is a premise that denies us the ability to ask this sort of question. And furthermore, that premise is even untestable. By some definitions, such a framework can be called a religion, rather than science." Hebrews 11:1 says: "Now faith is being sure of what we hope for and certain of what we do not see." (NIV) Multiverse theory falls pretty neatly into that categorisation.

38. **Igor Khavkine**
May 23, 2012

vmarko wrote: *The fact that so far we have no experiments to force us into looking for a stronger theory is no excuse to claim that there isn't one. Maybe the experimental data is just inaccessible for our current technological level.*

Lets take this argument to its logical conclusion. Just like any pattern that we see in the Standard Model requires an explanation by a deeper theory, it is "obvious" that any event requires the will of an intelligent agent (or agents) as a cause. The Big Bang is an event, so lets call the agents that caused it, say, Magical Pixies. Of course, having no experimental evidence that forces us to posit the existence of these Pixies is no excuse for not doing so. After all, their existence explains so much and the needed evidence could be just around the corner, say when the LHC pumps up its energy!

Both these arguments rest on a faulty premise. In one case that is more obvious than in the other.

Would you be content with the periodic table of atoms as basic structures in Nature, given no experimental evidence to the contrary?

Contentment can be learned, while the universe is the way it is whether wer are content or not. It's also worth remembering that identifying and documenting patterns in physical phenomena is useful in itself. This activity is not required to be a stepping stone to any more fundamental theory. Consider for instance the number of ways the periodic table has been rearranged. Each rearrangement, arguably useful for whatever is the intended practical purpose, is attempted despite that fact that we *already know* the underlying fundamental theory of electron shells.

39. **Peter Woit**
May 23, 2012

Mitchell Porter,

The Witten article that you quote does an excellent job of explaining the case for SUSY/GUTs/strings. However, note that it is ten years old, and mostly about ideas that were nearly 20 years old when it was written, which haven't received experimental confirmation. Quite the opposite actually, there's:

"Supersymmetric particles should be in reach of the LHC – and maybe of Fermilab – since the supersymmetric approach to the hierarchy problem does not make sense if they are too heavy."

The SUSY/GUTs/strings paradigm has so far been a failure, and it is this failure that has led to multiverse mania on the cover of Newsweek. Trying to claim this situation is not a problem for the field is not a good idea it seems to me…

40. **Giotis**
May 23, 2012

Well judging by the title of his public lecture in Strings 2012 apparently Witten still believes in the Universe.

http://wwwth.mpp.mpg.de/members/strings/strings2012/strings_files/public/public.html

My feeling though is that again he will wash his hands like another Pontius Pilate.

But anyway let's wait to hear what the big man has to say about this Multiverse controversy…

41. **Peter Woit**
May 23, 2012

Thanks Giotis,

Very interesting, of course I'm curious what he'll have to say. Funny that the title, which a few years ago would have seemed unremarkable, now sounds kind of polemical…

42. **Allan Rosenberg**
May 23, 2012

Beelzebud,

I agree that the hype is pointless outside selling books, and, were I a physicist, the multiverse would be right at the bottom of my list of research topics. But do you really think that the multiverse is unscientific? There's nothing inherently unscientific about raising a hypothesis. It only goes beyond science when someone makes claims about the truth or falsity of the hypothesis in the absence of evidence, and I don't think Greene has done that here.

More to the point is what difference does it make whether there is a multiverse? String theory's central problem is finding at least one string vacuum that reproduces relativity and the standard model in the low energy limit, not explaining why it can't find one. Would knowing that there is a multiverse bring us any closer to finding a useful string theoretic model?

43. **Curious Wavefunction**
May 23, 2012

I wonder if Greene has milked the last drop out of his writings. I wonder about what he could possibly write again that would have the same PR potential as his existing books. I have a post on my blog lamenting the sad state of the popular physics literature partly brought about by writers like Greene.

44. **srp**
May 23, 2012

David Nataf:

Thanks for the update on solar system modeling and theory. It makes sense that not just anything can happen when a star system forms, or at least that certain things are not very probable.

But note that the sole empirical test of these theories comes from extrasolar planetary observations. My point was that long before these observations were available, many hypothetical "laws" of the solar system were considered to be mere accidental patterns found in contingent events. The non-lawful nature of the solar planets themselves, with their weird, wonderful, and largely unpredicted features lends extra force to the notion that much of what we observe came from historical "accidents."

But maybe we are giving up too soon, and it will turn out that there is a class of star systems with inner, rocky planets, a couple of gas giants around Jupiter scale, and then some smaller gas giants, some of which have peculiar inclinations of their rotational axes relative to the ecliptic. We will learn this from empirical data if it is true, though, not from first principles of mathematical symmetry.

45. **Shantanu**
May 23, 2012

Peter, I agree with Danny and Chris. No one is paying attention to multiverse.
Maybe you could talk about conformal universe conference at PI
http://www.pirsa.org/C12027

which had talks by thooft

46. **Peter Woit**
May 23, 2012

Shantanu,

Glad to hear that no one is paying attention. The conformal universe conference talks look interesting. A good reason for me not to talk about them though is that I know hardly anything about that subject…

47. **Tim van Beek**
May 24, 2012

> Well judging by the title of his public lecture in Strings 2012 apparently Witten still believes in the Universe.

…

Thanks for the heads-up, I almost missed the fact that Strings 2012 takes place in Munich, Germany (it is not widely advertised, for reasons unkown, at least not in Munich itself 🙂 Although I'm sure that Peter intends to cover it, right?

I will see to it that I make it to that public lecture.

48. **Kyrilluk**
May 24, 2012

*Which is all just to say that the multiverse falls squarely in the domain of **high-risk science.***
High-risk science: is it the politicaly correct way of saying "pseudo-science"?

49. **Tammie Sandoval**
May 24, 2012

I thank Dr Porter and Dr Woit for their responses.

Regarding Dr Porter's recommendation , I agree that I should read that article by Dr Witten. At best however, it would be a huge amount of work to understand it. For that reason I'm secretly hoping that string theory falls, letting me off the hook.

I especially thank Dr Jogalekar for reminding me that most of physics is a quiet and serious endeavor. Its a fact that people care most about advancing their religion (or their lack of it). So things like string theory and the multiverse will always, and justifiably, grab the most attention. By contrast, chaos, turbulence, superconductors, and adaptive systems don't say much about our existence, but as sciences they are truly beautifu, and are making great progress.

Finally, I find the phrase "high-risk science" to be disgustingly false. Dr Green would do well to disown it. Whatever one can say about string theory, tenured professors working away in their specialty is not "high risk". What would be high risk would be trying something new. Take the military. It needs diligent people of many talents. But it is ridiculous when a procurement officer poses as a war hero.

Please note, this has nothing to do with the merits of Dr Greene's string theory, and whether he is right in persuing his specialty instead of abandoning it. But he should spare us the silliness.

50. **Bob Levine**
May 24, 2012

Multiverse 'studies' may indeed have hit the big time, as Peter suggests, in popular culture terms. But the thing to watch for is just how much of an impact they (will) have in academic physics, and I think the right metric here is not how many news releases or conference presentations by Susskind, Greene et al. we see over the next few years, but how many doctoral dissertations are written and defended, in major departments, which take the multiverse as the central topic, or even a crucial component. Speculation is free, but if I were betting I'd put (a LOT of) my money on that number being on the rather low side…

51. **ComeOn**
May 24, 2012

Completely agree with Bob Levine above. In academia you can go years without hearing anyone mention the word "multiverse". But in pop science, and blog science, it's infinitely more prominent.

52. **jg**
May 24, 2012

The Witten Lecture 'String Theory and the Universe' due at String 2012 has been given by him various times in the previous couple of years, you can watch one version online at IOP site:

http://www.iop.org/resources/videos/lectures/page_44292.html

53. **Giotis**
May 26, 2012

Yeah I've watched this lecture before; I wasn't quite remembering the title though. But even if his 2012 public lecture is exactly the same to this one there would be a crucial difference; audience's questions. Even if Witten does not want to elaborate or take sides the multiverse controversy would be certainly brought up by the audience and we may witness some interesting answers.

Although as I said I'm not very optimistic about it. My impression so far is that Witten is more or less agnostic about the subject. Like in this lecture he is very cautious and often says that we need more clues and more work needs to be done in order to decide whether the multiverse picture is really a prediction of the theory.

Nobody could disagree with that of course taking into account that M-theory is poorly understood. Yet again at this point it's hard to imagine how the multiverse paradigm shift could be evaded within the context of String theory. But you never know…

54. **Truth**
May 26, 2012

As Brian Greene points out, the multiverse idea appears in numerous directions of research. The properties of GR, quantum mechanics, inflation, string theory, dark energy, etc, all point in the same direction and provide independent circumstantial pieces of evidence for it. Right now it is our best idea about the world, given the information available to us. It is conceivable that it is wrong, but at the moment, it is more likely to be right than wrong.
Anyone who shows hostility to it are really just people who lack some level of imagination and want to just cling on to old archaic ideas.

55. **David Nataf**
May 26, 2012

Truth,

How do the properties of general relativity suggest the multiverse?

56. **Peter Woit**
May 26, 2012

David,

Presumably “Truth” is referring to eternal inflation models, which in his or her mind are now part of GR.

Truth,

If you’re representing Brian’s argument as it’s “more likely to be right than wrong”, I think you’re seriously misrepresenting what he has to say, which includes

“That there are ways, long shots to be sure, to test the multiverse proposal reflects its origin in careful mathematical analysis. Nevertheless, because the proposal is unquestionably tentative, we must approach it with healthy skepticism and invoke its explanatory framework judiciously….

But as with all rational bets, high risk comes with the potential for high reward…

The multiverse proposal might be wrong. But it might also be the next step in this journey, unveiling a breathtaking panorama of universes populating a vast cosmic landscape. For some scientists, including me, that possibility makes the risk well worth taking.”

Saying an idea is “high risk” means it’s more likely to be wrong, not more likely to be right. Also unlike you, I suspect that Brian’s point of view on the majority of the physics community is not that they

“are really just people who lack some level of imagination and want to just cling on to old archaic ideas.”

but that they have perfectly good reasons for being skeptical of a very speculative idea there is little evidence for, no matter how many articles about it appear in the popular press.

57. **Truth**
May 26, 2012

Peter, my first comment was my summary of Brian’s view. But from “Right now it is…” it was my own opinions.

As to your final comment that there are “perfectly good reasons” for thinking that there is only a single universe, I have never heard it. Given that the laws of physics were evidently sufficient to create at least one universe, I dare say it could create multiple, if not infinitely many. I suspect it is much harder to show that there is only one universe than many, especially when, GR, quantum mechanics, inflation, etc, are pointing in the other way.

58. **Truth**
May 26, 2012

Actually, I would add that in fact you are seriously misrepresenting Brian’s view. He does not say that the multiverse idea is likely wrong, he says that there are a few possible ways to test it directly (such as bubble collisions in the CMB) and it is unlikely that we will see that direct evidence. So, according to Brian, it is high-risk to pursue a proposal for direct detection, which may not materialize. But he is certainly not saying that the multiverse idea itself is unlikely to be true, it just may be difficult to test.

59. **Peter Woit**
May 26, 2012

Truth,

I didn’t say there are good reasons for believing there is only one universe. I said there are good reasons for being skeptical of the scientific multiverse proposal Brian is describing (and I suspect he might agree). The “high risk” in such proposals, which I think is what he is referring to, is that they may be inherently untestable in any way, and thus not science. A large majority of physicists see discussing the multiverse as an empty activity that is not science, since it is not testable, and claims to believe in either one or multiple universes are pseudoscience absent a plausible way to deal with the testability problem.

60. **Pravda**
May 26, 2012

“Truth” is, himself, proof of the existence of alternate universes, as he is obviously posting from one.

61. **Truth**
May 27, 2012

Certainly there are ways to test it, such as CMB data. So that kills your idea right there.

Secondly, even without direct evidence of that sort, the multiverse is an extrapolation of other well tested theories. Extrapolation is not only part of science, it is THE WHOLE POINT of it, as stated very eloquently by Feynman.

Anyone who goes around saying it is not science is being silly, and not engaging in the real issues at all.

62. **Bernhard**
May 27, 2012

Truth,

the multiverse is a speculation, not a theory. Speculations are a part of the scientific processes but not sufficient to be consider science. A scientific theory is something more rigorous and ultimately it needs to meet the criteria of testability and it must be falsifiable. Of couse one has the right to speculate about multiverses, say time is multidimensional and pretty much whatever you want, but without a theory and solid quantitatively predictions this stays in the realm of speculations. Some may find fascinating but others will find it boring, but anyway there is ever reason to be completely skeptical about it. Could be, could not be, without solid predictions, there is little to discuss.

The point you raise is that on the contrary, bubble collisions in the CMB are a real prediction of it and therefore it can be tested. This is certainly a scientific point you are raising. More specifically I believe you are talking about things like this paper: http://arxiv.org/abs/1012.1995

If you are read this paper carefully you will see there are many caveats and in particular their argument rests on azimuthally symmetric temperature modulations, which as the authors observe “are not unique to bubble collisions”. The paper is at best inconclusive. So, it might be that the multiverse picture will evolve into a robust scientific theory, but until then selling the idea as scientific consensus and making noise in popular articles confusing the non-scientists is not the best idea to do this, regardless if one thinks one or 20 universes are “more likely”.

63. **Truth**
May 27, 2012

Just because the CMB thing is inconclusive right now, certainly does not make it unscientific. There are numerous inconclusive things in the world. I dunno…GUTs, Higgs, what killed the dinosaurs, the origin of life, you name it…it is absolute garbage to suggest that work on these topics is unscientific because these issues remain inconclusive. The WHOLE POINT of science is to work on inconclusive things. That's what scientific RESEARCH is. We don't know the answers today, for instance, if there is a multiverse, if a meteor killed the dinosaurs, how the pyramids were built, etc, but we can work as hard as we possibly can to try and find out. Maybe we'll know in 1, 10, 100 years from now. That's science.

Sometimes the evidence fir things can be fairly direct and sometimes it is rather indirect, for instance, if it comes from extrapolating the predictions of a well tested theory. As I said before, that is the current situation for the multiverse proposal. It comes from extrapolating the predictions of GR, quantum mechanics, inflation, etc. extrapolation is what science is all about. To call it unscientific is simply wrong.

64. **Peter Woit**
May 27, 2012

Truth,

We've seen this misuse of the term "test" endlessly with string theory. In the conventional meaning of the term, a "test" is something you can fail, with negative consequences for your theory. Even the most enthusiastic multiverse supporters don't think there's much of a chance that new CMB data will actually vindicate multiverse theory. When Planck data comes in, sometime within the next year, I predict it's not going to contain evidence of bubble collisions, but no multiverse proponent is going to give up on the idea because of that.

You seem to misunderstand what the word "extrapolation" means, in Feynman's usage. He was referring to applying a tested theory to new domains, not a new theory. A multiverse with different laws of physics is not an extrapolation of any tested law of physics.

65. **Truth**
May 27, 2012

And of course, the multiverse did make a prediction. It predicted a small, but non-zero cosmological constant of the same order of magnitude that was later observed. Ok. So stop saying it does not make predictions. It did. It was observed. It is our only understanding of it. You may not accept this evidence as enough. Fine. Some people do. Some people don't. That is science. Get it?

66. **Truth**
May 27, 2012

100% wrong Peter. The multiverse is an extrapolation of inflation, which combines quantum mechanics with general relativity and some scalar field source. It is a tested theory.

67. **Peter Woit**
May 27, 2012

Truth,

The theory of inflation you are talking about involves a choice of potential for a single scalar field. If you extrapolate it way beyond what there is experimental evidence relevant to, you can get bubble universes, all with exactly the same physics as ours. That there's an infinity of bubble universes out there with exactly our physics is possible, but probably untestable, as well as not being very interesting since it explains nothing about our own. If you want to claim that the CC and other parameters are different in every different universe, and then use anthropics to "predict" the CC or anything else, (yes, lots of people think anthropic "predictions" don't deserve to be called "predictions", for good reason…) you need to invoke a new theory, like string theory, not extrapolate a conventional, tested one.

68. **Henry Bolden**
May 27, 2012

Multiverse theory predicts the existence of a universe where multiverse theory has been proven to be incorrect. Greene's paradox?

69. **MultipleMulti**
May 27, 2012

Re Witten, does anybody know why he's working on Khovanov homology now? What do knots have to do with String theory? Do the strings form knots? Do the Feynman histories form knots?

70. **Truth**
May 27, 2012

Well it seems we have made some progress Peter. At least you have agreed that by extrapolating inflation we get a multitude of universes. Ok, so that much is settled. It is an extrapolation and it is part of science.

Here your complaint is that the laws of physics are still the same though. Well, indeed there are different levels of the multiverse. Inflation forces on us a level, where there are many universes, although the laws can be the same. The universes do differ, however, in their distribution of matter. Eternal inflation generates every consistent distribution of matter. For instance, nc,uding universes with different values of the amplitude of density fluctuations.

As to having different laws of physics, for instance with different values of the CC, we indeed need a potential with multiple minima, which is a much more severe extrapolation. But it is an extrapolation, nevertheless.

71. **Peter Woit**
May 27, 2012

Truth,

You seem to know enough to know very well that the 10^500 different minima necessary to make the anthropic CC argument work don't come from any tested theory, even one as little tested as inflation. The KKLT mechanism and any of its variants invoke a huge array of speculative ideas from string theory, none of which have any experimental evidence for them. KKLT is an extrapolation of our current theory only in the same sense that any complicated, untestable, speculative idea for a theory of everything is an "extrapolation". I suspect Feynman is rolling over in his grave to have his name invoked in this way, it's pretty clear what he would think of your claims.

72. **Truth**
May 27, 2012

Again, I am glad that you admitted in your previous comment that inflation implies a multiverse from extrapolation.

In my most recent comment, I simply said that multiple minima are needed for different laws of physics. I didn't say anything about KKLT, etc. It is a straw man argument for you to criticize KKLT as a way of attacking my quite reasonable, and largely separate, comment.

73. **vmarko**
May 28, 2012

I am glad that you admitted in your previous comment that inflation implies a multiverse from extrapolation.

Khm, inflation does not *imply* a multiverse, at best it only *suggests* a multiverse. Namely, one can have inflation without multiverses. In loop quantum cosmology, for example, one doesn't even need an inflaton field to produce inflation. And one stays in a single universe after the inflationary period. You can take a look at gr-qc/0206054 for some details.

HTH, 🙂

74. **Marty**
May 28, 2012

"Truth",

You apparently believe that inflation is correct in its current form, a form which *does* appear to imply "many universes." This form may or may not ultimately be correct, but it is certainly not a "slam dunk" case. Here are a few links to talks and papers that you might find enlightening; they may help temper your confidence a bit:

Paper by Roger Penrose (1989; behind a paywall, unfortunately)
Penrose talks at Princeton, three total (inflation is #3; look at October 2003)
Steinhardt talk at Perimeter Institute, 2011
Turok talk at PI, 2011
The Inflation Debate (Sci. Am. article on Steinhardt's Princeton site; free)

There is very strong observational evidence for inflation, but as you will learn if you read and watch the talks the evidence is for the much simpler picture that emerged in the early 1980s. Since then, some severe *theoretical* difficulties with the inflation idea (not observational problems) have become apparent, and it isn't obvious how to fix them in spite of lots of effort. These problems have nothing to do with string theory, by the way — they are problems with inflation models themselves.

There is essentially zero observational evidence for eternal inflation, however. It is only implied by the inflation idea if general relativity plus quantum mechanics is the right framework to use prior to the Big Bang. If you study the theoretical problems, you may agree that it doesn't really make sense to use general relativity in a regime where it presumably breaks down, i.e., at and beyond the Planck scale.

Regarding observational tests of bubble collisions, it is extremely optimistic to think they will ever be successful. If bubble universes are real (questionable!), almost all such collisions that would be visible today would need to have happened at very early times, and their effects would generally be restricted to an extremely small angle in the sky, far too small to be discernible, much less provide useful observational evidence (the "look elsewhere effect" …). The only real hope is that relatively recent collisions occurred and left visible traces, but those are highly unlikely.

75. **Peter Woit**
May 28, 2012

vmarko and Marty,

The situation of experimental evidence for inflation is complicated, and multiverse maniacs typically start from some outrageous claim about how well established the theory is. It's very rarely pointed out though that even if you accept the most optimistic versions of the inflation story, that actually has nothing to do with the "extrapolation" that "Truth" and others are advertising. Even eternal inflation doesn't give you "different laws of physics" in different universes, it just gives you lots of universes with the same laws of physics. To get "different laws of physics: you need to introduce something like the hundreds of moduli fields of string compactification schemes, the exact hideous mess that has turned string theory unification into a failure.

76. **Truth**
May 28, 2012

Vmsrko and Marty,

Most of what Peter says here is wrong. As I mentioned before, eternal inflation gives you different universes with different properties, e.g., different amplitude of density fluctuations, different spectral index, curvature, etc. These universes would look quite different. It is a type of multiverse.

To get different microscopic physics, you do not need 100s of stringy moduli fields as Peter is advocating. A potential with just 2 local minima would suffice to have 2 different kinds of laws; that is enough for one to talk of a multiverse. And it does not rely on the validity of string theory at all, only quantum mechanics and GR. The only place where string theory enters the discussion is that it re-affirms this view with many, many fields and minima.

77. **Peter Woit**
May 28, 2012

Truth,

You know very well that cooking up an inflaton potential in standard inflation theory to have extra minima is not what is being advertised. This gives no anthropic explanation of the CC for instance, which is the main "evidence" given for this scenario..

78. **Truth**
May 28, 2012

Peter, I have addressed all these issues clearly and correctly in my previous posts. Inflation is well tested and when extrapolated it predicts a basic type of multiverse which look different. A potential with 2 minima gives different microscopic laws and is a more crude extrapolation. While many, many minima of the string theory type is a much more severe extrapolation, which is less likely to be true, but comes from extrapolating wuantum mechanics and GR to the extreme, as it is the only known consistent picture. But even if you hate the latter, a more basic type of multiverse does come from extrapolation. That is the point I am making. If others wish to focus on other issues, that is their business.

79. **Peter Woit**
May 28, 2012

Truth,

You just keep repeatedly abusing the term "extrapolation" (5 times in your latest comment). Repeated explanation from my why this is abuse of the English language and the memory of Richard Feynman would be pointless.

80. **Bernhard**
May 28, 2012

Truth,

can you point out one (or more) reference (s) that corroborates your claims? I think your use of the word "extrapolation" is not entirely clear, at least to me.

81. **ScentOfViolets**
May 28, 2012

I suspect it is much harder to show that there is only one universe than many, especially when, GR, quantum mechanics, inflation, etc, are pointing in the other way.

Looking at these last exchanges, it appears that "truth" is substituting some , er, nonstandard definitions of common terms for the usual ones and not telling anyone. The particular term I'm drawing attention to here is "skeptic" or "skeptical", which "Truth" seems to think is a synonym for "disagree". It's not.

For example, I'm skeptical of any sort of theorization which relies on the existence of a multiverse to make it work, but that doesn't mean that I disagree with the notion that there are multiple universes instead of just the one. It merely means that I'm agnostic wrt the number of universes.

Science being what it is, being a skeptic means that I don't have anything to prove; the burden of proof in this particular instance is on "Truth". And so far, he's not being very convincing. Name-calling is seldom an effective way to get people to agree with you 😉

82. **Truth**
May 28, 2012

Peter, above you admitted that when inflation is extrapolated you get many universes. These universes have qualitatively different properties, such as the curvature or amplitude of density fluctuatuions. So even you have conceded that the extrapolation of inflation leads to a multiverse. Here even you have used the term "extrapolated" in the same way as me, and indeed in the same way as Feynman. It is ridiculous for you to then mangle the issue by sneering at KKLT, or other such things, as though that were the basis of my argument which I have clarified repeatedly and consistently.

83. **Truth**
May 28, 2012

Scentofviolets, I never used the term "skeptic", and I never did any name-calling.

84. **harryb**
May 28, 2012

Truth et al,

May I quote from Feynman directly – The Character Of Physical Law, Chapter 7, Seeking New Laws. I quote at length because the original text it is well written and compact:

"In general we look for a new law by the following process. First we guess it. Then we compute the consequences of the guess to see what would be implied if this law that we guessed is right. Then we compare the result of the computation to nature, with experiment or experience, compare it directly with observation, to see if it works. If it disagrees with experiment it is wrong. In that simple statement is the key to science. It does not make any difference how beautiful your guess is. It does not make any difference how smart you are, who made the guess, or what his name is – if it disagrees with experiment it is wrong. That is all there is to it."
It seems the WHOLE POINT of science – according to Feynman – is for any smart guess to agree with experiment. The Multiverse may be a smart guess – but we need an experiment that rules it in or out.
The Multiverse sounds smart, and may well be correct. But we have to be smarter that just posing the guess – the hard work as Feynman knew – is in devising the experiment that will obviously – to many – make it more than just a good guess. Guesses are cheap – experiments to verify them are, very, hard work.

85. **Anonyrat**
May 29, 2012

Since inflation was proposed around 1980, and Feynman died around 1988, surely we must have some of Feynman's opinion of the idea instead of having to rely on extrapolation.

86. **Igor Khavkine**
May 29, 2012

@Anonyrat: Something slightly relevant. Here's Feynman weighing in on the somewhat larger question of the initial conditions of the universe. My interpretation: curiosity with extreme caution.

Feynman: Take the world from another point of view (3/4)
http://www.youtube.com/watch?v=uNOghidK2TY (from 7:10)
Feynman: Take the world from another point of view (4/4)

> http://www.iop.org/resources/videos/lectures/page_44292.html

Thanks for the tip. That is the standard history and motivation of string theory, so not very interesting to me, but probably for everyone who never heard the story before. I think it is safe to assume that Witten won’t invest much time to update the talk for Strings 2012 (no reason to).

Nevertheless, if I go to the strings 2012 talk and get the chance to ask a question, I’ll probably ask about what he thinks a young PhD should specialize in, or what he is currently working on and why, or something like that. But I’m taking suggestions 🙂

88. **Bernhard**
May 29, 2012

Tim van Beek,

I would be very curious to know Witten’s answer. Years ago (2004 if I’m not mistaken) a friend of mine asked him a similar question for which he answered (I’m quoting it this from memory so it’s more or less this): “Don’t know, but something with string theory”. Would even Witten give such an advice today?

89. **Chris Austin**
May 29, 2012

The British Astronomer Royal Sir Martin Rees, who seems to favor a multiverse picture, stated on page 115 of his 1999 book “Just Six Numbers” that a value of the relative amplitude Q = (delta rho)/rho of the primordial fluctuations substantially larger than 10^{-5} would make the universe too violent for life. This appears to contradict Paul J. Steinhardt’s statement, on page 43 of the Scientific American article by linked by Marty, that the universe is smoother than it needs to be to support life, so that anthropic selection cannot explain the value of Q. Is Rees’s statement now discredited, or is there no consensus on the matter?

90. **Peter Woit**
May 29, 2012

Tim van Beek,

There is something new since 2010, the fact that no SUSY (or anything else relevant to string theory) has shown up at the LHC. For years Witten and other string theorists have held out hope that the LHC would find something that would vindicate string theory (at least low energy SUSY). I’m curious to know at what point Witten will give up on this hope, and if that happens how it will change his view of string theory.

91. **Shantanu**
June 4, 2012

Peter and others, there is some discussion of multiverse in the panel debate on emergent spacetime at KITP conference.
http://online.kitp.ucsb.edu/online/bitbranes-c12/emergence/

92. **Peter Woit**
June 4, 2012

Shantanu,

There’s not much about the multiverse there, but interesting if you want to keep up on the latest thinking about emergent gravity. I gave up after watching for a while, seemed to me there was nothing new going on in this subject, in particular nothing new about the obvious question: “emerges from what?”

93. **Nick M.**
June 8, 2012

Let me preface my post by saying that although there have been over ninety responses to *“Welcome to the Multiverse”*, it has all been a very interesting and lively read.

> **“**So, I fear Brian is right: Welcome to the Multiverse, physics is going to be stuck with it for a very long time…**“**

A long time indeed, as it looks as though Stephen Hawking (along with James Hartle and Thomas Hertog) aren’t quite ready to give up on the Multiverse/String Theory paradigm anytime soon either; see version 2 of the this paper posted in arXiv on May 30th titled “Accelerated Expansion from Negative Lambda”. Incidently, I found this link via the New Scientist article “Hawking’s ‘Escher-verse’ could be a theory of everything”. (Note that you will have to be a registered user to completely read the New Scientist article.)

Friedrich Hirzebruch 1927-2012

May 29, 2012
Categories: Obituaries

The German mathematician Friedrich (Fritz) Hirzebruch passed away a couple days ago, at the age of 84. Hirzebruch was perhaps the most important mathematician in the Germany of the postwar period, responsible for the founding of the Max Planck Institute in Bonn, as well as the yearly Bonn Arbeitstagung conference. The Mathematics Genealogy Project lists him as having 52 Ph.D. students and 368 descendants. There's a wonderful interview and article about him at the Simons Foundation web-site.

Hirzebruch's first great mathematical achievement was the proof in 1954 of the generalization of the classical Riemann-Roch theorem to higher dimensional complex manifolds, now known as the Hirzebruch-Riemann-Roch theorem. This used the new techniques of sheaf cohomology and was one of the centerpieces of the explosion of new results in geometry and topology during the 1950s. Further generalization of this led to the Grothendieck-Riemann-Roch theorem, and the Atiyah-Singer index theorem. Hirzebruch's monograph on the subject *Topological Methods in Algebraic Geometry* was the essential textbook in this area for many years.

The last time I heard Hirzebruch talk was at the celebration of Atiyah's 80th birthday in Edinburgh, where Hirzebruch gave a talk about his interactions with Atiyah. He displayed some of their correspondence from this period, which makes fascinating reading and is now available here.

With the loss of Raoul Bott a few years ago, and now Fritz Hirzebruch, the math and physics communities are deprived of two of the great figures who built parts of modern mathematics that appear crucially in the structure of the Standard Model. Much of this connection between math and physics remains a mystery, and it's too bad they won't be around to help make progress unraveling it.

Update: The New York Times has a very good obituary of Hirzebruch here.

Comments

1. **Chris Austin**
   May 29, 2012

   Could you elaborate a little on the contributions of Bott and Hirzebruch to the mathematics of the Standard Model?

2. **Peter Woit**
   May 29, 2012

   Chris,

   This is a long story, and I wrote a significant amount about it in my book. The basic objects in the SM are the Dirac operator on spinors, coupled to a connection. These are exactly the same basic objects that appear in the Atiyah-Singer index theorem. The Hirzebruch-Riemann-Roch theorem is in some sense the crucial case of the index theorem, using the Dolbeault operator instead of the closely related Dirac operator. Bott's work made possible the general topological K-theory behind the index theorem. From the late 70s on, both Bott and Hirzebruch were very active in promoting the interaction of mathematics and physics, often giving beautiful expository lectures trying to explain this material to physicists, and relate the points of view of the two subjects.

3. **Chris Austin**
   May 29, 2012

   Thanks, Peter

4. **David Brown**
   May 30, 2012

   2 questions: (1) Is the problem mentioned at the end of Hirzebruch's Atiyah80 video/lecture still open? (2) Of the mathematicians who are roughly of the generation of Hirzebruch & Atiyah, which of them made the most significant contributions to the mathematics of the Standard Model of particle physics?

5. **Peter Woit**
   May 30, 2012

   David,

   I have no idea if anyone took Hirzebruch up on that challenge (he was asking for an embedding of E6/(Spin(10)xU(1)) in dimension 61, or, failing that, 62 or 63, hopefully showing that the non-embedding result in dimension 60 is sharp).

   Atiyah, Singer, Bott and Hirzebruch all have interacted strongly with physicists around issues raised by Yang-Mills theory, the Standard Model and attempts to extend it. Since the Standard Model was in place back in 1973, before they got involved, this isn't activity that has actually changed the Standard Model, rather led to a better understanding of it, especially issues related to anomalies and instantons. Atiyah and Singer have both been extremely active in working with physicists, with Bott only a bit less so, Hirzebruch significantly less.

6. **jg**
   May 30, 2012

   Hi Peter,

   no disrespect to a great mathematician, no doubt he made a beautiful contribution to pure mathematics, but isn't it a bit much to suggest the intricacies of the mathematical arguments Hirzebruch (et al) developed are relevant to Nature/Physics?

   I mean isn't this site devoted to the idea that over-elaborate mathematical arguments are not the way to understand Nature?

7. **Peter Woit**
   May 30, 2012

   jg,

   My problem is not with the use of mathematics to describe nature, quite the opposite. I believe that experience shows it is the deepest ideas in mathematics that are most likely to give us insight into fundamental physics at a deep level. The Hirzebruch-Riemann-Roch theorem is a very deep idea about mathematics, with close connections to things we have impressive physical evidence for (the Dirac operator, gauge fields), so this seems to me to be worth a lot of attention.

Yes, you can also use the HRR theorem to do some computations in horrifically complicated and ugly constructions used in failed attempts to get string theory unification, but there the problem is the construction, not the theorem. The HRR theorem ends up being useful in that case because it is so powerful and so general that it's one of the few tools that can say something about such a complicated mess.

8. **jg**
May 30, 2012

ah ok,

I personally don't believe the breakthrough requires a deep result in pure mathematics, but I admire your position on this 🙂

fxqi's 2012 essay question:

Which of Our Basic Physical Assumptions Are Wrong?
http://fqxi.org/community/essay

9. **P**
May 31, 2012

Peter,

HRR is very nice indeed, but perhaps your dislike of string compactification is causing you to leave out his surfaces, which are some of the simplest surfaces in complex algebraic geometry. 🙂

Cheers,
P

25 Years of Topological Quantum Field Theory

May 31, 2012
Categories: Favorite Old Posts, Uncategorized

It occurred to me today that right about now is the time someone should have chosen as the date for a celebration of the 25th anniversary of the birth of the idea of "Topological Quantum Field Theory", as well as some much less well-known ideas about the relationship of QFT and mathematics that still await full investigation.

Just about 25 years ago, from May 12-16 1987, there was a remarkable conference that I attended at Duke, to celebrate the "Mathematical Heritage of Hermann Weyl", two years after the centenary of his birth. The proceedings were published a year or so later. At this conference, Michael Atiyah gave an amazing talk with the title *New invariants for manifolds of dimensions 3 and 4*. In it he unveiled a vista of new ideas about topology that would dominate the subject for years to come. For symplectic manifolds he described Andreas Floer's unpublished new ideas about what came to be known as "Floer Homology" and how these gave new invariants of such manifolds and their Lagrangian submanifolds, invariants related to very recent work of Gromov (now known as "Gromov-Witten invariants"). Replacing 1d (Lagrangian paths) and 2d (pseudo-holomorphic curves) objects in a symplectic manifold by 3d (flat connections) and 4d (instantons) objects in a space of connections on a 4d manifold gave yet another whole new world of mathematics. This is the subject of Floer Homology and Donaldson invariants for 4d manifolds, possibly with boundary, (and was based on work of Floer and Donaldson that was still unpublished). Finally, the Euler characteristic of Floer Homology was identified with a new invariant due to Casson (also unpublished, it seemed like nothing Atiyah was talking about was yet written up), which was a 3d invariant that fit beautifully into the whole picture.

There's a copy of Atiyah's write-up of the talk online here (perhaps the AMS will ignore any intellectual property issues here for the greater good). I see that, increasingly like everything else in the world, electronic access to the book is controlled by Google, see Google Play, which I didn't even know existed.

An inspiration for Floer had been Witten's ground-breaking paper "Supersymmetry and Morse Theory", which dealt with the relationship between Morse theory and some supersymmetric quantum mechanics models. Atiyah explained some of these ideas in the talk and towards the end conjectured that quantum field theories were part of the story. His conjectural QFTs would have Floer homology as their ground states and would turn out to be the basic examples of TQFTs. After repeated prodding from Atiyah, Witten a year later produced such theories as twisted N=2 supersymmetric QFTs: a sigma model for the symplectic manifold case, and a supersymmetric Yang-Mills theory for the 4d case. In his final remarks, Atiyah raised the issue of knot invariants and the Jones polynomial, suggesting that this too would have a QFT interpretation, something that came to fruition a couple years later with Witten's Chern-Simons theory that won him a Fields medal. Witten was at the talk, and I recall him coming down to the podium to ask Atiyah some questions about the Jones polynomial immediately after the lecture.

The Duke conference was also significant to me for personal reasons. At the time I was a postdoc at the ITP in Stony Brook, looking for a job and trying to figure out my future. It was becoming clear that physics departments didn't want to hear from any young theorists interested in mathematics who weren't doing string theory. I had been spending a lot of time at Stony Brook learning more mathematics and talking to some of the geometers there, who were housed on the floor below the ITP. My trip to the conference at Duke was motivated partly by a desire to visit my grandparents who were in North Carolina for the summer, as well as a plan to investigate prospects for a career change into mathematics. The Atiyah talk bowled me over, convincing me that the intersection of mathematics and QFT had an exciting future. Getting to know a bit more about the mathematical community showed me it could be a great place to work, in many ways much more welcoming and open to new ideas than the physics community. I soon moved up to Cambridge for a year, where the Harvard Physics department let me use a desk, and found a part-time job teaching calculus at Tufts.

What's remarkable to me now looking at the conference volume is how much exciting material was being discussed, in addition to the fantastic Atiyah talk. Raoul Bott gave a wonderful talk on Borel-Weil-Bott (and its relation to quantization), David Vogan on representation theory in general (and its relation to quantization). Roger Howe has a contribution also about deep connections between quantum mechanics and what he calls the "oscillator representation". Jim Lepowsky was talking about Kac-Moody Lie algebras, vertex operators and the Monster group, Is Singer about quantizing gauge theory and string theories, and there were a host of other wonderful talks on topology and geometry.

One topic that I didn't really appreciate at all at the time was that of Langlands theory. Langlands himself was there, talking about Shimura varieties, and James Arthur talked about the Trace formula and its applications to Langlands theory. I think I may have missed Witten's talk, since I don't remember it, but his contribution to the conference proceedings is about how to abstractly think about the theory of 2-d free fermions, in a form that makes sense on an arbitrary curve. A few weeks later (June 23), his amazing paper Quantum Field Theory, Grassmanians and Algebraic Curves was submitted to *Communications in Mathematical Physics*. If I had to point to a paper that truly looks like 21st century work that fell by accident into the 20th century, this would be it. It gives some strikingly different ways of thinking about QFT in 2d, including tantalizing connections to the structures ("automorphic representations") that show up in Langlands theory, and has provided inspiration to many people over the years, including the geometric Langlands program. Atiyah's lecture pointed to new ideas relating QFT to cutting edge geometry and topology, ideas that quickly led to lots of progress, while Witten's ideas related QFT to representation theory and Langlands theory, in ways that we still have yet to fathom.

   May 31, 2012

   Memories. Wasn't at the conference, I was a brand new grad student, but a few years later my orals were to present that Witten paper. Took some work :-). There's a great book by John Roe which helped a lot. Of course, I was only interested in the math side…

2. **theoreticalminimum**
   June 1, 2012

   Thank you for this informative post, Peter.

   It's sad to realise that Andreas Floer would tragically end his life 4 years after that Duke conference, at the age of 35 and at a time when he was at the peak of his creativity.

   I would recommend the Floer memorial volume (Hofer et al.), which is the best collection of articles I can think of that captures the effervescence of the developments at that time in symplectic geometry and quantum field theories.

3. **Florin**
   June 1, 2012

   Hello,

   I've been quietly following with great interest your website for a couple of years now and although I don't have a formal training in mathematics I grew very interested in topics such as Langlands program or any other attempt to reveal stronger connections between mathematics and reality/physics. And while I somehow have some grasp on Noether's theorems and I have some kind of intuitive understanding of the importance of representation theory for say the quark model, the mathematical apparatus for even having a hint about the Langlands program seems to me very abstract and inaccessible.

So I was wondering, what would be the mathematical requirements for starting to approach this subject and also could you please indicate to a less mathematical introduction to the Langlands program?

Thank you, your answer would be much appreciated!

Regards,
Florin

4. **Peter Woit**
June 1, 2012

Florin,

The Langlands program brings together several fundamental areas of mathematics, so to really understand and appreciate it, you need some serious background in modern mathematics. Edward Frenkel's lectures this past semester at Columbia provide a good introduction and explain the links to affine Lie algebra representations and conformal field theory.

You could also take a look at this survey of the subject from Langlands himself

http://publications.ias.edu/sites/default/files/gibbs-ps.pdf

A good place to start might be the popular book by Ash and Gross, called ~~"Fearful Symmetry"~~.

[Oops, the correct title is Fearless Symmetry, thanks to all for the correction]

6. **MathPhys**
June 2, 2012

Jeff,

Which of John Roe's books were you refering to? The CBMS write-up? or the longer version? Which of these two in more readable?

7. **Jeff M**
June 2, 2012

MathPhys,

It's "Elliptic Operators, Topology, and Asymptotic Methods" from the Pitman Research Notes, 1988, No. 179. My orals predate his CBMS lectures 🙂 It's basically his lecture notes from a course he gave at Oxford.

8. **paddy**
June 4, 2012

Though I am also mystified about the connection between mathematics and physics:
(a)It is arguably a trusism that mathematics provides a framework for physics;
(b)it is certainly arguable that this framework has always seem to come after the fact;
(c)what delimits and leads physics forward is observation and experiment;
and (d) "shut up and calculate".

This is off-topic but I just thought it was pretty funny: http://arxiv.org/pdf/hep-th/0503249.pdf

11. **Peter Woit**
June 7, 2012

SA,

What's funny is that many theorists don't seem to think this is a joke, see

http://inspirehep.net/search?ln=en&p=refersto%3Arecid%3A679450

More comments maybe in an imminent posting…

12. **Florin**
June 7, 2012

Hello Mr. Woit,

Just wanted to say thank you for all the resources you posted in your comment, much appreciated. Also Ossicle, thanks for the lectures, watching the first videos really rendered me the scale of the program.

Not sure if I'll ever make it to approach and actually understand all the topics involved here, but I plan to go on with my calculus manual so that I can access general relativity and quantum field theory and in parallel maybe start learning some group theory, Lie algebra… Too bad I started this late..

13. **SA**
June 8, 2012

Peter,

Indeed that would be funny (and sad). However, if you take a look at those citing papers, you will see that most are citing tongue-in-cheek and the 1 or 2 other papers are citing it obviously based on a superficial keyword search.

High Drama

June 7, 2012
Categories: Experimental HEP News

It's exactly a month until new LHC Higgs results are to be unveiled at ICHEP. The machine has been running well, and right about now should be the cut-off time after which new data will arrive too late for analysis before ICHEP. So the integrated luminosity available for each experiment to analyze will be about 4.5 inverse femtobarns. See Tommaso Dorigo for an explanation of what this means. Very roughly, if the Higgs is there with a mass around 125 GeV, each experiment should see tentative signal similar to last year's, with the combination of data from both years and both experiments likely reaching the 5 sigma standard necessary to declare discovery. If no signal similar to last year's is seen, this will seriously re-open the possibility of no Higgs (or a very different Higgs than the SM one). Either way, should be very exciting.

For the other story people are following, the death of SUSY, see Nima Arkani-Hamed's recent talk. He lists as "High Drama for 2012" not just the Higgs, but also SUSY results on stops, gluinos and multileptons. Here I think most people have given up hope that evidence for SUSY will be found, so the high drama is the human one of how SUSY advocates will react as remaining possible SUSY hiding places are mopped up. The conference was in honor of Savas Dimopoulos, who has been working on SUSY models for more than 30 years, so Arkani-Hamed's talk didn't even acknowledge the possibility of no SUSY. He described the 2 alternatives available to physics as "natural SUSY", which is just about ruled out, and various versions of "split supersymmetry", where superpartner masses can be pushed arbitrarily high, out of the reach of the LHC or any conceivable experiment. He didn't mention the version one commenter here recently brought up, "super-split supersymmetry", which was an April Fool's joke, but may be the direction the field is headed.

Tommaso notes that the new data has been blinded by the experiments, meaning that even those working with it don't know anything about what the final result will be until the last stage of the analysis. Whenever that might be, I'm hoping reliable rumors will soon ensue.

I'm heading out on vacation tomorrow, to the bottom of the Grand Canyon, out of reach of the internet until about June 18th. During this time I'll have to shut off comments here. So, hold your reliable rumors until I get back….

Update: Seems that some of these reliable rumors just won't wait. Whatever Tommaso says about CMS blinding its data, either that's not the case at ATLAS, or some of it is now unblinded. I hear that the first chunk of gamma-gamma data is showing some signs (2 sigma) of a signal at about the same place as last year's data. Analysis of more data is proceeding, and very soon people at ATLAS will know whether there's a signal there. High drama….

Comments

1. **King Ray**
   June 7, 2012

   Peter, have a great and well-deserved vacation!

   One thing that occurred to me that others may find funny, in the nature of lolcat jokes:

   ICHEP = "I Can Haz Extra Particles?"

2. **Shantanu**
   June 7, 2012

   Peter or anyone, any exciting news from CIPANP 2012?
   Unfortunately I don't see any slides yet from it.

3. **Peter Woit**
   June 7, 2012

   Shantanu,

   At least as far as LHC results go, the likelihood is that we've already seen whatever is really exciting about the 2011 data, and the earliest results from 2012 data are targeted for ICHEP. So, I'd be surprised if there's any big news from the LHC at any conference before ICHEP next month.

4. **Hamish Johnston**
   June 8, 2012

   Is it realistic to expect that the "discovery announcement" will be made half-way around the world in Oz. Surely CERN will want a tightly-orchestrated press event in Geneva?

Too Much Ain't Enough Langlands

June 7, 2012
Categories: Langlands

I should be packing for my trip, but couldn't resist one last blog posting, since I've recently a run across a lot of interesting Langlands-related material, including:

- A Symposium this fall at the Fields Institute, in honor of Ngo's Fields Medal winning work, on Fundamentals of the Langlands Program. They have a symposium blog, and including a video with Jim Arthur who gives a little bit of historical background to the Langlands Program.
- This past semester the Fields Institute has had a program on Galois Represesentations, with an instructional workshop, lecture series by Michael Harris and Christophe Breuil, and lots more. Some notes are on the instructional workshop page, and lots of audio of the talks are available here (so you can see what trying to learn math will be like when you go blind).
- To hear from the man himself, there's something old here (notes here), something from last year here.
- In recent years Matt Emerton has written some wonderful expository pieces, often on Langlands-related topics, as the answers to questions on MathOverflow. He has collected links to them here.

The Higgs Discovery

June 17, 2012
Categories: Experimental HEP News, Favorite Old Posts

Just got out of 8 days in the Grand Canyon which was spectacular,

Reliable rumors couldn't wait, and they indicate that the experiments are seeing much the same thing as last year in this year's new data: strong hints of a Higgs around 125 GeV. The main channel investigated is the gamma-gamma channel where they are each seeing about a 4 sigma signal.

More later when I reach civilization.

Update: Back in civilization, or at least New York City. The above was the first posting I've ever written on an iphone, late at night. Now I have a real keyboard, so I can write a bit more. The "4 sigma signal" refers to the combined 2011 and new 2012 data. To oversimplify the situation, last year both experiments were seeing roughly a 3 sigma excess in gamma-gamma around 125 GeV. This was enough to convince many people that it was highly likely that this was the Higgs. However, that size excess is not completely convincing, it is not unheard of for there to be statistical flukes of such size.

The 2012 data that is being analyzed for ICHEP is of a similar size to the 2011 data. If 2011 was a fluke, you expect to see nothing much around 125 GeV in the 2012 data. If the 2011 signal really was the Higgs you expect the signal to strengthen. What I'm hearing from both experiments is that they are seeing an excess in the new data, strengthening the significance of the signal.

Exactly how much data they'll have analyzed by ICHEP and exactly what the significance of the signal in the gamma-gamma channel will be (as well as what other channels will show) is still to be seen. CERN will soon have to decide how to spin this: will they announce discovery of the Higgs, or will they wait for some overwhelmingly convincing standard to be met, such as 5 sigma in at least one channel of one experiment? The bottom line though is now clear: there's something there which looks like a Higgs is supposed to look. Attention will soon move to seeing if this signal is exactly what the SM predicts (e.g. will the excesses in different channels agree with SM predictions?).

More details about this from Philip Gibbs (who is speculating about what will be announced), and from Tommaso Dorigo (who is keeping quiet about what he knows, but providing context for what the ICHEP announcements will mean).

Update: Matt Strassler has more about this here. He provides about 20 links to his own blog, no link to the source of his information (this posting). It appears that this is because I'm a "non-particle-physicist blogger" engaged in a conspiratorial plot with some of the 6000+ people who know this latest news to "subvert the scientific process" by sharing it with others.

Update: There are stories about this at Wired, New Scientist and the New York Times. The New York Times article emphasizes that the Higgs results are now "Shrouded in Secrecy", with the spokeswoman for ATLAS pleading "Please do not believe the blogs".

According to Matt Strassler "the experimentalists can't possibly have their data in presentable form yet, so the rumors can't be correct in every detail". To clarify any confusion

"Exactly how much data they'll have analyzed by ICHEP and exactly what the significance of the signal in the gamma-gamma channel will be (as well as what other channels will show) is still to be seen"

means that the above rumors were based on just part of the data (significantly less than half in the ATLAS case, somewhat more than half in the CMS case).

Update: I think I'm too old to ever really understand Twitter, but it seems that #HiggsRumors is a "Trending Topic", whatever that means. More explanation available from Jennifer Ouellette, and sensible commentary from Chad Orzel.

Comments

1. **N.**
   June 17, 2012

   Good for Higgs, finally.

   Not so good for SUSY, as I understand.

   Congrats on the Grand Vacations!

   :)n.

2. **Sven**
   June 17, 2012

   Hi N,

   125 < 135, so a 125 GeV Higgs is perfectly compatible with the MSSM (not talking about more extended models).

   Cheers, Sven

3. **Gennaro**
   June 17, 2012

   Four sigma? Is that higher evidence than in 2011? Or less evidence? Please let us know…

4. **Chris**
   June 17, 2012

   4 sigma is significantly higher than last year. Still not enough to really claim discovery (5 sigma is the standard), but if they really are at 4 each then the combination would almost certainly do it.

5. **Susan Mones**
   June 17, 2012

Any plot supporting those rummors ?

6. **Truth**
June 17, 2012

The Higgs was discovered in the 70's when the standard model was put together; this is just the latest confirmation of the standard model. It once again disputes all the naysayers, who think the heirarchy problem is fake. No. The higgs is real. The standard model is real. Its properties, such as the heirarchy problem, are real. Nature has spoken, we have listened.

7. **OMF**
June 17, 2012

> No. The higgs is real. The standard model is real. Its properties, such as the heirarchy problem, are real. Nature has spoken, we have listened.

Be careful what you wish for! A 100% confirmation of the standard model by the LHC would in fact be the worst possible outcome for theoretical particle physics as a whole. Everyone would basically have to pack up their things and go home(and weep presumably).

Better to hope for a multichromatic Higgs or the like. Fingers crossed!

8. **Henry Bolden**
June 17, 2012

Where's the picture of Peter standing in front of the Grand Canyon?

9. **Brian**
June 17, 2012

@ Truth that is completely laughable viewpoint. You can put together a 1000 wrong theories that make predictions. Just because you have a theory that predicts something not yet been seen does not mean you have discovered something. The Higgs was predicted in the 70s and that is all. Theory only supplies a framework to predict outcomes in reality. Reality can turn a theory to ashes or lend it creditability, but that is about it.

10. **David Nataf**
June 17, 2012

Brian,

The same standard model that predicted the Higgs predicted many other properties and particles that have been borne out by experiment.

11. **anon**
June 17, 2012

Peter, when will you reach to civilization?

12. **Roger**
June 17, 2012

I agree with Truth. The Higgs mechanism is an essential part of the Standard Model and has been quantitatively confirmed since the 1970s. The value of the mass was unknown, and there is always the possibility of some other explanation for the data, but the Higgs was discovered in the 1970s.

13. **Noah Smith**
June 17, 2012

The Higgs was discovered in the 70's when the standard model was put together

the Higgs was discovered in the 1970s

Scientific method FAIL

14. **Dan D.**
June 17, 2012

Sorry, but I have to agree with Brian and Noah. The idea that the Higgs boson was *discovered* in the 1970s when the *theory* was fleshed out is ridiculous. It's enough of a triumph of the scientific method that a theory *predicted* the existence of such a particle 50+ years before it was finally (potentially) discovered, then to go overboard and claim a *prediction* is the same thing as a discovery. One may have high confidence in a prediction, but no matter which way you slice it, that's no substitute for experimental discovery. Lots of people in cosmology had high confidence that the Universe was slowing in its expansion, too, and we know how that turned out…

15. **Beelzebud**
June 17, 2012

I'm no scientist, but wouldn't it be correct to say that the Higgs was theorized in the 70's and is still awaiting discovery? Does experimental validation matter at all to some of you?

I think this is the sort of mindset Not Even Wrong and The Trouble with Physics was calling out. For something to be discovered, you must confirm it with experiments.

16. **Eric**
June 17, 2012

I am amused about these comments that infer the 'strength' of the standard model. If the model were so strong, it would have needed dozens of refinements over the years.

And please pardon my skepticism, but an sd of 4 sigmas is hardly a solid confirmation. There are 5 sigma+ level events that occur on earth regularly by random circumstance.

Why is the higgs pegged at 124 GeV in one very recent study, and 126 in another? If the resolution of the detectors is < 2 GeV, which I believe it is, then how can two ~3-sigma level findings 2 GeV apart mean the existence of a 125 GeV particle? The error exists on both the low-side of 124, and the high-side of 126. And the probability

DROPS OFF in between. If anything, attention needs to be paid to possibilities including: 2 particles 124/126, 3 particles 124/125/126, or more likely, zero particles anywhere near 125 because this is due to fluctuation.

17. **Eric**
June 17, 2012

The model "WOUDN'T" have needed dozens of refinements over the years, is what I meant to say.

And furthermore, I don't see much evidence that people are thinking about what other possibilities could exist at 125 GeV OTHER than a higgs particle. The existence is completely inferred by the detection of indirect mechanisms in the first place, and the inference is fairly weak when you consider there may be multiple explanations for the behavior in the detectors including a completely new physical mechanism.

18. **Anonyrat**
June 17, 2012

Civilization no longer exists. Peter may have a ETA for the urban jungle.

19. **tommaso dorigo**
June 17, 2012

To Eric above (on 124 vs 126):

I think your skepticism, although healthy, is a bit misguided.

– planes crash on almost a daily basis so 5-sigma events do occur, true – but we do not look for a new particle a million times a day. The 5-sigma bar was set in HEP by common wisdom, and it has been surpassed very rarely by things that later boiled down to be false. The 5-sigma criterion is imperfect of course, but it is a good hunch. Note that it incorporates the famous "look-elsewhere effect", in the sense that experiments are allowed to claim observation of a new particle based on local significance, i.e. not accounting for the trials factor.

– the issue of 124 vs 126 has been put forth many times by people with handwaving arguments. If you know a bit of Statistics it won't take you long to realize that they are fully compatible, and that the weighted average of two signals can then be taken. The exercise of 124+-2 oplus 126+-2 gives the maximum likelihood estimate of 125+-1.4; but you need to stop there since for the significance things are not as straightforward, so you should rather look at Peter Gibbs combinations (vixra log), which show that the global effect is of the order of 4-sigma for the Winter 2012 data (which had 3-sigmaish effects in CMS and ATLAS). The trick is that while the most sensitive channels have resolutions in the 1-2 GeV ballpark, the combined results of each experiment benefits from channels with lower resolution, so that the p-values have broad distributions.

Cheers,
T.

20. **anonymous**
June 18, 2012

Is there a vacuum instability issue with an SM Higgs at 125 GeV?

21. **Mitchell Porter**
June 18, 2012

Eric: the standard model "needed dozens of refinements over the years"

Could you list just one dozen refinements that it needed?

22. **ScientistfromMars**
June 18, 2012

Calm down, guys. The Higgs Boson had been discovered long time ago. Why all the noise now? I know CERN has to come up with results after eating up billions of taxpayer funds. But for what: I have one Higgs Boson in my freezer and another one stored in a vault. Both are really pretty, but a bit small tough. Now, I need to walk my dogs.

23. **Eric**
June 18, 2012

Hi Mitchell — Isn't every run of every experiment to find the Higgs a 'refinement'? The model doesn't predict the mass. I don't know how else you can look at it.

Hi Tommaso — Thank you for your insight. But can you further clarify what you mean by '[physicists] don't look for the Higgs particle a million times a day'? As above, isn't every run of every experiment a trial? And is it wrong to break it down further by counting every single quanta of energy hitting the detectors as a separate 'trial', such that you really are looking for it "a million" times a day?

Second, please forgive me for referencing a web page instead of working through the math myself, but I like 'handwaving' 🙂 :). Please read what Sean Carroll has to say about probability in terms of football coin flips, of all things:

http://blogs.discovermagazine.com/cosmicvariance/2012/02/04/a-3-8-sigma-anomaly

Finally, could you please offer some advice on what the true resolution(s) of the detectors are? I would like to put together a thought experiment, if I can find the time, to show that maybe there's a different way to look at these results. The fact that you mentioned the experiment relies on data from detectors with even lower resolutions than 2GeV is both interesting and worrisome to me. I do know a fair bit amount statistics (although not as much as you 'particle' guys. You guys know your stats like nobody's business!). Anyway, have you thought about applying the error in the detectors to model an explanation to describe a new/different physical mechanism at play here? Just curious.

– Eric

24. **Eric**
June 18, 2012

Tommaso et. al. Please don't take my skepticism in the wrong way. I am not trying to be rude, for sure. I'm just very interested in the experiments, and I think you guys are indeed doing a tremendous job with tremendously complicated equipment (which you built to perfection from scratch), faced with looking for a needle in a trillion haystacks.

25. **Truth**
June 18, 2012

Dear anonymous,

Thank you for asking a relevant and important question, while most others here seem to be confused about the nature of science and evidence.

To answer your question about vacuum instability: as is the case for EVERY value of the higgs mass, something bad happens at suficiently high energies, whether it is vacuum stability for light higgs, or a landau pole for heavy higgs. For a 125 GeV higgs, there is vacuum instability at an energy around 10^12 GeV. There is also an associated timescale for our vacuum to decay, but this turns out to be longer then the present age of the universe. So the standard model with 125 GeV higgs is META-stable. This is probably a bad thing that is fixed by new physics entering before 10^12 GeV, although perhaps meta-stability is okay, we don't know.

So the standard model is yet again holding true. It's heirarchy problem is, in my opinion, its strangest feature, that most people think imdicate that the new physics will enter far low than 10^12 GeV. Or the heirarchy is anthropic. Those are the only possibilities.

26. **emile**
June 18, 2012

Truth: you wrote: "The Higgs was discovered in the 70′s when the standard model was put together; " . Then you add: "while most others here seem to be confused about the nature of science and evidence.".

You are the one who seems confused. The Higgs has not been experimentally discovered yet. Maybe you are the only one for whom a "discovery" of a particle does not involve experimental observation. Seeing neutral currents in the 70s is not a Higgs discovery. Maybe "discovery" means something different to you (and you alone, because I don't anyone in this field who would support your statement above).

Let me blunt: if a student in experimental HEP said something like this during a PhD examination, he/she would not walk away from my University with a PhD if I'm on the committee. This is so "Scientific Method 101" that a "fail" is the only grade one can give.

27. **Peter Woit**
June 18, 2012

All,

I'm back in the office, can now try and get a grip on moderating this discussion. Unless you have something interesting to contribute about the latest news here, please refrain.

Truth,

"Those are the only possibilities"

Actually, no. For the obvious reason that at the edge of scientific research, we don't understand what is going on well enough to know the "only possibilities", and in this particular case, because of the subtleties of the "hierarchy problem". But that subject is both off-topic and already beaten to death at another posting. No more here.

28. **tommaso dorigo**
June 18, 2012

My answer to Eric above:

"But can you further clarify what you mean by '[physicists] don't look for the Higgs particle a million times a day'? As above, isn't every run of every experiment a trial? And is it wrong to break it down further by counting every single quanta of energy hitting the detectors as a separate 'trial', such that you really are looking for it "a million" times a day? "

Not really. The analysis is done once per year or so. And if you broke the data down in bits, you would have no chance of saying anything in any given bit. It would be stupid, and meaningless.

About what Sean Carroll writes in his blog on probabilities: after three years working side by side with statistics experts who have published groundbreaking papers on statistics for HEP, I believe S.C. does not qualify as a source for me. And that's just another topic on which he doesn't, after his showing his bigotry in the issue of my comments to Lisa Randall's physical appearance 😉

[Sorry for my attitude in the paragraph above, I must be late in delivering my weekly dose of venom.]

About resolution: mass resolution depends on the objects you use to reconstruct the decaying object. Of course we use that information in all our analyses. I am not sure I understand your suggestions, but please consider that routinely we extract results from a likelihood $L(m;x,\theta)$ which is a product of probability density functions of all the observed events. The latter are written as $P(m;x,\theta)$ where m is the measured mass of an event, x is a vector of additional parameters measured in that event, and θ a vector of nuisance parameters (for which we usually have additional priors from subsidiary measurements $\Pi(\theta)$ which multiply L).

Now, in θ are contained systematic effects, but x is a measured vector of event characteristics, from which the mass resolution is deducible. So really P() contains that information; for instance if your measurement of m is gaussian, you could write P as $G(m,\sigma(x))$. I hope this is clear enough.

Cheers,
T.

29. **Zathras**
June 18, 2012

Does anyone know something about the structural correlation between last year's experiment and this year's? Or can we just add the sigmas because they are structural independent?

30. **Peter Woit**
June 18, 2012

Zathras,

As far as I know, for the most important channels for the Higgs search, the errors are dominated by statistics. So, to a reasonable accuracy you should be able to combine the 2011 and 2012 analyses as statistically independent.

This is a complicated business though, and I'm no expert, so surely there are subtleties about exactly how to do this that I'm missing. The experiments definitely are both doing combinations of the data from the two different runs (which were at different energies). I don't know the details of how they do this. Maybe someone else here does…

31. **N.**
June 18, 2012

@ Sven:

I meant Sir Peter H. , not the particle 🙂

As for SUSY, no signs so far (as I understand it)?

n.

32. **Gennaro**
June 18, 2012

Peter,

in Germany, your blog announcement about the Higgs made its to the internet news (spiegel.de) and into radio today (monday). You are now a celebrity …

33. **Anonyrat**
June 18, 2012

A relevant physics question, I think. Matt Strassler wrote at the link provided in the update above, regarding combining 2011 and 2012 results: "So in combining them you are making a theoretical assumption about how the production rate for Higgs particles changes as you change the energy from 7 TeV to 8 TeV. "

Actually, at 7 TeV or 5 TeV or 8 TeV, the constituents of the protons are what are colliding, and these constituents have some energy distribution with non-trivial spread, and the physicists are making a theoretical assumption that they know the production rate along this energy spectrum. So I'm not sure what great additional assumption we are making in combining 7 TeV and 8 TeV results.

34. **Peter Woit**
June 18, 2012

All,

I don't seem to have made this clear enough: pointless arguments about the scientific method, what's a discovery, etc. don't belong here. Stop submitting them.

35. **tommaso dorigo**
June 19, 2012

Hi anonyrat,

indeed, the PDF of the proton constituents have to be used in determining the production cross section of a hard subprocess, in what is called a "factorization integral": this is (pardon my laziness of not using latex), say for producing a H particle inclusively ("+X", where X is "whatever else")

σ(pp–>H+X) = Σ_(ij) Integral [f_i(x_i) f_j(x_j) σ_point(x_i x_j s, H) dx_i dx_j]

where x_i and x_j are the momentum fraction carried by the partons which produce the hard subprocess, and f_i, f_j are their PDF; s is the squared proton-proton CM energy. As you see in σ_point enter only the partons and their energy, so this part "factorizes" from the mess of the proton-proton collision.

The above does not mean that one has trouble combining data at different values of sqrt(s). Indeed, one has already taken assumptions about her capability to compute the pdf at a given scale, when using the factorization integral for a given s. Adding sigmas for different s does not cause a further headache, since it only means a minor "evolution" of the PDFs from one scale of hard process energy to a contiguous one. In other words, one is not sampling the PDFs in widely different ranges of momentum fraction in changing from 7 to 8 TeV.

There is one further point to make. LHC experiments searching for the Higgs are basing their background predictions on data (and so do not care about sqrt(s) at which data is taken) or, in specific cases, on electroweak calculations (say for instance the ZZ background in the H–>ZZ searches) which are very well known and computed to NNLO accuracy.

Finally, even within each experiment the methodology of combining the results should be that of extracting them separately from the two datasets (7 and 8 TeV), and then combining with the same tools LHC has used since last Summer to combine ATLAS and CMS data on the Higgs search. In a sense there is no difference in combining H->ZZ, H->γγ, H->WW, H->ττ results together and combining the same set twice, one for each sqrt(s) point.

Cheers,
T.

36. **Juan Ramón González Álvarez**
June 19, 2012

SLAC claims that BaBar Data Hint at Cracks in the Standard Model. The excess decays has to be still confirmed, but they claim that data already rules out the Two Higgs Doublet Model.

https://news.slac.stanford.edu/press-release/babar-data-hint-cracks-standard-model

37. **jon**
June 19, 2012

About the last part of Peter's post ("will the excesses in different channels agree with SM predictions?") is there enough data already (5/fb of 2011 + 5/fb of 2012) to, in any case, answer it (i.e a summer annoucement possible) ? Or is the full 2012 run needed to beat any statistical bad luck (i.e. a spring 2013 announcement) ? Thanks!

38. **Peter Woit**
June 19, 2012

jon,

This depends of course on whether reality disagrees with the SM predictions, and by how much. The uncertainty in the size of the signal will be large at ICHEP, smaller by early 2013. If the SM prediction is dramatically wrong, there may be evidence of this at ICHEP, although likely not statistically convincing.

The size of the signal depends on the Higgs production cross-section x branching ratio. The SM branching ratio should be accurately known, the production cross-section much less so (I've seen estimates of theoretical accuracy of 10-20 percent for this). Looking at the ratio of signals in two different channels (e.g. gamma-gamma and ZZ goes to 4 leptons) gets rid of the production cross-section uncertainty, but adds a lot of statistical uncertainty as you take the ratio.

39. **Yuri Gershtein**
June 19, 2012

Dear Peter,

I can not comment on the rumors themselves, but I can comment on the "Update" that you posted. Indeed, leaking the information (or making up stories) from a 3000+ experiment is a problem for a scientific process. We do not hide answers from you because we are such teases. We just want to figure out what the data tells us first, and it is only people working on experiment who are qualified to making the pronouncement.

Since your postings are followed by people who may not appreciate the difference: the official word from the experiment is the reality. Everything else is just hot air and narcissism…

regards,
Yuri

40. **Peter Woit**
June 19, 2012

Yuri,

I understand that it's in the interest of the experiments not to have public announcements coming from them until the job of getting the most reliable possible result is finished.

At the same time, I just don't see the supposed problem posed by an accurate characterization of preliminary results appearing on this blog. Yes, it's in principle possible that some reader here may not understand that these results are preliminary, but there's a huge amount of misunderstanding of particle physics by the public, with very little of it caused by accurate information being posted here.

Let me repost here a comment I wrote on Michael Schmitt's blog, which is relevant:

" The bottom line here is that over the last couple weeks, 6000+ particle physicists, the majority of the particle physics community worldwide, have seen or heard about preliminary analyses of data from their experiments which pretty conclusively confirm the existence of the Higgs. This is huge, historical news, and I don't happen to see why it shouldn't be shared at this point with the rest of the particle physics community. Notice that I'm not posting plots, or much in the way of detail. We all look forward to the day not too far from now when the best results possible from the new data are released, and we can all give heartfelt thanks to those like you who worked hard to get there.

Blogs introduce a new vector for the spread of rumors, but surely you're aware that historically the news of a big result has circulated fairly widely among physicists in the days and weeks before an announcement, often in highly inaccurate form. The current official policy that no one on an HEP experiment should breath a word about results before the public announcement doesn't correspond to the historical reality of the field. For instance, I remember going to tea at Princeton one day as a grad student back in the 80s, where I joined a group listening to Carlo Rubbia explain to everyone, with details, that his group had the top quark "in the bag". That's obviously not much of a good model for how to do things either, but the model of "no one will say anything at all to anyone" is neither realistic nor grounded in past practice."

41. **Yuri Gershtein**
June 19, 2012

Peter,

while I love the Rubbia comment, Rubbia was may be the only person in existence to be able to present wrong results in Nobel lecture and keep his credibility. I don't think we have people like that at the LHC. It was also a much different time, when our funding came from the echoes of the Cold War.

Yes, "accurate characterization of preliminary results appearing on this blog" would not be a problem. This however is NOT what was posted on this blog, since there are no preliminary results out. And if you think for a moment that what you hear from the rumor mongers is THE TRUTH, just remember ATLAS'es 115 GeV higgs signal around Easter of last year.

Yuri

42. **LHC security kernel**
June 19, 2012

43. **Anon**
June 19, 2012

I think the blogs carrying these rumors have given a chance for many of us to feel the same "pre-we-know-for-sure" excitement before an official announcement that those in the collaborations and their friends with whom they share unofficially in the natural course of doing good science may be feeling. As long as the rumors are clearly labelled as rumors what is the harm that is done to science? In fact sharing a rumor on the internet as opposed to by word of mouth (that anyway happens) has the advantage that we know someone with a name and a face has originated it (on the internet)…..unless of course someone like Prof Matt doesn't reference the internet source in which case s/he becomes an independent source of rumors.

44. **Peter Woit**
June 19, 2012

Some more details about the Rubbia story, since I just did a little research, and many people may not know this history.

On July 4, 1984 CERN announced the discovery of the top quark by the UA1 experiment led by Rubbia, see here

http://cdsweb.cern.ch/record/714187/files/presscut-1984-011.pdf

The Princeton tea I remember must have been a couple months earlier, spring 1984, since I left Princeton summer 1984 and teas would have ended with the end of the spring semester. Rubbia wasn't just talking to physicists about this, see this May 9 story in the Christian Science Monitor:

http://www.csmonitor.com/1984/0509/050935.html

Of course it turned out that Rubbia's 40 GeV top quark was a mistake, with the real thing at around 173 GeV, and actual discovery waiting until eleven years later at the Tevatron. So, I'm not claiming Rubbia's behavior in this case as a good model for what the leaders of ATLAS and CMS should be doing…

45. **Thomas Wheeler**
June 19, 2012

Please keep sharing. I love your blog.

46. **paddy**
June 19, 2012

I second Thomas Wheeler's comments: thank you P. Woit. I need not, I think, go into why "blogs" provide some element of transparency which otherwise these days is not there. I also thank T. Dorigo for his insights (and will deny he has ever revealed anything he shouldn't have).

47. **Richard**
June 20, 2012

This "subvert the scientific process" prissiness is just hilarious.

The only people who *really* care about the results already know, via their own professional rumour mills, pretty much what is going on.

The only other people in the world who care are people like me: amateur science enthusiasts, washed-out graduate students, and technically inclined bystanders of the type any academic professional who cared about the political realities of funding his/her field would go out of their way to engage with; engage even to the awful, awful, awful, unprecedented level of letting slip bits of excitement and scandalous, terrible, non-peer-revived rumours.

Faster than light neutrinos were *really good* for physics. Higgs rumours are good for particle physicist's employment and for their grad students' prospects and for the public funding of incomprehensibly complex endeavours that no lay member of the public will ever comprehend except at the human drama level. Anything that gets anybody outside the experiments to give a damn about the way the universe works — and how science *really* works, warts and all — is good for humanity. These are massive, expensive, huge, public-funded collaborations, and human members of the public are interested in more than what a consortium Press Office approves for staged revelation.

As far as I know there's no neck-and-neck race on against the North Korean Muon Collider for publishing precedence and valuable electro-weak patent rights.

Pursed-lip tut-tutting about proper processes and the sanctity of Phys Rev B does nothing for anybody.

Save the secrecy and the dramatic revelations for blinded data analyses, where it actually does have any effect upon The March of Science.

48. **Anonyrat**
June 20, 2012

The New York Times: New Data on Elusive Particle Shrouded in Secrecy
http://www.nytimes.com/2012/06/20/science/new-data-on-higgs-boson-is-shrouded-in-secrecy-at-cern.html

Quote: Nobody who has seen the new data is talking, except to say not to believe the blogs, where a rumor of an enhanced signal has ricocheted around, and to warn that even if the signal is real, it may require much more data and analysis to establish that it actually acts like the Higgs boson and not an impostor.

"Please do not believe the blogs," Fabiola Gianotti, the spokeswoman for the team known as Atlas, after its huge detector, pleaded in an e-mail.

End quote.

49. **David Roberts**
June 20, 2012

Your New Scientist link is pointing to Wired's story.

50. **Peter Woit**
June 20, 2012

Thanks David, fixed.

51. **David Folsom**
June 20, 2012

Some great points Richard. I only half agree that super luminal neutrinos were good for science though. There are quite a few with influence in communities, churches, educational positions and politics that latch onto these things and say "See, they don't know what they're even talking about." The angle that those reporting the anomalous results were at least on some level asking for help in finding the error in their experiment is lost on that crowd (or even before that, at the media editor level).

All those people vote and have impact on science funding. The half agree part of me reminds myself that, as they say, there is no such thing as bad publicity. It's a thin crowd here in the "technically inclined bystander" demographic, but in reading your post, I'm reminded that I'm not alone.
.
Peter, I suppose the irony of "subvert(ing) the scientific process" by pointing out the lack of scientific rigor in string theory, etc. isn't lost on you. I hope you can at least find some humor in it. You're an inspiration. Thank you.

52. **Peter Woit**
June 20, 2012

Thanks David!

I agree that we could have all done fine without the OPERA business. I tried to ignore it on this blog….

Don't worry, I find the many accusations I've gotten over the years about how I'm ruining science quite a bit more amusing than upsetting.

53. **Anonyrat**
June 20, 2012

"You are subverting science but I cannot tell you just how, that too is a secret" – Strassler is all stressed out. And he cannot let go of his absurd position. One would think the effect of a blog post is to change the measurement! If the result is so fragile, the public needs to know that it funded a boondoggle.

54. **Anonyrat**
June 20, 2012

Peter, this risks going off topic, but the effect of having the 2011 results available is a far greater potential source of bias than any number of rumors. CERN really needs data analysts that know nothing about 2011 results, if the 2012 results are so susceptible to contamination. I read Strassler as not liking you, and so making up some reason or other to bash you. And if Strassler is in any way right, then this is a huge scientific scandal, billions spent on what is a very fragile result.

55. **Peter Woit**
June 20, 2012

Anonyrat,

I don't see any reason to take seriously Strassler's claims about the Higgs data analysis being compromised by my blog posting. The idea that it is that fragile is just kind of absurd.

You can be sure though that the experiments are doing the best they can with this very hard to see signal. It's been a topic of intense study for decades, and the situation of barely seeing a signal in one run, and trying to confirm it in the next is not exactly an unusual experimental design situation. I've heard a lot more this year about blinding and "opening the box". It's possible they are doing some things differently this year precisely because of the 2011 data, but I don't know. Tommaso Dorigo has been on the CMS statistics committee, so surely knows a lot about this, maybe he'll blog about it (after the results are made public).

56. **anon.**
June 21, 2012

This exchange has been remarkable and revealing. It's just about convinced me to completely stop reading one blog, and I don't mean this one….

57. **David Brown**
June 21, 2012

I see the Woit versus Strassler debate as a dispute over institutional control of information — both sides have some good points.

58. **Christian**
June 21, 2012

The notion that posting rumours of results can in any possible way subvert the scientific process is just absurdly precious.

They'd have to be an apology for working scientists that're working on the data if a bit of hype about what's been seen so far has any kind of affect on the outstanding work.

Heaven forbid the general public are allowed to get a teensy bit excited about the work (they funded) before the final results are in, eh?

59. **David Nataf**
June 21, 2012

Remember the Eot-Wash experiment?

There were rumors, sometime around 2006, that they had found deviations from the inverse square law at short distances. That didn't stop them from doing a competent analysis, and in the end their results were vanilla.

In that case I think the rumors were good for science. I was an undergraduate at the time and I thought it was really cool that these physicists were exploring fundamental science by basically building a super-sophisticated pendulum, aka applying classical mechanics. It certainly picqued my interest.

60. **Douglas Natelson**
June 21, 2012

Peter, your link to Chad points to a post of his from 2010. You want this one: http://scienceblogs.com/principles/2012/06/21/higgs-rumors-are-the-price-of-success/

61. **Peter Woit**
June 21, 2012

Thanks Doug, fixed.

62. **sasqwatch**
June 21, 2012

Only discovered your blog moments ago (through Coyne's "WEIT website posting"), though I thoroughly enjoyed "Not Even Wrong" a few months back. I also recommend Lee Smolin's popular works to readers here, having just finished
"Three Roads to Quantum Gravity". Thanks for continuing to make this stuff accessible. It is much appreciated!

63. **Yatima**
June 21, 2012

Woah this Higgs Discovery Meme is about to die of overexposure any minute now. But soon there will be another Greek Default or Lindsay Lohan story and things will calm down again.

I can only agree wholeheartedly with the sentiment that "pursed-lip tut-tutting about proper processes and the sanctity of Phys Rev B does nothing for anybody". Indeed. Getting stuffy in the ivory tower and making mysterious noises will just cause people to think one is in hock with the Synarchic Knights of Templar Rebirth to generate antimatter to kill the pope.

I'm off to quaff some beer while reading about quantum computing.

64. **Former CDFer**
June 21, 2012

Once upon a time I was a physics professor doing experimental particle physics in a large collaboration. My basic take is: an experimenter who finds that these rumors hamper their ability to search correctly for the Higgs is an experimenter who needs to turn in their badge and gun.

65. **M**
June 22, 2012

Actually the most important rumor/news is about the central value of the gamma gamma rates: in agreement with 2011 data they are ***(self-censorship)*** than what predicted by the Standard Model Higgs, both in CMS and in ATLAS!

66. **Neil Bates**
June 22, 2012

For a humorous interlude, here's my offering of what Dirty Higgsy had to say about all this:

I know what you're thinking: "Did we find five sigma, or only four?" Well, to tell you the truth, in all this excitement, I've kinda lost track myself. But being this is the LHC, the most powerful collider in the world, and would blow your mind clean off, you've got to ask yourself one question: "Do I feel lucky?" Well do ya, punk?

67. **Peter Woit**
June 22, 2012

M,

What are the uncertainties in the Higgs production cross-section? Could they be a fraction like **self-censorship** -1?

68. **jpd**
June 22, 2012

its the quantum theory of blogging:
posting a blog about an upcoming event changes the outcome of the event.

69. **lib**
June 25, 2012

Thanks for the post.
If the Higgs is found, how long will experiments continue at CERN in the field of dark matter research?

70. **Peter Woit**
June 25, 2012

lib,

The Higgs question very little if anything to do with the dark matter question. Research into dark matter will not be affected at all by what is learned about the Higgs at the LHC.

Higgs Discovery Announcement July 4

June 22, 2012
Categories: Experimental HEP News

I learned via [Physics World] that CERN will hold a press conference on Wednesday July 4 to give an "Update on the search for the Higgs Boson". More information has just [appeared] (including a press release [here]), showing that there will be a 2 hour seminar on the results starting at 9am Geneva time, followed by a press conference at 11am.

Reports from the experiments indicate that at least one of them, if not both, will reach the 5 sigma level of significance for the Higgs signal, when they combine 2011 and 2012 data and the most sensitive channels. So, this will definitely be the long-awaited Higgs discovery announcement, and party-time for HEP physicists.

One could note that the last major announcement of the discovery of a new elementary particle at CERN was also made on a Wednesday, July 4, back in 1984. That one didn't work out so well, but things are very different now, with results from two independent experiments and a high standard of evidence.

Comments

1. **Stan**
   June 22, 2012

   What particle was announced on July 4, 1984?

2. **Peter Woit**
   June 22, 2012

   The top quark, with a mass of about 40 GeV. Only problem is that the top quark really has a mass of about 173 GeV….

3. **Alfons Hoogervorst**
   June 22, 2012

   Long-time follower of HEP/Not Even Wrong here: A bit ahead of the news, unless you know more, Peter! (Because the press "ad" really says "update on Higgs search".)

4. **Peter Woit**
   June 22, 2012

   Thanks Alfons,

   There are some blogs out there with a policy of only discussing news approved by the relevant authorities. Not this one….

5. **Christian Takacs**
   June 22, 2012

   Please don't clobber me with criticism if I sound uninformed about this… but… though I do see all these articles, charts and graphs indicating something (large particle?) may have been found, I do not see anything (outside of a desire to find the Higgs) to indicate this IS the Higgs particle, nor do I see any explanation of how this will be demonstrated if a particle IS discovered. I would also ask, Isn't the Higgs boson/particle's existence based on the Standard Model's assumption that mass is granted, imparted, or virtually assigned by said particle? I just seem to be seeing lots of "There are indications of something there, if confirmed, it's the Higgs particle" statements. I see no mention of "What if it's just a newly discovered particle which is not the Higgs". I would just have thought they would first want to confirm that something was found, THEN go about some method to find out if the particle passes some falsifiable testing procedure for confirming it works as advertised.

6. **Peter Woit**
   June 22, 2012

   Christian,

   The Standard Model makes extremely detailed predictions about exactly what Higgs decays should look like, and the LHC experiments are carefully tuned to look for exactly these predicted signals. What they are seeing is exactly what they were looking for (with the interesting caveat that the production rate may be higher than expected, but that calculation is hard).

   So, either this is the Higgs, or if it's something different, you have to explain why it is doing precisely what the Higgs was supposed to do. Anyway, the big effort from now on will be trying to more precisely measure the properties of this signal to compare to the SM prediction.

7. **Anonyrat**
   June 22, 2012

   Continuing to subvert science, I see 🙂

8. **Eastender**
   June 22, 2012

   So who gets the Nobel prize ………

9. **SilverSB**
   June 22, 2012

   What will happen 4th of Jully is just the HEP will become less interesting. LHC is built to catch a Higgs, everything else would be a bonus (if the Nature is kind enough to throw at us hints for supersymmetry or dark matter at home-made energies – something I really doubt). So, yeah, the higgs is there. We have just saw the final battle in the first 5 minutes of the movie. How anticlimatic…

10. **emile**
    June 23, 2012

SilverSB: your are not 5 min. into the movie. The movie has been going on for decades… If a Higgs is confirmed, then I don't blame you from thinking that this would be anticlimactic. But if I've learned anything, it's that Nature doesn't care what we think.

11. **crandles**
June 23, 2012

So is pay $7 now to get $10 back if/when a paper is published in 2012 claiming a 5 sigma discovery a good bet?

Or is there too much chance that paper will wait for more information from different decay channels, and others hints of consistency with being a Higgs Boson and then be subjected to much scrutiny in peer review so that paper may not be published until 2013?

Or is there too much risk that judge will read a paper saying there is 5 sigma discovery of particle that is consistent with Higgs Boson as not being sufficient to say particle is the Higgs Boson? (If such a paper isn't sufficient, will anything ever be sufficient? and is that sufficient to ensure judge will decide that such a paper is sufficient?)

(Rules say "Confirmation of the Higgs Boson particle having been observed must be published in a major scientific journal for this contract to be expired.

Clarification (Jan 5th 2009): for the Higgs Boson particle to be "observed" there must be a "five sigma discovery" of the particle.")

BTW, there isn't much liquidity on this bet at intrade.com: 37 * US $7 is only pay US $ 259 to get US $370 less US $5 per month in fees less and bank/other fees for money transfers. Also by the time someone new to intrade gets that money into their intrade account, the opportunity might be gone. So probably not worth effort and risk for someone new to intrade.

(Now why do I suspect that Christian Takacs is an intrade trader?)

12. **SilverSB**
June 23, 2012

emile,
The LHC movie was decades in making, but only two years in playing. The Higgs is coming too soon, but the things are what they are.
Sure, Nature doesn't care what we think and what we want – it's not something we learned. It's something most people should understand.

13. **christian M**
June 24, 2012

Hi there,
Nice and happy news.

Just one comment/question.
We find allmost everywhere the misleading information that the Higgs boson gives mass. That is untrue in my opinion.
The Higgs boson is the trace left by something which gives mass. But not the boson itself. The scalar field responsible for giving mass has four degrees of freedom, three of which give mass to the W and Z. The fourth degree does not do anything. That's the Higgs boson. It is the remnant of this process. It's just an excitation mode of the scalar field, but it is the latter which gives mass.
That does not mean that it is not important to find the Higgs. It's like finding a trace left in the sand by a dinosaur : it proves that the dinosaurs existed.

14. **Henry Bolden**
June 24, 2012

[A rival Higgs discovery claim.]

15. **DB**
June 24, 2012

The Higgs will be the first fundamental boson discovered whose spin is not equal to 1. And the mass of 125GeV makes the building of a muon collider to probe the properties of the Higgs in fine detail a no-brainer. It also raises serious questions over the need for the CLIC upgrades to the LHC.

16. **Henry Bolden**
June 25, 2012

I'm hearing from someone (who does not wish to be named) who heard from someone else at the Perimeter Institute (whose name was not revealed to me) that the announcement on July 4 involves a Higgs which is NOT a Standard Model Higgs. Anyone else hearing this?

17. **Speculative**
June 26, 2012

Henry,

I'd be wary of anyone who is saying right now that we know the Higgs they're seeing is beyond the Standard Model. It will take a lot of careful measurements before we know for sure. If there is something about this particle that distinguishes it significantly from the SM Higgs that would certainly be very interesting and it might not even be the Higgs. My attitude is that we'll just have to wait and see until July 4th when more official data is released.

18. **Anonyrat**
June 26, 2012

It is time for corporate sponsorship, e.g., just like the MetLife Stadium, or the Citi Bank Arena, we could have corporations have naming rights on particles, such as the Disney Strange, the Dow-Jones Up, the Balenciaga Top, the Huggies Higgs. The proceeds of the sponsorships would go to support impecunious Superstringers, who promise to bring a whole lot of new particles and hence sponsorship opportunities, to the table. At least it would give some motivation for research. Some names might be already taken, such as Selectron Technologies' Selectron. Political parties might jump into the fray, such as the G.O.P. Dilaton. Social groups might enter the bidding too, such as the LGBT Spartner. The possibilities are limitless, we could further distinguish particles in different superstring vacua. With 10^500 possibilities, there will be enough for sponsorship by all the conceivable corporations the visible universe will ever contain. Hell, we can give each corporation sponsorship of an entire universe, why just a measly elementary particle?

19. **Tony Smith**
June 26, 2012

If the thing at 125 GeV “is NOT a Standard Model Higgs”
then
can they distinguish it from a non-Higgs particle such as for example
a technipion like that proposed by Eichten, Lane, Martin, and Pilon
in arXiv 1206.0186 (in the context of the CDF Wjj bump) ?

If it is not so distinguishable (and therefore not clearly any kind of Higgs),
then what should they call it ?

Tony

20. **Peter Woit**
June 26, 2012

Henry,

The signal seen in 2011 was already larger than the SM prediction (with large errors). The rumor that this year’s gamma-gamma signal is of similar size indicates that when they announce discovery next week, the size of the signal seen will not only be more than 5 sigma away from null, but also larger than the SM prediction.

There will be signals though in multiple channels: gamma-gamma, as well as ZZ to 4 leptons. The size of the signal is the product of the Higgs cross section x branching ratio. Whatever is observed, undoubtedly there will be dozens of theory papers promoting models supposedly explaining it. I’d love to hear from a Higgs phenomenologist about how good the SM Higgs cross-section calculation is, and what to look for in terms of deviations of the the signal sizes from the nominal SM predictions.

Maybe someone can convince Matt Strassler to stop complaining about what the recent NY Times article said about what nothing being seen would mean (which is irrelevant), and write instead about this.

21. **paddy**
June 26, 2012

Peter,
Not unusually you have hit the nail on the head–the things I have been wondering–and 3 times I might add:
(1) there are apparently hints of SM discrepancies in branching ratios–when does this become signficant?;
(2) uninitiated hep-ph folks like I would like to know the SM calculational “error bars” for such [fully of course realizing that the experimental notion of an error bar does not really apply]; and
(3) [at the risk of an understandably deletable ad hominem comment] I for one cannot fathom what particular axe MS has chosen to grind (this time).

22. **Anonyrat**

July 3, 2012

Yay, we’ve got a particle! Let’s just hope, it won’t turn into a difraction pattern when we stop talking about it 🙂

Higgs Update

June 28, 2012
Categories: Experimental HEP News

The Higgs discovery announcement will be at 9am next Wednesday. This is close enough that I can't reasonably be accused of "subverting the scientific process" and ruining the LHC Higgs analyses by reporting the results here. Unfortunately, no source has provided me with these results yet, so that won't happen anyway, at least not right now. However, I have learned the following, which may be of interest:

- On Monday at 9am Fermilab will try and steal a little bit of the LHC's thunder by announcing some new evidence for the Higgs from the Tevatron data. This uses the channel of a Higgs produced with a W or Z, the Higgs then decaying to pairs of b-quarks. This is a channel where the Tevatron is sensitive to a Higgs signal, but the LHC isn't (at the higher LHC energies backgrounds are too large).
- ATLAS and CMS each collected about 6 inverse femtobarns of data before the technical stop on June 18th, and they are rushing to get as much of it analyzed as possible. They are concentrating on the two most sensitive channels: H->gamma+gamma and H->ZZ->4l and are likely to have over 5 inverse femtobarns of 2012 8 TeV data analyzed in these two channels to present at ICHEP.
- There may not be any 2012 Higgs data from other channels presented at ICHEP. ATLAS will have a H->WW->lvlv analysis, but likely not ready for public release.
- To get the statistical significance necessary to claim a Higgs discovery, the experiments will be producing a combination of their best analysis of the 2011 data in all channels and the 2012 data in the H->gamma+gamma and H->ZZ->4l channels.
- There will be no CERN combination of ATLAS and CMS results publicly released. This is not because such a thing is hard to do (and I believe it is actually being done, just not released), but because of political reasons. I don't much understand these, but this blog entry gives some of the kind of reasoning being used.
- With no CERN combination, attention will focus on Philip Gibbs at viXra log who in the past has produced reliable unofficial combinations of data, and is likely to do so again.
- With the discovery a done deal, the attention of physicists will focus on the question of whether the signal being seen is compatible with SM predictions, or whether this new particle has unexpected properties. Here the main two numbers to look for are the ATLAS + CMS signal size in each of the two most sensitive channels. To get these, you can do your own combination of the separate ATLAS and CMS numbers, or wait for Philip. The signal size is a product of the Higgs production cross-section and the branching ratio for the channel. I've seen estimates of the reliability of the SM prediction of the cross-section varying from 15% to 25% (see more here). The branching ratios are much more accurately known.
- Probably nothing new about SUSY at ICHEP. New SUSY analyses are being targeted for the SUSY2012 conference in August.

Update: Resonaances has more here, including the news that CMS will report 2012 data about the H->WW->lvlv channel (about the significance of this, see the June 29 posting at viXra log), and possibly others. Whether the 5 sigma significance level will be reached by a single experiment remains unclear…

Update: Finally confirmation from a reliable media outlet… The Daily Mail reports God particle is 'found'. One evidence for this is that supposedly "Five leading theoretical physicists have been invited to the event on Wednesday". This may mean Englert, Higgs, Guralnik, Kibble and Hagen, with Anderson getting dissed as usual.

Update: Tommaso Dorigo is providing background to the imminent Tevatron announcement here, and I assume will be discussing the actual results immediately upon release. The papers with the results will be released here this morning.

Update: The interesting bottom line from the Tevatron is that they see an excess in the bb channel that the LHC is not sensitive to, of size 2 +/- .7 times that predicted by the SM for a Higgs of mass 125 GeV. So, a marginally significant signal, of size consistent with the SM. The LHC should soon report the sizes of such signals in 3 other channels. In a couple of days we'll have excesses in four channels, of sizes enough to claim discovery of a Higgs (or something very much like it, depending on how consistent the signal sizes are with the SM).

Update: The Tevatron paper on the Higgs combination is here. Most important number is the fit for the signal size for H->bb, for a 125 GeV Higgs. It's 1.97 +.74/-.68 (where the SM prediction is 1).

Comments

1. **Michael**
   June 29, 2012

   Dear Peter,

   nice summary of current rumors, that might be in the right ballpark. The CERN seminar will be very revealing, for sure. Concerning the ATLAS+CMS attitude toward combining results, Aidan's blog post has it right. It is very important that ATLAS and CMS establish independent evidence for a new particle of phenomenon and only combine once everyone is convinced that the discovery is real. There is a subtle but crucial distinction in the minds of experimental physicists when they know that their competitors might or might not confirm their results, and when they assume that they will and one will simply combine the results. Aidan and most collider physicists want to retain that distinction – and they are absolutely right in my opinion. Personally, I have no objection to Philip's unofficial combinations. But I don't agree with you that the reasons why ATLAS+CMS (not "CERN" by the way) are political.

   regards,
   Michael

2. **Peter Woit**
   June 29, 2012

   Thanks Michael,

   I see the argument about wanting independent discovery evidence. Still though, if neither experiment were to quite reach the discovery threshold, but the combination was well above it, few would take seriously official claims that the thing hadn't yet really been found.

   As the question moves to whether the cross-sections for different channels agree with the SM, it's going to be the combined values that people will look at. One could argue that providing the best combination is something ATLAS+CMS should be doing and not leaving up to Philip. In this case though, I guess anyone can add two numbers and divide by two….

3. **David Nataf**
   June 29, 2012

   Michael,

You wrote:

“There is a subtle but crucial distinction in the minds of experimental physicists when they know that their competitors might or might not confirm their results, and when they assume that they will and one will simply combine the results.”

Would you care to elaborate?

4. **Michael**
June 29, 2012

Hi Peter,

yes, for sure someone not on CMS and ATLAS very legitimately wants to see the combination. And an official combination will eventually be made. But first we need to see to what degree ATLAS and CMS agree, and that won’t happen in a serious way until the public announcement. This is why the combination comes some time after ICHEP (I honestly don’t know when). So there is no conflict between Philip’s unofficial combination and the unwillingness of ATLAS & CMS to make an official combination until well after ICHEP.

Hi David,

well, it is a question of wanting to avoid staking one’s reputation on a result that is later shown to be wrong. Think of the CDF di-jet anomaly, of muon bundles at D0, or of the OPERA anomaly for that matter. If you know you are measuring something that really exists, then you want to do the best possible measurement. That is challenging and stressful, for sure. But claiming to find new physics is the ultimate experience and no one wants to make a false claim and damage his/her career. So the emotions, mentality, fears and hopes are rather different when measuring something known and when claiming evidence for something new.

regards,
Michael

5. **OMF**
June 29, 2012

Two bucks says that the mainstream media makes an absolute hames of reporting the results and mass public confusion and ultimately annoyance ensues by Friday.

It’s the uncertainty principle of science reporting: (Significance of Story) x (Accuracy of reporting) < (Average Twitter post)

6. **Peter Woit**
June 29, 2012

OMF,

Actually I think the mainstream media has done a pretty good job on the Higgs, and will continue to do so next week. Part of this depends on CERN and the message they put out. In the interesting possible scenario of CMS and ATLAS independently having 4+ sigma but neither having quite 5 sigma significance, I hope CERN doesn’t try and add caveats, but sticks to claiming discovery.

Many of the problems in the past with bad media coverage of physics have been the fault not of the media, but of the scientists themselves. In this case there won’t be lots of theorists running around making ridiculous claims about string theory, etc. All the media has to do here is figure out that they should ignore Gordy Kane.

7. **Owen Patterson**
June 29, 2012

Could the Large Hadron Collider Discover the Particle Underlying Both Mass and Cosmic Inflation?

If the LHC discovers the Higgs boson or other theoretical particles, their existence could help explain inflation, one of the universe’s great mysteries

Full article here:

http://www.scientificamerican.com/article.cfm?id=could-lhc-discover-higgs-boson

8. **Peter Woit**
June 29, 2012

Owen Patterson,

A good example of theorists making grandiose claims in the press guaranteed to cause confusion. If you’re a journalist reading this, no, the Higgs discovery will not tell us about inflation and the Big Bang. If you’re a commenter who wants to discuss cosmology, sorry, that’s off-topic.

9. **Syksy Räsänen**
June 29, 2012

Peter:

This is an instance where your scepticism is misplaced. The Higgs field with a non-minimal coupling to gravity is a viable candidate for the inflaton, and in this case measuring the Higgs mass does tell us about inflation. (I am not commenting on the SUSY model also mentioned in the article, just a Standard model Higgs will do.)

10. **Peter Woit**
June 29, 2012

Syksy,

As far as I can tell, the various versions of this proposal discussed in the SciAm article have all sorts of problems, and hardly anyone takes them seriously. Polluting a serious discussion of real physics with implausible speculation about some relationship to the big bang is something theorists insist on doing far too often. Getting a story like this in SciAm to coincide with the discovery announcement of the Higgs does nothing to encourage the public understanding of this science, quite the opposite.

11. **Syksy Räsänen**
June 29, 2012

Peter:

I think you're straying a bit from your field of expertise! The original Higgs inflation model is taken seriously by the cosmology community (Wilczek, among others, has worked on it). I wouldn't recommend the above popular article for learning about the model. It's true that many people feel that the model has problems with ultraviolet completion and stability as an effective field theory, but there are no conclusive arguments.

12. **Peter Woit**
June 29, 2012

Syksy,

My point is just that theorists would do well to take a vacation on July 4th from promoting their favorite speculative ideas for which there is no evidence (such as Higgs=inflaton). The public and press deserve a break from having theorists trying to confuse them about what is solid science and what isn't. A headline about "source of the Big Bang discovered at CERN" is not what the field needs next week.

13. **piscator**
June 29, 2012

Agree with Peter completely. There are a million half-baked models of inflation out there and they don't become sensible just because a Nobel laureate worked on them. Next week is about results not speculation.

14. **gluino**
June 29, 2012

"I believe [the LHC combination] is actually being done, just not released"

I sincerely hope not. The CMS collaboration was only shown the combination this week. Personally I'd be pretty unhappy if ATLAS gets to see our results before I do!

15. **kbot**
June 29, 2012

Hi Peter,

The combination will eventually be done. The issue is that it requires the two collaborations to talk to each other to do the combination. The results are so new (putting all the latest data together) it won't happen in time for ICHEP. Of course if the two collaborations shared data it could be done faster – but the point is that you want the analysis to remain independent until they are finalized. That is one of the whole points of having two experiments in the first place. If you share data and information before you are finished with the analysis it ruins the independent confirmation of two separate results…

16. **Peter Woit**
June 29, 2012

gluino and kbot,

I may be wrong, but I was under the impression that the capability of doing a CMS/ATLAS combination was in place, just needing a limited amount of information from each experiment, and if one was willing to cut some minor corners, able to produce such a combination rather quickly. Philip Gibbs can do his version in a few hours if not less….

Now, getting both experiments to sign off on the result, that I understand can be time-consuming.

17. **Brian**
June 30, 2012

the Higgs is showing a small cross section into WW, which is quite puzzling.

18. **Christian**
July 1, 2012

Peter: Such a combination is, in fact, trivial if and only if one is willing to 'cut corners' as you say. These corners includes half-baked combinations of systematical error, which may be OK for Gibbs (I enjoy his page quite a bit), but certainly not OK for the ATLAS and CMS collaborations.

Regarding the cosmology: As long as the Higgs-Inflation model cannot make eg. a solid prediction of m_H = 125 GeV, even Wilczek should take a day off and enjoy the show.

19. **David Roberts**
July 1, 2012

The Daily Mail is being cited as a 'reliable media outlet'?? You're lucky they didn't claim the Higgs boson causes and/or cures cancer…
(evidence of their capability in this ridiculous article about scientific publishing: http://www.dailymail.co.uk/money/news/article-2160753/)

20. **Mithras**
July 2, 2012

Peter,

I haven't followed all of this for nearly as long as you have, but I was wondering about the "Anderson getting disssed as usual". Could you explain?

Also, I've made it through most of your book at this point, and have also finished The Infinity Puzzle, which you recommended. Is there another book or two you would recommend for those who wish to read about various aspects of particle physics?

Thanks!

21. **Jim Martindale**
July 2, 2012

Mithras,

On the right side of this web page there is a list of categories of links. Under the category "Categories" there is the category "Book Reviews". They're great. There are 26 reviews so far. I've read 'Massive' and 'Shape of Inner Space'. Both are excellent, as is 'Not Even Wrong'. Lee Smolin's 'The Trouble with Physics' is also great.

22. **Dave**
July 2, 2012

Anderson first came up with an early version of what is now known as the Higgs mechanism. This was (I believe) a non-relativistic approach in the context of solid state physics.

To leave him out of the festivities may well be unfair. Then again, he has been a vocal critic of particle physics so perhaps it makes sense not to invite the party pooper to the party.

23. **Peter Woit**
July 2, 2012

Mithras,

About Anderson, see

http://www.math.columbia.edu/~woit/wordpress/?p=3282

For other books, an older favorite is Crease and Mann's "The Second Creation". As Jim Martindale points out, much better than consulting my memory is to get the full list of book reviews I've posted here the past few years, which includes all the recent books on this topic that I've read through and enjoyed.

24. **David Derbes**
July 2, 2012

Not that it matters, but I was a research student of Peter Higgs's 1975-79. I have heard him speak about the history of his work more than once, and spoken with him about it many times. He invariably refers to about six or seven people, most especially Y. Nambu, G. Jona-Lasinio, J. Goldstone, P. Anderson and the other five guys recognized by the Sakurai Prize. (OK, that's nine.) He's a very modest person. For the longest time (and certainly for the four years I was in Edinburgh) he referred to "the well-known anonymous scalar" rather than a particle with his name on it.

It might be worthwhile reading the relevant papers anew. As far as I understand them, the Guralnik-Hagen-Kibble paper talks about giving mass to a vector, but there is a disconnected zero mass boson still about. That's not what seems to be going on in the data. To be blunt, there are a lot of people who deserve credit for the Higgs mechanism: the Sakurai Six, Phil Anderson and all the rest. But very frankly, the Higgs boson really seems to me to belong squarely to Peter Higgs. He may be embarrassed to have something named after him, but he deserves it.

25. **Anonymous**
July 2, 2012

@David Derbes

Things may get very interesting after Wednesday. According to articles it looks like many of those names will be at CERN over the next couple days.

Few points….

Until the Physics World Interview below (from a few days back), I never heard Higgs mention GHK – seemingly demonstrating a good understanding of Nobel math. I have seen the "Life of a Boson" speech in video and text a few times (recently and well after Sakurai Prize).

http://physicsworld.com/cws/article/indepth/2012/jun/28/peter-higgs-in-the-spotlight

Guralnik compares the papers in the GHK history posted on arxiv…clearly his view.

The History of the Guralnik, Hagen and Kibble development of the Theory of Spontaneous Symmetry Breaking and Gauge Particles

http://arxiv.org/abs/0907.3466

Additionally, the notion of zero mass boson in the GHK paper was posted on this blog in the comments section in the below link. Guralnik explains boson and how this differed from the Higgs paper (also inserted text directly from the above link).

http://www.math.columbia.edu/~woit/wordpress/?p=4306

The Beginnings of Spontaneous Symmetry Breaking in Particle Physics — Derived From My on the Spot "Intellectual Battlefield Impressions"
Authors: G. S. Guralnik
(Submitted on 11 Oct 2011)

http://arxiv.org/abs/1110.2253

p. 9

…

Recently it has been claimed that the GHK paper does not have the "Higgs boson". This claim astonishes us. We, far more than any of the other groups, keep very careful track of the degrees of freedom of our scalar electrodynamics model. On the bottom of the right column of page 586 of the GHK paper are the three equations for the leading order approximations to the 4 physical degrees of freedom. We observe that the two degrees of freedom of the vector field combine with one scalar boson to form the three degrees of freedom of a massive spin one vector field. There is one remaining scalar field, 2 in our notation, which in our approximation has zero mass. That this mass is zero has absolutely nothing to do with any dynamical constraint including the Goldstone theorem. The Goldstone theorem, if valid here, would only constrain the mass of 1. The zero mass is an artifact of how we pick the explicit action and the leading order approximation. This is different from the Higgs paper in that he puts in an explicit pure scalar interaction. In a 4 dimensional renormalizable theory that interaction is limited to being pure quartic. As was our practice mirroring that commonly used by Schwinger and associates, we did not put in this explicit quartic term in scalar electrodynamics but were fully aware that such a term is generated in higher approximations. Ultimately because, of renormalization, the GHK choice of the action is operationally identical to the one used by Higgs.

In summary, our purpose was to show that the Goldstone theorem did not constrain physical mass in scalar gauge theories. We demonstrated this generally and in a specific example. The mass of 2 happens to be zero in leading order, but as was obvious to us and every other experienced field theorist of that time, this would change order by order as the theory was iterated in a manner closely related to how it changes in unbroken scalar electromagnetism.

…

Hagen also spoke about this briefly in the Sakurai lectures.

http://www.youtube.com/view_play_list?p=BDA16F52CA3C9B1D

26. **David Derbes**
July 2, 2012

@Anonymous:

I have a friend who wrote a biography of Einstein (Walter Isaacson). A few years ago he was in Chicago because his daughter was looking at colleges, and my family and his family had dinner together. Aware of the "Nobel math" I asked Walter: Is the limit to 3 in the Nobel will? Said he: It is not. How did he know? "Because I've read the will." Historically and by tradition they never give the Physics prize to more than 3. But it ain't in the will, if Walter knew what he was talking about. I think the Sakurai folks did the right thing.

To be honest, I don't care personally if the Nobel folks wind up giving the prize to all of the living eight (R. Brout regrettably has died.) And I doubt Peter Higgs would care, either. He doesn't need the money (he doesn't care about money to tell the truth.)

As it happens 🙂 I have the first GHK paper in front of me. The Nambu-Goldstone potential is not present at all. I quote: (bottom of page 586, PRL 13 (20) 16 November 1964): "While one sees by inspection that there is a massless particle in the theory, it is easily seen that it is completely decoupled from the other (massive) excitations, and has nothing to do with the Goldstone theorem." It is also evident that their massive scalar has exactly the same mass as the vector. As far as I am aware, the to-be-announced scalar does not have the same mass as the W or Z.

I reiterate: Many people, including but not limited to Peter Higgs, came up, I believe independently, with the mechanism (by whatever name you want to give it.) I heard Peter use many names in connection with the work, and if I work at it I suspect I can find the relevant talks in which, prior to 1980, he gives GHK full credit for their work. That said, in my opinion, the scalar to be revealed in 36 hours or so belongs to Peter Higgs (if the data support this.)

27. **David Nataf**
July 2, 2012

Isn't Peter Higgs 98 years old? And he's getting on a plane? wow !

28. **Peter Woit**
July 2, 2012

David,

No, he's 83 and doing fine as far as I know.

29. **David Nataf**
July 2, 2012

"98 years-old" was said in reference to Peter Higgs in a talk I went to, by someone very informed, but now in hindsight I think what was meant is that they shouldn't wait the usual 15-20 years to award the Nobel prize, otherwise he'll be 98 years-old when they give it out.

30. **Anonymous**
July 2, 2012

David Derbes

You (and Walter) are smart and correct – it is not in the will (I knew that also). It is in the statutes.
>>>>>>>>>>>>>>>>>>>>>>>>
http://www.nobelprize.org/nobel_organizations/nobelfoundation/statutes.html

§ 4.
A prize amount may be equally divided between two works, each of which is considered to merit a prize. If a work that is being rewarded has been produced by two or three persons, the prize shall be awarded to them jointly. In no case may a prize amount be divided between more than three persons.
>>>>>>>>>>>>>>>>>>>>>>>>

I don't agree with you on the boson. It is clearly in GHK (but not stressed) and gains mass as it progresses in their model. They should have put in a sentence that stated and stressed "an essential feature of this theory is the boson" and it would have been more clear. 🙂

Will be an interesting Press Conference to watch with all those folks there…Englert can say boson was "obvious" and GHK can try to explain the massless vs. massive and degrees of freedom.

31. **David Derbes**
July 2, 2012

@ Anonymous:

Thanks for the clarification about the statutes, new information to me (and maybe also to Walter, who I will tell when I see him next.)

I clearly have no idea what the Nobel committee will decide. I am sorry that these statutes are in play (I would have liked to have seen N. Cabibbo get part of the Nambu award, for example, and Dicke/Peebles and Gamow part of the Penzias-Wilson award.) I think the Sakurai folks got it right, and would be happy to see all six (including the late Brout) split it. But it ain't up to us.

32. **Anonymous**
July 2, 2012

Pretty cool you know Walter Isaacson. I read his book 6 months back and thought it was great.

33. **Anonyrat**
July 3, 2012

Humorist Andy Borowitz has already had an interview with Higgs (the boson).
http://www.borowitzreport.com/2012/07/03/5-questions-for-the-higgs-boson-particle/

~~Proof~~ Evidence of "God Particle" Found

Besides the Daily Mail, the AP is now reporting Proof of "God Particle" Found. They include the caveat:

> But after decades of work and billions of dollars spent, researchers at the European Organization for Nuclear Research, or CERN, aren't quite ready to say they've "discovered" the particle…
>
> Senior CERN scientists say that the two independent teams of physicists who plan to present their work at CERN's vast complex on the Swiss-French border on July 4 are about as close as you can get to a discovery without actually calling it one…
>
> Rob Roser, who leads the search for the Higgs boson at the Fermilab in Chicago, said: "Particle physicists have a very high standard for what it takes to be a discovery," and he thinks it is a hair's breadth away.

which suggests that neither CMS nor ATLAS have quite managed to reach the 5 sigma threshold, and CERN remains dedicated to not discussing the obvious result of combining the data.

The AP report also has:

> CERN spokesman James Gillies said Monday, however, that he would be "very cautious" about unofficial combinations of ATLAS and CMS data. "Combining the data from two experiments is a complex task, which is why it takes time, and why no combination will be presented on Wednesday," he told AP.

From everything I've heard, my impression is that the reason no official combination is being produced is not because it would be technically impossible to do so on a time-scale of days, but because the decision not to do such a combination for ICHEP was made for reasons described here. The problem with this is that it may lead to a lot of confusing explanations like this in the AP report, which muddles how particle physics experiments are done and the obscure issue of 5 sigma/experiment or in combination:

> experts familiar with the research at CERN's vast complex on the Swiss-French border say that the massive data they have obtained will essentially show the footprint of the key particle known as the Higgs boson — all but proving it exists — but doesn't allow them to say it has actually been glimpsed…
>
> Roser compared the results that scientists are preparing to announce Wednesday to finding the fossilized imprint of a dinosaur: "You see the footprints and the shadow of the object, but you don't actually see it."

Better for CERN to just announce discovery and break open the champagne…

Update: Weird. The AP seems to have changed their title from "Proof" to "Evidence". This may be the first time in history that a media headline about particle physics is incorrectly pessimistic ("Evidence" usually means a 3-sigma signal, which existed last December, "Proof" would be a better way to describe a 5+ sigma signal, if that's what the combined CMS/ATLAS data shows).

Update: Curiouser and curiouser. I'm hearing that per-experiment combinations are around 5 sigma or above. Very unclear why the AP report is indicating no completely conclusive discovery announcement. Maybe the CERN administration is playing a game with us, downplaying expectations…

Update: As pointed out in a comment, Matthew Chalmers at Nature has

> The ATLAS and CMS experiments are each seeing signals between 4.5 and 5 sigma, just a whisker away from a solid discovery claim.

Update: The Atlantic covers the best blogs you should be reading to follow the Higgs story. They miss Resonaances and a few others. About me, they have:

> If the Higgs boson was a dead celebrity, Woit would be your TMZ — first to the scene, first to break it, and have it be right.

Comments

   July 2, 2012

   I have a bad feeling that this is just going to frustrate and confuse the public even more. I understand the arguments for and against officially combining the data to claim a discovery, and I see the merits of both sides, but given all the media buzz, it's going to seem now like a real let-down to much of the public if they come out speaking of it as simply "strong" evidence. Perhaps a compromise wording such as "we found it beyond a reasonable doubt, but we are going to continue to refine our analysis" might be in order. Of course, I'm not a particle physicist, and all this might be moot anyway, depending on how accurate this and other stories are.

   Of course, all this might be moot

2. **DB**
   July 2, 2012

   After the faster-than-light shambles CERN is playing it safe, and rightly so. It's taken nearly fifty years to get from prediction to validation, and it would be poor champagne indeed that couldn't wait a few more months to be uncorked.

   Let the media stew. When mankind looks back at 2012 five hundred years hence, the discovery of the Higgs Boson is all they'll care about.

3. **Dan D.**
   July 2, 2012

   DB,

   True enough. By the way, I found this article from Discovery News that is more clearly written (IMO) than the AP story about this issue:

   http://news.discovery.com/space/higgs-boson-discovered-120702.html

4. **Trulo**

July 2, 2012

The argument that there must be at least two experiments so that one can act as check to the other is understandable. In this case, however, I think it may as well be turned around. They won't combine CMS and ATLAS data yet, because they want to have a winner (like UA1 with the W boson), and the loser relegated to the role of verification (like UA2). Whatever. If both experiments see a 4+ signal separately, as far as I'm concerned is a discovery. And a simultaneous one, so a technical draw.

5. **Henry Bolden**
July 2, 2012

Here's what the journal Nature has to say:

http://www.nature.com/news/physicists-find-new-particle-but-is-it-the-higgs-1.10932

6. **Pumpkin Seeds**
July 2, 2012

Putting a Higgs "discovery" at exactly 5 sigma is a little arbitrary, isn't it?

7. **Peter Woit**
July 2, 2012

Pumpkin Seeds,

Well, you have to pick some number, and any such choice will be kind of arbitrary. The 5 sigma convention comes from wanting to pick a number so high that you're sure it can't possibly be a mistake. What CERN may be doing here though is taking that standard as a starting point and insisting on something much stronger: the 5 sigma can't come from combinations of the various different channels and different experiments.

If a single experiment were to report a 4 sigma signal at a certain mass in a certain channel, one might reasonably say that this wasn't absolutely certain to be a new particle. If you see several signals this size in two completely distinct experiments, all at exactly the same mass, then it's absurd to claim that doubt remains.

8. **Alp**
July 2, 2012

Could someone explain in simple terms how we know that this particle is Higgs (the same question Nature seems to be asking)? Is it due to very particular decay characteristics? How long will it take to confirm that it behaves as Higgs predicted?

9. **Peter Woit**
July 2, 2012

Hi Alp,

The standard model gives very specific predictions for the behavior of the Higgs, which are fixed by the distinctive properties of the Higgs field (spontaneous breaking of the SU(2) gauge symmetry fixes how it interacts with gauge fields, giving mass to fermions fixes its interaction with them). These predictions have for a long long time shown that if the Higgs mass is 125 GeV, it could not be observed until the energies and luminosities of the LHC were available, and then it should be seen with certain specific signal sizes in certain specific decay channels.

What the LHC experiments are seeing is, after decades of no such signal in these and similar channels, signals appearing in just the right channels, with roughly the right signal size. If this isn't a Higgs, it's something very like it.

The big question now will be seeing if the signal sizes in the various channels agree with the SM predictions. Initially the measurements of these sizes will be crude, but they'll get better with more data. The Tevatron signal today was 2 +/- .7 times the prediction. On Wednesday we should see numbers for 3 different channels from the LHC. Rumors are that some of them are larger than expected, one (WW) is smaller. These signal sizes though are just getting big enough to be sure they are there, so we're a ways away from a precise measurement of their amplitude. If these numbers don't agree with the SM, then you've got something that acts a lot like a Higgs, but is doing something somewhat different than expected, which would be quite exciting to find.

10. **Belizean**
July 2, 2012

In medicine if treatment is shown a couple of trials work to an accuracy of 3 sigma (< 0.3% chance of it being a statistical fluke), its unquestionably and uncontroversially regarded to be the discovery of a cure.

A 4-sigma signal would have a chance of less than about 6 in 100 thousand of being a statistical fluke, while a 5-sigma signal would have a chance of less than 6 in 10 million.

Peter is right in describing the press' uncharacteristic pessimissm as "weird".

11. **Peter Woit**
July 2, 2012

Belizean,

The particle physicist's use of statistics here may be somewhat over-optimistic, neglecting things like the "look-elsewhere" effect. But that's why the insistence on 5 sigma, otherwise 3 sigma really would be enough to claim discovery. In any case though, the numbers I'm hearing from the experiments correspond to a very, very high degree of certainty that they're seeing something at 125 GeV.

What's especially weird is the change in the AP headline. It looks like someone got upset at the initial "proof" headline (OK, "proof" is only really in math, but 5 sigma is a pretty close analog in science). I'm curious who decided to change it to "evidence", which is kind of seriously wrong here, since "evidence" is the standard term used for a 3 sigma signal, and we're well beyond that.

12. **Anonyrat**
July 2, 2012

In the annals of physics, what is the highest sigma signal that turned out to be spurious?

13. **Peter Woit**
July 2, 2012

Anonyrat,

Probably the best known example in HEP is the "pentaquark", where there were claims of 4-5 sigma observations, and this is probably the sort of thing CERN is worried about. I'm no expert on that story, but it seems to me somewhat different. For one thing, I don't think there's ever been a reliable theory predicting pentaquarks or how they should behave. So, if you start looking for the things, there's a monster "look-elsewhere" effect since you can look for them in all sorts of types of collisions and all sorts of channels. The scale of effort going into the LHC experiments and care taken in the analyses is way beyond that of the much smaller scale experiments that claimed to see pentaquarks.

By the way, I looked for the 1984 Rubbia top quark discovery paper to see what he was claiming. It's in Physics Letters B vol 147, page 493 (1984). I gather by the time they submitted the paper in October, their evidence had weakened from the July 4 time of the CERN announcement and press release. There's a reference to "a clear signal" but a caveat that "more statistics are needed to confirm these conclusions and the true nature of the effect observed". No quantitative statistical significance is quoted. It's clear that a statistical measure would be kind of irrelevant anyway, since they have a very small number of events and the problem is clearly whether they've actually understood those events, not exactly how many they are. All in all, a very different kind of analysis than the modern ones at CMS and ATLAS.

14. **Henry Bolden**
July 3, 2012

The Empire (Fermilab) strikes back, according to the New York Times:

http://www.nytimes.com/2012/07/03/science/physicists-inch-closer-to-proof-that-higgs-boson-particle-exists.html

15. **piscator**
July 3, 2012

In terms of sigma, remember DAMA have a continuing claim to have 10-sigma evidence for dark matter detection which essentially no-one believes. And recently OPERA had 6-sigma-ish evidence for faster than light neutrinos.

However the thing to remember with counting sigma is that all these experiments are big complicated beasts with lots of people working on them and lots of systematics that may or may not be understood. So when evaluating number of sigma we need more than just statistics – there also needs to be a sanity check about whether there are hidden systematics that may not be understood, or a bug in the code that leads to rubbish being spewed out.

So with DAMA, there is a 10-sigma evidence for annual modulation in their event rates – and this isn't doubted. However sceptics will point out that lots of potential systematics (such as the temperature) also modulate annually. So the significance of the claim relates to the ability of the experiment to control all annual modulations – and the judgement on this has nothing to do with `statistical' significance.

With the Higgs, (one of) the main channels is Higgs to 2 photons. The signal here appears as a bump on an otherwise smooth and falling distribution. It is hard to see how systematics could reproduce such a bump – particularly across two experiments and also with other supporting decay channels – making the `number of sigma' significance credible.

16. **piscator**
July 3, 2012

For further clarification: the bump in Higgs to photon-photon should be sharp and narrow, as the Higgs has small width. Such a sharp spike on an otherwise smooth distribution is very hard to reproduce by a systematic.

17. **SeanM**
July 3, 2012

What are the implications of a 125 GeV higgs for Susy? Does the LHC have enough energy to potentially find its Susy partner?

18. **Sven**
July 3, 2012

Hi SeanM,

a Higgs below 135 Gev was a firm prediction of the MSSM. So a 125 GeV Higgs (with somehow SM-like behavior) fits perfectly. However, it s basically impossible to derive the masses of SUSY particles, in particular scalar tops, from it. Anything between about 200 GeV up to (in principle) multi-TeV or even higher remains possible.

19. **SeanM**
July 3, 2012

Thank you Sven.

I thought because the higgs is relatively light it has to have a massive partner.

20. **Peter Woit**
July 3, 2012

SeanM,

To supplement Sven's answer, the problem with SUSY is that you have to break it somehow, and you can get a huge range of possibilities depending on how you do this. So, even once you know the mass of the Higgs, there are no definite predictions about other particles related to it by SUSY.

The interesting thing we'll learn soon is, at least crudely, what the cross-section x branching ratios are for several channels of Higgs decay. If these differ from the SM values, that will be very interesting, and surely there will be attempts to explain this in terms of SUSY. Note that, as far as I know, there are no SUSY predictions one way or the other about this.

21. **SpearMarktheSecond**
July 3, 2012

The Split A1 was an effect over 5 sigma.

It was most likely the result of experimenter bias.

Although the look elsewhere effect will now be greatly reduced, because the interesting region was already defined prior to accumulation of the new data.

But now the danger once again experimenter bias. It will be interested to hear how the experiments dealt with that problem… whether they were blinded and whether or not they applied changes after unblinding.

Looks like the Tevatron `hint' is all in H>b bbar. Curious, because the LHC saw better `hints' in H>gamma gamma… must be the terrific LHC em calorimeters.

22. **tdb**
July 3, 2012

SpearMarktheSecond,

The difference in channels between the Tevatron and LHC experiments really comes down to the fact that the LHC is pp, while the Tevatron is ppbar. In a ppbar collider the dominant Higgs production is qqbar->W(Z)->H W(Z) where the W(Z) essentially radiates a Higgs. These events are easy to trigger on because of the high energy leptons or missing energy associated to the W(Z) decay. A light SM Higgs primarily decays to bbbar, so this an easy thing to look for. Events with one or two leptons, lots of missing energy, and two b-tagged jets.

At the LHC where you have pp collisions, the dominant Higgs production is gg->H, where you get the Higgs and nothing else. The Higgs will still primarily decay to bbbar, but there's also ALOT of other QCD processes that will give you two b-tagged jets, so it's hard to "pick out" these Higgs events from the background processes. A light Higgs rarely decays to gamma gamma, but despite the low branching ratio this channel still gives the best signal to background discrimination at the LHC (at least in early data).

23. **CB**

Leaked CERN video confirming a new particle:
"News: Cern Higgs boson announcement: we have observed a new particle"
http://www.telegraph.co.uk/science/large-hadron-collider/9373653/Cern-Higgs-boson-announcement-we-have-observed-a-new-particle.html

24. **Redly Spent**
July 3, 2012

I love the Atlantic article. Right on the button. Well done Alexander Abad-Santos.

25. **paddy**
July 3, 2012

I havn't stopped laughing since reading the Atlantic article. I have already renamed some of my links as….well you know if you have read the article.

26. **David Kahana**
July 3, 2012

@Anonyrat

The signal for the `sub-millisecond pulsar' (1989B) that was `discovered' in the remnant of SN1987A by Pennypacker et al., being a simple frequency measurement, had an enormously high statistical significance. It was between 11 and 37 sigma depending on when the observations were made: it was an absolutely beautiful peak, way above the noise.

I remember that hundreds of suspect theoretical papers were written after the fact explaining how such an object could possibly exist. All of the ex post facto theory was very dubious because rotational velocities at the surface of such a quickly rotating neutron star would need to be very significant fractions of the velocity of light, and it was almost possible to imagine a high density equation of state soft enough to allow the thing to exist, and also allow for the supernova explosion. But that didn't stop the theoretical astrophysicists!

http://www.cbat.eps.harvard.edu/iauc/04700/04735.html

"The frequency of the pulsar during the Jan. 18 observation was tracked by dividing the data into independent half-hour runs; the statistical significance during these runs ranged from 11 to 37 standard deviations. The frequency exhibits a sinusoidal modulation; the 15 frequency measurements were within 5 percent (rms) of a sine function with a central value of 1968.629 Hz (barycentric), amplitude 3 x 10E-3 Hz (peak-to-peak) and period of 8 hr."

All theory aside, the `signal' turned out to be due to a resonance in a faulty radio camera: the experiment had two cameras: camera A and camera B, and it turned out the pulsar was seen in camera A but not in camera B. Pennypacker had to publicly retract the observation, but I don't seem to recall many retractions having been made by the theorists who explained it!

27. **David Kahana**
July 3, 2012

But the Higgs observation isn't likely to be in the same ballpark: the signal can't be misproduced so easily at CMS and ATLAS.

28. **SpearMarktheSecond**
July 3, 2012

Nice answer, thanks, tdb. Why is Higgstrahllung is not yet discernible at the LHC?

29. **tdb**
July 3, 2012

@SpearMarktheSecond

I'm far from an expert on the Higgs analyses, but I believe associated production, or Higgstrahllung, is about ~100 times smaller production cross section than gluon fusion; but bbbar decay for a ~125 GeV Higgs is ~1000 times more likely than gamma gamma decay. Of course then you have very different experimental uncertainties (b-tag efficiency vs. photon ID efficiency, etc.). To be honest I'm not sure how much data is needed for a Higgstrahllung channel to become a viable analysis at the LHC, but it's certainly more than the ~10 fb^-1 being analyzed now.

CERN: We Have Observed a New Particle

July 3, 2012
Categories: Experimental HEP News

A commenter here reports that a CERN video announcing that "We have observed a new particle" was released early, and is available here. Note that the language used refers to "observation" NOT "discovery", indicating that CERN has decided on a version of the 5 sigma discovery criterion that has not yet been met. "Observation" generally means a lower standard of evidence such as 3 sigma. However, it appears that they are sensibly playing this down, with nothing in the video mentioning the word "discovery" or their decision not to use that word. Most physicists likely will however use "discovery" to describe these results, since the combined CMS/ATLAS results should be way beyond 5 sigma (look to Philip Gibbs tomorrow for exact numbers).

In the video, there is reference to "very very strong evidence" for a narrow peak in gamma-gamma (presumably above 4 sigma, close to 5 sigma in each experiment), as well as "also evidence" for ZZ (4 sigma?) and "less conclusive" evidence in other channels.

Immediate Update: The word here is that CERN is claiming that this is just one of multiple videos made to cover all eventualities. Maybe tomorrow's version will substitute "discovery" for "observation"…

Update: As commenter Tim points out, this is a CMS video, not a CERN one, so it just refers to CMS results. Evidently CMS is not claiming "discovery", but that doesn't mean ATLAS doesn't have slightly better results and will make a discovery claim. Also, it doesn't show what CERN will say about the joint results of the two experiments.

Comments

1. **Tim**
   July 3, 2012

   Do note that Joe only speaks for CMS in this video.

2. **abbyyorker**
   July 3, 2012

   The Higgs boson is a solid prediction of the standard model no doubt: gauge invariance and renormalizability predict this esoteric particle and it has now been observed. It's great, if expensive, science.

   But let's face it: the hype is WAY overblown. It's just not that huge of a deal to merit multiple announcements. Last year we had celebrations of a "bump". Now we have an "observation" and not a "discovery". I am getting past giving a shit, to be honest, and I have a little physics background. I can't imagine what the average joe thinks about this hoopla. It's a sign of the decline that we spend so much bandwidth on this particle.

3. **King Ray**
   July 3, 2012

   Any word or details on possible variations from the Standard Model Higgs, such as in the gamma-gamma and WW channels?

4. **King Ray**
   July 3, 2012

   I think it's very important whether the Higgs is a Standard Model Higgs or something else. If it's something else, then that means that there's new physics ahead. Plus the search for the Higgs has eliminated a lot of speculative theories that many have worked decades on, now fruitlessly.

   Experiment makes theory bleed, and keeps it honest.

5. **David Derbes**
   July 4, 2012

   @abbyyorker:

   I completely disagree. (Disclaimer: Peter Higgs was my thesis supervisor, so I'm not unbiased.) This is the greatest prediction and confirmation since the 1919 eclipse by Frank Dyson and Arthur Eddington.

   That the taxpayers of Europe spent ten billion dollars on what amounts to a postcard of equations by a guy in 1964 is breathtaking. Not claiming Higgs is the equivalent of Einstein (that would be silly) but this prediction to me is as astounding as the bending of light (by the right amount.) There is nothing like the Higgs that we know of; a fundamental scalar? Wild. (Maybe it isn't fundamental, but who knows yet?)

   People have been chasing this beast for forty years. Anticipation alone justifies quite a bit of hype. Add to that the immense labor, frustration, investment of time and money of so many for so long, and it's not hard to see that this is really one hell of a day.

6. **Anonyrat**
   July 4, 2012

   This is the greatest prediction and confirmation since the 1919 eclipse by Frank Dyson and Arthur Eddington.

   I'd amend that that this is the greatest prediction and confirmation since the observation of the Z boson.

7. **David Nataf**
   July 4, 2012

   I'd be hesitant to say the Higgs is a more fundamental confirmation of theory than say, the Dirac equation's prediction of antimatter, or Schwarzschild's prediction of black holes, or Friedmann's prediction of an expanding universe, but yes, this is cool.

8. **BJM**
   July 4, 2012

abbyyorker says:
"…It's a sign of the decline that we spend so much bandwidth on this particle."

You're kidding!!!

In the general scheme of things, news on the Higgs is a blip amid the flood of meaningless celebrity gossip and mendacious political propaganda that comprises what is laughingly referred to as "news" these days. The "average Joe" will remain almost totally unaware of the Higgs "hoopla".

Happy Higgs Day

July 3, 2012
Categories: Experimental HEP News

I hear reports that mobs of possibly violent physics live-bloggers have massed outside the CERN auditorium where the Higgs results will be discussed tomorrow morning. I'm going to sleep through this, then wake up late tomorrow (it's a vacation day here…), have a leisurely breakfast and check to see where the numbers ended up, then try out Philip Gibbs's applet.

I don't know exactly what numbers the experiments will be reporting, but basically both CMS and ATLAS should each have 4 sigma-ish or better evidence for the Higgs in two separate channels, gamma-gamma and ZZ. So, that's four independent measurements of a narrow resonance, any one of which would be strong evidence for the Higgs. Best bet for one of these coming in at over 5 sigma is probably the ATLAS gamma-gamma result. Or, just combine any two out of four of these results using Philip's software.

Things to look for if you're following the talks and press conference:

- The "D" word. Will it be used? Kind of a silly question though. July 4, 2012 will go down in history as the date of the announcement of the discovery of the Higgs, no matter what people say tomorrow.
- What are the signal sizes in the two channels? You should be able to use Philip's applet to combine the CMS and ATLAS numbers, and get a combined gamma-gamma number and ZZ number. Are these consistent with the SM prediction? Already tonight, hep-ph is starting to overflow with phenomenology papers describing models where gamma-gamma is enhanced with respect to the SM. I guess that indicates that tomorrow's numbers will be higher than the SM prediction.

I hope there will be plenty of champagne involved!

Update: Today so far I've been mostly on vacation, celebrating Higgs/Independence Day by sleeping late, doing a short piece on TV for Al Jazeera, going out for an excellent lunch, and lying around in the air conditioning checking out the news from other sources (it's brutally hot out there…). Later maybe a movie, dinner and fireworks.

The news was pretty much as expected: a strong signal from both experiments in two channels, very close to a 5 sigma level when combined. CERN did the right thing by simply claiming discovery, avoiding the situation suggested by the early AP story, where they seemed to be trying to say that they weren't quite at the discovery level. For details, the slides are here, and the usual suspects (Philip Gibbs, Tommaso Dorigo, Resonaances, Matt Strassler) all did an excellent job of providing details in real time as they came available. Probably also other bloggers I haven't had time to look at.

I'm still trying to get together combined numbers for the signal size in the various channels. It looks though that in the ZZ channel the size is close to the SM prediction, 2-3 sigma too high in gamma-gamma (nearly twice the expected size). So, still compatible with the SM, but the gamma-gamma excess is intriguing. Theorists with even better information than me have already started yesterday flooding hep-ph with papers supposedly explaining it.

Now, back to vacation….

Comments

1. **Q. I**
   July 3, 2012

   Peter, you don't seem to be happy about the announcement.

2. **Peter Woit**
   July 3, 2012

   Q. I,

   Not at all. It's a fantastic achievement, and amazing after all these years to finally be exploring experimentally the Higgs phenomenon. I'm looking forward to seeing what the numbers say, whether they agree with the SM or not. Either way though, it's an important day and a time for the field of HEP to celebrate (experimental) progress.

3. **fred**
   July 4, 2012

   although this is great work by the experimentalists, lets also remember the great work of theorists predicting this phenomena about 40 years ago, back when it was impossible to directly probe anywhere near this kind of energy scale! A great triumph to the power of theory, logic, extrapolation, etc. All things that are currently used by theorists today to look ahead to the new challenges

4. **Chris Oakley**
   July 4, 2012

   It is curious that they should choose July 4 as the date to make the announcement. Maybe it was to give Americans something more meaningful to celebrate than disloyalty to the British crown.

5. **Yuval Sanders**
   July 4, 2012

   I was watching the announcement today and I wanted to comment here, since your blog is how I obtain a lot of particle physics news. CMS announced a 4.9 sigma confidence of the existence of a new boson that has decay channels identical to what would be expected of a scalar Higgs. ATLAS announced 5.0 sigma. They are careful not to claim discovery of a scalar Higgs, but they are announcing the discovery of a new boson.

6. **jg**
   July 4, 2012

   Both teams are being ultra cautious, but at the end of the ATLAS presentation of the 5.0 sigma result CERN Director General Rolf Heuer says "I think we got it, you agree?" and the audience go wild! (Well, Peter Higgs was a bit more restrained, but he did finally applaud too)

7. **A.**
   July 4, 2012

Both Incandela and Gianotti gave nice talks, even if they did try to cram too many details in. Clearly excited by the results.

Heurer's "I think we got it, do you agree?" fell rather flat. Clearly scripted to be the "one small step" moment of the conference, did anyone else notice the awkward pause before the applause started, during which the audience realised they couldn't really do anything but agree?

8. **csa**
July 4, 2012

http://cdn.memegenerator.net/instances/250×250/22942101.jpg

In addition to the whole "comic sans" discussion.

9. **csvargas**
July 4, 2012

Sorry, I'm not a physicist but as I understand, "what gives mass to the Higgs boson" is the Higgs field. In fact, the field would be the really important discovery and the boson would be just its proof.

Am I getting the picture right?

10. **TB**
July 4, 2012

Thanks for blogging, I've lurked for a long time, and I appreciate the clarity you bring.

A lot of talk about whether this is a standard Higgs or not. This non-physicist isn't sure what that means and what it's implications are. Seems people invested in multiverse theory are very excited about that, but I could be misunderstanding?

11. **MomentCaptor**
July 4, 2012

I am such a huge fan of this weblog; however, when are you going to respond? It's July Fourth in America already!!! I've been anxiously awaiting to hear your response now that the talks are over and the champagne has be popped. Let's have it!

12. **SpearMarktheSecond**
July 4, 2012

The bump at 125 GeV in gamma gamma definitely persisted in the new data, and in 2 experiments. It is impossible that the bump is a statistical fluctuation.

Didn't stay up for the talks, but the slides don't invest much effort in,`What else could this be?'. But the S/B is so low their aren't a whole lot of useful plots (like distribution of the events in time, space, etc) that could help. If it is a systematic problem, only clever graduate students and postdocs in the huge collaborations could know.

I think CMS's shifting of bin widths and final plot weighted by S/B are very odd, a bit of unwarranted massaging. Thought Atlas seemed more consistent.

The 4lepton signals seem fairly convincing too, and are quite convincing evidence that the gamma gamma peak is not a systematic effect. Liked CMS analysis better… used kinematics better.

All the rest is smush, except, maybe, the Tevatron.

13. **anonomous**
July 4, 2012

I should have gone to sleep but I couldn't help it and stayed up to watch the live webcast. What a great presentation – the excitement of watching it live was well worth it (especially the applause when Peter Higgs entered the room!). This has to be the biggest day in physics in the last 100 years!

14. **neo**
July 4, 2012

What are the implications of a *single* higgs @125-126GEV to SUSY extensions of SM? If the SUSY exists, should the LHC have detected multiple Higgs and not just one?

15. **Fred D.**
July 4, 2012

What is the actual probability that the discovered boson is something other than the Higgs? I would think that probability is very small.

16. **Casey Leedom**
July 4, 2012

So now that we "know" that there's "something" at 125GeV, would it be possible to construct a specific experiment/set of equipment to specifically look at this mass range in order to get more details more quickly?

17. **Sciency Sciencer**
July 4, 2012

Maybe they chose independence day because the US stopped funding their collider project and left it to a collaborative international effort?

18. **Peter Woit**
July 4, 2012

Fred,

Whatever they are seeing, its properties are close to those of the SM Higgs. From now on, attention will focus on measuring "how close". Quite possibly the result will end up being "it behaves exactly like the SM Higgs is supposed to, to within the accuracy we can measure". Much more interesting would be: "it behaves like the SM

Higgs, except it does X differently", which would be an exciting clue about how to do better than the Standard Model.

Casey,

There has been talk of muon-antimuon or photon-photon collider "Higg Factories", and now we know the energy they would have to be designed for. The problem with muons is their short life-time, but people are working on the concept. I don't know much about photon-photon colliders, but such a thing might be possible to build for less than the cost of the ILC.

19. **Obs**
July 4, 2012

As for the date, there's no need for conspiracy theories here — the annual International Conference for High Energy Physics (ICHEP) opened today in Melbourne, and the CERN seminar was synced with the opening reception (and not just the seminar — the LHC run schedule for 2012 was intentionally designed to produce as much data as possible before the conference.)

20. **Tony Smith**
July 4, 2012

Peter, as to muon colliders,
it is not the "… problem with muons is their short life-time …"
because relativistic time dilation takes care of that nicely.

The most serious problem is neutrino radiation.
See hep-ex/0005006 by Bruce King of BNL for details.

At first thought, neutrino radiation looks not harmful,
but in a muon collider the neutrino flux is so great that it irradiates
a lot of the surrounding land making it radioactive,
which secondary radioactivity is really serious.

If it were not for the neutrino radiation, it would be a no-brainer
to build a muon collider on the Fermilab site,
but the radiation would seriously endanger Chicago.

Maybe the Chinese Western Desert would be a good place to build it,
but a lot of development work could be done at Fermilab.

Tony

21. **Callum**
July 5, 2012

I have been looking for a comment on the difference between the CMS and ATLAS results – 1 GEV sounds a lot to me. Is this a result of experimental or analytical differences?
(sorry if this has been covered before…)

22. **piscator**
July 5, 2012

Callum: 1 Gev is not so big compared to 125 GeV. The error on the quoted results is about +- 0.6GeV for so a 1GeV difference is within 2 standard deviations so nothing to get excited about. If it persists as the error decreases then the experiments would need to look for systematic differences.

23. **Peter Woit**
July 5, 2012

Evidently at the Lindau meeting yesterday Rubbia made the case for a muon-antimuon Higgs factory, see here

http://physicsworld.com/cws/article/news/2012/jul/05/new-boson-sparks-call-for-higgs-factory

and here

http://www.newscientist.com/article/dn22021-physicists-propose-factory-to-spew-out-higgs-particles.html

Higgs, Higgs, Higgs

July 5, 2012
Categories: Experimental HEP News

I'm trying to get over my Higgs obsession, and move on to other topics, but one last posting about this for now…

The first thing to say is that this is the biggest thing to happen in fundamental physics in about 30 years (i.e. since the discovery of the W and Z). It's a remarkable event and huge success for high energy physics, vindicating at the same time the colossal efforts that have gone into making the LHC and its detectors work, as well as the theoretical framework of the electroweak part of the Standard Model. Today's New York Times has a front-page story by Dennis Overbye, above the fold, which is very well done. In general the press reports that I've seen have been quite good, with minimal speculative nonsense thrown in. According to Overbye, CERN DG Heuer made the right decision to go ahead and simply claim discovery only on Tuesday afternoon. All in all, CERN has done an excellent job of communicating this story to the public (except perhaps for the "don't believe the bloggers" business, but what else could they do…).

Attention will turn now to who gets rewarded for all this, in particular, who gets a Nobel Prize? Personally I think the experimentalists are first in line, and with no obvious figureheads, a prize for three groups: ATLAS, CMS and the CERN accelerator engineers and physicists would be highly appropriate. If it's not too late in their process, maybe this could even be done in time for this year's prize, announced October 9.

As far as theorists go, Frank Close has posted something about this here. With the restriction to three people, he argues for Englert, Higgs, Kibble. Personally I think Anderson deserves a piece of it, see here. There's also a good argument to be made that what has just been validated is not the older work on the Higgs mechanism, but the Weinberg-Salam model of 1967 (extended to quarks), and that has already been rewarded with a Nobel.

I've been trying to get accurate numbers for the signal sizes seen by CMS and ATLAS in the various channels, but the only information out there now is the slides from the two talks. Resonaances includes the crucial plot from each experiment giving the signal sizes normalized to the SM, and eyeballing these and averaging, one gets 1.0 in the ZZ channel, 1.75 in gamma-gamma channel, about .75 in the WW channel (only CMS reports 2012 data). In the bb and tau-tau channels, no significant signal is seen, but the expected signal size there is very small. The errors per experiment are something like +/- .4, which you can make your own judgement about how to reduce for the combination. The bottom line is that, within errors, everything is consistent with the SM predictions. The gamma-gamma channel is the one to watch, it is about 2 sigma high.

The DG also announced a new LHC schedule, extending this year's proton-proton run by two months, to mid-December. This will hopefully allow the experiments to each accumulate another 20 inverse fb of data, finishing this run and going into a two year shutdown with a total of 30 inverse fb to analyze and use to improve the results on the Higgs.

While this announcement is a great triumph for physics, unfortunately it significantly increases the probability of what has become known as the "Nightmare Scenario": a SM Higgs discovery and nothing else at LHC energies. Before the LHC results started to come in, this scenario and its consequences was easy to ignore, but we may be getting closer to the point where it needs to be taken very seriously.

Update: For a rather complete analysis of the data about the different Higgs decay channels, see this new preprint.

Comments

1. **Marc**
   July 5, 2012

   Alas, Nobel prizes (other than peace) can't be awarded to groups, so it can't go to the collaborations (if so, would they each get $200?). Any thoughts on what individuals would get it for the experimental discovery?

2. **David Derbes**
   July 5, 2012

   Peter, you're exactly right that the ATLAS and CMS teams deserve recognition, and it wouldn't be surprising if the next Nobel honored them first as opposed to the large numbers of folk behind the well-known mechanism. For one thing, there may be residual doubts about the Higgs-ness of the new particle (which I do not share, but very cautious people may have 'em.)

   All that said, had Brout not died, I think that the next Nobel should have gone to Higgs, Englert and Brout. I'm sorry that the Nobel statutes limit it to three; I have said here before that I think the Sakurai Prize committee did the right thing (though, now that I hear about the brilliant Migdal and Polyakov having had similar ideas, maybe they were short two.) I don't feel so strongly about Anderson who (a) has one, well deserved, and (b) did not, as far as I am aware, ever write down a model, not even a non-relativistic model. Were Nobels given for brilliant insights alone, Gamow would have won three (well, at least two in physics and maybe one in medicine/biology.) Frank Close's *Infinity Puzzle* is really excellent (and not only on weak interactions, either.) If he thinks Tom Kibble should get a third, the Nobel folks ought perhaps to listen to him. (Disclaimer: I almost went to study with Kibble and/or Salam, but very happily Peter Higgs took me on.)

   There are however two other avenues for a Higgs theory prize: give it only to Higgs and Englert; or give it to Higgs and Englert and a third not directly connected to the scalar, to be named later. I can think of several who might reasonably fit here. My only concern, very frankly, is that it come soon, as none of the founding fathers of this stuff are getting any younger, and they don't award 'em posthumously.

3. **Peter Woit**
   July 5, 2012

   Marc,

   If the obstruction to awarding the prize to groups can be overcome, this is the time to do it. And this case makes clear why it should be done. As far as I know, there's no sensible way to pick out specific people in CMS/ATLAS to award the prize to. On the other hand, if any experimental discovery is worth a Nobel prize, this one is. Effectively making HEP experimentalists ineligible for the prize, while instead devoting a lot of time to picking out theorists for their often somewhat obscure and marginally relevant contributions (the models BEHGHK worked with are far from the SM Higgs model that has just been experimentally validated) seems to me a really bad idea.

4. **Roger**
   July 5, 2012

   If the prize goes to Higgs-Englert-Kibble, then the tag line is going to be that the LHC did not find any new physics so they gave the prize for work done 50 years ago.

5. **Michael**
   July 5, 2012

   Hi Peter,

   I really like this particular post. Nice have something nice to talk about, eh? 😉

   Let me remind everyone that the Tevatron experiments showed their update just five days ago, on Monday. While their signals are not strong enough to claim evidence for a new state, and don't match the significance of the CMS and ATLAS results, the fairly significant excess in a bb final state (showing up in a the associate production VH channel) is an important piece of information. Apparently this Higgs boson does decay to bb at a rate close to what the SM predicts.

   I am puzzled that the CMS tau results show a deficit, but the statistical power of the tautau analyses is not strong enough for this to be important yet (especially since we do have the bb signal at the Tevatron). As you say, gammagamma is the interesting channel at present…

   regards,
   Michael

6. **Peter Woit**
   July 5, 2012

   Thanks Michael,

   You're right that I should have included the Tevatron bb result in the summary of signal sizes here. It's 1.97 +.74/-.68 (where 1 is the SM), so, a bit high, but not very significantly so.

7. **emile**
   July 5, 2012

   I would suggest that the prize be divided like this: one half to Higgs and Englert, one half to CERN (that would cover the LHC scientists, and the ATLAS, and CMS collaborations). They should find a way to make this happen, and make it happen this year before the theorists pass away.

8. **Beelzebud**
   July 5, 2012

   I'm curious about what happens if this "nightmare scenario" comes to pass. I'm a layman, so forgive my ignorance. If this plays out and nothing beyond the standard model is found, is it possible that the LHC could be upgraded to probe deeper, or would this pretty much require a whole new system to be built?

9. **neo**
   July 5, 2012

   "While this announcement is a great triumph for physics, unfortunately it significantly increases the probability of what has become known as the "Nighmare Scenario": a SM Higgs discovery and nothing else at LHC energies. Before the LHC results started to come in, this scenario and its consequences was easy to ignore, but we may be getting closer to the point where it needs to be taken very seriously."

   How does this finding "increases the probability of what has become known as the "Nighmare Scenario": a SM Higgs discovery and nothing else at LHC energies."

   125GEV Higgs is compatible with MSSM/SUSY and there is still the hierarchy problem

10. **Bob Levine**
    July 5, 2012

    I think the Higgs breakthrough signals not just a potential 'end of an era' in discovery in physics, but the end of the 'Nobel prize' approach to discovery itself. The heroic model of breakthroughs driven by individual genius, on the model of Einstein, Dirac and Rutherford is, as the whole LHC experience shows, a thing of the past. The first great advance in forty years required the work of literally thousands of experimentalists and, arguably, a dozen or so so prominent theorists at the very least, and the fact that there's so much room for debate about who deserves a share of the Nobel suggests that the award criteria for the prize should be rethought from the ground up.

11. **Marc**
    July 5, 2012

    Peter, emile –Alas, the restriction to individuals is explicitly in Nobel's will, so it can't be given to ATLAS/CMS/CERN. I agree that if there were ever a time to change it, this is the time, but it was Nobel's money, and his right to put those conditions on it.

    It would have been fun if Kibble's paper had been a little earlier. Then we would be talking about how vector bosons eat Kibbles to get mass.

12. **Seth Thatcher**
    July 5, 2012

    Peter, what do you mean that the excess in gamma gamma channel is intriguing and what could it mean that the signal is 2 sigma higher than expected. Any informed speculation for us physics junkies?

13. **Eli Rabett**
    July 5, 2012

    There is lots of precedent for giving the Nobel Peace Prize to groups (IPCC, IAEA, UN, Médecins Sans Frontières, etc., International Campaign to Ban Landmines) the Swedes merely have to get with the program

14. **Casey Leedom**
    July 5, 2012

    And in a somewhat fitting commentary on the entire announcement event, we have [What if Steve Jobs Had Discovered the Higgs Boson?](#) It's fun …

15. **Eric**
    July 5, 2012

At some point, there should also be a Nobel Prize for Ellis, Gaillard, and Nanopoulos for

J. R. Ellis, M. K. Gaillard and D. V. Nanopoulos, Nucl. Phys. B 106 (1976) 292

which basically told the experimentalists how to produce and search for the Higgs.

16. **cormac**
July 5, 2012

Nice post, but I disagree about the Nobel.
Q; Who cares? This discovery is bigger than any prize. It is too important to be reduced to 'who gets the prize'. For example, in the case of Higgs himself, having an important particle named after you is far more important (though it is a little unfair on the others)

I have an idea; perhaps physicists around the world should use this occassion as an opportunity to persuade the Swedish Academy of Science to relax their self-imposed rule. The three-body rule is an anachronism that has no relevance to the way science is done today, at least for experimentalists

17. **jg**
July 5, 2012

In Nobel's time Physics wasn't done by huge collaborations, and discoveries were often the result of the brilliant insight of a single individual or experimental work by a small group . Similarly for Biology and Chemistry.

I am sure that Nobel himself would have wished the rules be changed to reflect changing times.

Give the award to CERN/ATLAS/CMS, maybe donate the prize money to charity.

Higgs, Englert, Kibble etc have already had plenty of recognition (and honours), I'm sure they wouldn't begrudge the experimentalists their recognition.

18. **Peter Woit**
July 5, 2012

Beelzebub,

The LHC can be upgraded to produce more collisions, and that plan is already in place. In principle it can also be upgraded to go to higher energies (you need to design and build higher field magnets). There are also proposals for other machines that could get to higher energies. The problem with the "nightmare scenario" is that it suggests that if you do build a higher energy machine, you'll see nothing new, i.e. no new phenomena will appear unless you go to some astronomically high energy scale like the Planck scale, and that is way beyond any conceivable technology.

neo,

Finding a Higgs particle with exactly the right SM couplings is not evidence for SUSY, no matter how many people say that "125 GeV is good for SUSY" or something similar. It's evidence that for the non-SUSY SM.

As for the "hierarchy problem" argument, the popular version of it: "to stabilize the Higgs mass (125 GeV) or EW breaking scale (246 GeV), you need new physics at the TeV scale" has already fallen flat on its face. As far as SUSY goes gluinos and squarks limits are at 1 TeV and above (yes, the stop limit is lower, but there's no good reason for a light stop and every other squark heavy). I've argued endless here that the "hierarchy problem" is not so obvious unless you insist that you know what physics looks like at GUT or Planck scales, and want to keep those separate from the electroweak scale.

19. **Peter Woit**
July 5, 2012

Seth,

For informed speculation about what would enhance decays in the gamma-gamma channel, I suggest Matt Strassler's blog or Adam Falkowski's (Resonaances). They're phenomenologists who know lots more than I do about the possibilities. My general impression is that there are lots of models you can imagine, but nothing really motivates any particular one.

20. **yyy**
July 5, 2012

@Beelzebud
> If this plays out and nothing beyond the standard model is found, is it possible that the
> LHC could be upgraded to probe deeper, or would this pretty much require a whole
> new system to be built?
It would be very hard to increase LHC's energy: theoretically it is possible to change LHC's NbTi magnets to Nb3Sn ones and have 2-times stronger magnetic fields and double energy (28 TeV instead of 14 TeV) but the cost would be quite high.
Nevertheless properties of Higgs boson couldn't be measured precisely in the proton collider – high energy lepton collider must be built to do that and this would be next step. Currently 3 options are considered here: linear e+e- colliders (ILC or CLIC) and the recirculating mu+mu- collider (Muon Collider).

21. **Beelzebud**
July 5, 2012

Thanks for the information, Peter and yyy. I appreciate it.

22. **ohwilleke**
July 5, 2012

It seems that the only game in town based on the data to date to avert a "Nightmare Scenario" is the possibility that the diphoton excess relative to the Standard Model expectation will continue to appear and not fade into the realm of a statistical fluke.

If it does, you have some new physics (SUSY or a composite Higgs, perhaps) and good clues about where to look for it. If the excess fades as more data becomes available, then we are in the particle physics "desert" and it is likely there there will be "no new physics" at the LHC other than the discovery of a SM Higgs.

23. **Jim Rohlf**

July 5, 2012

Peter says "this is the biggest thing to happen in fundamental physics in about 30 years (i.e. since the discovery of the W and Z)" and I agree as I was there in the middle of it doing the analysis. The first Z event (after the W was in the bag) was found at midnight and I examined it for 7 hours before I called Carlo Rubbia at home and told him we discovered the Z. With 4 events we wrote the paper (see http://www.symmetrymagazine.org/cms/?pid=1000630). Now I am on CMS. This analysis is infinitely more complicated. There is a lot to do to show that this is the higgs. The lack of tau signal is a big deal because the Z -> tau tau is cleanly measured. In my opinion this (proving the higgs has been seen) will be difficult to do this this year and I have made two bets last December to that effect, one with my grad student and another with a CMS colleague. I hope I am wrong.

24. **neo**
July 5, 2012

For whatever it's worth Sean Carroll over at CV says "Preliminary thought #1: There is a "nightmare scenario" that particle physicists have worried about for years. Namely: find exactly the Standard Model Higgs and nothing else at the LHC. I personally assign the nightmare scenario very low probability."

25. **Thomas Wheeler**
July 5, 2012

Please don't get over your obsession with the Higgs. We are all obsessed with the Higgs
and will be for a long time. Any thoughts or information about the Higgs that you can share will be greatly appreciated .

26. **Peter Woit**
July 5, 2012

neo,

The arguments that Sean gives aren't very strong, and he admits that some of them, e.g. the idea that the Higgs is a "portal" to dark matter is just a "wishful hope". I also don't see how the idea that the LHC will solve the dark energy, strong CP or baryogenesis problems is much more than wishful thinking. About the "hierarchy problem" argument, that just hasn't worked out.

Maybe dark matter is a phenomenon that will be explained by the LHC. Could be, but I don't see a reason to assign this very high probability. And the other arguments he gives just don't seem to me to add up to a very high probability either. So, I think the "nightmare scenario" gets quite a bit more than "very low probability".

27. **SpearMarktheSecond**
July 5, 2012

Hooray for Jim Rolph. He is a gem!

If this particle is the Higgs… sure it will take a while to prove it. Not just with decays to b-bbar and tautau, but also no signals in ee and mumu (is that already done??) and c-cbar and 0-life jets. But if it is the Higgs it is super interesting what keeps it so darned light! SUSY is a good candidate… but whatever it is, it seems to have something to do with the Weak interaction, which is real interesting.

If this particle is not the Higgs… yoo-hoo, that is an even bigger deal.

28. **D R Lunsford**
July 6, 2012

What a great post, Peter, and don't we all have smiles on our faces? 🙂

Attention will turn to the excess in the yy channel, let's hear what you think.

A long distance since "String Theory, an Evaluation".

-drl

29. **Allan Rosenberg**
July 6, 2012

Peter, if you were the dictator of CERN, where would you suggest they focus their detectors, outside exploring the properties of the new boson?

30. **Peter Woit**
July 6, 2012

Allan,

My knowledge of experimental HEP is good enough to know I have no business advising people at the LHC how to do their jobs. As far as I can tell, they're doing just fine without me. About the only not very useful comment I can make that might be relevant is that they might want to not take so seriously what some theorists tell them about SUSY models…

31. **WW**
July 6, 2012

Hello,
Is it unreasonable to consider the 7 and 8 GeV CMS and ATLAS data as 4 independent experiments? In all of them an excess of about 2 has been observed in the 2 gamma channel. There is then a 1:16 chance for this to happen if it is only for statistical reasons.
For this and other oddities, I think it is really premature to discuss who of the theorists should get a
Nobel prize. If we eventually know better, this is clearly the merit of the experimentalists. Leaving them out would put the whole thing upside down.
[P.Higgs original paper was one page!]

WW

32. **David Nataf**
July 6, 2012

Peter,

When you have time, I'd love to hear your thoughts on the 4-sigma signal of a gamma-ray emission line (that could be a dark matter annihilation line) toward the Galactic center at an energy 130 GeV,

Discovery paper:
A Tentative Gamma-Ray Line from Dark Matter Annihilation at the Fermi Large Area Telescope
Christoph Weniger
http://arxiv.org/abs/1204.2797

Best analysis to date:
Strong Evidence for Gamma-ray Line Emission from the Inner Galaxy
Meng Su, Douglas P. Finkbeiner
http://arxiv.org/abs/1206.1616

The first version of the abstract of the second paper comments on how the energy is very close to that of the Higgs, I think they suggest the dark matter particle might decay into the Higgs. That is removed in the abstract of the second version.

33. **Peter Woit**
July 6, 2012

David,

My main thought about that is that I'm not an astrophysicist, and know pretty much nothing about the tricky subject of trying to extract some sort of dark matter annihilation signal from astrophysical sources. So, for this topic you have to go elsewhere…

34. **fred**
July 6, 2012

woits claims that the hierarchy problem requires us to known what happens at GUT or Planck scales is wrong. If the SM is correct to very high energies it is fine tuned. If it breaks down at a lower scale there is a chance to avoid the fine tuning. Those are just facts. we don't know which way it will go. will it be a fine tuned universe, or new physics? hopefully we'll be able to find out.

35. **truth**
July 6, 2012

what has so far been missed in almost all the discussions of the Higgs boson is the most central issue of all. Namely, the purpose of the Higgs boson:

THE ENTIRE PURPOSE OF THE HIGGS BOSON IS TO RESTORE UNITARITY!

The Goldstone models couple to the W, Z bosons to give them mass and the vev gives mass to the fermions. None of that requires the extra degree of freedom which is the Higgs boson. The only reason we have to add this extra degree of freedom is to ensure the theory is unitary at high energies.

So what the LHC has discovered is that unitarity is respected by nature. This is the real content of the discovery. It is quite interesting to me that unitarity is the guiding principle of string theory, i.e., string theory is the only known consistent theory of gravity that exactly respects unitarity. This is extremely interesting.

36. **A.**
July 6, 2012

Purely in terms of securing funding, I'm not sure the nightmare scenario is something to be feared. I think there's been sufficient publicity surrounding CERN and the Higgs that it's become part of the public and – more "importantly" – media conciousness, at least in certain European countries. Given the sickening power that the media has these days, such awareness will be all that's needed to make The Higher Ups sign off on the next accelerator proposal. (Scientifically, well, that's another matter, but if no-one tells them we've no clue then we'll probably get away with it.)

37. **Peter Shor**
July 6, 2012

Isn't the "nightmare scenario", that the LHC doesn't find anything other than the Standard Model, exactly what Occam's razor predicts? (Although I have been told that you can easily add sterile heavy right-handed neutrinos to the Standard Model, and that these could both explain dark matter and the low mass of the left-handed neutrinos [using the see-saw mechanism], so maybe Occam's razor actually predicts the Standard Model with added heavy sterile neutrinos. I don't know whether these could be observed by the LHC.)

38. **CWJ**
July 6, 2012

While I agree this is big, I think the discovery of massive neutrino was a bigger discovery of the last 30 years. The Higgs was long anticipated, and "merely" completed the Standard Model. Neutrino masses were the first, and so far only, extension beyond the original standard model. At the very least massive neutrinos compete with Higgs as a major discovery of the last 30 years.

To be sure, this is big…

39. **truth**
July 6, 2012

Peter I don't get your philosophy.

On the one hand you are saying that there is a good chance of the "nightmare scenario"; this is the scenario where there is a great desert between electroweak physics and whatever is the physics that relates the SM to gravity, and the other mysteries we have. Here you seem to be attacking phenomenologists for suggesting new physics would should up at the low electroweak scales.

On the other hand you dislike most research into quantum gravity, especially string theory. Here theorists speculate on physics at the highest of energy scales, possible related to the Planck scale, etc.

So you seem to be attacking both the PHENOMENOLOGISTS, who look at hints from the world around us, such as dark matter or hierarchy problems etc, to speculate on

"low energy physics" (meaning directly accessible energy scales).
But you are also attacking quantum-gravity THEORISTS, who use logical consistency and mathematics etc, to speculate on "fundamental high energy physics" (meaning not-directly accessible, as it might be Planckian, etc).

So you seem to be having your cake and eating it too. If someone thinks that new physics will show up just around the corner, you say that there is a nightmare-scenario that means there will be nothing. If someone thinks that new physics will come in at the Planck scale and formulates a theory of this, you say that this is just wild crazy speculation. So all groups of theoretical physicists interested in expanding our knowledge of the fundamental laws seem to garner your attacks. It seems rather illogical and inconsistent.

40. **truth**
July 6, 2012

Peter Shor,
I'm not sure that's what Occam's razor would say here. The Occam razor would say that the simplest explanation consistent with all the facts is probably the right one. Well, the Standard Model is not consistent with dark matter, unification, gravity, baryogenesis, inflation, hierarchy of scales, smallness of \theta angle, etc, i.e., various facts about the world. So Occam would prefer the simplest theory that encompasses all this, which cannot be the Standard Model, since it doesn't. After all, that's why we built the LHC.
Now I'm not saying that these things will show up at LHC. Some of them might, some might not. Its just that its unclear which way Occam's razor points with regards to the scales the LHC can probe.

41. **Peter Woit**
July 6, 2012

truth,

How about celebrating the experimental discovery of the Higgs with a one-week moratorium on hype about string theory?

As for my "philosophy", it's pretty much that hyping ideas that don't work is not a good idea, during Higgs week or any other.

42. **truth**
July 6, 2012

Of course I am celebrating the great experimental work. I am also celebrating the great theoretical work from almost 50 years ago to predict this. Quite amazing. Around 50 years ago theorists started putting together a highly abstract theory built on consistency, logic, and extrapolation of the principles of quantum field theory to understand the weak interaction. This was put together despite the fact that there was no direct experimental evidence for the Higgs whatsoever. Back then there were skeptics calling into question the audacity of such theorists to speculate on such high energy physics without the necessary experimental input, and physics was faced with a tremendously daunting task to ever sort it out experimentally. In fact we could even go back to the first observations of the weak interaction and the Fermi theory in the early part of the century. Well here we are, many decades later, finally seeing direct evidence that a consistent QFT describes the weak interaction (first the W and Z bosons were introduced to make the theory renormalizable, and then the Higgs to make it unitary; It was not some ad hoc set of ingredients, but the minimal set of ingredients necessary to describe a short-ranged interaction that mediates decays). Those so-called theoretical "speculations" were actually built on consistency and fundamental principles, and they proved to be entirely correct. This is the great accomplishment of theory and of course the follow up by experiment and observation many decades later. I would argue that theorists who study quantum gravity are engaged in the same qualitative exercise, even if there are skeptics who won't admit it. It is yet another great triumph of the scientific method.

43. **Roger**
July 7, 2012

't Hooft wrote an interesting letter criticising an attempt to expand the Nobel prize to include other areas (http://www.staff.science.uu.nl/~hooft101/NobelPrizesExtend_09.html). In some of these disciplines institutions would need to be acknowledged and not individuals. He's pretty much against it in those cases. I wonder what his attitude is to particle physics collaborations.

44. **The Fly**
July 7, 2012

I'm surprised to see that none of you paid attention to the most important thing Peter mentioned in his post: the two month extension of this year's run. Don't you wonder why this is? Ask a knowledgeable CMS experimentalist if you can find one.

45. **C.**
July 7, 2012

The ~2 month extension of the pp running at the LHC is to allow the experiments to gather as much data as possible on the Higgs decays before the long shutdown starting in early 2013. The schedule has been announced. The pp run will end December 17, at which point the machine will go into a "technical stop" until January 7. At that point operations will resume to prepare for the heavy ion run, actually p+Pb, which will go from January 17 to February 11. After that the LHC goes into the shutdown for the upgrades needed to double to the design collision energy.

46. **Chris W.**
July 7, 2012

In the latest issue of Symmetry Magazine, Joe Incandela draws an analogy with the discovery and *gradual* excavation of King Tutankhamen's tomb.
http://www.symmetrymagazine.org/cms/?pid=1000971

47. **someone2**
July 7, 2012

c.,

so p+Pb is the data what we need for precise obsevation for a certain model?

48. **C.**
July 7, 2012

The p+Pb running is not related to the Higgs physics. It does serve as a baseline ("cold nuclear matter effect") for the heavy ion physics program at the LHC where there are Pb+Pb collisions which happened in 2010 and 2011. The heavy ion physics program studies the Quark Gluon Plasma, an extended region of nuclear matter which has become so hot that the constituent protons and neutrons have melted into quarks and gluons and many more pairs of quarks and antiquarks have been produced. While the

ICHEP 2012 is the big international conference celebrating the pp type high energy physics, the Quark Matter 2012 conference in August at Washington DC (http://qm2012.bnl.gov/) is the premier conference in that physics. During the shorter heavy ion runs, the CMS, ATLAS, and ALICE collaborators are focused on acquiring that data.

49. **Mano Philips**
July 8, 2012

On the origin of mass; the hype seems to be that the Higgs field imbues all elementary particles with mass. Frank Wilczek (http://lanl.arxiv.org/abs/1206.7114) and Tom Kibble (http://www.scholarpedia.org/article/Englert-Brout-Higgs-Guralnik-Hagen-Kibble_mechanism)
tell a different story.
Kibble – "It is sometimes said that the Higgs field gives masses to all other particles, but that is not strictly correct. It is important to note that most of the mass of the nucleon in particular does not arise in this way. Only the masses of the quarks come from the Englert-Brout-Higgs-Guralnik-Hagen-Kibble mechanism. The larger part of the nucleon mass comes from a mechanism along the lines sketched out earlier by Nambu (see Englert-Brout-Higgs-Guralnik-Hagen-Kibble mechanism (history))."
Can someone explain.

50. **Peter Woit**
July 8, 2012

Mano,

In QCD the proton and neutron are massive, even in the limit as you take quark masses to zero. You can think of the mass as coming from the gluon field and from the phenomenon of confinement. This mass has nothing to do with the Higgs, would be there even without a Higgs. So, the statement that "all particle masses" come from the Higgs is inaccurate. You could claim that all "elementary particle masses" come from the Higgs. The proton and neutron are not elementary but composite states of quarks and gluons.

51. **Gilbert Weinstein**
July 8, 2012

"In general the press reports that I've seen have been quite good, with minimal speculative nonsense thrown in."

OK, this might be the exception that proves the rule, but I couldn't resist: http://on.msnbc.com/LI11Es

52. **chiz**
July 9, 2012

Nobel nominations have to be in by the end of January. The committee can add in extra names themselves, but, as I understand it, they have to do so before consideration begins.

53. **Juan Ramón González Álvarez**
July 12, 2012

And we can already find some people speculating that what was observed is not the Higgs, but a scalar top supersymmetric quark: "The Fermilab pair thinks that it could be emerging evidence for SUSY". Not that this would be considered seriously, but it made me laugh

Court Judgement in Nature/El Naschie Case

July 7, 2012
Categories: Uncategorized

Nature has finally won its court case against Mohamed El Naschie, see here. This was based on a 2008 Nature story by Quirin Schiermeier, which during the case was removed from the Net, but now is back up. The court found that this article was accurate, not libelous. I had talked to Schiermeier and was accurately quoted in the article. Over the past couple years, I've heard a few times from *Nature*'s lawyers that the case was in progress, but didn't know the details. The court judgement has full details, and is kind of interesting reading, it's available here (thanks to Hamish Johnston for pointing me to this).

I first came across El Naschie when a commenter back in May 2005 mentioned his papers here. It was immediately clear that the journal El Naschie was editing for Elsevier was highly problematic, and surprising that they hadn't done anything about it long ago. From the court documents it seems that they finally realized how much damage it was doing to their reputation and decided to shut it down, giving notice to El Naschie in June 2007. By then, much of the damage was done. If you talk to mathematicians who support the Elsevier boycott, the story of this journal is one that gets mentioned often as evidence for just how bad Elsevier's policies have been. It was the Elsevier problem that immediately caught my attention when I took a look at the journal and responded to the 2005 comment.

Neil Turok was brought in for the job of evaluating El Naschie's papers, and you can read the results in the court judgement. Perhaps the most striking thing about all this is not the weird El Naschie story or the problematic Elsevier story, but that it brings serious discredit to the British court system. This is a case that should have quickly been thrown out by any reasonable judicial system. Instead the defendant was forced to devote huge resources in terms of money and time to mount a defense. Many are pointing out that only a large corporate organization like *Nature* can afford to do this.

Update: There's an excellent piece in Nature this week by Quirin Schiermeier, the reporter who wrote the article about El Naschie that led to the lawsuit. While supported by Nature, he had to devote a great deal of time and energy to the suit, and he makes clear the intimidating effect on accurate reporting that the British libel system imposes, with effects reaching well beyond British borders.

   July 7, 2012

   The problems with British libel law have been recognised by the government after a successful campaign by free-speech and science-related interest groups. Actually, this has been a much debated issue in the UK ever since the British Chiropractic Association attempted to sue Simon Singh for stating scientific facts about Chiropractic in a newspaper column a few years ago. A libel reform bill is due to be debated in parliament this session (see http://www.independent.co.uk/news/uk/politics/new-bill-will-reform-libel-laws-7728516.html) and I am optimistic that there will be cross-party support. Hopefully, the El Naschie libel case will be the last of this sort.

4. **Anonymous Coward**
   July 8, 2012

   For anyone interested in the British libel issues, Ben Goldacre has written at length abouth this:

   http://www.badscience.net/category/libel/

   And the story about his book chapter is particularly chilling:

   http://www.badscience.net/2009/04/matthias-rath-steal-this-chapter/

5. **Roger**
   July 9, 2012

   That these people exist isn't a surprise. What is surprising to the extent to which he gained a foothold in the academic world. Why did Elsevier (a) appoint him in the first place and (b) carry out no meaningful oversight of the practices of the journal ?

   I guess we'll never know even though it would be useful information to prevent future problems popping up.

   I did a bit of internet digging on this story. There are quite a few pictures of El Naschie with Nobel laureates. He looks like a fan asking a star to pose with him. One picture, showing a large number of participants at an event, has been photoshopped such that it appears only he, Wilczek, Gross and t'Hooft were present and posing together. The original and manipulated picture are both available.

   The written judgement is interesting in that it shows by just how much El Naschie was driven by prestige. He demanded a one year "grace period" to step down from his editorship to avoid it looking like he was pushed.

   The details of the case (and of the man himself) become a little boring after a while since we all feel as if we know someone like him. The mystery is how he ever came to an edit an (apparently) respectable journal.

6. **Hamish**
   July 9, 2012

The answer to how he managed to maintain his charade is simple — he has (had) lots of money, which he used to both ingratiate himself within the academic community and perhaps more importantly, to bully his critics into silence.

7. **Roger**
July 10, 2012

Money can only take someone so far. This gentleman ended up founding and editing an apparently mainstream journal with no (or wholly inadequate) oversight.

8. **Bobito**
July 10, 2012

@Roger: Why these people exist, and how they exist is easy to explain. In my department there is a fellow who has published many of his papers in Chaos, Solitons, and Fractals. (These articles are without content). It had a decent impact factor, and so his curriculum was improved – in my country the curriculum is scored in a rigid manner in part by a paper count weighted by impact factor. People like this fellow have a vested interest in supporting people like El Naschie. They need overpriced incompetently edited journals – it gives them a place to publish articles which no one will read (if anyone read them, they might be discovered for what they are). Meanwhile, Elsevier makes money off the journal.

In countries with poorly functioning university systems, this sort of behavior can take a man to the top – his curriculum impresses outsiders – he is an editor, author of many papers with fancy titles, etc. – and with this he secures many grants – which he uses to further consolidate his position. When a system has within it few researchers of high scientific quality, and these people are struggling to find stable employment (as is often the case), there is no oversight or control worth the name, because those tasked with oversight and control lack the relevant scientific criteria. Charlatans can dominate the system. This situation is hard to understand if one has spent one's entire professional life in a typical US or UK university, where things work much better. One has to imagine that the a***** scumbag operators that are present in every department are all there is.

9. **StevenC**
July 11, 2012

For Elsevier, this could simply be just a simple oversight – the rubbish journal appeared to earn money, and Elsevier did not have enough resource to monitor every single journal that is under them… when eventually Elsevier did discover the journal was rubbish, they toke action, and El Naschie fought back.

I think the real punchline that we should be glad that the court did the right thing. I think there are more severe versions of the same problem in our society – rubbish journals may only affect careers of some, … and then we have Scientology and intelligent design which pretty use similar strategies to deal with critics (laugh – sorry if I get somewhat off topic or into politics).

One thing is that more respected university and insitutes did pay more attention will notice folks that publish only in small journals. I think it is impossible to weed out all the questionable elements in academia. I think many posters and readers of this blog will understand that just by looking at their own university or research insitute , and there always some folks that produce rubbish science who try whatever way to game to system to keep their career alive.

10. **OA_SOC_3=1**
July 12, 2012

Disclaimer: I was not involved in this case, although I know some of the principles.

The judgment by Mrs. Justice Sharp in El-Naschie v Macmillan impressed me as a paradoxical mixture of clarity, indirection, and oh-so-decorous evisceration of the Claimant, Mohamed El Naschie. A minor masterpiece of its genre, in fact.

The judgment is almost 100 pages long and contains much information not previously known to those not directly involved in the case. It constitutes a complete vindication of the public interest reporting by the journal Nature and their senior reporter, Quirin Schiermeier— and implicitly, of John Baez. I raise my glass to the victors!

But according to groups like Sense about Science and Index on Censorship which are working to effect long-overdue reform of the libel laws in the UK, the judgment does little to protect persons who criticize pseudoscience in blogs or other public discussion forums, or academics who debunk pseudo-scientific screeds or who in the public interest draw attention to apparent academic misconduct by their peers. It does nothing to protect "anonymous" referees reporting their scholarly opinion to a journal editor. And it does nothing to help people like Tim Gowers who are working to eliminate Elsevier's practice of forcing academic libraries to purchase subscriptions of dozens of minor low-quality journals in order to obtain a subscription to a major high-quality journal.

The judgment does set a precedent helpful to would-be reformers of UK libel law, but its only immediate effect may be to permit Nature to once again make available the Nov 2008 article by Quirin Schiermeier (which they did within minutes of the decision being handed down).

Because El Naschie has relocated outside the UK, it appears likely that Nature will not be reimbursed for its the legal fees arising from the three-year ordeal, which are said to run into the millions of pounds. The judgment probably does make it unlikely that El Naschie will be able to file further defamation lawsuits in a UK court unless he pays Nature's lawyers. But until the UK reforms its libel laws, other individuals will continue to threaten scientists, journals,and universities with defamation lawsuits arising from scholarly debate and public discussion of controversial issues in the public interest.

During the pre-trial discovery process, Elsevier took the unusual decision to voluntarily share with the defense team internal emails between El Naschie and his "supervisors" at Elsevier, and the judgment includes some excerpts. These snippets show that Elsevier had been concerned about the unusual editorial practices at CS&F for years, and by November 2008 they had in fact been trying for more than a year to remove El Naschie as editor. I had not known that.

In studying the judgment, I found it useful to construct a timeline (far too lengthy to post here) using this document and other sources. After doing this, I felt that I understood for the first time the hysterical tone of the many, many, many suspected sockpuppet posts in various discussion forums which took up the case of El Naschie. One of the Cafe bloggers assured me in Nov 2008 that there was much more to the story than was so far known to the general public, and now I think I know what he meant.

But I am also left with some unanswered questions, and hope that someone here can offer some insights.

I have long wondered why the universities did not band together years ago to sue Elsevier for effectively forcing them to pay thousands annually for such a completely worthless journal as CS&F became under El Naschie (the judgment makes it clear that this is the opinion not just of myself but of Mrs. Justice Sharp). Could the voluntary disclosure by Elsevier been intended to dissuade the universities from just such a lawsuit? By showing that they were in fact attempting to clean up CS&F, despite appearances to the contrary? The reputation of this company in academic circles probably does not make it likely that we will easily accept the more straightforward premise that Elsevier simply wanted to do the right thing.

The internal emails disclosed by Elsevier do however suggest that at least some Elsevier employees were genuinely concerned with quality control and wanted very much to remove El Naschie. The emails show that El Naschie responded to repeated demands for his resignation with (to paraphrase Mrs. Justice Sharp) an odd mixture of praise for the publisher, emotional pleas for mercy, and legal threats. This raises the question of whether Elsevier, which is said to be one of the wealthiest multinational corporations in the world, was actually deterred by legal threats from summarily firing their rogue editor. If so, this is just one more illustration of how current UK libel law makes it utterly impractical for all but a handful of publications (like Nature) or private individuals (like Simon Singh) to fend off even the most baseless of defamation suits. It is necessary to have not only the money but also the will; Elsevier clearly did not lack the first but may have lacked the second.

I learned from the judgment that Elsevier apparently bought CS&F and some other journals from Pergamon, and there are hints that they inherited from Pergamon a contract which was in some way unusual. I wonder whether this may have resulted in some strange legal obstacle bearing on the enduring mystery of why it took them so agonizingly long to fire El Naschie.

Another remaining mystery is the question of why Greiner and some other respectable people seemed to offer El Naschie "honors" which he plainly did not merit. A hint of one possible explanation might lie in an pre-Baez-blog email quoted in the judgment in which El Naschie pleads with Elsevier for a "face-saving" exit.

In the end I found the judgment to be quite depressing, despite the complete vindication of Nature, Schiermeier, and Baez. The reason is that it emerges that El Naschie and his close associates not only succeeded in creating and maintaining for decades a walled garden of pseudoscience under the imprimatur of a "respectable" publisher, but drew several non-scientists into the web of deception. And all for what? The impression I obtained from El Naschie's emails, quoted in the judgment, is that the ultimate motive may have been to support, not with money but with the academic appurtenances of a "respectable man", an elegant lifestyle which included good dining with a circle of loyal admirers of the self-styled "genius".

Are there any lessons to be learned from this shabby affair? I suggest these:

1. Scientific journals must have public quality-control measures in place in order to prevent abuses, which must have teeth, and which must be enforced,
2. Publishers of such journals MUST maintain the financial and legal resources AND THE WILL to remove rogue editors "for cause".
3. Parliament MUST act decisively during this session to reform UK libel law along the lines suggested by organizations like Sense about Science.
4. Congress should enact its own laws preventing US bloggers from threats of libel actions in the UK, Egypt, Turkey, and other nations whose laws fail to address the need for open debate on issues in the public interest, including scholarly debate.
5. Prominent scientists should not set up as the editor of a new journal a young scholar lacking a scientific reputation established upon unquestionably solid research, even if they claim to consider him a "genius". Putting so much power into the hands of someone of unknown scientific aptitude, untried character, and untested judgment is simply unwise, and risks embarrassment for the profession and personal disaster not just for the editor, but for his family and employees.

One minor footnote: there was at least one well-informed comment criticizing El Naschie's so-called "E-infinity" so-called "theory" even earlier than the 2005 thread in this blog
http://www.math.columbia.edu/~woit/wordpress/?p=192
and the 2008 thread in N-Category cafe which resulted in Schiermeier's news story. A 2004 thread in physicsforums.com featured mostly uncritical praise of El Naschie's "E-infinity theory" [sic]— in hindsight, one might say that these posts have a familiar ring. But the thread also included one critical comment from an established poster, Chronos, who drew attention to the 2000 incident in which arXiv editors removed the claim of DAMTP affiliation from a preprint co-authored by El Naschie; see #17 in
http://www.physicsforums.com/showthread.php?t=53682

11. **Peter Woit**
July 12, 2012

OA_SOC_3=1,

Thanks for the excellent summary. To me, the questions about Elsevier are

1. When did they first realize the problem with El Naschie, and why didn't they take action earlier?

2. It's easy to remove an editor who goes willingly, but in this case they had to be willing to act forcefully and go to court if necessary. It seems that for quite a while they were well aware that they were putting out and charging money for a disastrously bad journal, but didn't want to go through the trouble necessary to deal with the situation. They have paid a heavy price of their reputation for this choice.

12. **OA_SOC_3=1**
July 12, 2012

According to my timeline, it appears that some Elsevier employees were very mindful of the damage which El Naschie's antics were causing to their reputation, and by Oct 2006 at the latest, they were trying to have him removed:

18 Oct 2006:
Charon Duermeijer (Elsevier's quality-control person) emails her own supervisor, Martin Tanke, expressing concerns about the strange referee practices at CS&F, and naming 30 Jun 2007 as the "next opportunity" to remove El-N; a three-year contractual cycle, mentioned elsewhere in the judgment, may suggest that a previous effort in June 2003 had failed.

13 Jun 2007:
First letter terminating El-N as editor effective 30 June 2008, signed by several persons including David Clark, Publishing Director at Elsevier

21 Jul 2007:
El-N writes Elsevier complaining about changes to board of CS&F
…
4 Dec 2007:
Elsevier letter to El-N explaining reasons why they insist that El-N retire as editor
…
23 Jan 2008:
Letter from El-N to Elsevier insisting upon condition that something "does not touch my status as Editor-in-Chief"

26 Mar 2008:
Elsevier internal email states ""We are increasingly concerned that lax or inconsistent peer reviewing, plus questionable editorial standards, have severely damaged the reputation of the journal and threaten Elsevier's reputation for upholding scientific standards".
…
19 May 2008:
Email from Elsevier to El-N

21 May 2008:
Email from El-N to Martin Tanke boasting that CS&F was "without a trace of doubt the best journal publisher in the history of the profession"

29 May 2008:
Email from El-N to Martin Tanke pleading ""all I really want is a return to the immaculate relationship which has always prevailed between me and my publisher."

5 Jun 2008:
El-N meets with Martin Tanke, who insists that El-N retire.

6 Jun 2008:
El-N email to Martin Tanke pleads "I want an exit and an honorable one. I am 65 and intended to resign in 3 years anyway… After working for so long…I should not be kicked out like that, and I will not be, come what may… I need a minimum of one year grace period for an exit…"

…
29 Oct 2008:
El-N email to Martin Tanke requesting 4 months grace period

5 Nov 2008:
El-N email to Martin Tanke requesting 4-6 months grace period "so that I do not loose face"

9 Nov 2008:
John Baez, "The Case of M. S. El Naschie", N-Category Cafe

18 Nov 2008:
El-N email to Martin Tanke finally accepting his retirement

26 Nov 2008:
Email from El-N to Martin Tanke

27 Nov 2008:
Quirin Schiermeier, "Self-publishing editor set to retire", Nature

A few more links for the curious:

Permalink to an html version of the judgment, 6 July 2012:
http://www.bailii.org/ew/cases/EWHC/QB/2012/1809.html

The 2000 arXiv eprint coauthored with Carlos Castro, with a note from the arXiv staff saying "The incorrect affiliation of M. S. El Naschie was removed" (the falsely claimed affiliation was "DAMTP, Cambridge University, Cambridge" as you can see from v.2):
http://arxiv.org/abs/hep-th/0008056

13. **Peter Woit**
July 12, 2012

OA_SOC_3=1,

Besides the question of why it took until 2006 for them to be aware of the problem (if it really was that long), the next question is why El Naschie wasn't fired for cause in 2006, with Elsevier instead negotiating with him about his retirement into 2008. It's hard to believe that their contract with him allowed the kind of behavior he was engaged in .

14. **OA_SOC_3=1**
July 12, 2012

Yes, Elsevier certainly should have been well aware by 2000 at the latest that El Naschie was behaving badly:

15 Aug 2000:
arXiv staff remove false claim of DAMTP affiliation from eprint coauthored by El-N; email quoted in judgment indicates El-N thought this was due to a complaint from Michael Green

9 Apr 2001:
Acting on complaints from 5 genuine DAMTP faculty members, Prof Timothy Pedley, Department of Applied Mathematics and Theoretical Physics, DAMTP, Cambridge University, requests El-N to stop claiming academic affiliation with DAMTP
According to judgment, El-N responds with legal threats
…

15. **Mathematician**
July 14, 2012

I read the judgement out of curiosity. I was surprised to learn that El-Naschie chose to represent himself early on? (he had a law firm representing him at the beginning, but then he dropped them it seems?)

16. **Impartial Commenter?**
July 18, 2012

Please allow me to make what in my opinion looks as an impartial comment.
I have been following this case for some time now on both its scientific and non-scientific fronts, and I can add the following points:
1- To be more more accurate, it should be stated here that El Naschie was in fact the founding editor of the journal Chaos, Solitons & Fractals. It was first published by Pergamon then bought by Elsevier. So, he was not appointed by Elsevier as the editor of this journal.
2- The court judgement dealt exculisevely with the non-scientific side of the case. This has been made very clear by the new judge Mrs Justice Sharp, who replaced the first judge Mr Justice Eady for undeclared and, hence, unknown reasons. Mrs Sharp also repeated in her judgement that the scientific aspects of the case were left for judgement by standard scientific debate in standard scientific circles. Also, the "expert witness" to the defendants, Prof Turok, stated it clearly in his witness statement that he is not an expert on the pure scientific aspects of the matter, and that his witness statements dealt only with the other aspects of the matter such as the excessive number of papers published, their refereeing if any, their clarity and completeness, misprints and misnomers in them, etc.
3- I haven't personally seen so far a detailed scientific discussion of the scientific aspects of El Naschie's work published in scientific circles. His work hasn't been so far proved to be partially wrong, completely wrong or "Not Even Wrong". He claims that his work is based on the use of "transfinite sets", "fractal geometry", "Cantor sets", etc and their application to quantum physics in a new way. I know that these concepts are new to physics and have also been controversial in the mathematics community for some time. So, one cannot exclude that there may exist some misunderstanding of his scientific ideas which many see for this reason as pure numerics of no scientific

value. This last point shouldn't be taken as implying that his scientific ideas are correct, but it could also imply that they shouldn't be also decided as completely incorrect unless an impartial scientific debate is done and finalized. It also shouldn't be understood as implying that his editorial behavior, which is another matter that has been judged by the court, is justified. On the contrary, the court judgement may have implied that the misunderstanding of the scientific aspects of his work could be understood as being partially due to his incoherence and other presentation problems in his publications.

In the light of the above remarks, may I call for an impartial pure scientific debate about the scientific ideas of El Naschie to put the scientific aspect of his case to rest, as it hasn't been finalized by the court judgement in my opinion. This would be more in the interest of science than anything else that may have been exclusively the job of the court and was finalized.

Thank you.

17. **Impartial Commenter?**

http://www.math.columbia.edu/~woit/wordpress/?p=192
and the 2008 thread in N-Category cafe which resulted in Schiermeier's news story. …, Chronos, who drew attention … ."

I, as a humble mainstream physicist, have accurately and repeatedly read what has been written in 2005 on the webpage indicated above, and also what has been discussed in the 2008 thread in the N-Category cafe website, and cannot be able to see in them a detailed pure scientific discussion which can qualify as the "standard scientific discussion in standard scientific circles" referred to by Mrs Justice Sharp in the court judgement. This criticism applies more to the comment made earlier in 2004 by commenter, Chronos, on the physicsforums.com website which touched only on El Naschie's possible misuse of affiliations. We know, as scientists, that any scientific research paper is usually, and in most standard cases, refereed by at least three independent impartial experts to qualify for publication in a respectable scientific journal. Then, how can any one be convinced that these type of comments and opinions can be considered as final decisions on the pure scientific aspects of the case? I make this additional comment with the a priori understanding that the court judgement have indicated that some of El Naschie's papers may have not been properly refereed, and with all due respect to the people who have made the comments referred to above and their scientific standards and integrity.
To my knowledge, there are no other places where one can find the required detailed scientific discussion, but I may be wrong.

18. **Peter Woit**
July 18, 2012

"Impartial Commenter?" appears to be an El Naschie sock-puppet, writing from Cairo. Any reading of the court judgment will make clear that his claims are nonsense (see for instance point 120 of the judge's decision). Everyone who writes nonsensical papers about physics making grandiose claims wants to get other scientists to waste a lot of time reading their papers and trying to extract something intelligible from them. In this case, due to the dysfunctional nature of the British legal system, a highly competent physicist, Neil Turok, spent a lot of time on this, and the results are available in the court judgment. I strongly discourage anyone from wasting more of people's time indulging El Naschie (or his sock-puppet) in this regard.

19. **OA_SOC_3=1**
July 21, 2012

Anyone interested in this case who lacks the time to read Justice Sharp's clear but lengthy judgment, cited above, may wish to study instead the able summary by the UK-based legal writer Gervase de Wilde
https://inforrm.wordpress.com/2012/07/18/case-law-el-naschie-v-macmillan-claim-against-scientific-publisher-dismissed-gervase-de-wilde/
He sums up the case by saying: "The Claimant's defeat could hardly have been more comprehensive, with all of the … defenses [by Nature] succeeding and [El Naschie's] own integrity, as a scientist and as an individual, questioned by [Justice Sharp] throughout her judgment. If [El Naschie's] intention was to suppress questioning or criticism of his work then the strategy backfired spectacularly."

The substance of the comments criticizing the conduct of El Naschie and the dubious scientific merits of his CS&F papers, comments which appeared in on-line forums such as a Physics Forums thread in 2004, Peter's comments in this blog in 2005, various discussions of the work of Garrett Lisi which were hijacked by suspected El Naschie socks, the N-Category Cafe post by John Baez in 2008, and dozens more which appeared after the publication of the Nature article by Schiermeier, were found by Justice Sharp to be entirely correct:

1. The criticisms leveled by Baez, and echoed in court by Nature's expert witness, Neil Turok, that El Naschie's papers exhibit "a failure to define terminology and concepts, conclusions unsupported by reasoning, and meaningless, obscure and simply wrong statements", were all found to be justified on the facts.

2. The assessment by Baez and others that these papers lack any discernible scientific merit was found to be a reasonable conclusion.

3. The suspicion expressed by Baez and others, that CS&F appeared not to be following accepted practices of editorial review, was found to be fully justified: Justice Sharp concluded that El Naschie failed to produce any documentation of any CS&F referee reports and that in any case, the papers were of such poor quality that they would never have been published by any journal which did employ adequate review.

4. The opinion expressed by Baez and others that CS&F's high impact factor was the result of manipulations by El Naschie was fully justified.

5. This manipulation, and the publication of the worthless papers of El Naschie without proper review, were found to constitute "an abuse of [El Naschie]'s position" as editor.

6. The opinion expressed by "Chronos", Baez, and others, that the publicly available evidence suggests that El Naschie had made a practice since at least 2000 of falsely claiming several academic affiliations he did not in fact possess, was justified on the facts.

7. The opinion expressed by a half-dozen blog editors and forum moderators (including Peter) that emails making legal threats to Baez, Nature, and others, supposedly written by "legal advisers" to El Naschie, as well as hundreds of posts supporting El Naschie's claims, were made by sock-puppets of a very small number of personal associates of El Naschie, was found to be justified on the facts. Justice Sharp even named, ever so obliquely, the person she concluded was responsible for most of these writings, and added that she considered this serial sock-puppetry the most "bizarre" aspect of the case. Elsewhere in the judgment she dryly noted that if the person whom she concluded had written the legal threats had actually been a lawyer, that person would be subject to severe sanctions for professional misconduct. She even specified a stylometric trait characteristic of the sock-puppet screeds. (Neither Peter nor I want this discussion to degenerate into another Sockfest, so anyone who wants to know more about this aspect of the case should read the judgment.)

While Justice Sharp did attempt to draw a sharp legal distinction between her rather narrow and carefully worded findings and her opinion of El Naschie's scientific status, I believe that the above account is an accurate summary both of her findings and of de Wilde's own summary of her findings, in so far as these bear on the wider issue I want to discuss: institutional failures which can allow someone like El Naschie to engage in serious misconduct for many years.

Near the end of his report, de Wilde says that he feels that the British legal system has proven adequate to the challenge posed by unmerited libel actions such as the one brought by El Naschie, since in this case the defense of truth was upheld. This might appear to be true if one looks only at the final result, but I feel that the enormous legal costs carried by Nature (which they are unlikely to recover from the Claimant) and the three years of anguish to which a reputable and careful science reporter, Quirin Schiermeier, was unjustly subjected, are simply unacceptable. In my view, no editorialist, science reporter, or scholarly blogger should be vulnerable to the credible threat of such wildly unmerited actions, particularly when the costs of mounting a defense generally exceed one million pounds. As de Wilde admits: "The real issue here, and in similar cases, appears to lie not in the law itself but in the cost of litigation. Large media companies with deep pockets can afford the robust approach which leads to them defending claims in the High Court over the course of several years, others cannot."

To be fair, de Wilde's comments occur in the context of the phone hacking scandal, which involves shocking revelations tending to support the view that certain "tabloids" based in the UK have engaged for years in objectionable practices which exceed what most people would regard as responsible journalism. The resulting furore (which has resulted in a dozen official inquiries in the UK) is in my view justifiable, but unfortunately it has tended to distract attention from the merits of the arguments presented by groups such as Sense About Science and Index on Censorship which hope to enact badly needed reforms in UK libel laws. I hope this will not prove to be a case of two laudable reform movements canceling each other out, since I believe that it is possible and urgently necessary to enact provisions strongly discouraging both unmerited libel actions targeting responsible bloggers like John Baez, and improper "investigative methods" targeting relatives of crime victims and other innocents who were allegedly victimized for profit by the Murdoch machine.

To reiterate some points I made earlier: the decision by Justice Sharp constitutes a complete vindication of the criticisms of Baez and the reporting of Schiermeier, and will no doubt be cited by every court which hears a similar case in the future. But while the decision may embolden a handful of major publications like New Scientist and Nature to once again speak out against future cases of uncovered scientific misconduct, it does little to protect whistle-blowers, not even tenured professors like John Baez whom many believe to enjoy a legally recognized privilege of scholarly speech. In fact, it appears that no such privilege is generally recognized in the law, and I think that is a problem. Even those nations whose legal statutes apparently do offer some protection to "scholarly speech", such as the USA, have defined this so narrowly that most bloggers lack legal recognition as professional "journalists" or "scholars". And the notion of free speech generally has endured an unrelenting attack during the past decade. Furthermore, I see nothing in Justice Sharp's decision which might tend to mitigate against the obnoxious practice of "libel tourism", which appears to be used with increasing frequency by persons hoping to suppress scholarly criticism of dubious scientific claims.

John Timmer has just published a provocative (and funny!) essay in Ars Technica, which I found timely and germane:
http://arstechnica.com/science/2012/07/epic-fraud-how-to-succeed-in-science-without-doing-any/
Timmer's essay was prompted by the recent dismissal of a Japanese anesthesiologist, Yoshitaka Fujii, who published hundreds of obscure papers which upon investigation were found to be based upon faked data. See the Wikipedia article
https://secure.wikimedia.org/wikipedia/en/w/index.php?title=Scientific_misconduct&oldid=501219123
for some further examples of widely publicized cases of scientific misconduct.

I think we need to coin a term for the comparatively small number of dishonest persons hiding among the population of honest scientists, who cause damage disproportionate to their number or "intellectual weight". A term denoting those who engage in scholarly misconduct such as unethical experimentation on human subjects, undisclosed conflicts of interest such as corporate sponsorship of dubious "medical research", suppression of genuine data, concoction of fraudulent data, intellectually dishonest statistical manipulation of data, plagiarism, gift and ghost authorship, malicious impersonation of other academics, misrepresentation of academic affiliations, editorial misconduct, state and corporate sponsored trolling, publication of "propaganda journals" and "marketing journals", and other insidious distortions of the scientific process. I propose to name this noxious invasive weed Mendax mendax.

Anyone who has followed the woeful careers of such icons of mendaxity as El Naschie and Fujii has surely noticed numerous features common to the genus Mendax, and Timmer enumerates some of the warning signs. I'll pass over his list in order to discuss another feature common to many scientific scandals: whenever a Mendax infestation is discovered, people often ask "How could this have gone un-noticed for so long?". The answer offered by Timmer is simple: in most cases, it was noticed fairly quickly, but "nobody took any responsibility for investigating the prospect of fraud, despite requests made by other researchers who suspected something was amiss."

To which I would add: when well-founded suspicions are raised, they are often ignored, at least initially, and when they are not, the resulting investigations are often excessively timorous, and if they result in academic sanctions, all too often the charges, the investigation, and the sanctions are all covered up in order to protect the journal, the university, or scientific body which published, employed, or funded the miscreant from legal action. This suggests that the fairly small number of highly publicized cases in which people have been dismissed for cause may represent only the tip of a substantial iceberg. Some observers believe that various kinds of scholarly misconduct are running rampant in China, India, South Asia, and parts of the Near East, and such misconduct may be increasing in North America and the Eurozone, particularly in the lucrative field of medical research, with universities and scientific institutions increasingly distracted by worsening financial problems which in some cases threaten their very existence.

Decisive and timely intervention is necessary to prevent Mendax infestations from getting out of control, but prompt, firm, and public action is rarely taken before serious damage has been done to institutional reputations. All too often, the result has been that an individual miscreant simply moves on to another journal or another university in order to resume his scientific abuses. It seems to me that it should not be difficult to insert into employment contracts, funding grants, and paper submission forms language protecting institutions such as journals, universities, granting agencies, and professional societies, which are responsible for helping to ensure the integrity of scientific publications, from legal threats such as those allegedly made by the (allegedly nonexistent) "legal advisers" of El Naschie when Elsevier attempted to remove him. However, such measures would do nothing to protect whistle-blowers like Baez from retaliation, and legal reforms protecting whistle-blowers generally may be needed to address this point.

Curiously, with the possible exception under some circumstances of improper medical experimentation resulting in death (which according to some physicians happens more often than most people realize), even the most severe scholarly misconduct does not appear to be considered felonious under the law. Possibly it should be.

Timmer adds: "Investigating scientific fraud is a slow and painful process. A false accusation can ruin someone's career, so these investigations tend to be careful, thorough, and done completely in private, in case the accusations are off base". No-one could object to that. The problem is, "nobody really wants to be the one on the hook for running [such an investigation]." This is an inherent human weakness which can and must be addressed by suitable institutional measures which ensure that someone takes ownership of a suspected problem and addresses it effectively, before it gets out of hand.

Scholarly misconduct is an international problem, for reasons which include but are not limited to points touched upon by both Timmer and de Wilde. I applaud everyone who puts themselves at risk by fighting corruption and scholarly misconduct. Particularly in countries like China where the consequences for speaking out can be especially severe.

Can anything positive come of such widely publicized instances of mendaxity as the recently terminated careers of El Naschie and Fujii?

If these cases stir serious discussion inside faculty rooms and professional societies, discussion which results in measures effective in suppressing future cases of scholarly misconduct, then something valuable will have been achieved. If not, all the toil and trouble over the voluminous but worthless writings of El Naschie will remain just what it is today: utterly pointless.

Short Items, Higgs-free

July 7, 2012
Categories: Uncategorized

- The Simons Foundation has some more wonderful interviews with mathematicians. There's one with Pierre Deligne, and another with Robert MacPherson. The MacPherson piece describes not just mathematics, but also the unusual personal and professional collaboration of MacPherson and his student Mark Goresky.
- James Milne has a wonderful article explaining John Tate's mathematical achievements, for the Abel Prize volume.
- Science Watch has an interview of Nima Arkani-Hamed by Gary Taubes, about supersymmetry, with Arkani-Hamed rather defensive on the topic. These Science Watch pieces are built around the researcher's most highly-cited papers. In this case these would be not about supersymmetry, but about extra dimensions, and it would have been interesting to hear discussion of LHC results relevant to those. While extra dimensions at the TeV scale got a lot of attention from 2000 on, the topic disappeared from view once LHC results started arriving.
- Jim Holt's book Why Does the World Exist? was reviewed on this blog here, and is now available. If you're interested in Nothingness, you must read this book.
- OK, I can't resist one Higgs-related item. One explanation for why Gordy Kane's claims to have predicted the Higgs mass from string theory haven't made it into recent media coverage of the Higgs is that not only do physicists not take it seriously (Matt Strassler characterizes this as "garbage and propaganda"), but even string phenomenologists feel "animosity" towards these claims. For more, see this report from a recent string phenomenology conference.

Update: One more. Oisin McGuinness pointed me to a new web-site at the IAS run by Dennis Hejhal, which has various hard-to-find material relevant to Atle Selberg. It includes an unpublished interview of Selberg by Betsy Devine (who is Frank Wilczek's wife).

Update: Yet one more. A couple weeks ago the KITP hosted a talk by Nova's Paula Apsell,their Journalist in Residence, entitled Controversy in Science. She covered the topics of Evolution, Climate Change, and the Multiverse. Go to about 43 minutes into the program for the segment on the multiverse, which dealt with Brian Greene's hour-long program on the subject. David Gross objected strenuously to the program and how it was made, criticizing it for not distinguishing solid science from speculation, being manipulative and not seriously presenting the arguments of opponents. Gross explained that he had been interviewed for four hours for the program, but what went on the air was virtually all Brian's point of view, with only a short bit from him which he felt didn't represent his arguments. Joe Polchinski however thought it was just fine…

   July 7, 2012

   Gordy Cane's prediction of the Higgs boson mass is a historical fact. How significant that prediction is, and whether he predicted it for the right reasons are debatable. I have left comments making this clear several times on this blog, and given the views you advocate I think you have some obligation to report this fact correctly, even if you dont believe he did it for the right reason. If you want string theorists to be more focused on experimental predictions then why don't you give credit when they do exactly that? Let alone when the predictions are proved *correct*.

   The way you continue to frame this is bordering on dishonesty.

2. **Peter Woit**
   July 7, 2012

   Cliff,

   I'm just reporting the views of Matt Strassler and Kane's fellow string phenomenologists. You can try arguing the case with them, although first you might want to figure out how to spell Kane's name correctly.

   The problem is not that string theorists don't want to use string theory to make legitimate scientific predictions, it's that it's a failed idea so can't possibly be used for this purpose.

3. **Shantanu**
   July 8, 2012

   Cliff , what do you think of Shaposhnikov and Wetterich's claim of 125 Gev Higgs boson
   http://arxiv.org/abs/0912.0208
   that was almost three years ago.

4. **Speculative**
   July 8, 2012

   I think most of this controversy over predictions of the Higgs is quite ridiculous. The 126 GeV Higgs is compatible with many models: MSSM, SM without SUSY, some ST models and apparently an asymptotic safety model. Unfortunately we don't know which one is right yet, but we will soon. Right now, until something new is discovered the only thing we can determine is what models are compatible with results. Kane's idea is compatible with the results, that should be granted, but I'd hesitate to call it a prediction. Same with the asymptotic safety. We need a lot more data. Until then I'm not pinning my hopes on any particular idea.

5. **Peter Woit**
   July 8, 2012

   My mistake for not keeping this completely Higgs-free. But please, no more about this here except in the highly unlikely event that someone has something new and interesting to report about the Kane "prediction".

6. **Chris W.**
   July 8, 2012

   As a complement to the Arkani-Hamed interview, see this talk (on YouTube) he gave last January in Jerusalem. It starts with an extended and illuminating discussion of the point of view motivating much of his current work in which the work of Zvi Bern and others plays a central role.

   (I stopped at ~45 minutes. To be continued…)

7. **Anonymous**
   July 8, 2012

You know, the whole Goresky-MacPherson thing makes me uncomfortable. There are serious ethical problems with having affairs with PhD students. Most universities have explicit policies to this effect — at mine, you could lose tenure for doing so.

My feeling is that they are given a pass for two reasons. First, they are both top-notch mathematicians, and MacPherson especially has built up lots of good will (and rightly so). Second and even more importantly, however, is the homophobia thing. No one wants to openly criticize perhaps the most prominent gay mathematician for his love life (including me — there's a reason I'm anonymous). But I'd like to think that everyone should be held to the same ethical standards, gay or not.

8. **milkshaken**
   July 9, 2012

   anon 9:08: if you listen to MacPherson interview, he says they were not romantically involved while he was Goresky's thesis adviser, it developed later after their separation by distance.

9. **Yatima**
   July 9, 2012

   > Most universities have explicit policies to this effect — at mine, you could lose tenure for doing so.

   But this policy is just written down to prevent and counter abusive behaviour on the part of the supervisor. Once the supervisor (who is supposed to have the better judgement) lowers his guard (so to say) and there is no problem on either side, then that policy should in no case be taken out of toolbag. Indeed, in my book, someone threatening to do so would be in need of some after-hour attitude adjustment.

10. **Anonymous**
    July 9, 2012

    To anon 9:08 I agree with you there… if it happened today. Giving this sort of thing a pass legitimizes this kind of behavior for other professors, for whom it might not work out as well as it did for MacPherson and Goresky. I think many of us have heard of straight versions of that.

    But during the 70s so many people considered all gay relationships to be morally wrong, so you could argue that back then they had no real reason to abide by the rules and mores society had for them. Also it was much harder for gay people to date normally, so for a shy gay mathematician this would be a way to find someone.

    But I do think nowadays it's very different, and the standards people have for straight people should apply.. even if occasionally it works out, more often it wouldn't and it's best just not to go there.

    And to Milkshaken: we'll probably never know when it got romantic between them. They might be hesitant to tell the truth not just because of the professor-student issue but also because they were both married at the time, and may also have other reasons to hide what was going on.

11. **Peter Woit**
    July 9, 2012

    Please, I understand that the way of the internet is to take any interesting story and turn it into an uninteresting debate about one of a small number of hot-button topics that everyone seems to care about (e.g. sex between students and teachers). Enough here though about this particular debate.

12. **Eric Habegger**
    July 9, 2012

    I watched the Black Board Lunch video at KITP on the topic of controversies in science. I found Paula Apsell's defense of the program on multiverses quite disturbing and uninformed. She really came across as misunderstanding what the science community (and herself also) don't know yet. Nobody on either side seemed to bring up the fact that there was a distinct difference between Nova's handling of evolution and global warming and how it handled the subject of multiverses.

    In the case of evolution and global warming there was an unspoken but tacit goal in the Nova programs that the scientific evidence is in. Nova then tried to explain the evidence to the lay public showing why they are true, despite high profile opponents.
    In the case of multiverses, which has no physical evidence, the program attempted to convince the audience, that despite it's lack of physical evidence, it also was a good theory. At one point Ms. Apsell admitted that the dirty little secret was that programs are motivated by the creators interest in the subject. I really see that statement as admitting in the case of multiverses as having the same motivation that creationists and GW deniers have. I wish she understood that.

13. **paddy**
    July 9, 2012

    On the KITP lunch video: I find it disturbing that the speaker by content raises Multiverse theories to the level of evolution of climate science.

14. **Cliff**
    July 9, 2012

    Right, that would be Gordy Kane, apologies. Im just leaving his August 2011 presentation pdf here in my name-link, so hopefully no one will waste time arguing over whether those claims were manufactured the day after the rumor appeared again.

    To Shantanu, I dont find the asymptotic safety scenario a convincing possibility, but as long as someone disagrees then its very good to derive these predictions. On its own it doesn't mean much to me, but the task should always be to account for as many of these implications as we can. If I already was impressed and had a high prior for AS, then I would be much more excited about it, i.e. if it was joining other solid motivations. On the other hand I have very high theoretical priors for string theory, and I dont agree that Kane's scenario is completely "generic", but it is an interesting baseline case. So its interesting to keep that scenario and its other implications in mind. Like for example, in case a stop squark were observed, then if string theory is correct one of his assumptions would have to be violated, and that would have implications for what kinds of scenarios are physically possible. If there is some flaw in his reasoning then I would very much like that case to be made in a paper, so I can assess it. Matt didn't have any arguments to back up what he said other than his unspecified "friends" and their completely mysterious arguments.

    So Peter, if you see that case made in a specific fashion anywhere, by all means post it for me.

15. **Beelzebud**
    July 9, 2012

    paddy: It helps to keep in mind the context of the presentation, that being science in the media. For the layman, the multiverse theory is what is presented to us on television as current physics. If you watch science shows on TV it's presented right along with those other topics.

16. **Tim May**

July 9, 2012

I got my start in physics as a teenager in the 1960s. I read a lot of speculative stuff in "Science News" about tachyons, wormholes, etc. But I also knew this stuff was wildly speculative, and likely not to be either true or of any significance in the likely future.

But I didn't see stuff on tachyons, black holes, etc. on t.v. (I wished I had, I suppose.) I got my speculative fix in SN and my solid, stolid articles in "Scientific American." (SA has since slipped closer to "New Scientist," to my regret.)

And even as I was reading the fluff about time travel and wormholes and tachyons in "Science News," I was struggling as a 17-year-old kid to make sense of Feynman's wonderful Nobel Prize acceptance paper. I Xeroxed a copy at my local library and pored over it again and again.

Today, I tune in to a "Nova" show, expecting to see science, and instead see M. Kaku ranting on about the 10^500 universes that co-exist with us. Baaa! I read the first Brian Greene book (skimmed the second and third ones) and wasn't much impressed.

But, as a result partly of this site, I've looked at a lot more of the stuff from Nima Arkani-Hamed, Ed Witten, and others. AdS/CFT, scattering, the hierarchy problem. Familiar stuff to many of you, but new to me. I particularly enjoyed the 5 lectures N A-H gave at Cornell as the Messenger Lectures.

The math is intriguing. Who'da thunk Grothendieck would appear? (Topos theory is one of my major interests, though not so much from the physics side. Still, what Chris Isham is attempting is interesting.)

I saw recently a quote from Nima saying something like "Whatever we're talking about, it ain't about strings!" (I may've made his "ain't" more colloquial than it was.)

Of course, we may be many orders of magnitude in energy away from testable and confirmable/falsifiable predictions of scattering. But, then, I pretty much thought this was the case with GR/black holes in the mid-70s, and was part of why I moved instead into solid state and went to work for Intel. Turns out I was wrong, that a whole bunch of interesting stuff thatt I'll loosely call "black hole phenomenology" really hit the big time these past couple of decades. Lots of predictions, lots of observations. Wow.

The jump closer toward the Planck scale may take a lot more decades (centuries?).

I thank Peter for the heterodoxy of this site, which has helped to lessen the hype and maybe to help sharpen the arguments on all sides.

17. **Truth**
July 10, 2012

One of many reasons why Woit's opinion on string theory gets ignored by physicists is the following illogical position:

Headline: LHC sees no supersymmetry.
Woit: String theory predicts low energy supersymmetry, so it is falsified!
Headline: String theorists correctly predict mh=125 GeV.
Woit: String theory makes no predictions, so it is not falsifiable!

18. **Jon**
July 10, 2012

Another non-Higgs short item you may have missed: this article in Libération about Grothendieck, and how french mathematicians are actively trying to have five boxes of archives held in Montpellier classified as National Treasure, thereby allowing to bypass Grothendieck's interdiction to have a look at them, and digitize it all.

19. **Peter Woit**
July 10, 2012

Truth,

See my response to Cliff. No one in the field except perhaps Kane himself believes that he has a prediction of the Higgs mass from string theory. I'm not arguing the case here, just reporting this fact. We report, you decide…

20. **Peter Woit**
July 10, 2012

Jon,

Thanks, that's fascinating. Very intriguing to know what is in those documents and whether they'll ever see the light of day.

21. **Truth**
July 10, 2012

Peter, thank you for proving my point. You wish to argue that Kane did not make a real prediction because you believe string theory makes no predictions and is not falsifiable. But when it suits your goal, you switch and say it is falsified, such as the lack of evidence for supersymmetry at LHC. This is 100% contradictory.
So which is it, do you think string theory is falsifiable or not?

22. **Peter Woit**
July 10, 2012

Truth,
Again, I'm not the one claiming here that Kane did not make a string theory prediction. That's Matt Strassler, the participants in the String Phenomenology conference, and many others (e.g. Brian Greene). Go argue with them.

As for SUSY, of course string theory predicts nothing about that either, since you can have any scale of SUSY breaking you want. String theorists over the years have often claimed that "SUSY is a prediction of string theory", so seeing SUSY at the LHC would be evidence for string theory. I confess to pointing out every so often for many, many years that, if this is true, finding no SUSY at the LHC would be evidence against string theory. String theorists however seem to use their own idiosyncratic definition of what a scientific prediction is, one in which if the prediction fails to work, that doesn't count against the theory. Besides the 125 GeV Higgs, Kane also claimed that string theory "predicted" that gluinos were there below a TeV, and would be found in "a few months" after last December. The fact that this prediction didn't work somehow doesn't count against string theory either.

23. **paddy**

July 10, 2012

Save your breath Peter. For objective physicists–whether hep or nonhep–SUSY will remain not a matter of "truth" but of whether experimental observation supports it or not. The rest is midrash.

24. **truth**
July 10, 2012

Peter, why avoid the question? I am not asking you to give me your versions of what you think Kane, or Strassler, or Greene, etc believe. I am asking a straightforward question:
In your view, is string theory falsifiable or not?

25. **Peter Woit**
July 10, 2012

truth,

No string theory is not falsifiable, in any conventional sense of the word, since it makes no conventional scientific predictions.

This has gotten completely off-topic, and I've already wasted far too much of my time in the past arguing about the subtleties of what "falsifiability" means. I'm not going to start on that again here. Unless you've got something new to contribute to the topic of Kane's bogus string theory "prediction", enough already.

Please stop submitting endless tendentious argumentative comments here that have nothing to do with the posting.

26. **Stefan**
July 11, 2012

The Simons' Foundation videos aren't working at all for me… am I alone in this?

27. **theoreticalminimum**
July 11, 2012

Jon & Peter:

Thanks for the bringing the article to our attention, Jon. Peter, I bought Holt's book, and it's a fascinating read so far!

Sorry, my question will be off topic. Does any of you have any idea why they say the following about the use of motives: "Les physiciens qui traquent le boson de Higgs … l'utilisent pour essayer de rapprocher leurs observations et leurs calculs." Does this even make sense?

28. **Peter Woit**
July 11, 2012

theoreticalminimum,

There has been a lot of work recently on the relationship of scattering amplitudes and things like grassmanians and polylogarithms, which also show up in one corner of the mathematics of motives. For some examples of the kind of work going on, see the program of last week's workshop:

http://www.icmat.es/congresos/periods-and-motives/program.html

For an actual explanation of these topics though, you need someone other than me…

29. **David Metzler**
July 11, 2012

Peter, thanks very much for the link to the MacPherson interview. I didn't realize that it would be Robert Bryant doing the interviewing…it was a treat to see two of my favorite people in the world having such an interesting conversation.

30. **Anon**
July 11, 2012

Those who are involved in TV programs presenting their wildly speculative multiverse theories as if they were fact have to take some of the blame, in my opinion, for the difficulty the scientific community has in convincing the public of real scientific facts such as evolution or anthropogenic climate change.

31. **Cliff**
July 11, 2012

There is a much better framing to adopt for considering Kane et al's work than just "Is 125 GeV Higgs a prediction of string theory or not".

All scientific predictions are conditional, and Kane's is no exception. He explicitly makes several assumptions: that supergravity is the first valid field theory description, that SUSY breaking occurs by gravity mediation, that the matter content is only that of the MSSM, and also of course his predictions are advertised as applying only to compactified string theories. It seems pretty obvious to me that this kind of thing can be valuable, assuming none of his reasoning is demonstrated to be invalid, because if any of his predictions are violated that would mean that his whole large class of scenarios is excluded, and then we'd learn that one of these very general assumptions is violated. Its not like this is pie-in-the-sky stuff. The Higgs could have easily turned up outside the region 120-130 GeV, or we also could easily still find a scalar superpartner, either of which would falsify his setup. The dark matter experiments could as well. (the remark about the gluinos isn't right though, see the charts from the presentation or his papers. I would check the wording of your quote.)

If I were the type of person who lost sleep every night because theoretical physics is too disconnected from experimental predictions I would be jumping for joy at this kind of work. And moreover I think its an appropriate example of the kind of predictive work that is possible; to make predictions you don't necessarily have to prove that something is absolutely mathematically certain, its enough to show that a result holds in the overwhelming majority of cases unless you pathologically tune things to avoid it. This really just brings the meaning of "prediction" closer to the one understood in most of science. Theoretical physics is somewhat unique in its expectation for mathematical certainty.

32. **Peter Woit**
July 11, 2012

Cliff,

"the remark about the gluinos isn't right though"
Actually, it is. Kane last December described the time-scale for finding gluinos as "months", see for instance his posting on Lubos Motl's blog. Or, at Nature (see my posting from last December for the link), he had this to say:
"gluinos should be found with masses around a TeV, maybe less, by summer"
It's summer now, time is up. His string theory prediction is wrong, so I guess string theory is wrong.

Your remarks about Kane's "prediction" are pretty much unadulterated hype, with statements like

"This really just brings the meaning of "prediction" closer to the one understood in most of science."

sheer nonsense. No one is saying anything remotely relevant to "mathematical precision" here.

Again, before you keep spreading nonsense about this, I think you should take a minute and think seriously about what it means that one of Kane's friends who has every reason to be sympathetic towards him (Strassler), refers publicly to this particular claim as "garbage and propaganda". This is not me, this is the conventional wisdom among Kane's colleagues.

33. **theoreticalminimum**
July 12, 2012

Thanks for the link, Peter. A friend pointed me to this preprint.

34. **Cliff**
July 12, 2012

Wow, so "Truth" really is right, then. You really cannot decide if you believe string theory is unfalsifiable or falsified.

Assuming you're right, and string theory is falsified because gluinos haven't been detected as of July 2012, can you please point me to the gluino search documents from the two experiments using 8 TeV data? Because I would be extremely interested to see them if you have access to them!

Im not impressed by your managing to locate a single memorable quotation from one non-string theorist. Forgive me for having zero confidence in your assertion about what the string community thinks of this work, despite you inability to identify even one technical argument against it.

Ive checked both of Kane's articles. The Nature one says "Particles such as gluinos — superpartners to gluons, which mediate the strong force — have not yet been searched for explicitly in the decay modes predicted by the string theories, mainly decay to top and bottom quarks. They COULD be found in these modes by the middle of next year." The word "summer" does not appear anywhere on this page. On TRF he says gluinos should be detected at the LHC "in the coming months". Well its still the coming months.

I am amazed you're trying so hard to massage Kane's words to mean something else, and what for? So that the outcome of the 8 TeV run doesn't matter? That's clearly the implication of what you're saying, which is pretty richly ironic.

35. **Peter Woit**
July 12, 2012

Cliff,

The Kane "summer" quote is at
http://www.nature.com/news/live-qa-the-hunt-for-the-higgs-1.9642
at 4:18. We're going to be in the "coming months" for the rest of our lives…

CMS reported 8 TeV SUSY exclusion results at ICHEP. Note that Kane was predicting gluinos not at the summer conferences but "before".

Strassler has worked on string theory. I've given on this blog references to quotes from Brian Greene about this, as well as the report from the string phenomenology conference. How about you find me a single quote from a string theorist not a collaborator of Kane saying he or she agrees that Kane has predicted the Higgs mass from string theory?

36. **Rhys**
July 12, 2012

There have indeed been some 8 TeV analyses released by CMS; see for example the overview talk here (from today). It's far from clear to me what the implications are for the scenario advocated by Kane et al. (the LHC experiments can only produce exclusion plots for certain benchmark models, and I don't think they have looked at the case of very heavy squarks).

In any case, all this tit-for-tat about time scales for discovery and 'falsifiability' is really childish.

Implications of LHC Results

July 16, 2012
Categories: Experimental HEP News

The past few days at CERN there has been a workshop on Implications of LHC results for TeV-scale physics. This is the third in a series of these workshops, which have a goal of evaluating the implications of LHC results for choosing what new HEP facilities to design and fund.

One can argue about the implications, but the LHC results so far are in some sense very simple

- the Higgs has been discovered, with properties consistent with SM predictions, more detailed tests of this consistency to come.
- no evidence has been found for non-SM phenomena. The LHC has produced stringent bounds on extra dimensions and strongly interacting superpartners. The only remaining hope for a strongly interacting superpartner in the current data is for the stop, but evidence against that is accumulating, see for instance here.

The hope that the LHC would see extra dimensions was always quite a stretch, but the idea that it would see strongly interacting superpartners has been conventional wisdom for a very long time. It seems to me that many theorists who have spent the majority of their careers arguing for this conventional wisdom are having trouble admitting what has happened.

For some perspective on this, I recently ran across a 1997 Physics Today essay contest, which asked for submissions that would reflect what a "Search and Discovery" piece from the future might look like. The winner was Gordy Kane's Experimental Evidence for More Dimensions Reported. It's supposed to be from May 2011, and assumes that GUTs and supersymmetry were discovered long ago, even

> fully accepted in 2000 after the discovery at Fermilab of the needed supersymmetric partners.

According to Kane, 2011 would see discovery of extra dimensions at the LHC, through observation of a 950 GeV KK state.

Michael Peskin also submitted something similar to the Physics Today contest, purporting to be an October 2016 Search and Discovery column entitled Do Squark Generations Show Geometry? In Peskin's account, the first superpartner was found at LEP in 1999 when it got up to a center of mass energy of 200 GeV, By 2008 a large number of superpartners had been discovered, with ATLAS reporting precise values for four squark masses. Like Kane, he not only conjectures that by now we'd have a huge, well-tested SUSY phenomenology, but that our decade will see the discovery of extra dimensions, of a sort predicted by string theory. For Peskin, the discovery of extra dimensions comes about in 2016 from an electron-positron linear collider operating at a center of mass energy of 1.7 TeV.

Today Peskin gave a talk entitled Will there be Supersymmetry at the ILC?. He starts off by explaining his motivation as follows:

> One often hears:
>
> "If SUSY is not found at the LHC before the shutdown, then we will know that SUSY will not be found at the ILC."
>
> People attending this workshop know that this is incorrect. I hope that this will be explained clearly in the report to the European Strategy Study.

Despite the negative LHC results, Peskin is still trying to argue that one can expect to find supersymmetry at the ILC (which operates at a much lower center of mass energy than the LHC). He asks the question "Are light SUSY particles excluded at the LHC?" and answers it with:

> I will first give some sociological evidence against this
> statement:
>
> 1. No theorist who believed in SUSY before 2009 has renounced SUSY in the light of the LHC exclusions. (*)
>
> 2. Model builders are still building models with 200 GeV charginos.
>
> (* Gordy Kane might be considered an exception.)

I'm assuming the remark about Kane is a joke…

He goes on to argue that surely at least one strongly interacting superpartner (the gluino) will be found after the long shutdown, when the LHC operates at or near design energy:

> So, when we eventually reach the gluino at LHC 14 TeV, the
> generic jet+MET observables will begin to work and SUSY will be discovered unambiguously.
>
> The light SUSY sector will still be hard to explore at the LHC. We
> will feel lucky that we are already constructing the ILC !

After the long history of LHC SUSY predictions that haven't worked out, I'm not sure how seriously this will be taken as an argument for funding the ILC. There's a draft of a section of the report on the implications of the negative LHC results here.

I suspect that arguments about whether to build the ILC over the next few years will revolve around its capabilities in terms of doing a much better job than the LHC to study the properties of the Higgs. Attempts like Peskin's to argue that it should be built in order to look for supersymmetry are not likely to be taken very seriously by anyone outside the community of those who have been devoting the last few decades to thinking that SUSY is right around the corner, and still are unwilling to give up on this.

Bonus Higgs section: The last couple weeks have seen about a hundred Higgs-related things I could have linked to. For a random sampling, see this interview with Higgs, this from the Daily News and this survey of atrocities.

Bonus culture section: From last night's first episode of the new season of *Breaking Bad*:

> "We're living in a time of string theories and God particles. Feasible, doable, why not?"

Update: Geoff Brumfiel at Nature has some quotes from various theorists, including

- From Joe Lykken:

  > Under the weight of the LHC's hard evidence, SUSY and other beloved theories are feeling the strain. "There's going to be a huge massacre of theoretical ideas in the next couple of years," predicts Joe Lykken, a theoretical physicist at Fermilab in Batavia, Illinois.…

> And hopes of finding extra dimensions that would mysteriously swallow up energy from collisions in the LHC are evaporating faster than the postulated microscopic black holes that also failed to make an appearance. "I was one of the people who pushed the idea of extra dimensions that we could see in our lifetime," says Lykken. "Now that we have data, I'm becoming much more conservative."

- Frank Wilczek is hanging in there:

  > It is too soon to write off SUSY, agrees Frank Wilczek, a physicist at the Massachusetts Institute of Technology in Cambridge who was awarded the Nobel Prize in Physics in 2004 for his work on the standard model. "The last man standing, as far as ambitious ideas beyond the standard model go, is supersymmetry."

- Last year Gordon Kane was predicting SUSY discovery (gluinos) this summer. Now:

  > It will take years' more data to test some of the most promising ideas, says Gordon Kane, a theorist at the University of Michigan, Ann Arbor, and a longtime SUSY champion.

Update: At Berkeley they had an event to explain the implications of the Higgs to the public, which learned that we need to go beyond the "three known multiple universes":

> …the Standard Model Higgs has problems. To fix them, alternatives have been proposed that involve a composite Higgs – one composed of other matter particles – that has extra spatial dimensions beyond our three known multiple universes and something called supersymmetry.

Comments

1. **articles**
   July 16, 2012

   The statements about the articles by Kane and Peskin are mean-spirited. They are not to be compared to Kane's recent "prediction of the Higgs mass at 125 GeV" which rightly deserves the scorn heaped upon it. I recall reading the articles in Physics Today, and it was openly a contest to write science-fiction articles about "what might physics be 50 years hence." (I quote from memory.) So the authors were explicitly encouraged to make up stuff. So they made updates and discoveries. So what? I do not recall if Daniel Kleppner wrote an article about physics 50 years hence. He did write an invited article on something of the kind (in Physics Today), although perhaps not in 1997 and not as part of a contest. If the statements in such articles do not pan out, as the years roll by, what of it? Many people (not all string/SUSY theorists) were anticipating that BSM physics would appear at TeV scales. Perhaps SUSY, perhaps not. To date, new physics has appeared at new decades of energy ~ there has been new physics at scales of eV. MeV, GeV … why not TeV? The actual energy scales do not follow a strict pattern (arithmetic or geometric), but why not new (BSM) physics at TeV scales?

   Mankind has been waiting for the Second Coming of Christ far longer than mankind has been waiting for the appearance of SUSY.

2. **Peter Woit**
   July 16, 2012

   articles,

   I don't think my comments about the Kane/Peskin articles (which were projecting not 50 years into the future, but 13 and 18 respectively) were mean-spirited. Note that I just commented that that these provide "some perspective" on what they were arguing for back in 1997-8. Both of them thought superpartners were likely to appear at LEP or at the Tevatron, and if not there, then were a sure thing for the LHC. You can find many other locations where they made such predictions. Yes, they were less sure about extra dimensions, and that's why they made these the topics of their speculative Physics Today pieces.

   The long history of arguments for SUSY that haven't worked out is highly relevant to evaluating current arguments for SUSY by the same people. In this particular case, I think Peskin has devoted a lot of effort over the years to the SUSY argument for the ILC, with the laudable motivation that the ILC is the only viable idea for putting the US back at the energy frontier in HEP research any time soon. But this has always run up against the argument that one should wait and see what the LHC had to say about whether there really were SUSY particles and what their masses were. Peskin needs to acknowledge that LHC results are in and have blown a huge hole in his SUSY argument for the ILC.

   I think there's probably a good case to be made for some kind of lower energy "Higgs factory" machine, maybe some version of the ILC, maybe something else. Unless something else turns up at the LHC though, this case needs to be made in terms of studying the Higgs. The failure of popular arguments for SUSY at LHC scales is a major implication of LHC results and can't just be ignored. The "OK we didn't see SUSY at the LHC, but we think it has to be there at lower energies at the ILC" argument is just not going to fly. Maybe superpartners will soon appear and save the day for him, but it's much more likely that things will just get worse as SUSY exclusions get stronger. Making a big public case that the reason to build the ILC is SUSY is not going to end well in 2015-6 if that's the time frame for a decision by some government to finance the project as well as when the design energy LHC results come in, finally completely closing the door on TeV-scale SUSY.

3. **articles**
   July 16, 2012

   They were asked to write speculative articles, and the postulated timelines and discoveries in those articles don't mean anything. On the other hand, talks (Peskin at Lepton Photon or whatever) on SUSY at LHC and/or ILC energies are indeed to be rebutted.

4. **future 1**
   July 16, 2012

   Lubos contemplates "ATLAS: a 2.5-sigma stop squark excess".

5. **Peter Woit**
   July 16, 2012

   future 1,

   Besides the "stop excess", in other recent blog posts Lubos has argued that CMS is suppressing evidence for SUSY because of Tommaso Dorigo, and that there is something fraudulent about Barack Obama's Social Security number. I suggest you stick to more reliable sources of information, e.g. the slides of today's talk that I linked to, which give the latest from the ATLAS collaboration about stops. Enough about Lubos, please.

6. **Thomas Larsson**
   July 17, 2012

"Mankind has been waiting for the Second Coming of Christ far longer than mankind has been waiting for the appearance of SUSY."

Are you suggesting that these events are in the same category?

7. **Nex**
July 17, 2012

"Mankind has been waiting for the Second Coming of Christ far longer than mankind has been waiting for the appearance of SUSY."

Well, SCOC had a head start on SUSY, but the difference is bound to become insignificant.

8. **Jess Riedel**
July 17, 2012

Hi Peter,

For what it's worth, I agree with 'articles' that your main post does not make it clear enough that the essay contest was supposed to be fun and speculative sci-fi. (I certainly don't find this mean-spirited, it just gives the wrong impression.) Maybe you could clarify by quoting the description given by Physics Today?

If Peskin et al. have been arguing in a serious setting for the likelihood of SUSY at the Tevatron or the LHC, these talks shouldn't be too hard to find and highlight. As you say, that would be very useful for people deciding whether to listen to them when justifying potential LHC successors.

9. **Peter Woit**
July 17, 2012

Jess,

Here's the description of the contest:

"Physics Today, has announced an essay contest, "Can You Write Physics Tomorrow?" in celebration of the magazine's 50th anniversary in 1998. This is an invitation to write an imagined "Search and Discovery" story about a future discovery, advance in physics, or new technology. "

They ran at the same time a separate request for short humorous pieces. The Kane and Peskin pieces are now quite humorous, but I'm pretty sure that was not the intention of the writers, or of Physics Today in c0mmissioning them.

I'm not claiming that these pieces represent Kane and Peskin's 1997 solid predictions for the future, what they represent is their hopes for the future (experimental study of extra dimensions). In both pieces SUSY is in the background as a given. They didn't think it was worth promoting SUSY as a speculative discovery 15 years in the future, because they thought it was quite possible it would be discovered very soon (the LEP beam energy had just been increased).

To find predictions about SUSY at LEP/Tevatron you have to go back to before they were turned on, late 1980s/early 90s, which takes some effort since this was before everything was easily available on-line. For LHC SUSY predictions, 15 seconds of Googling turns up for instance this from 2007:

http://www.umich.edu/~mctp/SciPrgPgs/events/2007/kanefest/peskin.pdf

which has, in red:

"So the discovery of supersymmetry is not just the hope for this machine; it is the expectation."

I've heard many talks like this over the past decade, often making claims like this one, that the problem with the LHC will be such a complicated pattern of SM violations that it will be hard to disentangle them and figure out all the SUSY particles, their masses and couplings (remember the "LHC Olympics"?).

For those willing to do some searching, I'd be curious if anyone can find any example of a SUSY proponent arguing pre-LHC that maybe the LHC wouldn't see anything, but the ILC would. Personally I think trying to make such a case now doesn't pass the laugh test, but maybe someone can point to such an argument.

10. **David Nataf**
July 17, 2012

I don't really understand the arguing behind the arguments (metarguments) for the LHC successor.

From the perspective of particle physics, an LHC successor should be built regardless of what the LHC finds. Different physical concepts will likely influence what kind of successor, but there should be a successor period. The standard model is not a complete description of nature: it doesn't include dark matter, dark energy, and gravity among other proven concepts. I'm not sure if its consistent with matter's domination over antimatter. It would be irrational, in my opinion, to stop building particle accelerators after the first accelerator that has less success than the prior accelerators, there should be a more objective criteria.

There's a 4-sigma significance for a dark matter annihilation line toward the Galactic center at E ~ 130 GeV, with some arguing its two lines. We will soon know if its real. If it holds up it will in and of itself justify several experiments — from a scientific perspective. I think you would want to be build an ILC just to know if it produces this particle.

Now, with all of that said, it's hard for me to imagine that government civil servants care about any of these arguments. I'm just having a hard time seeing a government bureaucrat turn down the money for an ILC on the basis that supersymmetry wasn't found at the LHC. These scientific megaprojects are built to promote national prestige, like the space shuttle, or the olympics for that matter.

11. **Peter Woit**
July 17, 2012

David,

I agree there should be a successor to the LHC, the question is going to be of what kind. Such arguments need to be scientifically solid though. I think you seriously underestimate the competence of "government bureaucrats" who will have to be sold on such a project and get it funded. Many of them are trained physicists who can easily tell the difference between a good argument and a bogus one.

The possible dark matter signal you mention is a good example. First it has to hold up. Then it could be a good part of a justification for a linear collider, but you need some serious arguments about why it could not be seen in the LHC data, but would be visible at an LC. A crucial question about an LC that your arguments must address is what energy it should run at, which dramatically affects the cost.

12. **successor**
July 17, 2012

Indeed there should be an LHC successor regardless of what the LHC finds. That is to say, a search-and-discovery successor machine. Recall that after the b quark was found (at Fermilab in 1977), it was immediately postulated that there must be a partner top quark. The structure of the SM said so, and the SM by then was widely believed to be correct. But the SM did not give a mass for the top quark. So it was a case of go out and search. PEP, PETRA and TRISTAN were all built to find the top quark. Nature was unkind in that respect, the top quark was beyond the reach of those machines. But PETRA did produce good physics of 3 jet events and the discovery of gluons, also violations of scaling, vindicating predictions from QCD. An LHC successor will simply have to go "out there" and explore.

A Higgs factory is a separate issue, although also a successor to the LHC. Clearly the immediate interest will be to study the properties of the Higgs, although eventually the machine will push to higher energies. In that respect, LEP operated initially as a Z factory, but it did eventually push on to sqrt{s} = 209 GeV.

13. **Peter Woit**
July 17, 2012

successor,

Yes, but the question will be specifically whether the 250-500 GeV/beam ILC design makes sense as a search and discovery machine, after you've already operated the LHC at high luminosity and 7 TeV/beam. Is there really plausible physics that would be invisible at the LHC, but could be discovered at the ILC? Personally I don't think SUSY models cooked up to fit this description qualify.

14. **anon.**
July 17, 2012

If the 130 GeV gamma ray line holds up you would *absolutely* have a case for a linear collider since it's almost airtight that it implies the existence of new charged states and making charge states is what a linear collider does. You could imagine that at the LHC these states would be buried in QCD.

Similarly, if the Higgs really does have an enhanced branching ratio to two photons, you have a no-lose case for a linear collider.

Similarly, if an electron EDM is detected you have a case for a linear collider.

But let's be honest: right now, there is no compelling justification to spend the money on a linear collider. In a year or so that may change.

15. **successor**
July 17, 2012

SUSY has nothing to do with it. CERN had already produced the W and Z at the SppbarS, and for that matter CERN (or Rubbia anyway) had already discovered the top quark at 44 GeV/c^2 and monojets and supersymmetry, but CERN built LEP anyway. LEP produced good physics, but no BSM. In the 1970-80s, Fermilab was building the Tevatron, having already operated the Main Ring for years. Yet the NSF funded the construction of CESR at Cornell, even though CESR could not possibly match the physics reach of the Tevatron. (BTW note that CESR was not a DOE machine.) And then the SCOC (ok, the b quark) was discovered at Fermilab, at precisely the energy range of CESR, and the mission of CESR changed completely, and CESR became a dramatically successful Upsilon spectroscope.

Factories are well and good (nay, excellent), but the concept of a factory implies that the object of study has already been discovered. Search and discovery is something else.

The real problem is ultimately economic, that the machines are simply so expensive to build and operate. So the funding agencies (govts, ultimately) want to see some prospect of a return on investment. And it has to be a short term return. ("right now, there is no compelling justification to spend the money on a linear collider." Indeed.) It is the sheer cost that is the stumbling block. Pure search and discovery is just too difficult a concept to sell, at such a high price tag.

16. **s n d**
July 17, 2012

None of this would be an issue of the successor machine cost 1% (say) of what the actual successor machine is likely to cost. Let us say (very approximately) $10B for a linear collider or muon collider. So suppose instead that the successor machine cost $100M. That is still a lot, but the US could fund such a machine all by itself, without outside contributions. There could be two such machines in the world (or even in the US), say an electron linear collider and a muon collider. (Gloss over the radiation problems, etc.) Credible SUSY models would not matter, although something of the kind would in practice be offered as a justification to build the machines. The machines would be built, and the search for new physics would be pursued. Powerful senators would of course have to be cultivated, but such individuals have existed, in California, Illinois, New York and Texas. They are not an extinct breed. And if BSM physics was found, it would not matter if it was SUSY or not. All that would matter is that it is BSM.

Ultimately, the way forward probably resides in a breakthrough in materials science and technology. If 100T magnets can be mass produced, by industry, at a fraction of the cost of existing LHC magnets, then compact next-generation accelerators can be proposed at reasonable size and cost. (Even protons would emit synchrotron radiation at such energies and small bending radii, but let us say that the heat load in sc magnets can be dealt with. After all, this is all hypothetical …) The stumbling block is simply the cost, not the lack of plausible physics scenarios.

17. **strong field physicist**
July 17, 2012

"The real problem is ultimately economic, that the machines are simply so expensive to build and operate"

The cost of the ILC is about that of 2-3 stealth bombers. Lets see… fundamental knowledge of benefit to all of humanity versus mass murder of villagers… hmm…

or to put it another way… you could have 2 ILC's for the price of the bonuses City of London bankers paid to each other last year from public bailouts

18. **particle bombs**
July 17, 2012

"The cost of the ILC is about that of 2-3 stealth bombers." It doesn't work that way. It never has. Money poured in to science in the years after WW2 very much because nuclear physicists made atomic bombs. There was a ticker tape parade for the nuclear physicists in New York city, they were celebrated as heroes. Bonuses to City of London bankers … I imagine the New York thieves will take umbrage that you chose London over NY as your example.

19. **Peter Woit**
July 17, 2012

All discussions of the cost of HEP research tend to quickly degenerate into the "they cost no more than socially undesirable X" argument, and from there into the idiocy of internet political discussion. Just stop right here.

I will exercise my right as czar here to comment that the comparison to a few bombers makes me think "hey, that's not so much money, it's easily affordable", whereas the comparison to half the City of London bonues makes me think "wow, that's a lot of money.."

20. **martibal**
July 17, 2012

Off topic (Peter please apologize): I know you do not feel like to moderate a discussion on the possible dark matter annihilation line toward the Galactic center at E ~ 130 GeV, but could anybody indicate some links to read about this topic (a kind of "Not Even Wrong" devoted to astrophysics) ?

21. **David Nataf**
July 17, 2012

martibal,

This is the most recent analysis:
http://arxiv.org/abs/1206.1616

This is the discovery paper:
http://arxiv.org/abs/1204.2797

22. **martibal**
July 17, 2012

Thanks David.

23. **King Ray**

David, thanks also for the links.

24. **Thomas Larsson**
July 19, 2012

It might be sobering to recall what Wilczek wrote in his Future Summary from 2001:

"Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, there must be several accessible to the LHC."

25. **S. Molnar**
July 19, 2012

The two missing commas in the "three known multiple universes" quotation is faintly amusing, but not as good as the two extra commas in "eats, shoots, and leaves". Still, it provides evidence that a comma conservation law holds in our universe(s).

26. **Peter Woit**
July 19, 2012

S. Molnar,

Two extra commas would help, but I'm not convinced they can be placed so as to turn that particular word salad into something grammatically correct that makes sense.

27. **S. Molnar**
July 19, 2012

Surely the intent was to say "To fix them, alternatives have been proposed that involve a composite Higgs … that has extra spatial dimensions beyond our three known, multiple universes, and something called supersymmetry." Awkward, I grant you, but not total rubbish. I actually thought you knew that and just found the error entertaining. Am I being naive?

28. **Peter Woit**
July 19, 2012

S. Molnar,

It's clear what input the theorists involved provided. I suspect though that the incoherence of the end-result in the article is not due just to typos, but expresses the writer's failed attempt to make sense of what he was hearing (which, yes, is rather entertaining…).

29. **Xezlec**
July 22, 2012

"Despite the negative LHC results, Peskin is still trying to argue that one can expect to find supersymmetry at the ILC (which operates at a much lower center of mass energy than the LHC)."

Wait… are you implying that it's the center-of-mass energy alone that determines what can be discovered, and whether it's a pure electron-positron collider like the ILC or a hadron collider like the LHC doesn't matter much? I'm not a physicist, but that goes against everything I thought I knew about what a "parton distribution function" was and how it mattered.

I'm actually not sure there's a missing comma in that Berkeley quote. Reading your blog, Lubos' blog, and Flip Tanedo's blog, I feel like the three of you must surely live in different universes.

30. **Peter Woit**
July 23, 2012

Xezlec,

You can crudely think of proton-proton colliders as colliding bags of partons together, and a proton as mostly 3 quarks. Then the LHC is providing parton-parton collisions with about 1.3 TeV/parton (although with a very wide energy spread). As you can see from Flip Tanedo's latest posting, Z-primes are getting excluded up to about 2.5 TeV, so this crude estimate is reasonable. In 2015 the LHC energies will nearly double.

The initial ILC design is for 250 GeV + 250 GeV, very much below the 1.3 TeV + 1.3 TeV rough estimate above of what the LHC is doing. The LHC partons are colored, which gives it much higher cross-sections for producing colored particles, but, as the Higgs discovery shows, it also can discover new color-less particles. The main advantage of the ILC is that the fact that the initial state is not strongly interacting makes for a much simpler environment and much lower backgrounds. A Higgs discovery at the ILC would have been much much easier, and for getting detailed info about the Higgs it certainly would be a huge improvement over the LHC.

I'm sure one can come up with SUSY models with no new particle states observable at the LHC, although some that could be seen at the ILC at lower energy, but such things are rather contrived and I think few people will take them seriously. The argument for the ILC has always been that it would be the right tool not for discovery of particles at the energy frontier, but for the detailed study of things first seen much more crudely at the LHC.

Personally I think I'm in the same universe as Flip, but you're right, Lubos is evidence for the existence of another one.

31. **Xezlec**
    July 23, 2012

    Thanks for the explanation.

Two New Experimental Results

July 18, 2012
Categories: Experimental HEP News

Today brings news of two new experimental results, both consistent with the Standard Model:

- At the Higgs Hunting 2012 conference starting today, ATLAS reports results from the WW decay channel for the Higgs. At the July 4 joint announcement, CMS had reported results in this channel, but not ATLAS. Analyses of last year's data had indicated fewer excess events in this channel than expected from a 125 GeV SM Higgs (see here). The 2012 data from CMS and ATLAS now show an excess in this channel of a size quite compatible with an SM Higgs. For more about this, and a nice summary of the latest combined data for various Higgs channels, see viXra log. The gamma-gamma channel Higgs signal is high, the tau-tau channel is low, others close to expected, but deviations from the SM predictions are not especially significant.
- At DarkAttack2012, Columbia's Elena Aprile gave a talk this morning presenting new results from Xenon100. These show no evidence for a dark matter detection and provide the strongest exclusions yet of conjectural high mass WIMPs such as SUSY is supposed to provide. The Xenon100 results now rule out most of the region where pre-LHC CMSSM SUSY model fits showed a dark matter WIMP was supposed to be (see for instance slide 31 here).

Update: There's a press release about the Xenon100 result here.

Update: At Higgs Hunting 2012, two excellent summaries today of the theory implications of the Higgs results, from Matt Strassler and Michael Peskin.

Comments

1. **anonymous**
   July 18, 2012

   For those interested, DarkAttack2012 will be presenting some of the indirect search results (like Fermi LAT) tomorrow as well. Stay tuned.

2. **Yatima**
   July 19, 2012

   Probably the most aesthetic PowerPoint presentation I have seen:

   http://www.itp.uzh.ch/events/darkattack/talks/Evans.pdf

   Comic Sans users take note!

3. **Artie**
   July 19, 2012

   Yatima: really? We must have very different taste. I find Slide 20 particularly vile…

4. **David Nataf**
   July 19, 2012

   Slide 20 has some information on it that is likely to be incorrect (it implies Monoceros is a stream) but other than that how is it vile?

   Though personally I don't think the PP has great style. I think it's bad style to have 100 words per power point slide. I was taught to focus on figures.

   David

5. **Anonyrat**
   July 19, 2012

   I find the font very pleasing, but am unable to find out what the name of the font is, lacking Adobe Acrobat Professional. Using this website, http://www.identifont.com/ , with "Fonts by Appearance" did not help. If anyone knows the name of the font, would appreciate it.

6. **anon**
   July 19, 2012

   It's not powerpoint, it's a keynote presentation, to be precise it's done using the "Showroom" template. The font is Gill Sans.

   The pure text slides could use some highlights… overall I would say it's on the better side of presentations, but nothing extraordinary

7. **Artie**
   July 19, 2012

   David Nataf: "vile" was an exaggeration for comic effect. My objection to Slide 20 is the crudeness (and seemingly random colouring) of the annotations on the figure.

   By contrast, I don't find the slides too text-heavy at all. (If you want to see overloaded slides, look at any presentation by a mathematician…)

8. **Peter Woit**
   July 19, 2012

   slides about indirect searches now up at

   http://www.itp.uzh.ch/events/darkattack/programme.html

   which can be examined by experts for new physics or for excellent fonts.

   I'm no expert, but about the 130 GeV gamma line supposedly in the Fermi LAT data, see claims of such a line discussed here http://www.itp.uzh.ch/events/darkattack/talks/Hektor.pdf

and the Fermi LAT presentation is here

http://www.itp.uzh.ch/events/darkattack/talks/Murgia.pdf

which just says
“Comprehensive Fermi LAT team analysis on line searches based on 4 years of data (Pass 7) ongoing”

9. **Dan**
July 19, 2012

Looking at the presentations Peter links to, I think we have a new winner in the aesthetics stakes, the title slide in particular is quite special.

10. **Anonyrat**
July 21, 2012

So Peskin thinks the ILC is justified because the LHC has ruled out heavier particles; the way forward is high precision measurements of the Higgs?

11. **Peter Woit**
July 21, 2012

anonyrat,

In an earlier posting I wrote about his recent talk making the case that it still made sense to search for SUSY at ILC energies despite negative LHC results. That seems to me kind of implausible. The precision study of the Higgs does seem to be the best argument for a linear collider. Now that the Higgs mass is known, I wonder if the ILC design will be redone to optimize it for studying the Higgs. Perhaps a lower-cost design is possible if one is not trying to go for higher CM energies.

How the Higgs can lead us to the dark universe

July 22, 2012
Categories: This Week's Hype

The media frenzy surrounding the Higgs discovery announcement has on the whole consisted of stories that reasonably accurately deal with the scientific implications. Journalists have for instance by now learned that "string theory predictions" are a good thing to ignore. As usual though, theoretical physicists themselves can be counted on to inject some misleading hype into the press coverage when they get a chance.

Sean Carroll is doing his part, with a new piece at CNN entitled How the Higgs can lead us to the dark universe, which begins:

> The incredible discovery of the Higgs boson will open up new ways of probing the part of the universe that is invisible to our everyday senses: beyond ordinary matter, into the extraordinary world of dark matter.

Since most people just read the title and first paragraph of stories like this, CNN's readers will likely go away believing that Carroll's favorite speculative hypothesis, one which hasn't been working out very well, is the important significance of the Higgs discovery. What he's referring to are "Higgs-portal" models of WIMP dark matter. For examples of some recent papers discussing what the LHC has to say about such models, see here and here. In recent years experimental results have not been kind to these models. Negative recent results from direct detection experiments like Xenon100 haven't helped, nor have negative results from monoject searches at the LHC. The significance of the Higgs discovery for the Higgs-portal to dark matter idea is not that it provides evidence for this, but quite the opposite. Seeing signal sizes in various channels that roughly agree with the SM puts new limits on this kind of idea (because if it were true the branching ratios would be non-SM, as the Higgs had a new and potentially large possible decay channel to dark matter particles). Since one can construct a wide range of possible models of dark matter of this kind, many with behavior indistinguishable from the SM, there's no way to rule them out completely. It's of course possible that detailed future studies of the Higgs will find non-SM branching ratios that give evidence for a coupling to dark matter. My impression though is that most theorists find this rather unlikely, and I'd be curious to know what probability Carroll assigns to the idea that he is promoting. Back in 2008, he gave 15% as the probability for any kind of evidence of dark matter at the LHC, and the negative results about SUSY (which he assigned 60% probability) rule out many of the most popular models with LHC-visible dark matter.

Carroll has a new book coming out about the Higgs in November, The Particle at the End of the Universe: How the Hunt for the Higgs Boson Leads Us to the Edge of a New World. The table of contents and the description of the book here look quite promising, but unfortunately he seems to have decided that the way to market a book about the Higgs story is with the dark matter hype:

> A doorway is opening into the mind boggling, somewhat frightening world of dark matter. We only discovered the electron just over a hundred years ago and considering where that took us—from nuclear energy to quantum computing—the implications of the Higgs discovery hold the potential of changing the world.

I'm somewhat curious to know why dark matter is "frightening". In Carroll's last book the big speculative idea being marketed was the multiverse, it's interesting to see that he's chosen to move away from that particular mania to much more solid physics, although keeping it hype-free seems to be too much to ask.

First out of the gate post-discovery with a book about the Higgs won't be Carroll, but maybe Lisa Randall, with an e-book entitled Higgs Discovery: The Power of Empty Space, which I know nothing about, other than that it's supposed to be available Tuesday. Presumably it's an update of material in her recent Knocking on Heaven's Door, where, like Carroll, she moved away from the highly speculative material about extra dimensions of her first book, Warped Passages.

I have seen an early version of one quite good new book about the Higgs, Jim Baggott's Higgs: The Invention and Discovery of the 'God Particle', which is scheduled to be released August 13 in the UK~~, September 6 in the US~~ and the US. It will come with a foreword by Steven Weinberg, which is already available here.

Update: Over at Resonaances, Jester, who is an expert on this topic, comments:

> Finally, a simple and neat theory of dark matter that annihilates or scatters via a Higgs exchange, the so-called Higgs portal dark matter, is getting disfavored because Higgs would have a large invisible branching fraction, and thus a suppressed rate of visible decays.

Comments

1. **Yatima**
   July 23, 2012

   > dark matter is "frightening"

   You wouldn't be relaxed if a solar-mass neutralino ball were wandering into the Solar System! 😉

2. **higgs+bsm**
   July 23, 2012

   Many books and articles tell about the Higgs and the SM, essentially the search for the Higgs as the culmination of the quest to find all the pieces of the SM. That is well and good, to explain the SM to the lay public. But to do so it is at the same time also to look backwards, at what has already been accomplished, not to look forwards to ask 'what next'? So Sean Carroll has his take, and perhaps Kaku and Kane, etc. have even more outrageous pet ideas to peddle. Consider the hype that was promoted after WW2: everyone assumed that nuclear power was the unquestioned energy source of the future. And indeed millions (of not billions) were spent on nuclear power plants. Now that was real hype. Go to CNN and broadcast an interview "The Higgs is the culmination of a decades-long search to find all the pieces of the SM. Now we have (almost certainly) found it. It is a magnificent accomplishment, and it provides us with no clues at to what comes next, it says nothing about dark matter, or dark energy, and provides no pointers as to where to look for the next level of particle physics." See what happens.

3. **Tammie Sandoval**
   July 23, 2012

   I have a question on dark matter.

   When certain experiments first detected dark matter, an alternative theory was offered: That theory held that dark matter is an illusion. Instead, the experiments are explained if the simple law of gravity is incorrect, at least at long distances.

   Has this alternative theory been falsified?

4. **Peter Woit**
   July 23, 2012

Tammie,

The whole issue of “dark matter” is quite complex, with many alternative sorts of explanations of the phenomenon. I’m no expert, so not competent to moderate a discussion of this large topic here. Look elsewhere for debates about “MOND”, a modification of GR to accomodate the effects ascribed to dark matter. My impression is that such GR modifications both look rather ad hoc and don’t agree with some astrophysical evidence. But you really need to consult an expert…

5. **JR**
   July 23, 2012

   Tammie, This book provides one point of view on your question: http://www.amazon.ca/Reinventing-Gravity-Physicist-Beyond-Einstein/dp/0887622828

   there is a review of it here:
   http://www.eetimes.com/electronics-blogs/engineers-bookshelf-blog/4208974/Book-Review–Reinventing-Gravity-by-John-Moffat

   JR

6. **Will**
   July 23, 2012

   Carroll’s most recent blog post is about the Xenon100 results: http://blogs.discovermagazine.com/cosmicvariance/2012/07/20/dark-matter-still-hiding

   He certainly admits it’s evidence against the “provocative hints” he though previous experiments showed, and although I don’t understand any dark matter physics well enough to say whether this was much of an oversight, he makes no connection to the Higgs or his theories about it’s dark matter interactions.

7. **SpearMarktheSecond**
   July 23, 2012

   Or, maybe the dark matter particle doesn’t couple to the Higgs. I thought one of the components of the neutralino (the Bino?) did exactly that.

8. **David Nataf**
   July 23, 2012

   The Higgs has to couple to dark matter as dark matter particles necessarily have mass. If there’s no coupling of the Higgs to dark matter then it’s not a standard model Higgs.

   Peter, MOND is a modification to newtonian gravity not to GR, hence the name “modified newtonian dynamics”. The relativistic extension of MOND is TeVeS, I don’t know that it’s the unique extension.

9. **truth**
   July 23, 2012

   Daniel Nataf, that is not true.
   The Higgs is part of the Standard Model; it must give mass to the Standard Model particles.
   How the dark matter acquires mass is unknown; that requires an understanding of physics beyond the Standard Model.
   It is conceivable that its mass comes from the Higgs, but quite possible for it not to also – for instance, the axion acquires mass from QCD effects separate from the Higgs.

10. **In Hell's Kitchen (NYC)**
    July 24, 2012

    IMO, Carroll is the quintessential blog scientist…as a sci-fi fan I wouldn’t count anything he writes for more than its entertainment value or its value as a seed idea for a good novel.

11. **Tmark48**
    July 24, 2012

    > higgss+bsm wrote : “It is a magnificent accomplishment, and it provides us with no clues at to what comes next, it says nothing about dark matter, or dark energy, and provides no pointers as to where to look for the next level of particle physics. See what happens.”

    Frankly who cares if the field of HEP comes to a halt (except for high energy physicists that is) ? The LHC by itself will be productive for a good decade even if no new physics is discovered beyond the SM. Is this the end of physics ? Not by a long shot, physics even fundamental or theoretical physics is not reduced to HEP.

    ——

    People that believe this have a very distorted view of physics. Progress in astronomy will continue to be made, LHC or no LHC. As for dark matter, building better detectors in astronomy could provide an answer as to its nature. Why not neutrinos as dark matter ? They are massive and interact very weakly with ordinary matter. Progress in quantum mechanics will continue to be made, wether or not we nail down a consistent theory of quantum gravity if this is even possible at all. The same for many other branches of physics.

    ——

    If the field of HEP becomes stagnant because we don’t have the resources to takle whatever energy level is required to target supersymmetry (assuming it stops being a moving target) then so be it. No need to be delusional or hysteric about it. Invest the hundreds of millions, or billions of € on fields that are not stagnant.
    In 3000 years when we have the technology to probe space at the Planck scale, by all means construct that super duper particle accelerator that will give our descendants insights into quantum gravity and maybe string theory if it isn’t forgotten by then 😉 .

12. **Pravda**
    July 24, 2012

    Peter, is this article as foolish as it seems to me (“me” being a non-scientist)?
    http://www.theregister.co.uk/2012/07/24/what_next_for_higgs/

13. **Peter Woit**
    July 24, 2012

Hell’s Kitchen

I don’t think you’re fair to either Sean or “blog scientists”. There’s a huge range of quality of material put out on blogs from scientists, much of it I think better coverage of science news than you’ll find anywhere else. Yes, most of the best scientists in the world aren’t blogging or letting anyone know what they think, and if you can talk to them privately, they’re your best source of info, but for most people that’s not possible.

As for Sean, in general I think the content on his blog is accurate and of high quality. To the extent that I see a problem with it, it has to do with the way he writes about very speculative ideas that there are excellent reasons to be highly skeptical about. He is presenting himself as the voice of the scientific establishment, but not always making clear the distinction between when he is talking about settled science where most experts agree, and when he is talking about something highly speculative that some prominent people are enthusiastic about, but which most of their colleagues don’t take seriously (e.g. the multiverse). For a good example of the problem, follow the pingback above to a fanatical intelligent design site to see what kind of trouble Sean’s behavior is creating for the cause of serious science.

14. **Peter Woit**
July 24, 2012

Pravda,

The Register is fond of over-the-top British tabloid ways of expressing things, but I don’t think that’s a particulary inaccurate story. One of the main goals of the LHC is to look for SUSY (“mirror universe theory” I suppose) and extra dimensions. They’re just quoting one LHC physicist about how this is what they’re looking for. One can argue with some details, but the gist of the story is kind of right.

Would be more accurate of course to have the main point of the story be “LHC not seeing any SUSY or extra dimensions, as most people always expected”, but that’s a hard story to sell to the press.

15. **Jim Clarage**
July 24, 2012

Peter, thanks for pointing out Baggott’s book, and Weinberg’s review. Reading Weinberg’s review reinforced a confusion I’ve always had on the Higgs mechanism and electroweak symmetry breaking: as he says the mechanism gives masses to force carriers (Ws and Z), but is it an extrapolation to say it gives *all* particles mass (e.g., electron, quark)? In popular writing it seems the LHC Higgs is responsible for all known particle masses.

16. **Peter Woit**
July 24, 2012

Jim,

What I’d call the “Anderson-Higgs” mechanism discovered in 1963-4 gives masses to gauge fields (the W and Z). These mass terms come from the kinetic energy terms for the Higgs, since in gauge theory these use covariant derivatives involving the gauge field.

For fermion fields, things are a bit different, and weren’t discussed in the 63-64 papers. There you get masses from the Yukawa interaction terms coupling the fermion field to the Higgs. I’m not sure who first wrote these down, by 1967 Weinberg certainly did, but maybe someone did this earlier.

As often mentioned, there’s another source of mass: strong coupling in QCD, which provides most of the mass of protons and neutrons.

Simons Investigators

July 26, 2012
Categories: Uncategorized

The Simons Foundation has announced the surprise selection of 7 mathematicians and 9 theoretical physicists as [Simons Investigators](). Those selected will get \$100,000/year for 5 years, renewable for another 5, their departments \$10,000/year, their institutions \$22,000/year.

According to a [Washington Post story](), this is just the beginning of the program, which will continue to make these $1 million no-strings-attached awards to prominent mathematicians, theoretical physicists and theoretical computers scientists every one to two years.

This isn't something you can apply for, the Simons Foundation has a panel which made the selections. These awards are being compared to the [MacArthur Foundation "Genius Grants"](), which provide the same unrestricted \$100,000/year size grants, but only for five years. When the MacArthur program started back in the early eighties, particle theorists and mathematicians were often chosen (Witten and Wilczek were among the earliest choices), but in recent years that has been very uncommon. Two of the seven mathematicians chosen (Terry Tao and Horng-Tzer Yau) were also MacArthur Fellows.

The goal of the Simons program is to provde "a stable base of support for outstanding scientists, enabling them to undertake long-term study of fundamental questions." I guess this means the idea is to make it possible for them to work on longer-term more ambitious projects without worrying about the NSF cutting off their grants. It's interesting that the Simons Foundation sees this as a problem to be addressed, given that these are about the most prominent people in math and theoretical physics, among those least likely to ever have a grant application turned down.

In other Simons Foundation news, Yuri Tschinkel, an algebraic geometry from NYU, will take over from David Eisenbud as Director of the Division for Mathematics and Physical Sciences. Eisenbud is returning to MSRI in Berkeley for a second stint as Director there.

Comments

   July 26, 2012

   For whoever has, to him more shall be given, and he will have an abundance; but whoever does not have, even what he has shall be taken away from him.

2. **mark callaghan**
   July 26, 2012

   I like the idea in principle, but surely Terry Tao couldn't possibly get any more productive,as wonderful as that would be, and i'm sure the same goes for the other recipients.To be charitable, so to speak, i think they have missed the target.

3. **theoreticalminimum**
   July 26, 2012

   I think the "big names" were chosen to give some legitimacy and credit to the money awarded (money is not a big deal for Simons after all). I am happy to see Chris Hirata on that list. He's a fantastic young researcher! He's also recently won a Presidential Early Career Award.

4. **Michał Kotowski**
   July 26, 2012

   I guess it's alright to give such awards to big shots if the money is in turn used to support postdocs, graduate students etc. – ultimately the younger scientists benefit from such an arrangement. But it's a good point that "the Matthew effect" may be dangerous and it is likely to increase (instead of bridging) the gap between the very top places and other institutions.

5. **Christopher Long**
   July 27, 2012

   I agree, all deserving people, but it's the piling of resources on people that already have everything they need to be productive.

6. **Bugsy**
   July 27, 2012

   One of the problems afflicting the world of today is the "star system" whereby, say in professional sports, a few people are paid millions (those are the ones we hear about); 10 times as many are paid 10 times less, and so on, until the bottom rung of pro players are paid barely enough to survive. Now it can be argued that a star is worth it because he/she is making the goals/solving famous open problems. But they are standing on the shoulders of so many others, and couldn't shine as brightly without that framework. So it is vital to keep that framework alive and happy. This is a parallel to the income inequality discussion of the 1% or .01% versus the rest of us, where one of the central points is that a truly healthy society needs a large and healthy middle class.

   In academics we are much luckier than athletes or jazz musicians in that there is at least some basic framework of support; however in many places in recent times that system has been seriously damaged, so that many very deserving individuals (sometimes even those who have done key work in a given area) struggle to find a reasonable job.

   Sometimes there is an ultimate happy success story, but perhaps more often enthusiasm turns into disappointment or bitterness over time, as the realization slowly dawns that certain dreams will likely never be realized.

   I wish granting foundations could find an effective way to contribute to the overall health of the scientific/academic enterprise in this sense. One possibility might be to give many smaller awards, say for great papers by people without already all the prizes and benefits of the Ronaldinhos and Beckhams…

   The CNRS system in France gave one way of doing that, but perhaps the framwork of permanent research positions could be replaced by say a rotating 5-year grant system coupled with permanent jobs (a sort of post-postdoc system).

   What do people basically need? A short answer is simply more money, whether to buy books or a house with or to pay for a child's education. But beyond that there is a huge need for serious time off from teaching obligations to do research. Of course it might be difficult to get institutions to go along with that: there would definitely have to be some sweetening of the pot for the employers.

It is easy to think that the “best” have already floated to the top but undeniably, those who have had large advantages of location, salary, better students, grants, and reduced teaching loads have had all the conditions which foster more productivity, while the opposite has the opposite effect (maybe Grothendieck after leaving IHES is an extreme example) so there are feedback loops at play, and such a grant system might break some of the negative downward spirals and contribute greatly to the overall health and well-being of the fields involved.

Short Items

July 26, 2012
Categories: Multiverse Mania, Uncategorized

A few short items:

- To compare and contrast to the activities of the Simons Foundation, there's the Templeton Foundation, which has a $1.7 billion or so endowment to spend:

  They have a new Big Questions Online site, which asks Does Quantum Physics Make it Easier to Believe in God?

  At Oxford and Cambridge, Templeton is putting $1 million into Establishing the Philosophy of Cosmology, by, among other things, having a conference in January on Is God Explanatory?

  > This miniseries will explore the theological and, by extension, metaphysical questions that pertain to cosmology. The origin and order of the cosmos have helped inspire belief in a "Supreme Being" or "First Cause" for millennia; but what bearing, if any, does the modern scientific approach to studying cosmology have on such beliefs? Does introducing God into the discussion add anything?

  This week this Foundation is funding a Workshop on Philosophy and Physics in Tuscany, with blogging from Sean Carroll and here.

  An apt quotation from Carroll a few years ago would be this one:

  > The problem with the Templeton Foundation is not that they coerce scientists into repudiating their beliefs through the promise of piles of cash; it's that, by providing easy money to promote certain kinds of discussions, those discussions begin to seem more prominent and important than they really are.

- Sometimes you'll see trackbacks in the comment section to Intelligent Design blogs which have become my fans since I'm critical of the multiverse. Often these get identified by the spam filter as spam, but when they get through I tend to leave them, partly because I've had my own problems with trackback censorship (see here), partly because they provide some insight into how the Intelligent Design people are using multiverse mania for their own ends. From one of these links I learned about a recent article in the Skeptic Society newsletter by Michael Schermer. At some point I wrote to him to warn him that claims of scientific testability for the multiverse were bogus, so he should consider avoiding this as an argument with IDers. After some e-mails back and forth it wasn't clear if I had made any headway with him. The new article shows that he hasn't given up on this, but maybe my arguments had some effect.
- For an update on the sad story of Paul Frampton, who earlier this year was the victim of a scam that ended putting him in jail in Argentina on drug-smuggling charges, see here, here, here, here and here. A website to provide support for him has been set up here. It includes letters of support from various people including Edward Witten.

Update: There's an article in the Telegraph about the Frampton story here.

1. **God**
   July 26, 2012

   QM doesn't make it easier to believe in me, but it does prove that I have a sense of humor.

2. **Hansi**
   July 26, 2012

   Peter, why do you not comment on strings 2012 which ends tomorrow?: http://strings2012.mpp.mpg.de/

3. **Peter Woit**
   July 26, 2012

   Hansi,

   I'm curious to see what the concluding talks there will have to say, probably will write something after those appear.

4. **imho**
   July 27, 2012

   "…Williams said Frampton thought he was meeting a young woman from the Internet, but instead an agent asked him to take a suitcase to the United States…"

   Why should we support him? How do we know his intentions? Why do we trust him over the Argentinian authorities?

5. **Anonyrat**
   July 27, 2012

   Obviously, you support Frampton only if you find him credible.

6. **quotes**
   July 27, 2012

   Today you cite an 'apt quote' from Sean Carroll, but a few posts ago you criticized the same for advertising the Higgs (on a CNN interview) as a `portal to dark matter' (or something like that). Unlike God, Carroll is only human (ok, I don't know that for a fact) … it really wasn't so bad, what Carroll said about the Higgs. Realize that it will be the same with many other people. Prof Sir Martin Rees peddles the Multiverse these days, I think. Perhaps his lordship will speak at the conf in Jan? What then?

7. **Peter Woit**
   July 27, 2012

   quotes,
   I don't understand your point. I agree with most of what Sean Carroll or Lord Rees has to say, disagree with them on certain points (promoting Higgs portals or the multiverse).

8. **Name Here**
   July 27, 2012

   Peter, Nicolai concludes about non-string quantum gravity efforts: "Confirmation or refutation by experiment/observation even more of a challenge than for string theory!" (last page of his .pdf).

   What do you think? And does this mean quantum gravity research is not science?

9. **Peter Woit**
   July 28, 2012

   Name Here,

   Seems to me Nicolai is arguing "well, as an idea about unification, or as something that can be connected to experiment, as a theory of quantum gravity string theory sucks less than the alternatives". That's kind of the main argument for string unification right now: "OK, it's a failure, but so is everything else". May be accurate, but not necessarily a good argument for pursuing the idea.

10. **Hansi**
    July 28, 2012

    @Name Here:
    Of course, especially in gravity, there are many things which are solid science even if they can not be experimentally verified. For example, the Hawking Penrose singularity theorems are certainly not something that can be experimentally verified. But they can be proven from general relativity. Similarly, research on quantum processes in gravity is most solid, when it is solely based on mathematical proofs. For example, Hawking radiation is derived from curved spacetime geometry and quantum field theory. If a theory of quantum gravity could be similarly derived, it would be very very strong science. Unfortunately, no one has found a way for such a derivation yet. From the phenomenological viewpoint, quantum gravity is always problematic, as it will always be difficult, if not impossible to test such a theory. In practice, it can be seen as a relative success in this field, if one comes up with something, that does not disagree with known physics.

11. **BH**
    August 5, 2012

    Looks like John Templeton Jr. has been secretly bankrolling anti-Obama evangelical political organizations. The story is in today's (8/5) Huffington Post.

12. **Peter Woit**
    August 5, 2012

    For those who want to follow up what BH is talking about, the reference is to

    http://www.huffingtonpost.com/2012/08/05/mega-donors-bankrolling-religious-right_n_1735337.html

    which mentions the funding from John Templeton Jr. of "Let Freedom Ring", a right-wing political organization. I don't know that there's any way of finding out the current size of his financial contributions to this.

    For discussion of this topic though, please use the Huffington Post….

Strings 2012

July 28, 2012
Categories: Strings 2XXX

The big yearly string theory conference was held this year in Munich over the past week. Strings 2012 was the latest in a series of conferences that started more than 20 years ago. I've now written something about so many of these things that I've added a category for them, so you can review the last eight years of the history of these conferences by clicking here.

This year the conference drew 385 participants, a bit lower than the 400-500 that showed up at many of these things when held in Europe in the past, but higher than last year's 259 (conference was quite expensive) or 2010's 193 (conference was in the middle of nowhere in Texas, off-season). The week before Strings 2012 there was String-Math 2012, which brought nearly 200 mathematicians and physicists to Bonn. This is the second in a series, which seems intended to supplement or rival Strings 2XXX, with plans already in place for String-Math 2013 (Stony Brook) and String-Math 2014 (Alberta). Unfortunately the String-Math talks have not been posted yet, although I hear there are plans to do this.

One important aspect of Strings 2XXX conferences in recent years has been their role as PR events designed to promote string theory to the public and the media, and fight the perception of a failed subject. This year a press conference was scheduled last Tuesday, but there seems to be no publicly available record of it. About the only Strings 2012 story in the press that a quick search turned up was this one, which had nothing from the press conference, but Thomas Grimm explaining how everything is fine with string theory and maybe the LHC will find extra dimensions.

Another part of the PR activity at Strings 2XXX is promotional talks for the public, which this year included one from Witten about String Theory and the Universe. In honor of the Higgs discovery Witten said that he would add material at the beginning of the talk about particles rather than strings. He is still holding out hope for SUSY at the LHC, although now down-playing the fine-tuning argument and pointing to split supersymmetry as the thing to hope for, with answers to come "within a few years".

The question session was unusually skeptical and challenging, beginning with a very hostile and long-winded question about whether he wasn't worried that he had led physics down a 30-year path of failure. Unfortunately the questioner was intent on making a hostile speech, and much time was wasted trying to get him to shut up so that Witten could address the question. His answer was basically that 30 years wasn't so long, the Higgs discovery had taken 50, and he gave other such examples. I don't think any of his examples addressed the real issue, which is not that practical tests of string theory are far away, but that it makes no predictions, even if you had the technology to test it. To defend the falsifiability of string theory he gave the dubious argument that if table-top experiments showed quantum mechanics to be wrong, that would show string theory was wrong.

Mathematician Michael Hutchings was there, and he blogs about the public talks here, including a description of the question period:

> The most interesting part was the question period afterwards. The first questioner launched into a very aggressive rant about how Witten was abusing his scientific responsibility by leading thousands of people to waste their intelligence on a theory for which there is no experimental evidence. The chairman basically needed to shut him up (and should have done so earlier)….
>
> Anyway I was kind of shocked to see such an agressive attack from the general public. I'm glad I don't have questioners attacking me because my work does not have enough real-world applications or whatever.

This was the first Strings 2XXX post-conclusive LHC evidence ruling out the discovery of SUSY in the form expected from arguments about "naturalness" and the "hierarchy problem". Even the talks that tried to make some contact with the real world mostly ignored the SUSY problem, but the talk of Savas Dimopoulos on What Has the LHC Done to Theory? did address this head-on. On "naturalness" he quoted Samuel Beckett ("I'd wait till it was black night before I gave up"), arguing that one should hang in there with this until the bitter end, which he saw as coming late this year or early next year after the data from the 2012 run is analyzed. His basic point of view was that there are only two choices: versions of SUSY that solve the fine-tuning or naturalness problem (which are about to be ruled out), and versions of SUSY that don't (e.g. split SUSY), which imply the multiverse to deal with fine-tuning. The only other option discussed was "high-scale SUSY" (SUSY broken up near the Planck scale). I guess the concept of SUSY extensions of the SM just being wrong is not within the realm of conceivability, given that they are part of the standard ideology of how to connect string theory with particle physics.

The slides from the talks are available here. I didn't notice anything really new, just much the same topics as have been popular in recent years (e.g. adS/CFT and connections to condensed matter, amplitudes, higher spins). At Strings 2011 there was a lot of comment that few of the talks involved strings and string phenomenologists were shut out. This year's conference had more stringy talks, as well as some on string phenomenology, possibly because it was organized by Dieter Lüst and his group in Munich, which does string phenomenology. Only one multiverse talk, Ben Freivogel on Predictions from Eternal Inflation, which, not surprisingly, had no predictions (but he did ask anyone who had one to get in touch with him, since his future employment would require some).

Hiroshi Ooguri's summary talk reviewed his summary talks from 2004 and 2008, which featured many of the same topics and much the same story. The LHC results were completely ignored, and one of his slides seemed to me just delusional:

> Significant progress has been made in understanding how to derive the Standard Model of Particle Physics from Superstring Theory.

Claims of such progress have been made at every one of these conferences for more than 20 years, with actual string theory predictions getting farther and farther away. There's a reasonable case to be made for continuing interest in string theory, but I find it hard to believe that even many string theorists seriously believe there has been progress in recent years towards using string unification to predict anything.

The one talk that hasn't yet been posted is David Gross's Outlook and Vision. He has given such talks at a large fraction of these conferences, so one knows pretty much what to expect. I do wonder though if he'll address the negative LHC results about SUSY, which at some point are going to cost him money, since he has made bets on this.

Update: I suppose I should ignore Lubos, but his reaction to the questions at Witten's talk is pretty amazing. It seems that they are somehow all my fault (and Lee Smolin's), and he gets into the spirit of Munich of a bygone era with his "endorsement of the creation of gas chambers for this scum" . The suggested way for Strings 2XXX conferences of the future to deal with this problem is to have all questions submitted in advance to make sure there aren't any ones like this year's.

Update: Video of David Gross's "Outlook and Vision talk" is now available. It struck me as much more defensive and hype-ridden than versions of this from past years. We're told that there is "every reason to be optimistic" that the LHC will discover how forces unify and how things fit into the string framework, with the standard arguments for LHC-scale SUSY given, no mention of the negative experimental results. About string theory, Gross claims "unbelievable progress every year", and it includes everything that is "nice" and "consistent" about fundamental physics, including all consistent QFTs.

He echoes Witten's argument that string theory is falsifiable since testing quantum mechanics tests string theory with his own claim that evidence for the SM is evidence for string theory (the SM is the "foundation" of string theory). He describes the press conference held last Tuesday as involving a lot of journalists complaining about the lack of testability of string theory, and Maldacena coming up with the argument that the LHC has successfully tested string theory since it hasn't found anything incompatible with it.

The one substantive remark was that he thinks work on higher spin symmetries may provide a hint about what he sees as the fundamental problem with string theory: no one knows what the theory is, or what symmetry principle it should be built upon.

Comments

1. **Hansi**
   July 28, 2012

   I would find it a bit more interesting (and funny) to know what Lubos has to say on the talks which say that the MSSM would perhaps be ruled out by the LHC in the end of 2012.

   What does Lubos want to do with lecturers writing such plasphemic things, and what does Lubos want do with the LHC after it has ruled out the MSSM?

2. **Yatima**
   July 28, 2012

   Cough. Peter, that's not Munich, that's Wannsee. Officious bureaucrats and psychopaths setting up a "social improvement" scheme for the good of everyone.

3. **Klaus**
   July 28, 2012

   It is hard to recognize a person from his voice only, but the first questioner might be a known German physicist who wrote a book which is so critical and nasty about string theory that compared to it, "Not Even Wrong" is a laudatio of the string idea. He appears regularly in the media.

4. **Peter Woit**
   July 29, 2012

   Hansi,

   It's not the MSSM that is getting ruled out, it's the idea that supersymmetry "stabilizes" the weak scale, that it provides a "natural" way to avoid the "fine-tuning" problem introduced by the Higgs. That whole set of ideas is more general than the MSSM, and has always been given as one of the main motivations for SUSY. "Unnatural" versions of SUSY like split SUSY are still versions of the MSSM.

5. **Alexander Unzicker**
   July 29, 2012

   To avoid too many interpretations without the facts, here is what I actualy said after Witten's public lecture:

   This was an impressive talk. I am sure many people are impressed. I am also sure that with your work you are making the best out of your extraordinary capabilities.

   I am not quite sure however that you are fully aware of the responsibility towards science, the search for the laws of nature…. It was Isaac Newton who said Nature created everything by number, weight and measure. Thus it is the theorist's business to predict numbers the experimentalit's business to measure these numbers. And as everybody can see supersymmetry and string theory in the past thirty years did not devliver a single result which Isaac Newton had called physics.

   So, aren't you afraid of being the scientific leader of an entire epoch of physics that might lead to nowhere? Aren't you afraid of misguiding the concentrated intelligence of seven billion people on a planet? (chairman tries to interrupt)

   Of course, nobody can prove you wrong, but it's the history of science which gives a clear indication: the real revolutions of physics have always been pushed forward by skeptic individuals, never by the euphoria of the many. And this is where your problem lies.

   Your risk is that you are playing mathematical games of with their link to reality is still a promise, concepts of which the link to the physical realiy you do not understand. Thus I'd like to urge you to reflect upon your role in science. Please, get back to reality.

6. **Hansi**
   July 29, 2012

   Peter, maybe this is hairsplitting, but I thought MSSM means "Minimal Supersymmetric SM". The name "minimal" would imply, I think, that split Supersymmetry is distinct from the MSSM. This naming convention is also the one in wikipedia:

   http://en.wikipedia.org/wiki/Split_supersymmetry

   "Split supersymmetry makes predictions that are distinct from […] the Minimal Supersymmetric Standard Model "

   To me, this split susy model looks more a bit like a joke than a serious proposal anyway.

   And regarding to these "attacking questions":

   Well, germans are often perceived not to be as "friendly" as people in other countries. For example, one almost can not! expect friendly questions in such a discussion in germany. I have seen Luest being asked similar questions (although shorter of course, and not only for self-distinguishing) by experimental physicists, when Luest hold an introductionary lecture at the technical university in munich.

   There are some experimentalists, especially experimental solid state physicists, who hold the viewpoint that mathematical physics (that is, to use physical ideas for doing mathematics) is not useful at all, and everything that does not lead immediately to an experiment should be abandoned. So, there is some hostility in germany against theorists. Especially against mathematical physicists.

   Historically, this may have to do with the early influence of Phillip Lennard and others in the 1930. They criticised the theory of relativity as "against common sense". Because of Lennard and others, the official Nazi doctrine, to forbid those new theoretical ideas as "jewish physics" had a fruitful basis in german academia.

   Then, after 1945, most theorists were gone, and one had to staff the majority of physics chairs with experimentalists. In many physics departments, the experimental physicists successfully block the installation of new chairs for theoretical physics since those early days. As a result, the rare theoretical physicists are often watched with suspicion and hostillity in germany. In many of germany's physics departments, experimentalists are quite fast to raise the question, whether a theorist uses money that could be better invested for some new experiment. And if a german theoretical physics professor retires, experimentalits often try to convert the chair into an experimental one. That is the situation in germany.

That some persons in the general public have, like some of the more practically minded experimantal colleagues, very hostile views against mathematical physics, this is not that surprising, unfortunately.

7. **Hansi**
July 29, 2012

@Mr Unzicker:
Physics does not only predict numbers. As physics uses mathematical modelling, it contains mathematical proofs. Mathematical physics is a scientific subject which takes physical ideas and does mathematics with it. This is most of what string theorists do. That is especially true for the research of Edward Witten, who won a fields medal in mathematics.

By writing "you are playing mathematical games" you are saying that you, Mr Unzicker, do not like mathematics.

Without doubt mathematics and mathematical physics is a wonderful science that proves interesting things. It is not just "some stupid game".

For this reason, Mr. Unzicker, nobody in the universe cares about whether you do not like mathematics. This is your own problem and so you should simply refrain from telling mathematicians, fields medal winners, and mathematical physicists that they should abandon mathematics.

Also, as you seem to have problems to understand those mathematical Ideas, it seems it is you, Mr Unzicker, and not Witten who should get a grasp of reality. The reason is that reality obviously contains mathematics.

8. **vmarko**
July 29, 2012

@Hansi:

Doing research in mathematics is not the problem. Selling this research as something that has physically observable predictions is the problem. String theory just doesn't have any predictions. Spending 30 years researching this is ok when done by a moderate amount of people, but recruiting almost 90% of young and knowledgeable people to do this research is just unproportional to the possibility of string theory delivering those promised predictions. And Ed Witten, as an important figure in both physics and mathematics, a Fields medalist, helped in this recruitment.

I believe Mr. Unzicker was just asking Witten to acknowledge his share of responsibility for this. Some others should too.

9. **P**
July 29, 2012

"I don't think any of his examples addressed the real issue, which is not that practical tests of string theory are far away, but that it makes no predictions, even if you had the technology to test it."

It's fine that you're once again stating what you think the real issue is, Peter – and one can have a hearty debate about the ability to distinguish between string vacua and effective field theories at the TeV scale- but you've clearly spoken too strongly here, with the assertion that it makes not predictions even if one had the technology to test it.

This is manifestly NOT true. ALL four dimensional string compactifications have a compactification scale and one will start exciting KK modes at energies above that scale. Moreover, probing with energies near the string scale one can begin exciting the infinite tower of string modes and these have observational signatures that have been studied in detail. They are also generic, as all string theories have them.

So if one had the technology to access these scales, one would definitively be testing string theory.

10. **Hansi**
July 29, 2012

vmarko wrote:
but recruiting almost 90% of young and knowledgeable people to do this research
end quote.

In germany, i bet around 70-80% of the physicists go into experimental physics, perhaps 10-15% in theoretical solid state physics, quantum physics and statistical physics. High energy theorists make in germany perhaps around 5% of all physicists. And they are mostly phenomenologists. Only a very very small fraction of the theoretical physicists in germany goes into relativity or quantum gravity research. The german chairs that are occupied with gravity or some form of quantum gravity or string theory can be counted with your fingers. And one must see this compared to dozends of solid state physics chairs.

And no, the string theorists in germany do not sell anything. Selling is something that german professors traditionally do not do. However, as this Unzicker guy adressed this to Ed Witten: Well, Witten indeed has not much string phenomenology papers. However, Witten has articles on the geometric langlands program. Everyone who reads Witten's papers immediately sees Witten's research his is mostly of (very high) mathematical value, and not something that could be used for constructing a measurement device. Arguing, like Unzicker, that this kind of research would be "only a game" and therefore of no value is just stupid. Nobody cares if Unzicker does not like mathematics.

11. **vmarko**
July 29, 2012

@P:

So if one had the technology to access these scales, one would definitively be testing string theory.

I think that Peter is not talking about testing one particular variant of string theory, but about the fact that there will always exist *some* version of ST that will be compatible with any experimental data at any given energy scale.

The problem is not in string theory having predictions, but in the fact that there are as many string theories as there are vacuua in the landscape.

String theory is not a single theory, but a framework for theories. That is why it has no predictions. The similar situation is with QFT — it is a generic framework, and becomes a concrete theory only after one writes down some particular Langrangian (like QED, SM, MSSM, or otherwise). Only then one can give falsifiable predictions.

So first go ahead and choose one particular vacuum from the landscape, one particular compactification scheme for extra dimensions, etc., and then you might get a testable string theory. And after it is tested against (hypothetical) Planck-scale experimental data, two things can happen:

(1) the theory could be correct, or
(2) the theory could be incorrect.

But then in case (2) you could just change your initial choices about vacua etc., and create a new string theory (a model different from the tested one), which would be in accord with experiment.

That is the lack of predictability of string theory framework. It is too general, you can fit it to any experimental data, just like QFT. There is no added value in it.

12. **vmarko**
July 29, 2012

@Hansi:

I wasn't talking about 90% of physicists in general, but 90% of hep-th/gr-qc physicists. You are indeed correct that the number of such chairs in Germany is single-digit or so. But even in Germany most of those are string theory (although statistics is lousy on a small sample, one should look planet-wide instead just Germany).

As for Ed Witten, I am not disputing the importance of his work in mathematics. Nor am I saying that math should not be done. But still, selling pure math as physics (N.B. "selling as" = "advertizing") does not always have merit, especially on such an unproportional scale.

People often get confused by the concept called "mathematical physics", and think that it is somehow a fusion between math and physics which sort-of creates a new scientific discipline. This is wrong. As a researcher in that area, I can tell you that there indeed is a fusion between the two, but in a very specific way (that I don't want to elaborate here). And no new discipline gets created — mathematicians stay mathematicians, physicists stay physicists. We just interact a bit more than usual, to obtain some knowledge, ideas and tools (and sometimes manpower) from the other side.

So, it is completely ok if Witten does research in math that may (or may not) be relevant to physics. But claiming that there is no difference between the two is not ok, IMNSHO. 🙂

13. **MathPhys**
July 29, 2012

Mr Unzicker,
Some of us may disagree with E Witten on this or on that, but we all admire not only his intellect, but also his personal and scientific integrity.
To achieve your 15 minutes of fame, you have attempted to corner and embarrass a very respectable man.

You have also done damage to your cause. There were many better ways to do this. You chose the worst.

14. **Roger**
July 29, 2012

@MathPhys

I think the question that was put to him was a valid one i.e. whether or not he should feel responsible for leading thousands of scientists down what may be a blind alley ? The problem was that the question was posed in a very confrontational way. This is a pity since a good discussion of the question can address useful topics, such as how a community of nominally free thinkers operates in practice and the roles of "leaders".

15. **DB**
July 29, 2012

I like the idea of high-scale SUSY, close to the Planck scale. It will save me having to listen to promises that SUSY is just around the next corner, nonsense I've been listening to for thirty years.

16. **Robert McNees**
July 29, 2012

Peter, let me start by saying that I'm more sympathetic towards some of your arguments than you'd probably expect. But you could do without statements like the following:

I don't think any of his examples addressed the real issue, which is not that practical tests of string theory are far away, but that it makes no predictions, even if you had the technology to test it.

If you had the technology to perform scattering experiments at the string scale you would see soft scattering. That's a basic prediction made by every string model, and there's no way around it. Do I think it's likely that we'll develop that technology? I doubt it; the string scale is probably too high.

The claim that there are no "in principle" testable predictions of strings is wrong. The ongoing debate about strings isn't advanced by presenting a misconception as if it were healthy skepticism.

17. **Bernhard**
July 29, 2012

Robert McNees,

pardon my ignorance, but could you kindly point out any article (since this is so basic) where one can see the details of how a "soft scattering experiment at string scale" would look like? Are the possible phenomenological consequences of such an experiment unique to string theory? Are you talking about definite quantitative comparison or qualitative comparison?

18. **Peter Woit**
July 29, 2012

Hi Bob (this is also a response to P and Bernhard),

I suppose I should get around to putting this question in the FAQ for the blog I started but haven't gotten back to…

You and I discussed this point almost exactly 7 years ago, on Sean Carroll's blog, see here http://blogs.discovermagazine.com/cosmicvariance/2005/07/21/two-cheers-for-string-theory/

and after a while even Sean seems to have agreed with me, see

http://blogs.discovermagazine.com/cosmicvariance/2005/07/21/two-cheers-for-string-theory/#comment-260

For those who don't want to wade through the endless discussion back then, the point is that the "prediction" of soft scattering amplitudes once you get higher than the string scale suffers from the problems that:

1. You don't know what the string scale is.
2. This prediction comes from a perturbative string theory calculation, but this is only reliable if the string coupling is small. Generically in M-theory this won't be true and you don't know what scattering amplitudes will be like.

19. **critical thinking**
July 29, 2012

I find quite bizarre the tone often adopted in discussions about the nature of string theory. I don't necessarily agree with the line of argument by Unzicker (especially the social responsability arguments he advanced here), but I don't see why skepticism about string theory should be considered out of the norm from a scientific perspective. Simplifying a lot, but I would like to confine myself to a few lines. Once there is widespread experimental confirmation of the predictions of a given theory, discussion normally ceases and the theory becomes — by most reasonable and informed people — acepted. Until then, skepticism is the norm, theories are work in progress and/or working hypotheses. In the end, it's that simple. It can well be that Witten et al. intuition is outstanding, and that "his" theoretical program will prove the most fruitful. But we have no way of knowing it in advance. Furthermore I suppose no one contests the quality of his mathematical contributions. So I find all this outcry to Unzicker's questioning as much ado about a completley expected scientific controversy. Unless someone thinks that dissent from the dominant theoretical approach should a priori be discouraged.

20. **Bob Jones**
July 29, 2012

Alexander Unzicker,

I don't know how much background you have in math and physics, but your comments at Witten's talk suggest that you don't completely understand what string theory is about. Like most critics of string theory, you focus on its failure to produce testable predictions, and you believe that scientists are wasting their talent on a failed idea. At one point, you even suggested that Witten's ideas might "lead to nowhere".

I think you should seriously consider Witten's response to your comments, especially the part where he explained how string theory has helped us better understand theories we already have. This is an aspect of string theory that has not been very well communicated to the public, but it's one of the major reasons why there's been such a sustained interest in the theory. In addition to providing a candidate for a unified theory of physics, string theory has provided valuable insights into other parts of physics and mathematics.

In physics, the biggest success of the theory was probably the discovery of the AdS/CFT correspondence. This result provides a concrete realization of the "holographic principle" which appears to be a very generic feature of quantum theories of gravity. The correspondence shows that quantum field theory and string theory can provide equivalent descriptions of the same physics, and it can be used to understand qualitative features of certain condensed matter and QCD systems.

In mathematics, the impact of string theory has been enormous. Ideas from string theory have led to important developments in mathematics like mirror symmetry, Gromov-Witten invariants, and the proof of the monstrous moonshine conjectures. In each of these subjects, string theory provides crucial physical intuition which has guided the development of the mathematics and led to new conjectures. Since you also mentioned supersymmetry in your comments, it's worth pointing out that a certain supersymmetric field theory called Seiberg-Witten theory has led to revolutionary developments in the topology of 4-manifolds.

Those are just a few of the applications of string theory, but it should be enough to convince you that Witten's ideas have not led to nowhere…

21. **Peter Woit**
July 29, 2012

Bob Jones,

I pretty much agree with you, that there's a case to be made for string theory research based on other things it has led to, even though the unification idea has failed. If you look at what most "string theorists" are working on, it is typically such spin-offs, rarely string theory itself (Witten's recent work is kind of an exception). "String phenomenologists" are now somewhat of a marginalized subfield, sometimes like last year even shut-out of the most prestigious string theory conference.

That said, it's remarkable that leaders of the subject keep trying to sell it with a hard-sell for string unification, ignoring the signs of failure of the idea. It is reasonable for members of an audience being sold this to question it, but too bad that Unzicker chose to speechify, since a real question expressed politely might have gotten a more interesting response from Witten, who surely is aware there's a difficult issue for him here.

22. **M**
July 29, 2012

String theory degenerated into carpet selling when, 15 years ago, the most influential string theorists failed to acknowledge that the brane revolution ruined the predictive power of the theory. Hiring of string theorists could have been stopped at that stage. On the contrary, some famous institutions hired only string theorists, with the result that now they are almost outside from physics.

I think that this a real responsibility.

23. **David Nataf**
July 29, 2012

I find it so unbelievably condescending that anybody would imply Witten is responsible for hundreds of young physicists going into string theory. It implies these young people are sheep with no internal direction, they're simply feeling the wind and thinking "Witten, he's the smartest, I'm going to go do whatever he's doing!!"

24. **Robert McNees**
July 29, 2012

Hi Peter,

Thanks for reminding me — I knew this discussion sounded familiar. Here is my take on the issue: I agree with both of the points you list, but I don't agree with your interpretation of them.

First, it's true that we don't know what the string scale is. For the sake of argument I am willing to accept a scenario where the string scale is taken to be near the Planck scale. If you don't see some indication of soft scattering as you approach the Planck scale, then it isn't there.

Second, it's true that I'm referring to the results of a perturbative calculation (As a note to Bernhard, you should be able to find this calculation in most string theory text books). But I don't see this as nullifying falsifiability. If string theory is weakly coupled then near the string scale you begin to see soft scattering. If it is strongly coupled then it's true that I don't know what the physics looks like. But I know what it doesn't look like: the same QFT that was used to describe the physics at lower energies. In a stringy framework the predictions eventually have to take a turn from the low-energy description, and if you don't see that then the framework is falsified.

For what it's worth, I think everyone should be skeptical of strings. I just don't agree with the claim that there are no in-principle falsifiable claims.

P.S. Sorry it took so long to reply. Today was our first case of "vomiting five month old baby".

25. **anonomous**
July 30, 2012

I think Strings 2012 falls into the category of high (human) drama that you mentioned several weeks ago, where everybody is looking for something to keep this field alive. Personally, if I had anything to do with string theory I don't think I would have shown up at this conference – it sounds more like a consolation party.

26. **Anonyrat**
July 30, 2012

A 10^19 GeV collision can produce a huge number of say, 125 GeV higgses; I find it hard to imagine that such collisions will be dominated by the few particle amplitudes that are typically calculated in introductory texts. Therefore even in a weakly coupled string what should start appearing at the string scale is not clear to me.

27. **M**
July 30, 2012

Anoyrat, suppose you build a proton-proton collider at 10^19 GeV. As you need a radius as big as the Galaxy, turning it on would require at least 100,000 years. Before being able of computing string predictions, you need to find a string model that contains protons and all the SM physics. At the moment no example is known, and this might be as difficult as building the Planck collider. But presumably there are about 10^400 such models, that will give you about 10^400 different string predictions. In practice this means no prediction.

PS: David, young people have internal directions, but in practice they need a stable position before they can work on what they like independently of the community.

28. **piscator**
July 30, 2012

M:

Exactly wrong. The number of different realisations of low energy physics is irrelevant for what happens at high energy scales. Once you hit the high scale, you start hitting string excitations, which have a basic general structure – softness of scattering amplitudes, exponential growth in number of states with energy, Regge excitations, etc.

Also note that soft scattering comes from the extended nature of the string – so the answer to Peter's comment is that as long as your particle-like excitations become replaced by extended objects, which holds in all limits of string theory that I know, you should have soft scattering at high enough energies.

29. **Tmark48**
July 30, 2012

Unzicker's question is right. After 30 years people have the right to question the "social" and scientific cost of having had an entire generation of theoretical physicists waste their time on such a hopeless quest (unification of physics). And this was true after each "string revolution", we went from bad to worse. And the situation right now is that String Theory (but should we be calling it String conjectures ?) is not in any sensible way a physical theory. By its very nature it cannot predict anything (it's like having a logical model that is inconsistent, you can derive without any problem contradictory theorems).
And who are more responsable for this situation than the leaders of this field ? A very unsettling question to be sure, but one which the powers that be should thruthfully answer.
—
Now having some theorists work on ST is a good thing, as is a good thing having theoretical physicists work on other "speculative models of the universe". But putting all your eggs in same basket is never a good thing. And sometimes fields in physics just die. I think ST is one of those. You simply cannot keep alive such a framework that has nothing to show for it after decades and decades. Saying that ST has helped to understand "superconductivity" etc… is all fine and dandy, but let's get serious.
The raison d'être of ST was to unify physics, and in this respect is has been a colossal failure.
—
Witten was awared the Field medals for his mathematical acomplishments using ST. Good, so he is a very talented mathematician. Has he or will he ever be awarded the Nobel prize in physics ? That I think will never happen. So as a theoretical physicist he hasn't done such a good job after all.
—
Leave physics (experimental and theoretical) to physicists, and mathematics to mathematicians (or mathematical physicists).

30. **Bernhard**
July 30, 2012

Robert McNees,

but then let us assume string theory is strongly coupled and that I don´t observe soft scattering at say, the Planck scale. Since we know nothing about Planck scale, saying how it does NOT look it´s not really very convincing. I have no trouble seeing QFT would break down there, but my understanding of your argument is the following: at the Planck scale we should see soft scattering (if string theory is weakly coupled) or ANYTHING at all that is not QFT, and this last "prediction" could be used to accommodate the non observation of soft scattering. If the case you were making was: no soft scattering = no string theory, OK, I agree this would be in principle falsifiable, but there seems to be, as always, a caveat that could be used to evade negative results.

31. **Tmark48**
July 30, 2012

> Hansi wrote :

> "For this reason, Mr. Unzicker, nobody in the universe cares about whether you do not like mathematics. This is your own problem and so you should simply refrain from telling mathematicians, fields medal winners, and mathematical physicists that they should abandon mathematics.

—
It is ironic because no one is hitting Witten on the head for his mathematical accomplishments. But as you say, we shouldn't ask mathematicians to abandon mathematics, but by the same token we sure as hell should ask or demand that mathematicians abandon physics research. Somehow theoretical physics departments have been inundated by wannabes mathematicians. And this is a disaster for physics and physicists.

A mathematician has no problem dealing with a "physical theory" that offers 10^400 possibile solutions. He doesn't care about physical predictions so anything is fair game. But try to pass this kind of "theory" to a real theoretical physicist (and if he isn't senile or deluded) he will throw it out the window together with the person the presented it.

Right now what theoretical physics is lacking are good PHYSICISTS.

32. **AcademicLurker**
July 30, 2012

Both Peter Woit and Lee Smolin have chapters in their respective books describing how hiring works in HEP theory and how this has had the effect of chocking off alternate, non-ST approaches.

An interesting question now that ST seems no longer to be in the invincible position it once held is: will things change for the better? That is, if the sociology of the field remains the same – "Whatever the hot thing is today, that's what everyone MUST work on if they want any chance at a job." – will it matter if the hot thing is no longer ST but something else?

33. **Anonymous**
July 30, 2012

Tmark48:
" "social" and scientific cost of having had an entire generation of theoretical physicists waste their time on such a hopeless quest (unification of physics)"

You should better ask about the social and scientific cost for wasting a whole generation of PhDs as quants in the financial bogus industry.

34. **MathPhys**
July 30, 2012

You know why string theory is a very attractive subject to work on, or even only to follow? It's because, by and large, the smartest people in the physical sciences, including some of the brightest young talent, work on the subject, and it's a great pleasure to listen and to talk to these people.

I go to stringy meetings and to non-stringy meetings and the difference in average IQ, and in breadth and depth of knowledge of physics and mathematics, is palpable.

Forget about the hype (which is infinitely less today than, let's say in the mid 80's) and forget about all pretensions to compute the mass of the Higgs and all that (very few people still talk this way, and they _are_ not string theorists). Just follow the intrinsic logic of the _theory_. It's hypnotic.

35. **Peter Woit**
July 30, 2012

Hi Bob,

Good luck with the baby!

About the "string theory predicts soft scattering at high enough energy" prediction: I think here the bottom line is pretty clear. I'd describe the situation as an empty glass, Bob and others want to argue that there's still a smidgen of moisture at the bottom (at some unknown scale, amplitudes will fall off exponentially in some unknown way).

Tmark48,

I think it's incredibly unfair and unreasonable to blame the string theory debacle on mathematics and mathematicians. Of the large number of speakers at the conference none are mathematicians. Quickly scanning the list of nearly 400 attendees I don't see any names that would be recognized by people in the math community other than Witten's. The problem with string theory is not that it uses math or mathematical standards, but that it is based on a wrong physical idea about unification. The people pursuing this are physicists, trained in physics departments, hired by other physicists, funded by physics grant panels. If you listen to the arguments being made for string theory at this conference, they are about physics, not mathematics. There's a healthy and interesting area of research going on at the boundaries of math and physics, inspired often by things that came up in string theory, but people doing this are not getting hired by physics departments.

AcademicLurker,

The problem of very few jobs in particle theory, leading to hiring only of people working on the "hot" topic, is independent of string theory. Lee Smolin made this very explicit in his book, I hope this point was clear in mine. For quite a few years now, physics departments in the US have stopped hiring string theorists, but instead only hired "phenomenologists" working on things like dark matter or BSM LHC physics. With nothing of this kind turning up at the LHC, this may be as much of a dead end as string theory. The backlash against string theory has also led to a trend of not hiring anyone doing anything mathematically sophisticated of any kind. This I think will turn out to be a big mistake, a complete misinterpretation of the string debacle as due to mathematics.

36. **AcademicLurker**
July 30, 2012

Peter,

Both your and Smolin's books were pretty clear that the "sociology" of HEP theory had origins independent of ST.

I was just wondering whether the prospect that 90+ percent of the brightest folks in the field might have spent the last 30 years chasing a single idea into a dead end might result in a greater appreciation of the benefits of intellectual diversity.

It sounds like the answer to that question may be "no".

37. **Peter Woit**
July 30, 2012

AcademicLurker,

Yes, the answer is a pretty definite "no". The lesson physics departments are taking away from the failure of group-think about one trendy subject is just to change to a different trendy subject.

38. **M**
July 30, 2012

piscator,
Planck-scale string states are just many particles.
You don't know how they couple to SM particles, unless you have a model of SM particles. All quantitative predictions depend on the unknown compactification.
You can only have qualitative expectations, such as the presence of black holes and other effects that can be understood in semi-classical approximation.

Notice that some people considered the possibility of extra dimensions and strings and the TeV scale: string theorists did not provide any solid prediction.

39. **Friedrich**
July 30, 2012

The problem of string theory is not that it makes no predictions; it is that string theory has no clear principles. The issue is usually avoided. But which alternative theory does? None. So the real failure is that hundreds of people with high IQ are not able, not willing, or not allowed to think about the principles for a unified theory.

Yes, string conferences are full of really bright people. But they do not talk about the real issues. They squander their IQ. Every single day.

40. **Peter Woit**
July 30, 2012

Friedrich,
Gross acknowledges explicitly the problem of no clear principles, and points to work on higher spin theory as an attempt to get some new insight into possible principles. Witten and many others have devoted a lot of effort to finding some foundational principles for string theory.

The problem may be not the failure to acknowledge the problem, but that the problem may be insoluble. The conjecture that there is some wonderful M-theory based on some unknown symmetry principles that gives known string theories in various limits and can be used to unify physics may simply be a wrong conjecture. I'd argue that there's now 20 years of evidence for this.

41. **Jack Lothian**
July 30, 2012

Last week I bought Smolin's book for a $1 at rummage sale. It was a great buy – the first time I read it – it really helped me understand the debate on this blog. If there is another illiterate on this board other than myself, I strongly recommend it.

As to Alexander's intervention – I think the reaction was a bit over-the-top. Sure he was confrontational but I have been to dozens of symposiums/conferences & I have heard several extreme confrontational exchanges – often between well-known academics. Sure he unfairly lays the fault on the one person who happens to be most physicists' choice for the greatest living physicists. But I bet Einstein also received some equally bad & unfair public attacks. We live in a free society & with freedom comes the right to say unpleasant things. While I recognize there are real limits to how uncivilized a person can act in a formal setting; I do not think Alexander really crossed that line. Witten's purported response suggests that he accepted the factual content within the remarks & ignored the emotions – good for him.

42. **Peter Shor**
July 30, 2012

Tmark48: Mathematicians are generally kept down to earth by the need for rigorous proof. Theoretical physicists have generally been kept down to earth by the need to match experimental findings. When you remove both of these constraints, …

43. **Alexander Unzicker**
July 30, 2012

The comments on my question led me to reflect upon some points I'd like to clarify.

I see that some people felt my comment was quite long. Actually I could not hear the chairman's words but I had – and still have – good reasons to assume that it was the content which annoyed him, rather than the duration. For that, I continued.

I don't quite understand why some people saw a hostility on my side which I don't feel. I didn't question Witten's integrity nor his mathematical intelligence. But maybe for that very reason, I think he is not interested in history or sociology of science, which I think are essential if one wants to evaluate the actual state of physics. And likely, for the same reason, he is plain uninformed about physics, e.g. about the missing evidence of gravitational waves (arxiv:0909.3583).

That might all be fine, and I have no problem if string theorists do math in their
meetings. But this was a public and highly publicized event which on purpose
created the impression that the big science experiments – Heuers talk was just before – meet the top theories of physics. But string theory is not physics. It is a problem that string theory is not falsifiable, another problem that its reasoning is entirely metaphorical (see e.g. Bert Schroer's papers), but the biggest problem is that it is still labelled as science.

Yet I do not even blame Witten in first place for that false declaration. But as everybody else on the planet, he has to reflect upon the consequences of what he is doing. I am sorry that those who complained about inappropriate words havn't been
able to tell it to their friend in a nicer way. But that had to be said.

44. **Bob Jones**
July 30, 2012

Tmark48,

"And sometimes fields in physics just die. I think ST is one of those."

I hate to disappoint you, but I think string theory is here to stay. For one thing, we know that it's equivalent to interesting quantum field theories like the N=4 super Yang-Mills theory. In addition to equivalences such as this one, we know that string theory subsumes a wealth of interesting effective quantum field theories related by dualities. For these reasons, string theory has become an important part of the mathematical formalism of quantum field theory.

"The raison d'être of ST was to unify physics, and in this respect is has been a colossal failure."

You realize that string theory was originally a theory of the strong force, right? Nowadays, many string theorists view their subject as a mathematical framework whose role in physics is not yet clear. Although unification was always the main advertized goal of the theory, I think it's oversimplifying to say that unification is the "raison d'être" of string theory.

"Witten was awared the Field medals for his mathematical acomplishments using ST. Good, so he is a very talented mathematician."

Here I think you're oversimplifying the relationship between string theory and mathematics. None of the results that made Witten famous are "mathematics" in the usual sense. The concepts that string theorists work with are fundamentally nonrigorous because they are based on the notion of a Feynman integral, which doesn't have any rigorous meaning. They are physical concepts, and I don't think mathematicians would have discovered them without help from the physicists.

45. **Bob Jones**
July 30, 2012

"he is plain uninformed about physics, e.g. about the missing evidence of gravitational waves (arxiv:0909.3583)."

Are you serious?? You think Edward Witten is uninformed about physics?

46. **Peter Woit**
July 30, 2012

Bob Jones/Tmark48,

It's simply not true that Witten won the Fields Medal for "mathematical accomplishments using string theory", although this has been repeated so often that everyone seems to believe it. I've written about what actually happened here:

http://www.math.columbia.edu/~woit/wordpress/?p=99

Alexander Unzicker,

You are behaving like a crank. The point of a question session after a public talk is not for everyone who feels like it to stand up and comment on what the speaker said. By doing this at length and refusing to shut up and let Witten speak you were rude to him and to the rest of the audience, who were there to hear what he thought, not your thoughts. You could have made your point with a concise question rather than a speech, which would have been a lot more interesting for everyone.

By going on about gravitational waves and Witten not being informed about the absence of their detection, you remove all doubt in the minds of those suspicious about whether or not you are a crank. If you think you are doing the world a service by your behavior, saving us from string theory and its excesses, please be aware that you are doing the exact opposite, making people think that those skeptical of string theory are cranks who don't know what they are talking about.

47. **Bob Jones**
July 30, 2012

Peter,

Yes, you're right. I didn't mean to imply that Witten got his Fields Medal for work on string theory (though Chern-Simons theory is certainly related to string theory).

48. **Peter Woit**
July 30, 2012

Note to all,

I'm not going to host any more discussion between Unzicker and other commenters here, that kind of thing is a crackpot magnet I want no part of.

49. **amused**
July 31, 2012

MathPhys wrote:

I go to stringy meetings and to non-stringy meetings and the difference in average IQ, and in breadth and depth of knowledge of physics and mathematics, is palpable."

This is a familiar tune.
If any of these brilliant young string theorists have anything interesting to say about physics, let them go publish it in Physical Review Letters.

MathPhys, so that you can more fully appreciate the efforts the organizers of those high IQ meetings make to keep out the rabble, here's a little story:
Some years ago there was a Simons workshop on Geometry and Physics (or something like that). String theory was listed as one of the topics to be covered, but it was supposedly also open to other math-phys QFT-related topics. Young people who wanted to attend had to put in an application, listing 3 recent publications, and get a recommendation letter from a senior person. I decided to give it a shot, so I listed 3 of my papers on mathematical aspects of chiral gauge theories on the lattice, 2 in NPB and 1 in PRL, all single-author, and got a recommendation from a big-shot theoretical physicist at one of the major US universities with 7000+ citations (or maybe it was only 6000+ at that time) who was one of the main people working on that topic at the time.
My application to attend was of course turned down. The organizer wrote "Sorry, that fact that you are not working on string theory shows that you are ignorant and have a low IQ, so we don't want you at our meeting."
(OK that's not what he really wrote, but I'm sure it's what he was thinking 😉)
Afterwards I looked up the list of participants and they were all string theorists or mathematicians doing ST-related stuff. This of course just reflects the fact you mentioned that the smartest folks do string theory.

50. **piscator**
July 31, 2012

M: you are missing the physics of soft scattering. It is not something mysterious that requires pages of mathematics to understand, it is a feature of extended objects. Scattering at high energies probes structure at the corresponding inverse length scale, and if you have no structure at that scale – ie if all your objects are extended – then you cannot scatter hard. This is why Rutherford was surprised by hard scattering of alpha-particles, he thought the atom was some extended object rather than having a hard pointlike centre.

With regard to models of TeV scale strings, it wasn't string theorists who were responsible for the gross overhyping of these ill-defined and poorly motivated models.

51. **Henry Bolden**
July 31, 2012

It turns out the speculative physics = big money. So there is an application after all. Read about it the New York Times:

http://www.nytimes.com/2012/07/31/science/9-scientists-win-yuri-milners-fundamental-physics-prize.html

52. **Yatima**
July 31, 2012

"Milner Prize"?

"Where anthropic principle and philanthropic capitalism meet"?

I can only approve.

In case anyone is curious about that September 2006 A. Connes talk for other reasons besides the quote just mentioned:
http://www.newton.ac.uk/programmes/NCG/seminars/090415301.html

And a followup talk that October
http://www.newton.ac.uk/programmes/NCG/seminars/100214002.html

Fundamental Physics Prize

July 31, 2012
Categories: Favorite Old Posts, Uncategorized

String theory may not be doing so well in the popular press or among physicists, but at least a fabulously wealthy Russian investor is a fan. Yuri Milner recently deposited \$3 million each in the bank accounts of 5 string theorists (basically the theorists at the IAS and Ashoke Sen) and four others, choosing them himself as recipients of the "Fundamental Physics Prize". It seems he intends to keep doing this in the future, making "Fundamental Physics" a very lucrative business to be in.

Update: Now that I'm awake, I noticed what is odd about this prize, after realizing that the winners are kind of a list of the most prominent people in the field who haven't won a Nobel Prize. What this does is turn the Nobel Prize on its head; you get it for doing work that is untestable or wrong, but that has a high profile:

> Unlike the Nobel in physics, the Fundamental Physics Prize can be awarded to scientists whose ideas have not yet been verified by experiments, which often occurs decades later. Sometimes a radical new idea "really deserves recognition right away because it expands our understanding of at least what is possible," Mr. Milner said.

Peter Higgs's ideas from 50 years ago have finally been verified by experiment, and as a result, if he can hang in there, he may share (probably 1/3) a Nobel Prize of nearly ~~\$1.5 million~~ \$1.2 million (reduced recently from \$1.5 million). The Fundamental Physics Prize winners get about ~~six~~ 7.5 times more for ideas that have gotten a lot of hype, but no experimental test (or at least not enough to satisfy the Nobel Committee of physicists). Even better, you get the prize for your over-hyped ideas even if experiment does show them to be wrong:

> Dr. Arkani-Hamed, for example, has worked on theories about the origin of the Higgs boson, the particle recently discovered at the Large Hadron Collider in Switzerland, and about how that collider could discover new dimensions. None of his theories have been proven yet. He said several were "under strain" because of the new data.

One wonders about the implications of this for the future of theoretical physics: why should young theorists work on unpopular ideas and/or try hard to find testable ones? That will get you only ~~\$500K~~ \$400K, and there's \$3 million to be had if you work instead on a speculative and untestable idea that you see on TV.

Update: The Fundamental Physics Prize Foundation has a website here. The board consists of Yuri Milner and Steven Weinberg (although it is specified that only Milner chose the prize recipients). The goal of the prize is to "bring long overdue recognition" to its recipients and "more freedom and opportunity to pursue even greater future accomplishments". It's not quite clear why the particle physics professors at the Institute for Advanced Study (all of whom got a prize) have been suffering from a lack of freedom and opportunity to purse their research.

Update: For a profile of Yuri Milner by Michael Wolff at Wired, see here.

Update: Geoff Brumfiel at Nature has a story about this here. Ian Sample covers the story for the Guardian here.

Update: Adrian Cho at Science reports this story as Russian Gazillionaire Lobs Money at Theoretical Physicists:

> David Lee Roth, the sometimes singer for the legendary rock band Van Halen, supposedly once remarked: "Money can't buy you happiness, but it can buy you a yacht big enough to pull up right alongside it." If so, then nine theoretical physicists can now afford to join the next-to-happiness flotilla, thanks to the generosity of Russian billionaire Yuri Milner.

Update: Another article about Yuri Milner is here. It seems that he has had a dramatic effect on the venture capital business in Silicon Valley, with his tactics there somewhat analogous to his tactics in setting up this prize. Where Jim Simons has put a lot of effort into making carefully targeted investments of different sizes in math/physics research, Milner has just dumped large sums of Russian money indiscriminately on the main figures in the "hot" area of the subject with no-strings-attached, which is somewhat the same as his investment philosophy in Silicon Valley. He had a lot of success there with investments in things like Facebook, but it's still to be seen whether this was a bubble that will burst. One big difference with physics though is that in the business world you're ultimately judged on whether you make money or not. In physics you're supposed to be judged on whether your experimental predictions turn out, but his investments in physics are structured to evade exposure to that problem.

Update: There's an article about Sen getting the prize here. Note the headline: this is now referred to as "Physics highest honour".

Update: Another article about this, from Luca Mazzucato, Fundamental Physics Prize: A Russian money shot for string theory which explains:

> Every physics student's wet dream when they join grad school is to ascend one day to the Olympus of Nobel Laureates, up there in the clouds with Einstein, Feynman and the like. And, of course, Barack Obama and the Secretary of Energy Steven Chu. But most grad students who score the highest points, like the proverbial fly to honey, get inevitably attracted to string theory – that is, the ones who ditch Goldman Sachs job interview. And their Nobel Prize aspirations will never have a chance of materializing – just like that dream house in the Hamptons. That's because string theory, a.k.a. The Theory of Everything, despite its appalling beauty and tremendous fascination, is not going to come close to the real world any time soon. And since the Nobel Prize may only be awarded to those scientific predictions that pass the merciless test of experiment, that brightest students' wet dream – alas, among many others – stands no chance of being fulfilled.
>
> This was the status of string theory up until a week ago, when Yuri Milner – Russian tycoon, Facebook shareholder, and former theoretical physicist himself – dropped the bomb: nine overnight wire transfers to as many physicists' bank accounts, that instantly turned the reclusive scientists into millionaires.

Update: There's an interview at the Times of India with Sen about the prize, which includes the question and answer

> **How does the discovery of the Higgs boson impact your research?**
>
> It's one of the great discoveries of our time. Its discovery has been eagerly awaited since the time Peter Higgs, the British theoretical physicist, proposed the Higgs boson 50 years ago. It tells us that standard model and string theory are correct and that I and every other theoretical physicist who has been working under the assumption that it exists are not on the wrong path after all.

This echoes David Gross and Juan Maldacena's similar claims at Strings 2012 that evidence for the SM is evidence for string theory.

Comments

1. **Anonyrat**
   July 31, 2012

   " Mr. Milner personally selected the inaugural group, but future recipients of the Fundamental Physics Prize, to be awarded annually, **will be decided by previous**

winners.
….
According to the rules, the prize in future years may be split among multiple winners, and a researcher will be able to win more than once. Mr. Milner also announced that **there would be a $100,000 prize to honor promising young researchers.**

Unlike the Nobel in physics, the Fundamental Physics Prize can be awarded to scientists whose ideas have not yet been verified by experiments, which often occurs decades later. Sometimes a radical new idea "really deserves recognition right away because it expands our understanding of at least what is possible," Mr. Milner said.
—-
This gives the current recipients a lot more clout – have any prior group of physicists had the power to confer instant millionairedom (or 100Kdom) on a fellow physicist? – and it might encourage clique-ishness among physicists.

5. **q**
July 31, 2012

I wonder if Michael Faraday would qualify for the price, shortly after his claim, that "magnetism can produce electricity", which claim as we all know – has been ridiculed by the top "mainstream physicists" of his time, but BEFORE electromagnetic induction discovery?
My impression is, that he wouldn't qualify both BEFORE and AFTER the discovery. Taking into account present, 21 century standards his discovery would be called for sure: "highly dangerous speculation", that has nothing in common with real, experimentally confirmed physics, like String Theory.

6. **Martin**
July 31, 2012

Just a minor correction, Peter: the Nobel Prize has recently been lowered to around $ 1.2 million. So 1/3 of that amount would be $ 400k and the ratio of the "payouts" for proven vs. highly speculative ideas is even worse.

Btw, I very much enjoy your site – I attended several talks at Strings 2012 in Munich (without registration as there was no verification procedure at the entrance to the lecture hall) and it was very interesting to read your comments on the talks and the overall coverage here on your blog. I was also able to attend the Nobel Laureate Meeting 2012 in Lindau at Lake Constance and talk to Laureate David Gross. I can assure you he is still totally convinced of Supersymmetry and String Theory describing Reality.

Even being among so many Nobel Laureates and approx. 550 international young researchers from various fields of Physics the very same week of the Higgs discovery announcement (there was live broadcast of the press conference and a panel discussion with CERN scientists at the meeting), your site was actually my main source of information on everything Higgs-related. You were the first to report the news and they have been very reliable. Thank you very much for this website!

7. **lun**
July 31, 2012

Some considerations:

i) The guy is a crook. He is did not make his money by being a "venture capitalist" (you need lots of money to become one), but by being the CEO of a crooked bank in the 90s, a bank that made money by ripping off Russian pensioners and the like. Unlike Khodorkovsky&co Milner even managed to stay friends with Putin after his involvement in that. This means he is not just a crook, but a crook^2.
The facebook response is hilarious: A few months ago physicists were all enthusiastic about occupy Wall Street. Now you are salivating that a guy who makes the worst Wall Street CEO look like Robin Hood is giving physicists 0.0001% of what he took.

ii) In the last few years there were all kinds of enthusiastic debates about whether modern theoretical physics, with its lack of experimental contact and mathematical rigor, was really science.
It seems the debate is settled: What defines science is the ability to impress a very rich guy with limited specialist training. Throughout history, this was a great indication of pseudo-science, but I guess homeopathy, astrology, Kabbalah, reincarnation, perpetual motion machines and mediums were underrated: Each has its legion of very rich supporters who swore up and down it was true.

iii) As the prize also extends to maths, it is revealing that two people who _unquestionably_ changed mathematics and are still alive and economically far from wealthy, Alexaner Grothendieck and Grigori Perelman, did not get anything (Grigori Perelman lives on his mother's 60 Euro pension, which by the way is 60 Euro because of the stuff Milner&co did in the 90s). Of course both are crazy, but the fact that their "PR dept" is no match of that of the winners also plays a role. It would also be amusing to just give them the money as a surprise, because they refused such prizes before.

8. **piscator**
July 31, 2012

I have to say this seems like a terrible idea. Three million dollars (or even a hundred thousand dollars) as personal cash is a lot, and giving the decision rights on it to a small set of big shots seems to embed cronyism into the subject. Furthermore, history shows that the big names of one generation have not in general been good at picking the winners of the next.

9. **Umesh**
July 31, 2012

I really cannot understand your problem with the winners of this generous gesture from a wealthy individual. Just reading the names would make it clear that everyone in that group, from the great Prof. Witten to Prof. Sen have contributed much much more to the understanding of not only strings, but quantum field theory and so on which are ‘fundamental’ in every sense of the word.

10. **Peter Woit**
July 31, 2012

Thanks Martin!

I’ve updated the post with the more accurate Nobel information. I don’t doubt Gross is still convinced about SUSY, although I wonder if this will still be true after he has to pay off bets he has made about this at some point in the next few years.

11. **prizes**
July 31, 2012

Anyone can endow any prize for whatever reason. A large part of the reason may be to bring reflected glory on Milner himself. (Had you ever heard of Milner till now?) Complain if you wish. As Liberace would say “I cried all the way to the bank.” Yes the stated criteria for the prize do encourage the wrong kind of attitude. Yes it is bad. (BTW the Templeton Prize is intentionally more than the Nobel Prize. It says so.) Then again, why should a bright young PhD want to pursue “honest” physics? (In this context physics means theoretical HEP.) It’s already more lucrative to enter the financial industry, fresh diploma and glowing testimonials in hand, and become a thief.

12. **Peter Woit**
July 31, 2012

Umesh,

I should make clear that those getting the money have significant accomplishments, some of them spectacularly so (e.g. Witten). My comments in the posting should make clear though what I see of concern here.

13. **Thomas Larsson**
July 31, 2012

The prestige of the Nobel prize does not only stem from the fact that it is very old and very big (although I am not aware of any prize that beats Nobel on both age and size), but also from the fact that the Nobel committees have almost never given the prize to somebody unworthy. Well, not in the sciences anyway. I doubt that the world will care much about a prize that a Russian robber baron sets up explicitly to award people who don’t live up to the high criteria of the Nobel prize.

14. **Peter Woit**
July 31, 2012

lun,

The Michael Wolff article says nothing about Milner making his money as “CEO of a crooked bank in the 90s”. If you can document that, please do. Otherwise, don’t use anonymity here to slander someone.

15. **Marty**
July 31, 2012

I guess the Higgs theorists not eligible? The prize site does say “Should recognize major achievements, with special attention to recent developments.” How “recent” is recent?

The boson’s zero-spin has not been determined so to say on this site that “ideas from 50 years ago have finally been verified by experiment” appears aggressive.

Seems like Higgs, Englert, Guralnik, Hagen, Kibble (and some experimentalists) could have been included…unless this is focused solely on “new” physics or young physicists.
Those geezers are certainly not young I guess.

Anyway, very interesting prize.

16. **Peter Woit**
July 31, 2012

Marty,

Guth’s work on inflation was from 1980, 32 years ago. Higgs was 1964, 48 years. So, I guess the cut-off for “recent” is somewhere between 32 and 48 years ago.

17. **Anonyrat**
July 31, 2012

Quote: “Milner, 49, is not an oligarch. He never wangled an oil company or iron mine from the Kremlin at knockdown prices or formed a private army to protect his family. But he has been close to two of the richest and toughest of them. In the 1990s he worked for Mikhail Khodorkovsky, who acquired Yukos Oil Co. and later gained fame as Russian business’ most famous martyr to then-President Vladimir Putin. (Khodorkovsky received a second long jail sentence while Google was courting Groupon last December.) Milner’s financial partner now is Usmanov, who served six years himself in an Uzbek prison on a conviction that was later overturned. Usmanov then built a Russian metals empire worth an estimated $17.7 billion while simultaneously heading an arm of OAO Gazprom, the state-owned natural gas monopoly.

Read more: Close connections – The Deal Pipeline http://www.thedeal.com/magazine/ID/038812/2011/close-connections.php#ixzz22DKKkJNL

18. **lun**
July 31, 2012

Pardon my unnecessary cynicism, Milner obviously made billions in 90s Russia by honest hard work and inventiveness. In particular, he was the deputy CEO of investment in Menatep, I will leave the anonymous writer of Wikipedia to do the slandering.
http://en.wikipedia.org/wiki/Menatep

19. **Quantum Computer Scientist**
July 31, 2012

Alexei Kitaev didn’t start doing his best work (all connected with quantum computing) until the late 1990s. So “recent” can certainly mean in the last 15 years.

20. **JollyJoker**
    July 31, 2012

    Are there any recipients that are not doing fairly prominent work right now? Looking at the list I assumed the idea is to support ongoing work.

21. **Trulo**
    July 31, 2012

    From the NYT article:

    > The \$3 million has already appeared in Dr. Guth's bank account, one that had had a balance of \$200. "Suddenly, it said, \$3,000,200," he said. "The bank charged a \$12 wire transfer fee, but that was easily affordable."

    I wonder what it feels like, waking up one morning and suddenly finding three million in your bank account. It goes without saying that this is all unmitigated madness…

22. **Peter Woit**
    July 31, 2012

    Trulo,

    When I read that I thought that perhaps I missed my chance at the prize. Various e-mails in recent months have promised me millions if I just send them my bank account information, but I deleted those without paying close attention to whether they came from a Russian billionaire.

23. **MathPhys**
    July 31, 2012

    My concern is how this sudden influx of personal wealth will affect the research of those who will get it.

    Next year's (or next time's) winners will be decided by this year's winners, so some of us have a good idea who these will be. But all of these accomplished people are already great professors with prestigious positions that already offers them very good salaries and plenty of freedom. They are already very well-recognized and rewarded.

    I also wonder about the effect of power that this year's winners will have on prospective candidates. They had better be really nice to them from now on.

24. **Peter Woit**
    July 31, 2012

    MathPhys,

    Used to be that giving a talk in Sweden was a cherished opportunity to put oneself before people who would decide whether you get the $400K. Now that $3 million is on the line, the IAS should have little trouble recruiting prominent speakers.

25. **MathPhys**
    July 31, 2012

    Peter,

    I think you have a pretty good idea who the next winners will be. They don't need to give talks at IAS.

26. **David Nataf**
    July 31, 2012

    I don't see how this is different from the Nobel Prize, Shaw Prize, Templeton Prize, etc. It was inevitable that somebody would set up an alternative prize scheme to the problematic Nobel prize, and indeed many groups have done so.

    Peter, think back to the reverence in your words when you discussed how the CMS and Atlas collaborations should get the nobel prize, and how the rules should be amended. You wrote of prize-giving as if it were something objective. It's not.

    Within popular media, the Nobel has been lionized as the greatest achievement in the sciences, which is ridiculous. See Lise Meitner, Rosalind Franklin, John Bahcall, Fritz Zwicky (discovered dark matter), et cetera. Alternative prizes have been set up, and there will be many more.

27. **Peter Woit**
    July 31, 2012

    David Nataf,

    I have no problem in general with rich people setting up prizes for scientists, including to compete with, supplement or even duplicate the Nobel. The Nobel was just discussed in this context because it's the best example of a long-lived prize that has kept very high scientific standards in its awards. You won't see me saying anything critical about the Kavli Prize, the Shaw Prize, or a long list of others. I do think there's a problem though with the Templeton Prize (rewarding those who bring religion into science) and this prize (which to some extent rewards work on over-hyped failed ideas).

28. **kdl**
    July 31, 2012

    This new prize from nowhere is quite odd. The proper approach to make such a prize or award creditable and long term commitment should be a foundation or trust setup in the name of Milner or his choice with certain amount of allocated fund set aside. Many wealthy people who support fundamental research in general would follow such approach either setup a Prize, an Institution or both. Like Shaw, Kavli, Simons, and Lazaridis did in the past, just name a few.

    The impression is that the award is given by Mr. Milner personally, from his bank wired to the recipients' bank accounts based on the various reports link. Very unprofessional done on the surface. Although 27 million is quite large amount of money, to spend it in such manner, it's more like a cheap shot for instant fame of the giver. No guarantee of long term availability.

29. **Tmark48**
    July 31, 2012

Thomas Larsson is spot on. The value of the Nobel Prize is not just the money, but the acknowledgement from your peers that you have done something worthy in science. This kind of scientific recognition CANNOT be bought.
So what if some crook russian guy donates milions of $ to "theoretical physicists" that haven't furthered their field. Their peers will continue to have a mediocre opinion of them, money or no money.

30. **Hack**
July 31, 2012

Wow, the theoretical physics field is crazy, now a bunch of 'top' physicists in string theory and other areas with untestable theories get 3 million dollars each for ostensibly over hyping their discoveries? It seems you should be a better PR guy than physicist now a days and you'll be more successful. Plus as several people have stated earlier in posts, this just reinforces the old guard. They get to choose who gets next years prizes? Wow.

As an aside, how can physicists who champion untestable, unproven ideas past any reasonable time frame remain so revered? Seriously, doesn't that indicate that they are lacking intelligence in certain areas? Say like common sense? I'm not trying to be insulting or inflammatory, I am asking a serious question.

31. **Allan Rosenberg**
July 31, 2012

Peter,

Anyone who has a serious shot at winning the FuPP could easily find a job at a quant fund that would pay more than \$3 million a year, so I wouldn't worry too much about billionaires perverting science–Witten isn't in it primarily for the cash. If a billionaire wants to back string theory research, let him–it makes it that much easier for funding agencies to move their support to other research programs.

If it will make you feel better, I know a couple of billionaires, and I'll ask them if they're interested in awarding some prizes in the application of representation theory to multiverse studies. 8)

32. **Anonyrat**
July 31, 2012

I think this blog, among others, has championed the idea that it is bad for physics if everyone simply plays follow the leader. Well, now the leaders get to decide what is interesting not just by sheer intellectual prowess but also by large money prizes. And this helps the "follow the leader" problem just how???????

33. **MathPhys**
July 31, 2012

You really think that this year's winners will continue to do research as if nothing has happened? And given their financial power over the rest of their colleagues, you think their relationships will stay as natural?

If someone had an incredible amount of money and wanted to sabbotage a subject, you think there is a more effective way?

Mr Milner could have started a new, well-funded institute dedicated to fundamental research in physics, along the lines of the Perimeter Institute, but this time in a different continent. He could have subsidized the research of a very large number of young, talented scientists (including many in Russia who live hand to mouth). But he decided to take the easy way and splash incredible amounts of cash on those who need it least.

34. **Bernhard**
July 31, 2012

Allan Rosenberg,

one cannot compare someone´s year salary with a prize that is deposited at once in your bank account. No idea if and how much taxes are payed, but still, this is a LOT of money even for Ed Witten. But this prize is really a joke as its contenders were chosen by Milner himself, who is nobody in condition to judge scientific merit, no matter how a genius he is as an investor. He should have arranged a serious and as neutral as possible scientific committee, then this would be a total different story.

Now the problem for the future is obvious. Witten, Maldacena, Arkani-Hamed et al are of course people of the highest scientific standard, but means also this will become a string theory prize (or a "hype" prize, who knows).

I´m sure they are all aware this prize means absolutely NOTHING from a scientific point of view, but again, they are also aware they are world leaders in the field and since the money is really good, it is really hard to say no…

35. **piscator**
July 31, 2012

Hack: in some cases – clearly Witten, Maldacena, Sen and to some extent Seiberg – the main achievements are in mathematical physics. Such results are clearly `true' and as such have an intrinsic importance independent of whether or not the world at sufficiently short distance scales is made up of vibrating strings. So the answer to your question is that the results are eternal and impressive, and are justly respected.

Sure, anyone can set up a prize for whatever reason. However the more I think about it the more I think that this is just terrible for the subject. There is the sheer arbitrariness of the selection – for example awarding inflationary prizes to Linde and Guth but not Mukhanov. There is a lack of regard for what really makes the best physics – Arkani-Hamed gets a prize much more valuable than the one Feynman, Gell-Man, tHooft, Weinberg etc got? As several have pointed out, it makes the problem of follow-my-leader physics worse. As it is there are too many young people whose work is based on what is fashionable at Princeton, and the prospect of a 100k/3M dollar carrot will just make this worse.

The commenter who suggested this is a secret plan to destroy particle theory may be on the money…

36. **fp**
July 31, 2012

I'm interested to hear how young people in the field feel about this. I can only speak for myself, a graduate student, but reading this news (and the news last week about the Simons Foundation grants) makes me less excited about doing research, not more. The merits of research should be decided gradually over time by the consensus of the scientific community. A billionaire giving awards to his favorite people feels arbitrary and, ironically, it cheapens the whole endeavor. And it feels immoral to give millions of dollars to IAS professors who already have everything they need. A far better way to tap into unused potential would be to donate the money to support physics education in underprivileged areas. Find the creative, hard working kids who's talents are going unused. Again, I'd be interested to hear whether this announcement has a motivating or chilling effect on other young researchers.

37. **David Nataf**
July 31, 2012

    Well, this is probably just the beginning of prize proliferation.

    If some of you are unhappy about this, you may be suffocating very soon.

38. **Peter Woit**
July 31, 2012

    Tmark48,

    I'm afraid that at least in the US, money does talk, quite loudly, especially for university administrations. The \$27 million Mr. Milner has just spent and the millions more to come will buy him and the people he has given it to a lot of influence.

    One aspect of this influence will be that you will see very little public criticism of this prize coming from academics. My impression is that most particle theorists who have done well enough to have some sort of permanent career are convinced that only the minor matter of experiments being too difficult is what keeps their work from being rewarded with a Nobel prize. They're not going to jeopardize their shot at \$3 million by shooting their mouths off in public…

39. **Chris Herzog**
July 31, 2012

    I hope that the winners spend the prize money on their research. Heck, if Arkani-Hamed, Seiberg, Maldacena and Witten pool their winnings, they ought to be able to endow a few new positions at the IAS. Maybe they can even reduce their tax burden with such an approach.

40. **Trulo**
July 31, 2012

    On second thoughts, funny how nobody seems to have rejected the prize. It seems Perelman is one of a kind.

    On the other hand, what on Earth is Weinberg doing in the Board together with this guy (appropriately described above as a "Russian robber baron"). I strongly suspect that if I invited SW to give a talk at my Department he would politely decline… could it be true that money can do the trick?

41. **Peter Woit**
July 31, 2012

    Trulo,

    We don't actually know if anyone turned down the prize. If they did, I doubt this fact would have been publicly announced. Maybe there were originally supposed to be 10 prizes. Hard to think though of someone who would naturally fit in with the other 9, but would turn down \$3 million.

    If you were to call up Weinberg to tell him you needed help spending \$20-30 million and you were sending your private jet to pick him up, you might have better luck getting his attention.

42. **anonymous**
July 31, 2012

    I had predicted Kitaev would win a Nobel prize if someone ever makes a qubit out of a non-abelian anyon, which might happen within a reasonable time scale, maybe a couple decades. Now that the Nobel committee will see he doesn't need any more money, I may have to cancel the prediction. Congratulations in any case! This prize, like his previous MacArthur Fellowship, is very well deserved.

    For the rest of you worried about cronyism, just chill out. There's no precedent. We should give this year's winners the benefit of the doubt that they'll do the right thing.

43. **Alp**
July 31, 2012

    I think this is welcome news. Nobel was more and more starting to become a self congratulation by the liberal establishment — influenced more by politics than merit. Even the president got it with hardly anything credible.

    If anything, it is more commendable when people choose to support ideas with their own money than with others'. I doubt any of the negative commenters would turn that reward down if they were chosen as one of the recipients.

44. **Peter Woit**
July 31, 2012

    Alp,

    I freely admit that I, for one, would not turn down \$3 million if some eccentric Russian gazillionaire wanted to deposit it in my bank account. Eccentric Russian gazillionaires should be free to do what every they want with their gazillions, to the extent that they are legally obtained gazillions.

    Spare us though the political commentary about "liberals", and I'll ruthlessly delete any further comments that try and enter into the usual tedious political discussion that you want to bring up. One wonderful thing about the Physics Nobel, as well as the arguments about string theory and related issues is that they have nothing at all to do with this.

45. **Henry Bolden**
July 31, 2012

    This has got to be disastrously bad for the future of theoretical physics. Now we've got a clique of cronies, the initial prize winners, who get to decide which of their friends are going to be rich. The scheme might be sufficient to corrupt even Witten which I would have thought to be impossible.

    The prize winners are certainly a talented bunch and well worthy of accolades, pats on the back and fancy plaques for their office walls, maybe even a marching band with 70 tubas, but giving them a whole lot of cash seems pointless. The IAS permanent members are well paid and already have the freedom to do whatever research they like.

    What's next? Maybe Tony Soprano will sponsor a big prize in arithmetic algebraic geometry? That will get the subject going. Or else.

46. **David Roberts**
July 31, 2012

So is Kontsevich a physicist now? There's a big difference between theoretical physicists who work on string theory and mathematicians who work on string theory. One of them can claim proof of their work.

47. **anonymous**
July 31, 2012

Kontsevich's work isn't just string theory. His deformation theory stuff is pretty cool. The phase space formulation of quantum mechanics, for which deformation theory provides some foundation, happens to be my personal favorite. The Kontsevich quantization formula sets up some fun generalizations. Sure, it has difficulties making the transition into relativity, but maybe this prize will encourage some brilliant graduate students to revisit this line of attack for, say, quantum gravity?

I'm really surprised by all the negativity in these comments. This prize should be an inspiration for promising young theorists to take some risks in their work (like the idea that Avi Loeb has been promoting) without having to worry about the volatility of public funding. They can use the money to attract new students, pass the funds along to experimental research that may corroborate or rule out their theories, or donate it to a charity.

And I'll reiterate that you all shouldn't assume the worst in people. These winners are not likely going to be corrupt and resort to cronyism. These guys already got their prize, so they're bound to pass around the torch to different branches of physics. Jeez.

48. **Robert Rehbock**
July 31, 2012

No strings were attached these awards, right?
These recipients are all top scientists. They get to choose what to do with the money. I am confident that they will use it more wisely than many persons who possess and use their money.

49. **Henry Bolden**
July 31, 2012

Here's a way that the Yuri Milner lottery winners, at least the IAS members among them, can show solidarity with the math/physics community. They can donate half their winnings to the IAS and that will be matched by the Simons/Simonyi $100 Million Challenge Grant:

http://www.ias.edu/news/press-releases/2011/08/18/challenge-grant

50. **Giotis**
August 1, 2012

Finally justice was served…

We were tired to see mediocre physicists winning the Nobel prize just for being lucky (a characteristic example is Penzias and Wilson but there are more) or for some unimportant shallow discoveries while the true giants of theoretical physics and their revolutionary frontier research remained largely unappreciated by the general public.

The Milner's prize certainly fills this gap.

51. **Bernhard**
August 1, 2012

"Hard to think though of someone who would naturally fit in with the other 9, but would turn down \$3 million."

Since this is just a high-profile prize, what about Lisa Randall? Well, she will end up winning anyway, now that is up to the stringy guys to choose the next winners.

52. **Bernhard**
August 1, 2012

Sorry, I misread, I don't think Lisa would (will) turn down 3 million, my comment is restricted to "someone who would naturally fit in with the other 9".

53. **M**
August 1, 2012

I propose a prize to Ereditato for superluminal neutrinos!

Speaking seriously, while awarding a prize for inflation is reasonable, giving a prize for speculations not confirmed by LHC is less reasonable.

54. **Anonyrat**
August 1, 2012

In reply to Giotis, physics is about the world, and not about theoretical achievements, and not about IQ. Penzias and Wilson accomplished more for physics than a lot of IAS physicists – they actually discovered something.

55. **Thingumbob**
August 1, 2012

Modest suggestion. Prize should be renamed physics of the fundament. Thank you.

56. **gurplesnork**
August 1, 2012

Hawking and Penrose would seem to be good candidates for this prize.

57. **Tmark48**
August 1, 2012

I think the correct term for this prize should be "Milner's Prize for speculative thinking". The general public will have a distorted (if it isn't already the case) of what

theoretical physicists do. This is what happens when a generation of theoretical physicists the caliber of Feynman and Wheeler (among others) passed away with no replacement in sight. Theoretical physics reduced to speculative thinking has nothing to do with physics.
I wouldn't have awarded the prize to anybody. Maybe put it on the backburner for Alan Guth waiting for experimental confirmation of cosmic inflation. As for the others no.

58. **Tmark48**
August 1, 2012

> Robert Rehbock wrote : "No strings were attached these awards, right?"

—
I'd say ONLY strings were attached to this prize. ^_^

59. **P**
August 1, 2012

Peter, Tmark, and other people with similar sentiments,

I'm a bit surprised by the anti-string talk regarding this award. You often distinguish, Peter, between the use of strings for attempts at unification (on which we disagree), but acknowledge that strings have made very important contributions to our understanding of mathematics and quantum field theory. I'm confused, then, by the attitude in

"String theory may not be doing so well in the popular press or among physicists, but at least a fabulously wealthy Russian investor is a fan"

for example. First, it doesn't really matter how string theory is doing in the popular press, because we physicists tell the non-expert public what they should think, anyways. Second, the issue that some physicists take with strings is (or should be, if one takes issue with anything) entirely related to unification, not the formal work which sheds light on other subjects. How does one take issue with this award, then, given that all of the recipients who work on string theory have used it for important not-unification-related purposes?

This is a serious question. Even if we disagree on unification, it's important to delineate between the different types of work done by string theorists. In my opinion, the animosity in the comments is unfair to direct towards these men.

And, if anyone thinks these men aren't deserving, please name who you think has done more significant work! I'm curious to hear ideas.

Cheers,
P

60. **Peter Woit**
August 1, 2012

P,

You're completely ignoring every argument I made here, so it's hard to see much point in repeating any of them. Again though, the basic point is that this is the largest award ever given to scientists, and it is being given explicitly for work that can't be experimentally tested, or has been tested and failed. The nine people given this award are a mixed bag, with very different accomplishments, but I think it's clear that if you gathered together a reasonable group of the most respected physicists in the world, and asked them to put together a list of the nine most important people in the subject, you wouldn't get six out of nine with a connection to string theory.

As for the animus about string theory, look at the previous posting. Last week, Maldacena and Witten were featured at a press conference promoting string theory in Munich. Did they acknowledge that string unification is not working out? No, instead they said all is fine, the field is making great progress, and made the absurd claim that string unification is testable because quantum mechanics and the SM are testable, and that's what the theory is based on. This kind of nonsense has been going on for 20 years, it has been really effective in misleading people about the true situation of string theory and making sure that string theorists get rewarded far beyond their due. If you want to know where the animus is coming from, that's it.

61. **MathPhys**
August 1, 2012

And, if anyone thinks these men aren't deserving, please name who you think has done more significant work! I'm curious to hear ideas.

The collective powerhouse of bright young people with no tenure, or with heavy teaching workloads, would greatly benefit from a fraction of 3 million dollars each, to allow them the opportunity to think in peace and to get some research done.

The great men of IAS and IHES have all the job security and the opportunity that they need.

62. **ex**
August 1, 2012

We just needed this prize, now that with some experimental data the community was starting to heal from decades of deviant thinking, of demagogic push for untenable arguments, of trivial or useless model building, of ignorance for the number of phenomenological open problems, of bad influence on students, of aggressive lobbying in career selection..

I guess that this prize is exactly what it is announced to be – a money prize for those who will never win a nobel physics prize. Let's hope they get their boat, and leave public recognition, personal satisfaction and happiness to Higgs.

63. **ex**
August 1, 2012

And it would be really nice to hear what Weinberg has to say about the selection and the fact that he is funnily on the Board, while not participating in it.

Weinberg has never been a critic of string theory, I guess for fear of being isolated by the community.

64. **David Derbes**
August 1, 2012

I want to disagree a little bit with the claim that the winners have no experimental evidence to back up their ideas. That may be true of the string folks, but it seems to me not true with respect to Alan Guth. Guth's work on inflation (in my opinion) has been confirmed by the size of the anisotropies measured by the Wilkinson MAP and by the harmonics predicted by Wayne Hu et al. I'm sorry that Alan Guth hasn't yet won a Nobel, and this Milner prize is nice consolation, well deserved. (For the record I had a undergraduate advanced mechanics class from Guth in 1973, during the all too short time he was at Princeton, and thought him one of the best teachers I'd ever seen. Forty years later that's still true.)

65. **anon**
August 1, 2012

It's interesting to compare the behavior of Simons and Milner. Simons gives out lots of small grants to young researchers in math — e.g. his 5000 travel grants are smaller than anything the NSF will give out, and are very useful for postocs. Although he has invested far more, and far more usefully, than Milner in science, he has (arguably) achieved less publicity. For example, Milner's prize was a prominent story in the NYT, whereas Simons had to take out an ad there to announce the Simons Fellows winners.

Milner's investment will probably not change science in any way: Witten, Kontsevich, etc. will continue doing the same great research but with a fatter bank balance (unless they decide themselves to donate some of this money to other, more needy, researchers). Simons has given many young researchers the time and money to pursue their research.

That said, I'm also surprised by the negative comments about the prize winners. If the title of the prize was changed to "mathematical and fundamental physics" no-one could possibly object to awarding it to Witten, Seiberg, Konstevich, etc. all of whom have made incredible contributions. All of their contributions are still great if you subtract anything to do with string theory.

66. **Bob Jones**
August 1, 2012

"there's \$3 million to be had if you work instead on a speculative and untestable idea that you see on TV."

"I think the correct term for this prize should be 'Milner's Prize for speculative thinking'."

I hope you guys aren't referring to the IAS physicists when you talk about "speculative" ideas. One of the things I admire about these physicists is that so much of their work is not speculative. As others have pointed out, much of their work is mathematical in nature and doesn't postulate anything about the real word. If you look at the citations on the website for the prize, you'll see that it's recognizing the laureates for a lot of perfectly legitimate things like

"the exploration of new mathematical structures in gauge theory scattering amplitudes"

"insights into a range of problems from high temperature nuclear matter to high temperature superconductors"

"exact analysis of supersymmetric quantum field theories"

"non perturbative duality symmetries"

I wouldn't say that any of these ideas are "speculative", and it makes no sense to say that they're "untestable". All of the IAS scientists have made outstanding contributions to science, and honestly, I think the sort of work they do is far more valuable than most of the testable phenomenology that other people work on. If theoretical physicists were just about coming up with testable hypotheses, it would be nothing more than a bunch of speculative and poorly motivated models, almost all of them wrong.

67. **Peter Woit**
August 1, 2012

Bob Jones,

There's no denying these 9 people have made significant contributions to science. These include however some of the most over-hyped work in the subject (among your examples, insights into "high temperature nuclear matter" is an example, going through all the things you left out of your list would provide many more). They have also benefited greatly from every reward academia has to offer, to some degree because of the huge hype level. Given this, the question is whether an order of magnitude jump in the rewards reaped for this sort of work is a healthy thing or not…

68. **ex**
August 1, 2012

Bob Jones – I think you have it in front of your eyes.

Higgs – Anderson – Weinberg – Glashow – Feynman – Wilson – Pontecorvo – Occhialini – Dirac – Majorana – Fermi – Bohr – Heisenberg – Einstein – Oort – Chandrasekar – Maxwell – Newton – Galileo .. a long and partial list.. All people leaving milestones in the comprehension of some physical phenomenon. Not technical analyses, but understanding of the dynamics, with a world of new phenomena coming out.

Please speculate like they did, but soon get reconnected like them to experiment, not to some unreachable very high energy frontier, which inevitably becomes obscure and demagogic. In this respect also inflation is at the boundary of being physics – we will never test it – we will never see the inflaton and its potential, with its 10^-20 small slope. Instead – we saw the higgs, we see the W, neutrino oscillations, Fermi interactions and so on.

69. **Sammy**
August 1, 2012

It is better to be 25, unknown and broke than 65, famous and worth $3m.

70. **Peter Woit**
August 1, 2012

I should also point out that I'm all in favor of work on speculative ideas, well aware that good ideas are often untestable for a long time if ever, and very much of the opinion that progress in physics needs more mathematics not less. The problem is the hype level surrounding string theory, which has brought huge attention to a very narrow range of ideas, coupled with a vigorous campaign to deny obvious failures. Hep-th has been full for nearly twenty years with papers on "non perturbative duality symmetries", leading to some results that are interesting, but often very much oversold, and no acknowledgement of the massive failure of the research program still used in the marketing of this work.

There's a universe of fascinating and poorly understood topics on the borders of fundamental physics and mathematics, with very little of it getting any attention, and with likely career suicide awaiting anyone who tries to work on many of these topics. Witten himself is responsible for a wide range of such ideas and he fully deserves the recognition and a huge prize, but the industry that developed around one aspect of his work doesn't. Young physicists need to be provided with financial support to try something new, not with millions of dollars dangled in front of them to encourage them to work in the same narrow, overhyped area.

71. **Tmark48**
August 1, 2012

@ Bob Jones :

—
I think a physics prize should reward physics accomplishments. Theoretical physicists have in past been awarded the Nobel Prize, so they arent' in any way penalised with respect to the rest of the physics community.
—
To be clear, I think we need theoretical physicists in all branches of physics (quantum optics, high energy physics, astronomy, astrophysics, condensed matter physics and so on…) and we also need a small number of theoretical physicists working on what I would call "highly speculative and non testable models" of reality.
But this second group has to know that while the community at large will recognise their accomplishments (if they have any), they don't deserve a physics prize.
Maybe a maths prize if the work they've done warrants it, but certainly not a physics prize. Nobody will say that Penrose or Hawking haven't done important discoveries in theoretical physics 50 years ago. Do I think they deserve the Nobel Prize in physics ? Not by a long shot. Unless someone comes up with an experiment that confirms that black holes actually evaporate.

72. **Raznol**
August 1, 2012

@Peter Woit: You say it's career suicide to work on these other topics.. how sure are you of this? Do you know of individuals who have done good work in less popular areas whose careers were ruined? I personally think it's more that people are afraid to try riskier routes, and moreover it's easier to travel down the paved road than to branch out into the wilderness, so the chance of success is lower and that deters people.
I'd prefer to stay anonymous here, but I've worked in pretty nonconventional areas (of math) and I didn't get much resistance. I don't think it hurt me careerwise. It always seemed to me that if you did good stuff in a different way, you'd get respected… just that most people were either unable to, or more commonly, not inclined to really try to.

73. **Bright Matter**
August 1, 2012

Yuri Milner approach to encourage fundamental physics is wrong because it fundamentally distorts the motivation and incentive for doing such research.

Fundamental physics is NOT a Silicon Valley tech startup. Where venture capitalists dump big money on big ideas to fund risky initiatives. Hoping for a big return from the marketplace.

Yuri Milner thinks by paying huge financial rewards for hot ideas, scientific discoveries will happen. No. Scientific discoveries happen because of two things: the ingenuity and dedication of the researchers, and the experiments to prove the theories. Paying for ideas, or even theories, without proof, is NOT science.

Researchers are already well-paid. Their reward is success of theories and recognitions. I can tell you none of them entered this most difficult field because of the money.

74. **Peter Woit**
August 1, 2012

Raznol,

I should have made clear that I was talking about careers in physics departments. Math departments are a very different story, with a different culture, and a better ratio between the number of smart people needing jobs and the number of jobs.

These days in physics, the job market for anyone doing anything involving sophisticated mathematics is dismal. If you apply for a post-doc or tenure-track job and are working on a short list of the hot topics pursued at the IAS (basically amplitudes, higher-spin gauge theory, or exact results in N=2 4d gauge theory), you have a slim chance of finding a job. Go through Witten's papers and pick any one of a large number of interesting topics that deserves to be followed up, then submit a job application saying that's what you want to work on. I think you'll then understand the "career suicide" remark.

75. **Sammy**
August 1, 2012

What is truly dismal is that PhD physicists cannot find jobs in high schools.

76. **Bob Jones**
August 1, 2012

Peter,

Fair enough. Do you think there's anyone else who deserves $3 million, or are you saying the whole idea of the prize is misguided?

77. **Bob Jones**
August 1, 2012

ex,

Your list might seem like a long one, but when you think about how many theoretical physicists there are, you realize that it's actually quite sort. Most theories of physics turn out to be wrong. My point was that if everyone in physics were doing phenomenological work, the subject would be more speculative, not less.

78. **Bob Jones**
August 1, 2012

Tmark48,

"But this second group has to know that while the community at large will recognise their accomplishments (if they have any), they don't deserve a physics prize. Maybe a maths prize if the work they've done warrants it, but certainly not a physics prize."

You may disagree with the choices that Milner made, but he can do whatever he wants with his money. If he wants to give a prize to a bunch of mathematical physicists, he's free to do it. If he wants to call it a physics prize, he's free to do that too.

"Do I think they deserve the Nobel Prize in physics ? Not by a long shot. Unless someone comes up with an experiment that confirms that black holes actually evaporate."

Should Hawking get the Nobel prize? Again, the prize committee can do whatever it wants. It doesn't matter what we think. Does Hawking's work deserve to be recognized as some of the most important physics work of the last 50 years? Absolutely. It makes no difference if we can't observe Hawking radiation because, like all of the other results I mentioned, Hawking radiation is a formal consequence of well tested theories of physics. It's a statement about what our theories predict, and such results are interesting and important even if they don't describe the real world.

79. **Peter Woit**
August 1, 2012

Bob Jones,

I think the whole idea of giving multi-million dollar prizes to the most prominent people in math and/or physics is misguided. There's no reason it should help with their work, and academia is already enough of a star system as it is. The sizable number of current $1 million-scale prizes (Nobel, Kavli, MacArthur, Crafoord, Kyoto, Shaw, Abel, Millenium, maybe others) seems more than enough, with the people who get them not exactly languishing in obscurity before they get the prize, or doing better work after getting it. Going to \$3 million seems unnecessary, other than to emphasize how wealthy the financier putting up the money is. He should stick to using his \$100 million house for this purpose.

80. **John Preskill**
August 1, 2012

@David Derbes: I also took that classical mechanics class from Alan Guth in 1973 … it was fabulous! He was the best physics lecturer I ever had aside from Sidney Coleman.

The criticism that the recipients already have all the freedom they need applies to any high profile prize doesn't it? Prize winners usually have very successful careers before they win their prizes.

One can always point to other worthy candidates, but these nine are very great scientists, and I'm sure they'll take seriously the responsibility of choosing the next winner. If someone is to chair the selection committee, Alan would be a good choice because he is so organized and conscientious.

81. **Tmark48**
August 1, 2012

@ Bob Jones :

Milner is abosolutely free to do as he pleases with his money. But I am free to criticise those that receive this "physics" prize. Now as a matter of principle I'm not opposed to awarding monetary prizes to theoretical physicists. But and this is were we have differing opinions, you think that any speculative idea is worthy of a prize, I on the other hand do not.

As for Hawking lets get real. Black hole radiation has been derived within a semi-classical model. And for good reason, no quantum theory of gravity exists at all. So what is in principle a quantum gravity effect has been derived by neglecting the important part. So we don't know wether this effet is real or not. General Relativity assumes space time is a 4 dimensional differentiable manifold. How can we assume that space at the planck scale is continuos ? It's a pretty ardous proposition with nothing to back it up.

82. **q**
August 1, 2012

Yuri Milner should give his prize to CMS and ATLAS people. As far as I know, there are 3000+ members in each team, so 27M divided by 6000 it is still a lot of money, all heavily working experimentalists absolutely deserve.

83. **Bernhard**
August 1, 2012

@ John Preskill:

"take seriously the responsibility of choosing the next winner. "

This is perhaps true, but although they are all, undeniably, excellent scientists, they are still humans and still in favor of their programs , which is only natural (after all one good reason they pursue their line of work is because they believe in it). You cannot choose 6 string theorists to decide "who did a great speculative job in physics" and expect the winners will not lean strongly to string theory. Physics has tons of models of physics in particle theory too, the vast majority of them (probably all) just as wrong as string theory. Again, this was not a prize for ideas, if it was, only the scientific community was in position to decide which ideas deserved a prize. Milner excluded from the equation the only thing that could make a scientific prize to have any credibility, the scientists.

84. **ex**
August 1, 2012

Bob Jones,
yes my list is short, exactly the ones I may think deserve any prize for "fundamental" physics.

On your point, I don;t know you should probably clarify what you mean by speculative, and whether it has negative meaning.

When Majorana was suggesting to Fermi new nuclear particles, neutrons, instead of a sum of proton+electron, do you think this was a useful or a useless speculation? It was really tied to ongoing experiments.

And when he was introducing neutral fermions being their own antiparticles, do you think this was useless speculation? To him, that was really a pure speculation, but in the same year ('37) it was recognized as possibly giving rise to neutrinoless double beta decay (measurable today).

The lesson I get is that you should speculate, but not escape in exotic constructions with weak or no motivation, which for its sustainment ends up needing mediatic overhype on the partial results, military occupation of academy, elimination of critic voices, etc – this reminds me of cultural fascism. It happens to societies, it happened in science.

I was discussing with collegues: the only sad question is why Weinberg had to follow them. He had other choices. He was a respected physicist with an impressive record of physics… I just compare with Anderson or Glashow – who did keep their mind clear.

85. **Anna**
August 1, 2012

First of all, it is worth noting that it is his money to do with as he pleases and it would be wonderful if more seriously wealthy people used their funds this way. Most of the complaints sound a bit like sour grapes. All contributions and rewards for research should be applauded – these are after all credible and serious researchers, not cranks.

Secondly, established funding mechanisms (government money decided by scientific peer review) are pretty good at excluding the patently crazy, but poor at picking out the high risk high return research which would largely be driven by very young researchers – decided as it is by what is effectively a gerontocracy. And so funding largely goes to the safe established middle. 'Big science' is making it harder for young people to do anything except join 'established' teams – it is no longer possible to come up with a revolutionary theory while sitting in a Swiss patent office and government funding is risk averse further pushing the safe middle option. Maybe the venture capital model is exactly the stimulus needed at this point in time for some radical thinking in the field.

Finally, there is space for speculative fundamental research – it is how great leaps forward occur, and whatever the success of the LHC in confirming the Higgs, no-one can deny that such a rethinking is required – unless Nature really is perverse. A null result is as important as a positive when that work has a feasible basis, is intellectually demanding and makes significant contributions to other fields. And whether a researcher picks a correct model or not is often a matter of luck and serendipity.

(P.S. I am not a string theorist.)

86. **John Preskill**
August 1, 2012

@ Bernhard: I concede that the prize might have more credibility if the initial winners had been chosen by a panel of scientists instead of by Yuri Milner. Regarding future winners, I'm inclined to give the selection committee the benefit of the doubt. I know all this year's recipients except for Kontsevich … not only are they extraordinarily deep thinkers, they are also pretty broad scientists with knowledge of and appreciation for physics outside of their specialties. Of course everyone has prejudices, but they will do their best to be fair.

87. **anonymous**
August 1, 2012

Nobody will say that Penrose or Hawking haven't done important discoveries in theoretical physics 50 years ago. Do I think they deserve the Nobel Prize in physics ? Not by a long shot. Unless someone comes up with an experiment that confirms that black holes actually evaporate."

I had predicted Penrose could share a Nobel prize with Schechtman and maybe one other person for their work on quasicrystals. When the Nobel committee award the prize to Schechtman alone this last year by taking the chemistry angle, they missed their opportunity. Oh well.

As for Hawking, the Nobel committee could lump him together with some of the [UBC team] or similar for a shared prize. These kinds of "fun" Nobel prizes aren't without precedent.

88. **Peter Shor**
August 1, 2012

Even in math departments, working in unpopular areas can be close to career suicide. I know at least one case of a good mathematician whose career nearly went down the tubes because he had a very good thesis in a very unpopular area (he managed to find a job, do some great work in a better known area after his thesis, and is doing very well now). However, in math, a much broader range of areas will get you a good job.

89. **anonII**
August 1, 2012

@piscator "Furthermore, history shows that the big names of one generation have not in general been good at picking the winners of the next."

Good point, I just read how Heisenberg told Hagen and Guralnik the Higgs Theory was "junk". Clearly he couldn't pick 'em.

Also, physics prizes in general will get a lot more attention in the next couple years as this prize announces its second set of winners and the Nobel Prize has to deal with how to handle the 5 remaining Higgs theorists (E-H-G-H-K).

90. **Truth**
August 1, 2012

A wonderful prize and a wonderful selection of truly worthy winners…deep, creative, imaginative thinkers. They have taught us a lot about deep properties of general relativity and quantum mechanics in strange and interesting ways. Some of their ideas are definitely correct, such as quantum computing, others have been rather well tested, such as inflation, others are surely connected to our world in one way or another, such as gauge/gravity duality, other ideas generate beautiful connections between physics and mathematics, such as formal string theory, and other ideas are just rather speculative, such as large extra dimensions.

"Imagination is more important than knowledge" Albert Einstein.

The only odd thing in my mind is that he decided to give \$27 million to 9 physicists. Why not \$27 million to 100 physicists, or so? Share the love…Wonderful nonetheless.

91. **Anonyrat**
August 1, 2012

The real worry is not about these 9 recipients, it is about the effect of this prize on every other physicist.

92. **Peter Woit**
August 1, 2012

Thanks to all for the unusually high quality of comments here. Some even are from people (John Preskill and Peter Shor) of high accomplishment who seem to me viable candidates to join the "next-to-happiness flotilla" if the committee does as good a job as one would expect.

Perhaps there are other such here among those who prefer to stay anonymous. I'm guessing for example "Truth" might be in a category where this would work out if the numbers were expanded as he (or she?) suggests. In any case, good luck to all of us in this new world we've entered where, as one venture capitalist described the situation to me "financiers are handing out \$3 million checks to scientists like so much candy." As our economy evolves into one dominated by the activities of a sizable group of multi-billionaires, often with math/physics background, they can't spend it all on yachts, mansions and jets, so surely even more will come our way.

93. **Low Math, Meekly Interacting**
August 1, 2012

Interesting thing about the Nobel: Almost no one talks about the money. As for the Milner Prize, money is all anyone is talking about.

94. **Michael Kovarik**
August 1, 2012

I don't believe that this is going to negatively impact the physics community. It won't combat the fact that the American job prospects for those who research quantum gravity has never been worse and it is given to such an exclusive club that it won't propel any research in any direction (no one does physics research for exorbitant prize monies). Perhaps if Yuri had split that \$5 million into 1,000 micro-grants, it might be a problem.

95. **Bob Jones**
August 1, 2012

ex,

When I say a theory is speculative, I mean there's a good chance it's wrong. For example, I would say that most of the theories predicting BSM physics at the LHC are highly speculative. On the other hand, the sort of formal string theory that people at the IAS are doing is not speculative at all because it's not the sort of thing that requires testing. Such ideas are known to be correct because they have been proven mathematically (at least by physicists' standards).

I would prefer to see more well motivated mathematical work, rather than millions of badly motivated predictions of LHC physics.

96. **Joydip Ghosh**
August 2, 2012

Alexei Kitaev — For the theoretical idea of implementing robust quantum memories and fault-tolerant quantum computation using topological quantum phases with anyons and unpaired Majorana modes.

@ John Preskill: Happy to see Kitaev as one of the laureates. Since you are perhaps the best person to talk about his research, I have a question for you: It's not clear to me from the above if he got that for topological quantum computation (with non-abelian anyons) or topological quantum error correction (with surface code).

97. **Raisonator**
August 2, 2012

I can't help myself, but there seems to be a certain bias towards people from English- or Russian speaking countries – or at least they work in such countries.
Yet I do fully appreciate the work of these 9 people and think that they have well deserved the prize.

98. **ex**
August 2, 2012

..On the other hand, the sort of formal string theory that people at the IAS are doing is not speculative at all because it's not the sort of thing that requires testing. ..

I would prefer to see more well motivated mathematical work, rather than millions of badly motivated predictions of LHC physics.

Ok, this is the point – very well, but I believe that may be mathematics or mathematical physics, but it is not physics, and it is not fundamental physics.

Thus, it should not be sold as such, let aside the purported "final theories", "elegant universes" or whatever. All these things already said, of course.

99. **piscator**
August 2, 2012

To those who think this is good news:

The issue is not that the awardees are not worthy of recognition. They are all good people who have done good work. Some I think are truly outstanding who have contributed continually across many areas, some I think were in the right place at the right time, some have extraordinary personal charisma and salesmanship. But they are all good people.

The big issue I have is when visualising the following type of scenario. Laureate X is on a committee handing out postdoctoral fellowships with Y who is not a laureate but could credibly be one. One of the fellowship candidates A is a student of X. Does the existence of this award make it more or less likely that Y will speak honestly about A?

Furthermore, it is clear from the history of science that brilliant people can also have ideas that are cranky or just plain wrong. The scientific ideal – again, hard to realise because scientists are people too – is that no matter who they are, other people can tell them that they are talking bollox. The existence of such a prize with this recurring structure only serves to act against and not for this.

It is of course worth reiterating that 3M is a lot of money for academics, even those with tenure at the IAS. The IAS is private, but if anyone doubts this you can look up online salaries of comparable people at public institutions, eg David Gross in the UC system.

100. **Rene Benthien**
August 2, 2012

This harkens back the days in the renaissance when the wealthy elite of the Italian city states, the Medici and the Sforzas, were commissioning the great works of Bernini and Michelangelo. To the time when the Dutch Royals and the merchants of Amsterdam patronised the works of Rembrandt or Van Dyke. An era where the Kings, nobles and bishops felt it necessary to fund the work of Copernicus, Brahe and other great philosophers.

There was a time when the reputation of a man, his pedigree and refinement, was based on his appreciation for and the encouragement of the arts and the philosophies.

In today's world where it seems the only thing that matters is the balance in someone's bank account, I think it is great that someone feels that the value of scientists and the work that they do be held at a greater esteem in society than it is currently.

101. **Clayton Pickering**
August 2, 2012

Low Math, Meekly Interacting said:

"Interesting thing about the Nobel: Almost no one talks about the money. As for the Milner Prize, money is all anyone is talking about."

Apropos, Low Math. Perhaps, as a suggestion, those who have won the three million dollar prize should do what Milner has done. Take 100, 000 dollars and find a big idea by some unknown. Now that's a 9 to 1 ratio whereby you folks empower yourselves.

102. **Peter Woit**
August 2, 2012

Clayton,

The four winners from the IAS already completely control about 20 research positions at the IAS, which typically pay more than 100K over the time the person is there. To the extent that there are "unknowns" with a "big idea" that meet their approval, they've always had plenty of jobs to hand out to them (although I guess one big advantage of a 100k check versus the job is that you wouldn't have to live in Princeton…)

103. **Peter Woit**
August 2, 2012

Rene,

I'm missing how depositing \$3 million checks in the bank accounts of successful academics fights the attitude that the only thing that matters is the size of one's bank account. Seems to me it reinforces that attitude.

And the idea of reverting to the world of the Medicis, with hedge funds and Russian oligarchs playing their role, also is not obviously progress.

104. **John Preskill**
August 2, 2012

@Joydip Ghosh: Kitaev's 1997 paper discussed too related ideas — using surface codes (systems supporting abelian anyons) for robust quantum memory, and using systems supporting nonabelian anyons for both robust quantum memory and fault-tolerant quantum computing. Both are great ideas and have had a huge impact on quantum computation research.

I think the nonabelian version was the deeper and more original idea, but surface codes might wind up being more useful for future quantum technologies. My reading of the prize citation is that the proposal to exploit nonabelian anyons is being recognized, but I agree it is not completely clear.

Actually, both ideas are quite timely, in view of the evidence for Majorana fermions in quantum wires reported this year by the Delft group, and the recent excitement about realizing surface codes using superconducting circuits (e.g. work by the UCSB and IBM groups).

105. **Low Math, Meekly Interacting**
August 2, 2012

But is it "the value of science", or the vainglorious act of a prestige-hungry Russian oligarch who likes to swing his fiduciary dick around. I myself don't know the answer to that question, but I think the answer matters.

106. **Low Math, Meekly Interacting**
August 2, 2012

I should say I hold the ricipients blameless for Milner's failings, real or perceived. And I don't think they should have refused the cash. There's controversy to this day about the value of the Nobel, despite its venerable status. No reason to use kid gloves on the Milner Prize, such as it is.

107. **Clayton Pickering**
August 2, 2012

"The four winners from the IAS already completely control about 20 research positions at the IAS, which typically pay more than 100K over the time the person is there. To the extent that there are "unknowns" with a "big idea" that meet their approval, they've always had plenty of jobs to hand out to them (although I guess one big advantage of a 100k check versus the job is that you wouldn't have to live in Princeton…)"

Understood, Peter. However, are these monies approved and overseen by the university? The largesse given by Milner is private. Correct? Does Milner have oversight with the monies allocated? The whole point of the three million dollar gift is for those recipients to have a degree of autonomy to explore new concepts by fostering independent research through THEIR own allocation. As you are aware many of funds and grants for R & D are drying up. My point is that physicists can pick up the ball and run with projects outside the purview of universities. Is this done?

108. **Trulo**
August 2, 2012

It's going to be interesting to see who's going to get the prize in the next ten years or so. If six or seven prizes, say, are awarded every year, the number of candidates with achievements even remotely comparable to Witten's is going to decrease exponentially. Will they have repeat laureates then?

It could be also interesting to see how many of the laureates in the next ten years (perhaps a bunch of between 50 and 100 people) will take the opportunity to quit working. Once a laureate has pocketed the money, there's no reason why he/she could not decide to retire and live as a rentier.

Finally, I assume there's a small crowd of people who may now feel the temptation to max out all of their credit cards, knowing that next year they will be rich. Seen who's in the committee, it's not hard to imagine that D-branes, certain types of extra-dimensional models, F-theory, and the like, are going to get a lot of monetary appreciation in the next few years.

109. **Trulo**
August 2, 2012

Sorry about the typo. It should be "Seeing who is…" not "Seen who is…"

110. **Peter Woit**
August 2, 2012

Clayton,

The IAS is not a university, it's a private research institution. The four IAS particle theory professors determine who the institution hires, and they can hire anyone they want. They have a lot of positions, and each year they spend a lot of time sitting down and deciding who to choose. I don't see any reason at all why they should choose different people to give Milner money to versus the IAS money they are responsible for distributing. The only difference is that the IAS money comes with a requirement that you actually spend your time in Princeton.

111. **Peter Woit**
August 2, 2012

Trulo,

It seems the plan is to award typically only one \$3 million prize each year, the nine awards at once was just to get the thing started.

112. **Trulo**
August 2, 2012

> It seems the plan is to award typically only one \$3 million prize each year,

Yes, I think you're right. The rules don't say so explicitly, as far as I can tell, but the statement "can be shared by any number of people" suggests that's how it's going to work in the future.

113. **Clayton Pickering**
August 2, 2012

Yes, Peter. I am well aware that IAS is not a university. However, your point is that IAS money requires that a person spends it time at Princeton. The university is still the anchor. Private money frees the professors from this obligation. Milner's prize does the same thing as far as I am aware.

114. **Michel Audiard**
August 2, 2012

120 commentaires !
Quand on parle pognon, à partir d'un certain chiffre, tout le monde écoute.

115. **Peter Woit**
August 2, 2012

Michel,

Yes, if Milner had set up an award with a medal and \$10,000, no one would have paid any attention at all.

I just added a link to the original posting to a news story which refers to the prize as the "Physics highest honour", which I guess is how the Milner Prize will often be described and thought of.

116. **R**
August 2, 2012

I work on an experiment which is currently being built to try and answer some (testable) questions in "fundamental" particle physics. (Though our research once got called "uninteresting" by one of the Serious Men on this list.) We're facing a budget shortfall somewhere in the range of \\$3 million dollars. I guess the only solution is to make friends with some more grad school dropout Russian oligarchs…

117. **Bernhard**
August 2, 2012

Peter,

I don´t believe (or perhaps don´t want to) people (at least not physicists) will compare the honor of getting a Nobel prize to this "tons of cash prize chosen by some rich guy". I think the Indian newspaper was simply pushing it in a nationalistic gesture.

I think the Milner prize will become a string theorist prize (time will tell), with very rare exceptions, which is maybe a good idea since string theory, being separated from science, indeed deserves its own separate prize.

118. **Peter Woit**
August 2, 2012

Bernhard,

Well, in future years, the Milner prize will have the imprimatur of a group of very prestigious physicists, and I'm sure they will choose other very prominent people, not always string theorists. It won't have the history and name recognition of the Nobel, but will be something more like the Shaw prize, except x 3. I think Milner knew exactly what he was doing when he set the prize level above any other prize, significantly so. That will make sure his prize gets reported and paid attention to, with "highest prize/honor in science" often the way it is reported.

The only thing that will change this will be when some other financier or oligarch institutes a \\$5 million prize….

119. **Z**
August 2, 2012

I can see this prize being a positive for other theory areas. Now funding agencies have another excuse to shift fundamental science grant money away from string theory.

120. **Jiav**
August 2, 2012

Congrats to the winners and many thanks to Yuri Milner for making famous several outstanding scientists.

121. **srp**
August 2, 2012

Maybe the committee of Milner winners can branch out a little and ask their colleagues in other physics fields if there are any worthy recipients. Given the relative lack of publicity for condensed-matter and nuclear physicists, for all I know there could be more-obscure deserving folks whom their peers see as water-walkers.

122. **perelmanfan**
August 3, 2012

Time for a Perelman prize awarded to scientists who refuse prizes above let's say 100K.

123. **David Rod**
August 3, 2012

There is an interesting article in Canada's The Globe and Mail (Friday, August 2), Report on Business Section, Page B2, by Chrystia Freeland (editor, Thomson Reuters Digital) about Yuri Milner's bequests. It is titled "Beyond the Big Bang: A Russian billionaire's investment". This article probably appears in other newspapers. Worth reading.

124. **MathPhys**
August 4, 2012

There was a time when we were all in awe of the Clay Inst prizes. Now that's small money. Don't think about the millennium problems, young man. Go for the real thing.

125. **Bob Levine**
August 4, 2012

I may be missing something, but I don't really see the logic of this excerpt from Mazzucato's piece. It's *still* the status of of string theory that, Milner or no Milner, it is not a Nobel-able field of research, for exactly the reasons he's stated, and, 3M or no 3M, the Nobel is still, and almost certainly evermore shall be, the highest aspiration of theoretical physicists—we're not going to talk about 'Milner Laureates', I suspect, no matter how many zillions he winds up giving away. Winning a Milner will never let you claim that you walk in the ultra-exalted company that LM himself alludes to: Planck, Einstein, Born, Feynman and the other immortals, and the 'wet dream' of all those grad students, in LM's ugly phrase, is exactly that walk, not the bucks that go with that prize, or with anything else (here's a thought experiment: imagine asking 100 physics grad students whether they'd rather (i) win a Nobel prize, or (ii) get a university position that, surreally, paid them five times annually what the Nobel pays—which set of responses would you want to bet on as the majority vote here?) Three million dollars makes you a multimillionaire; it *doesn't* make you a titan in the history of physics, which is I strongly suspect is what any healthily ambitious young physicist really wants.

Of *course* there's plenty to complain about so far as the Nobel is concerned: the names Jocelyn Bell and Rosalind Franklin are a good place to start, and let's not even get into the issue of the Peace prize. But the arguments take place precisely because of the cachet that the Nobel, unique among science prizes, has earned (a large chunk of which comes from the admittedly imperfect way in which Nobel laureates are themselves selected)—ultimately, from the epochal stature in the various Nobel disciplines that, by consensus, is conferred by each award. I can't see the Milner cash dump ever earning anything like that halo.

126. **Mitchell Porter**
August 5, 2012

perelmanfan: "Time for a Perelman prize awarded to scientists who refuse prizes above let's say 100K."

This is a cute idea… A Perelman prize can be a stipend of 60 euros a month (see lun's comment at the start of the thread). Milner's \$3 million per year would then translate to over 3000 Perelman prizes. Milner could support everyone who posts to vixra and still have plenty left over.

127. **Lufgang**
August 5, 2012

I happen to know Yuri Milner well and wanted to make a few comments.

1. He did work for Khodorkovsky in the 90s for a couple of years, but only as one of the managers and never made significant money at that time.

2. Yuri first significant capital came from Mail.ru, the largest Russian Internet portal that he founded in 2000, but not before he took it public in London in 2010.

3. In addition to that, he made a few early bets on companies like Facebook, Groupon and Zynga as an investor in 2009-2010. All these companies also went public in 2011-2012.

Peter, thank you for keeping the conversation fair.

128. **Tmark48**
August 5, 2012

What happens when one of the speculative ideas that has been awarded is falsified through experiment in 10, 20 or 30 years* ? Will they give the prize back ? This is why I think it makes no sense to award speculative ideas in physics. This problem doesn't exist with the Nobel Prize because the Nobel committee makes damn sure that the prize goes to a real physical discovery.
Lets be honest and call the Milner Prize a mathematics prize, in this sense wether or not physics turns out to be correct, the mathematics still stands on its own.
I don't know, I have the impression its all a big joke.

* or maybe it becomes dogma so no one shall ever question its experimental valdity.

129. **Clayton Pickering**
August 5, 2012

"R" wrote:

Who would ever have thought years after the Cold War that a Russian oligarch would be awarding monies to some Americans and the institutions they are associated with. I wonder if Michio Kaku would call this Type I economic largess?

130. **loopy**
August 5, 2012

re: Fundamental Physics Prize

Since several string theorists have received the prize, do you think Loop quantum gravity theorists (Abay Ashketar), noncommutive geometry (Alain Connes) should also receive a prize, in future years?

131. **Peter Woit**
August 5, 2012

loopy,

I think by publishing “The Trouble with Physics” Lee Smolin ensured that the field of LQG research won’t be in line for any prizes where decisions about awards are made by leading string theorists.

It will be interesting to see which direction the prize committee goes in the future. Since the prize is new, and its description is fairly broad, including mathematics as well as physics, they have a large number of plausible candidates to consider, with Connes one possibility.

132. **Bob Jones**
August 5, 2012

I’m sure that Alain Connes will get this prize eventually. I was actually surprised that he was not one of this year’s recipients…

133. **Bernhard**
August 5, 2012

“It tells us that standard model and string theory are correct”

OMFG, these guys have really absolutely no respect for anybody else´s intelligence? Are they serious?

My only consolation to these absolutely ridiculous claims is that this is being recorded for history and that future physicists will know how much full of crap these guys are. Sorry to spit my guts here, but the audacity of these guys never end and I just can´t understand why is not all community laughing about this.

Kane is not alone, after all.

134. **M**
August 6, 2012

“It tells us that standard model and string theory are correct”.

Ironic science needs a good sense of humor.

135. **Tmark48**
August 6, 2012

“It tells us that standard model and **string theory are correct”**.
—

Ok, maybe we should award these guys some prize. What about the Ig Nobel ?
Maybe not, even the Ig Nobel requires a scientific achievement, as trivial as it is. ^_^

136. **john smith**
August 8, 2012

I think that giving a three- million-dollar prize for string theory research undervalues what science is all about. It would have been much better if this money had been spent in raising the quality of education in our elementary schools and high schools where our real “fresh minds” are, and are in need of such money.
Giving such a prize to IAS professors (or any other group of well-established scholars) will not foster more fundamental research; rather it will distract them to think how they should spend such a large sum of cash.
There was a reason why Perelman didn’t accept the Fields medal or the Clay millennium prize. Think about it.

137. **john smith**
August 8, 2012

I just read this in the nature article. So I guess I’m right.

> Andrei Linde, a cosmologist at Stanford University in California, found out about his good fortune only late last week. How will he spend his money? “This is a problem that is much more complicated than the physics problems I’m trying to solve,” he says.

138. **Bugsy**
August 8, 2012

Though the money could arguably have been better spent, ala Simons, I’m not too worried. My guess (and hope) is the winners will use the main part of the money where it can really do some good scientifically (as in, supporting promising young researchers in whatever part of physics or math, not necessarily just in their specialty). However funding more post-docs really won’t help; what is needed are permanent positions, and also grants which give a few years of teaching relief for folks (young or not so) doing good work and already with positions somewhere but overloaded with obligations. Also research grants could ease financial burdens on those struggling on that account. I think the winners will feel embarrassed if they use it only to buy a big house or a yacht with a submarine for themselves, as everyone will be watching what they do. In that sense it’s not really free money; since it is a very public prize, unlike with lesser grants, there will be peer pressure to do the right thing. Besides, these folks already have all they need in terms of working conditions; if they use the money for extraneous things it will only divert their time and energy from what they care about most, which is their work.

139. **David Roberts**
August 8, 2012

@Tmark48:

“Lets be honest and call the Milner Prize a mathematics prize…”

the problem is, most people on that list are not doing mathematics. When Witten got the Fields medal it was a small scandal as he was doing mathematical physics – I’m reading his relevant late-80’s paper on Chern-Simons theory and knots, and it is definitely not a mathematics paper, it’s all theoretical physics intuition with bits and pieces taken from mathematics (and, I freely admit, a great achievement).

140. **Peter Woit**
August 8, 2012

David,

I agree. Kontsevich writes math papers, and Witten is sui generis, but the other seven haven’t done much of anything that mathematicians would recognize as significant mathematical advances. In the case of Witten’s Chern-Simons paper, it may not have looked like a math paper, but unexpected and amazing relationships between quite different areas of mathematics (knot invariants, gauge theory, representations of affine Lie algebras, algebraic geometry of moduli spaces) could readily be extracted from what he was saying. Not everyone was convinced at the time that this deserved a Fields medal, but a few years later, when he wrote down the Seiberg-Witten equations, revolutionizing the subject of 4-manifold topology, the doubters were quieted.

141. **Tmark48**
August 10, 2012

@ David Roberts : I think it’s safe to say that mathematical physics tends more towards the mathematical side than the physics side. Physics can guide you, but in the end if you’re to make clear and mathematically unambigous and rigorous the operations (tools, equations etc..) in question you’re going to have to resort to what mathematicians do.
Theoretical physicists don’t really concern themselves with such trivialities. Can you imagine physicists going into metaphysical mode about wether or not the Dirac function is a well definied concept ? Or the Feynman path integral ? It works, it gives us the means to formulate predictions that can be verified. It passes the test. Who cares wether you can really do infinite dimensional integrals in infinite dimensional spaces ? Mathematical physicists care, mathematicians may care, theoretical physicists by and large don’t.
The scandal that you’re mentioning has more to do with a certain “narrow mindedness” of the mathematical community. Mathematical physics is like a fish out of its element. Not totally in the mathematical camp, not totally in the physics camp.

142. **Bernhard**
August 20, 2012

This interview was a bit interesting:

http://ibnlive.in.com/news/science-neatly-strung-together/283719-60-121.html

Among other things, Ashoke Sen says:

“To this I should add that while string theory naturally combines gravity with quantum mechanics, one of its goals is to also explain the theory of other forces and other matter. For this one needs to establish that for the kind of energies which the present accelerators can produce, string theory can be approximated by the standard model of particle physics. There are strong indications that this might be possible, but this has not been proven. This is at present one of the most active areas of research in string theory (and is commonly described as string phenomenology). If successful, this program will automatically explain the origin of the Higgs boson in string theory.”

143. **Peter Woit**
August 20, 2012

Bernhard,

Well that’s better than the previous claim that the Higgs discovery “tells us that standard model and string theory are correct”. He’s right that “if successful”, string theory unification would explain everything, although he’s neglecting to mention that it has so far been a dismal failure…

Interview(s) with Vladimir Voevodsky

August 3, 2012
Categories: Uncategorized

Vladimir Voevodsky is a mathematics professor at the IAS in Princeton, most famous for his proof of the Bloch-Kato conjecture, work which won him a Fields Medal in 2002. This conjecture relates the K-theory of fields and their étale cohomology (note that there are other, different, Bloch-Kato conjectures on special values of L-functions). For a description of Voevodsky's ideas from 2002, see this by Soulé. The proof of Bloch-Kato was only finished later, including work by other people, for more about this see Weibel's lectures on the proof, or Voevodsky's talk at the IHES conference honoring Grothendieck. For a popular talk by Voevodsky, see "An Intuitive Introduction to Motivic Homotopy Theory", video here, write-up here.

Voevodsky has had a somewhat unusual career, for an interview from 2002 where he discusses his early years in Moscow and at Harvard, see here. A recent interview with him by Roman Mikhailov in two parts has appeared (in Russian, I'm relying on Google Translate to get the gist of it) here and here. He describes what appear to be various delusional episodes, especially during a period in 2006 and 2007 when he was unable to work.

In recent years he has moved away from his work on K-theory, towards topics in applied math (for a while he was investigating population genetics) and foundations of mathematics. This year the IAS will run a year-long program he is organizing on what he calls Univalent Foundations of Mathematics. Back in 2010 he gave a popular talk at the IAS, entitled What if Current Foundations of Mathematics are Inconsistent?

Comments

1. **Yuri Danoyan**
   August 3, 2012

   Interview with Vladimir Voevodsky in Russian contain some mystical stuff
   http://baaltii1.livejournal.com/200269.html
   Very interesting…

2. **Alex R**
   August 3, 2012

   Anyone interested in Voedvosky's foundational work, or who has viewed the video of his talk in 2010, should also take a look at the discussions on the FOM email list in May of last year, which included much discussion of this talk and his foundational views. One can start with this post, if one likes:
   http://www.cs.nyu.edu/pipermail/fom/2011-May/015407.html

3. **P.**
   August 3, 2012

   What's the advantage of basing the foundations on homotopy theory?

4. **plm**
   August 3, 2012

   I think it is more type theory itself which has applications in automated theorem proving. The main general theorem proving environment is Coq, I think, based on type theory, and which can interface well with human-style proofs, because of the ease of making definitions.

   I also think the connection to homotopy theory is not very useful in applications yet, it is more something interesting to explore mathematically. And it seems to provide a natural framework for the connection between logic and algebraic geometry/topology. So perhaps we can say it is useful psychologically, it clarifies our ideas of what is possible.

   This is a quote from Awodey's survey on the subject:
   "The homotopy interpretation of Martin-Löf type theory into Quillen model categories, and the related results on type-theoretic construc- tions of higher groupoids, are analogous to the basic results inter- preting extensional type theory and higher-order logic in (1-) toposes. They clearly indicate that the logic of higher toposes—i.e., the logic of homotopy—is, rather remarkably, a form of intensional type theory."

   (I only comment this because nobody replied. If someone can make a real answer instead, please do.)

5. **Igor Khavkine**
   August 4, 2012

   The mystical bent of the two part interview with Mikhailov is somewhat shocking. For those who might be curious, Voevodsky himself takes part in the extensive discussion attached to the interviews under the screen name vividha. On, the other hand, from what I can tell, the mystical and mathematical parts appear to be disjoint for Voevodsky himself.

6. **wesolyromek**
   August 5, 2012

   http://www.wired.com/business/2012/08/ff_wallstreet_trading/all/

   Deserves a separate note.

7. **Urs Schreiber**
   August 12, 2012

   P. asked: "What's the advantage of basing the foundations on homotopy theory?"

   From the point of view of formal logic it makes the whole theory more coherent to regard also the notion equality "constructively", hence to consider intensional identity types and thus homotopy type theory. See

   http://ncatlab.org/nlab/show/homotopy%20type%20theory for more. What is remarkable, and this was Voevodsky’s insight, is that with this assumed the formal logic is automatically one that describes homotopy theory in its modern guise of “infinity-category theory”. This is remarkable since the latter is seen more and more to be of fundamental relevance in many areas of mathematics.

And of fundamental physics. Adding one extra axiom to Voevodsky’s homotopy type theory, that of “cohesion”

http://ncatlab.org/nlab/show/cohesive%20homotopy%20type%20theory

makes a large chunk of aspects of quantum field theory appear pretty straightforwardly from the formal logic itself, see

http://ncatlab.org/schreiber/show/differential+cohomology+in+a+cohesive+topos .

8. **Urs Schreiber**
August 20, 2012

Some more dedicated discussion of the relation between _Quantum gauge field theory in Cohesive homotopy type theory_ is now here

http://ncatlab.org/schreiber/show/Quantum+gauge+field+theory+in+Cohesive+homotopy+type+theory

Grigori Perelman, the Movie

August 5, 2012
Categories: Uncategorized

I've checked the date on this, and it's not April 1, so maybe this is actually true. According to the website of the Russian television news network RT, [James Cameron to produce story of reclusive Russian genius](#):

> Celebrated Russian mathematician Grigory Perelman, the man who solved a century-old problem then turned down a $1 million prize, is to be the subject of a Hollywood movie produced by James Cameron.
>
> Throughout his career, Perelman has made several breakthroughs in mathematics, geometry and topology. And though Perelman is known for leading a secluded life and avoiding journalists, he agreed to participate in the project dedicated to his milestone achievements. Avatar and Titanic creator James Cameron is rumored to be producing the movie.
>
> Israeli producer Aleksandr Zabrovsky told KP Daily that it took him three years to convince Perelman to sign on to the project. He then approached Cameron with the idea, who was reportedly enthusiastic about it.
>
> The film is due to be shot in the US, with an as-yet-unnamed professional actor covering the role of Perelman.

I'm finding it hard to figure out how Hollywood will dramatize the story of reclusively thinking about the Ricci-flow equations for seven years or so. I guess it will all be in the special effects, for which Cameron is famous.

One should perhaps take this with a large grain of salt, considering the following (from the [Wikipedia Perelman entry](#)):

> In April 2011 Aleksandr Zabrovsky, producer of "President-Film" studio, claimed to have held an interview with Perelman and agreed to shoot a film about him, under the tentative title The Formula of the Universe. Zabrovsky says that in the interview, Perelman explained why he rejected the one million dollar prize.
>
> A number of journalists believe that Zabrovky's interview is most likely a fake, pointing to contradictions in statements supposedly made by Perelman.

Comments

1. **Richard**
   August 5, 2012

   I'm still waiting for a movie about E. Galois!

2. **Armin Nikkhah Shirazi**
   August 6, 2012

   I don't think this is very well known, but James Cameron studied physics before he dropped out and went his own way. And if one thinks that the life of a mathematician thinking about highly abstract issues cannot be effectively dramatized, just remember 'A Beautiful Mind'.

   In fact, if this is true, it is really refreshing to have a movie about someone like that than the gazillion movies about artists, sports figures, business people and politicians. There are not very many people in this and related fields known to the general public, and think what one will about Perelman's idiosyncrasies, the ideals that he is trying to uphold and the significance of his work are worth knowing by more people.

   And yes, Galois' life would definitely be extremely well-suited for dramatization.

3. **Armin Nikkhah Shirazi**
   August 6, 2012

   Also, I just noticed an amusing sentence on the same RT page you linked:

   "The CERN laboratory in Switzerland has found a flaw in an experiment that was set to prove Albert Einstein's social theory of relativity wrong."

4. **Giotis**
   August 6, 2012

   I think his life has already been dramatized:

   http://www.youtube.com/watch?v=DVpmkRwVRfs

   Press cc for english subtitles…

5. **Tmark48**
   August 6, 2012

   @ Richard : Spot on. Galois is such an amazing character, would love to see a modern film about him. I'd prefer some french director to lead the project, there is no need to overdramatize his life which in fact was something surreal. Hollywood might just go too far and jump the shark. Oh and what about Fourier or even Grothendieck ?

6. **Thomas Larsson**
   August 6, 2012

   Some other possibilities:
   Majorana – a mystery.
   Planck – a tragedy.
   Beurling – a thriller.
   Teichmüller – a villain.

7. **Stefano**

August 6, 2012

James Cameron defamed the heroic William McMaster Murdoch in his Titanic movie, then as reparation offered a few THOUSAND dollars to a charitable prize in Murdoch's name, see http://en.wikipedia.org/wiki/William_McMaster_Murdoch for more information. Any movies by Cameron, on any topic, should be shunned by people of conscience.

8. **Navneeth**
August 6, 2012

And if one thinks that the life of a mathematician thinking about highly abstract issues cannot be effectively dramatized, just remember 'A Beautiful Mind'.

But John Nash's life had a nice "curve" (and a detailed biography) which could be further bent and shaped to fit the scaffolding of a Hollywood movie.

Here you have Perelman: a great mathematical achievement under his belt, yes; but too much with which to trouble the general public. You then knock on the door to his mother's apartment to find out more about the man (which is what will be central to the film) and he doesn't open it.

9. **Cesar Laia**
August 6, 2012

It's my opinion, but 'A Beautiful Mind' (even winning several oscars) is not a good movie.

James Cameron did good movies many years ago, and I still regard "Terminator" as is best. Probably wants to show that he can also do non-action movies… who knows, he still is a great director, even considering that "Avatar" sucks. If I was a film director, I would go for Majorana. Or Heisenberg and Bohr (it would be a great plot).

10. **Trulo**
August 6, 2012

Cesar, I agree… Having read the extremely detailed and well documented biography of Nash before watching the movie, I found the latter shallow and boring. Personally, I'd not be interested in a movie on Perelman at all. Now, a biography by Sylvia Nassar or someone equally talented, that would be most interesting. But I guess Perelman is still too young for a biography, which would probably need to be added several chapters twenty years from now.

11. **tristes_tigres**
August 6, 2012

The real question is who's badas enough to play the lead: Chuck Norris, Rutger Hauer or Harrison Ford?

12. **Blendletan**
August 6, 2012

I always thought the life of Grothendieck would make a more interesting move….

13. **Peter Woit**
August 6, 2012

Trulo,

I've been reminded that there is a biography of Perelman, Masha Gessen's book Perfect Rigor. For more about the book, see

http://www.math.columbia.edu/~woit/wordpress/?p=2435

14. **Rikki**
August 6, 2012

I would definitely pay to see this film. However, I doubt it will happen. While we're suggesting potentially great subjects for biographical films, I can look no further than the life of J. Robert Oppenheimer.

15. **Tim May**
August 7, 2012

There've been at least two films or miniseries about Oppenheimer. One was within the past 20 years, the other was with Sam Waterston ("Law and Order") as RO in a long 1980 miniseries.

Personally, I found neither of them very compelling. Nuclear scientist, conflicts about warfare, conflicts about loyalty to U.S. versus loyalty to world peace and communism, blah blah.

I liked "A Beautiful Mind" because of its abstract focus, along with the psycho. aspects. It was well-handled by R. Howard, but most directors would go for the money shots.

A film about Grothendieck would probably have mostly scenes of him teaching in Hanoi suburbs as bombs fell, perhaps with him (fictionally) meeting Jane Fonda in a gun emplacement. Blech.

A film about Perelman would, my guess, be mostly a riff on "Rain Man."

Not to sound too negative, nor too sympathetic toward strings, but I'd really rather watch Nima Arkani-Hamed's 5-part Messenger Lectures for a third time than sit through a political drama about Oppenheimer, or Teller, or Grothendieck or even Perelman.

And I can only imagine what other folks would want to sit through. (Probably not N. A-H., but also probably not Yet Another Oppenheimer biopic, etc.)

August 7, 2012

OK, I must get out my two pet peeves about A Beautiful Mind:

1) They get Nash equilibrium wrong. It's a simple and conceptually elegant idea and for no good reason the scene in the bar gives the exact wrong intuition and result.

2) They did that Hollywood thing of making Princeton University out to be a formal and stuffy place. The actual introductory lecture to incoming doctoral students described in the book was pretty much the opposite of the one Judd Hirsch's character gives in the film. In the book, Lefschetz banged his wooden hands on a table and said that at Princeton we don't care about baby stuff like whether you go to class or dress nicely, but only care whether you create important mathematics.

And what was up with that hallucinogenic presentation of fountain pens to Nash at the faculty club? Was Ron Howard channeling his bar mitzvah experience?

Perelman hypothesized from James Cameron

Author: Stuart Cain

James Cameron announced that he would make a film about the Russian scientist Gregori Perelman.

The plot of the future masterpiece is kept secret, but when a famous Director in St. Petersburg, he coaxed a scientist filming visited our editorial chat and we were able to learn about the little-known details of the new project.

The movie itself will be built in a period of relative obscurity scientist opposed to his fundamental discoveries and a short period of time immediately after the award of the prize of the Fields.

Cameron said that it was important to show how the scientist's quiet life invasion begins. Grigori Perelman, proving the Poincaré conjecture, suddenly became interested in the scientific world.

This world, Kèmeronu, using a known mathematical problems solved, wants to make himself popular, despite the fact that it criticises the power within him and Perelman. Thus, the Director intends to show how, kommercializuâs', success is not only individual but also national traits.

The second line will be built around it, will be a renunciation of the Russian narration mathematics from 1,000,000 dollars. Cameron hopes to demonstrate the true causes of this Act. Based on the testimony of major General of Justice of St. Petersburg, the Oscar winner will deploy peRed zritelem epic picture of the battle state machines and little man.

In the years in which the Clay Mathematics Institute wanted to transfer dollars to the account of Perelman, St. Petersburg had strict instructions of Valentina Ivanovna the doubling of the budget, and naturally a major taxable income immediately drew the attention of the tax inspection of large taxpayers.

At the time of inspection, as told by Kèmeronu source, fulfilled the plan for the quarter, revenue from Gazprom, Rosneft were not as high as expected, so it was decided to take 13% of the million of Perelman before the end of the reporting period to finish the year with double overfulfilled the task. The Director was able to talk to the man who had appointed the Coordinator of operation "Perelman.

The operation was carried out on a grand scale: there were bikers who lit up at night in the apartment of the scientist, alluding to buy housing in another area were special raids with the fivefold increase in prices in stores where purchases Perelman were huge puppets-pig who accompanied Gregory in shops and on the streets.

Selected people, similar to his old friends and acquaintances whose task it was to ask the debt, telling about their own nesčast'h and the troubles, and the entrance of the House was obkleem advertisement charities, many real and imaginary persons with disabilities were planted on the pavement near the House of a scientist. Planned even a kidnapping, but … Perelman, not noticed.

Immersed in the world of theoretical mathematics, it's indifference forced power wasted throw 220 thousand dollars trying to exert pressure on him, and then retracted the award. Error is the Coordinator of the Perelman, "he was a young officer, who, in desperation, came into the House of a scientist with the Declaration of income.

This persistence state tax inspector need you to have a share of the million! "made the break, look in the Perelman cheque, which he stayed with the latest purchase, see bun bread for 200 rubles grayscale and forgo bonuses. The scientist did not want to give money to parasites.

The tax was left with nothing and, to somehow compensate for their expenses — bikers fined for riding without a helmet, shops for breach of the Competition Act, pig suits sold by homeless activists and friends dispersed to their homes.

This story is going to show his new film James Cameron. At least in that he tried to convince the editor of FogNews, while being our guest.

About Oppenheimer, I liked this movie a lot: http://www.imdb.com/title/tt0097336/

20. **Giotis**
August 7, 2012

"I've been reminded that there is a biography of Perelman, Masha Gessen's book Perfect Rigor."

I've read it. It was excellent except that at the end of the book she implied autism. I strongly disagree with such off-hand speculations. People are not obliged to align with society's norms to be considered "normal"…

21. **bjm**
August 7, 2012

@ srp says: "OK, I must get out my two pet peeves about A Beautiful Mind…"

As someone who never heard of Nash before the movie, the film took me on a fun ride. I thought it was well made, imaginative, and entertaining. I understand the pain of someone who sees that the movie got the facts all wrong, but at least now I have heard of Nash and can research the facts about his life if the urge strikes.

22. **Jeff McGowan**
    August 7, 2012

    As far as "A Beautiful Mind" and the real John Nash, a story which maybe gives some insight into how far off the movie (and even the book really) are –

    I had a professor in grad school who was an undergrad at MIT when Nash and Paul Cohen were both there as postdocs. He used to hang around the math lounge all the time, since Nash and Cohen spent a lot of time trying to each prove that they were smarter than the other, giving impromptu lectures on various interesting topics. Nash got to know my professor because of this, and one day he handed him an offprint of one of his papers. My prof opened it up, and noticed that on the inside cover was a very elaborately drawn thing, which upon inspection he discovered was an "intergalactic drivers license," valid in perpetuity. This well before anyone had any thoughts about Nash's lucidity. He didn't say anything, but several years later, after Nash had been hospitalized, my prof got a letter from him telling him that unfortunately even though the license had said "valid in perpetuity" Nash was going to have to rescind it, and could he please mail it to Nash. Needless to say he kept it, and still has it 🙂

23. **Bugsy**
    August 7, 2012

    My God but Google translate can be bad!

    Re math films, I did like especially the beginning part of A Beautiful Mind (the craziness was a bit painful to watch) and also liked Good Will Hunting a lot. But my favorite by far is Proof. I can't believe how good a job the actors (who all apparently were zeros in science in reality) did of catching the spirit of math research. Plus it was great to see again the environs of the U of Chicago, though the Northwestern math dept was replaced by a much more modern building!

24. **Craig**

    Many RT stories are weird self-parodies. So this might hold as much water as an April fool joke. They've had ostensibly serious discussions with guests about the cia colluding with space aliens.

Article for Il Manifesto

August 8, 2012
Categories: Uncategorized

Around the time of the Higgs discovery announcement last month I was contacted by someone from the Italian left-wing newspaper *Il Manifesto*, who asked if I'd write something for them about the Higgs. I told them that it would be much better if they could get an experimentalist to write about that topic, since the discovery was really an experimental achievement. They managed to get Tommaso Dorigo to write that piece for them (see here), but I agreed to write something for them a bit later, about the significance of other results from the LHC. That piece appeared in the newspaper today in Italian translation, an English version follows here.

This was written last week, under the combined influence of watching some of the Strings 2012 talks and thinking about the possible impact of the new $3 million Fundamental Physics Prizes, which largely went to string theorists. For this venue, I was unable to resist channeling my inner leftist (normally the only newspaper that wants me to write for them is the *Wall Street Journal*…) and making Russian financier Yuri Milner to a large extent the bogeyman of the piece.

A very serious concern that I wanted to raise is that of the long-term danger that fundamental physics faces in the combination of string theory ideology and the possible "nightmare scenario" of the LHC finding nothing that disagrees with the Standard Model. For decades now the theoretical side of the subject has been dominated by one specific set of not very compelling ideas: 10d superstrings at the Planck scale, with a SUSY GUT at slightly lower scale, and low-energy SUSY explaining the supposed "hierarchy problem" created by the vast difference between those scales and the scale of electroweak symmetry breaking (of order 100 GeV). The force most likely to challenge the hegemony of this ideology has always been the LHC, which was supposed to see superpartners responsible for stabilizing the electroweak scale. Watching the speakers at Strings 2012 made clear that the failure of this experimental prediction would not cause them to give up on this ideology, but instead to redouble efforts to prop it up at all costs.

The fundamental problem is the deeply entrenched nature of string theory ideology in the power centers of the academy and among the most talented theorists. Milner's choice to provide out-scale rewards to such talented people is not the main problem, although he provided a convenient target for me in the piece. If we really do end up with the "nightmare scenario" of experiment not coming to rescue, it's now all too clear where we end up: the textbooks of string theory and supersymmetry have already been written, and that will be codified as humanity's best understanding of fundamental physical reality for the indefinite future.

Maybe some new theoretical ideas will somehow bloom, but otherwise our best hope to get out of this will be the efforts and innovations of talented experimentalists, likely requiring expensive equipment. It will be a challenge to continue to find public resources to fund this. Maybe if the trends of recent decades continue, it will be up to the financiers to decide whether humanity continues down the experimental path. Luckily, a lot of them seem to be interested in physics.

The article follows, you might want to skip it if you're a regular blog reader here, since you won't hear anything new and it's a bit of a rant…

> Last month came an announcement from Geneva that physicists of my generation had been anxiously awaiting since our student days nearly forty years ago. Experimentalist Tommaso Dorigo wrote in this newspaper about the great achievement of the Large Hadron Collider at CERN and his 6000 or so colleagues, who came together to produce and make the first measurements of a new fundamental element of nature: the Higgs particle.
>
> For theorists like myself, this was a bittersweet victory for our subject. The Higgs particle showed up more or less exactly in the manner predicted by the so-called Standard Model, a wildly successful fundamental quantum theory developed between 1967 and 1973. This theory had passed critical tests time and time again, but until last month the trickiest part of the theory had not been tested by direct observation. Perhaps we were missing something important, and the real world would slap us in the face with results contradicting the theory, and giving us clues about how to find a better one. Instead, we saw the equations of our textbooks dramatically confirmed. We now await a long process of detailed investigation of this new phenomenon, a process which will keep Tommaso and his colleagues busy for many years to come.
>
> The Higgs discovery emerged as a single sudden announcement, but over the last two years an equally important discovery has slowly come into focus, one small piece of data from the LHC at a time. Unlike the case of the Higgs, this discovery has been a vigorous slap in the face to the theoretical particle physics community, telling us in no uncertain terms that we've been wasting most of our time for the past thirty years. For these three decades, the subject has been dominated by research into an elaborate speculative scenario which has been investigated in exhaustive detail.
>
> This scenario goes under the name of "superstring theory", referring to a set of ideas that form not exactly a well-defined theory, but rather a conjecture that a theory with certain properties should exist. This theory would unify the Standard Model with Einstein's theory of gravity known as General Relativity, embedding both in a complicated structure involving six extra dimensions of space. The possibility that these new dimensions would put in an appearance at the LHC has often been used to impress the public with flashy claims about the dramatic things that CERN's new machine could find, things that sounded like (and were) science-fiction. Whatever they told the public, few physicists were expecting such dimensions to be observable in the data, since the conventional speculative scenario put their size at far too small a value to be seen at the LHC. No one has been surprised at all by the failure of any sign of extra dimensions to show up at CERN, despite a careful search for any possible evidence.
>
> The "super" in "superstring" though is a different story. This indicates a crucial property of the conjectural unifying theory: each fundamental particle should come paired with another one of very specific properties, the particle's "superpartner". The electron should be paired with a new particle named the "selectron", each quark with a "squark", etc. Over the years an increasingly rigid ideology explaining the supposedly wondrous properties of this "supersymmetry" which would dramatically improve upon the Standard Model. That supersymmetry provided none of the powerful explanations of past observations we have come to expect from new symmetry principles was an inconvenient issue best ignored. As each new generation of accelerators came to life at CERN and at Fermilab in the United States, superpartners were looked for, but never found.
>
> Supersymmetry entered the textbooks anyway and has now been taught to generations of graduate students. Always part of the story being told was the claim that superpartners should have masses roughly similar to the mass of the Higgs particle. When the Higgs was found, the superpartners had to be there too. Consistency of the Standard Model demanded that the Higgs could not be too massive, so long before the LHC was turned on, it was a sure thing that if the Higgs particle was there the LHC would find it. That part of the story worked out perfectly, but it has been accompanied by a huge embarrassment: no sign of any superpartners at all. Not only were they supposed to be not too much heavier than the Higgs, but many of them were supposed to be much produced much more copiously, and thus be much easier to see. By now the LHC experiments have shown that such expected particles are absent, unless they are made inaccessible by pushing their masses up to more than an order of magnitude higher than that of the Higgs, a value far beyond what had been advertised as reasonable.
>
> The implications of this attack on theorists by the reality principle are just beginning to sink in. The big yearly conference of superstring theorists was held this past week in Munich, with different speakers taking different approaches to dealing with the problem. One speaker advocated not doing anything until next year, hoping against hope that newer data would give better results. Others took the attitude that it had been clear for quite a while that superstring theory wasn't going to show signs of existence at the LHC, so best to just work on finding other uses for it. In the conference final "Outlook and Vision" talk, the illustrious speaker announced that all was well, and didn't mention the LHC results at all. The ostrich-like tactic of burying one's head in the sand seems to be on the agenda for now, but this will become increasingly difficult to maintain as time goes on and more and more conclusive negative experimental results arrive.
>
> As a physicist, one problem with having an experiment tell you that your ideas are wrong is that it means you are ineligible for a Nobel Prize. Your hopes for a right to a part share in $1.2 million have been dashed, and, no matter how famous and well-paid an academic star you may be, you will have to content yourself with living on your salary, supplemented perhaps by smaller, less well-known consolation prizes.

Around the time of the end of the superstring theory conference though, dramatic news came from billionaire Russian financier Yuri Milner. Known for building the most expensive house in the United States, he decided to help support physics by depositing $3 million dollars per person in the bank accounts of 8 prominent physicists and one mathematician, rewarding 6 of them for their work in superstring theory. He has modeled himself after Alfred Nobel, announcing a new foundation that will give out Fundamental Physics Prizes each year. Unlike the Nobel, these prizes can go to work for which there is no experimental evidence. What he's looking for are "transformative advances" like superstring theory, which have gotten the seal of approval of popularity among high-status academics. Even if experiment shows the ideas to be wrong, as in the case of the latest data about supersymmetry, that doesn't matter. What does matter is that the recipients should reflect the conventional wisdom in the academy. The choice of who to give the Prizes to included giving them to every single professor of particle physics at the world's most prestigious academic institution, the Institute for Advanced Study in Princeton. The question of competition with the Nobel prize was dealt with by setting the value of the prize far above that of the Nobel, at a level significantly higher than any other academic prize in the world.

The slap in the face by experimental data and its threat to impose the reality principle on the most powerful figures in the world of theoretical physics has thus been met by a riposte from another powerful force. This is another reality, that of entrenched academic interests, funded by the billions of dollars available to financiers who want to impose their will upon the world, or at least the small part of it that will write the textbooks of the future. Which of these forces will carry the day? Will the budget cuts imposed on physics research in Italy and elsewhere cripple the ability of the LHC experiments to continue to reveal the structure of nature, leaving our future fundamental science in the hands of powerful interests who will decide which version of reality they like best?

In the longer term, the physics community now faces difficult choices. Any machine more powerful than the LHC will be expensive and require multiple decades to design, finance, build and operate. The temptation will be there to again promise discovery of exotic new dimensions and supersymmetries in order to convince governments to provide funding. Instead of such empty promises, physicists should just make the case that humanity deserves the chance to continue the experimental investigation of the fundamentals of physical reality. The alternative is all too clear: the lack of public money to fund experimental investigation will put those with private money in charge of deciding what our scientific reality will be.

Comments

   August 8, 2012

   The FPP is not a price, it's just a research grant. So what is the problem.

   I still think the scientific method will eventually tease out the correct theories.

   Maybe Gross and co will wrestle that "maximally super symmetric N=4 Yang-Mill with infinite color, split the susy, …..” to the ground and dual it up with the QED sooner than later so we won't have to hear about it forever, ………..

   In his lectures it sound like it should be 1-2 years.

2. **Tammie Lee Sandoval**
   August 8, 2012

   Dear Dr. Woit

   Please, don't worry.
   You and Dr. Smolin have succeeded, much more than you imagine.
   Everyone knows the score.

   Physicists are not car dealers. Not their nature.
   And they wont be, even for 100 times Milner's money.

   You go into physics to show how smart you are.
   And you wont get there with a wild goose chase.
   So the young guys will ditch string theory.
   The old will soldier on, thanking God for tenure.

3. **Bernhard**
   August 8, 2012

   "Maybe some new theoretical ideas will somehow bloom, but otherwise our best hope to get out of this will be the efforts and innovations of talented experimentalists, likely requiring expensive equipment."

   I think a theoretical bloom of ideas is urgently needed.

   It might be that the next successful model beyond the Standard Model will really be just some conservative extension using model building rules for renormalizable gauge theories. This kind of work should continue because experiments still need guidance to what to look for, even knowing that in the end only ONE model can be correct. This is a key aspect because ultimately it affects trigger design (as the SUSY history shows).

   However, if the next model of nature is not as simple as extending the SM gauge sector to some SU(whatever) group then this is likely a deeper theoretical problem in QFT we oversaw and when we do see it, we really might get a good idea to what to look for next. This is the theoretical bloom we need.

   An experimental breakthrough would also be very welcome, specially if the technology to get TeV collisions could be made much much cheaper. This is what I believe many young accelerator and detector designers should pursue, if this field is to survive as science and not as string theory religion.

4. **Peter Woit**
   August 8, 2012

   s. Vik,

   The Fundamental Physics Prize is a prize, not a research grant (you may be thinking of the Simons Investigator 100K/year awards, which are research grants). The intent of the FPP is to reward appropriately the most successful people in the field, not to support their research. Of course they can do whatever they want with the prize money, including using it to support research, theirs or someone else's.

5. **Bob Jones**
   August 8, 2012

"Maybe Gross and co will wrestle that 'maximally super symmetric N=4 Yang-Mill with infinite color, split the susy, …..' to the ground and dual it up with the QED sooner than later so we won't have to hear about it forever, ………."

Have you even tried to understand what you're talking about? What you meant to say is that there may be a string theory dual to QCD, not that N=4 SYM is dual to QED. Doing computations in QED is already well understood. Needless to say, split supersymmetry has absolutely nothing to do with any of this…

6. **Peter Woit**
   August 8, 2012

   Bob Jones,

   I had assumed that s. Vik was joking, making fun of string theory hype, not intending to make sense (the "1-2 years" seemed a sure giveaway that it was a joke). Of course, in this business these days, it's not always clear what's a joke and what isn't. Some people for instance seem to think super split supersymmetry is not a joke.

7. **David Nataf**
   August 8, 2012

   Is there not a tremendous amount of data from cosmology that requires extensions to the standard model? What about the existence of gravity?

   From far away, it seems that implicitly requiring new physics to come from terrestrial particle accelerators is poor philosophy. It's very possible I'm missing some important information here, but the history of science teaches us the particle accelerator is merely one method to learn about nature.

   If you want even more requirements for new physics then there is already, the LHC is only one possibility. There are also amazing pendulum experiments, Fermi telescope, dark matter scattering experiments like XENON100 and DAMA, Planck mission, air showers of 10^6 TeV cosmic rays, and in the future possibly LISA. There are obviously more that I've never heard of.

   Today, a fascinating nuclear physics paper that is anthropically-relevant was posted:
   http://arxiv.org/abs/1208.1328

8. **Peter Woit**
   August 8, 2012

   Bob Jones,

   Just deleted the last from "s. Vik". You were right and I was wrong.

   David Nataf,

   Of course there are other possibilities than the LHC or other energy frontier machines, but it's not clear that any are very promising ways to see something that violates the SM. Dark matter has always been the most likely thing that might show up, but so far nothing, and no reason to believe a new generation of experiments will change things. As for an expensive spacecraft experiment like LISA, funding is also a big problem (and, even if you ever build such a thing, it seems likely gravitational wave observations would tell you about astrophysics, not more fundamental physics). Basically, it's not impossible that any one such experiment will turn up something and they're worth pursuing, but the probability of success in each case looks low (unlike the LHC, where we pretty much knew it would find either the Higgs or something more interesting).

9. **MathPhys**
   August 8, 2012

   Standing in a supermarket queue this morning, I saw a picture of Jennifer Aniston (an actress, for those of you with better things to think about) on the cover of a local tabloid, so it occurred to me to check how much money she makes.

   It turns out that she makes between 3 and 8 million dollars per film, she can make at least one film per year (that's a Milner prize, minimally, once a year), and that during the final two seasons of 'Friends' (a TV sitcom, for those of you who only watch Nima's lectures) she was paid 1 million 4 per episode, so that's once a week for many weeks a year (and a Milner prize once every 3 weeks of work).

   So ——-, putting things in context, I now do believe that Witten and co richly deserve their Milner prizes.

10. **Bob Jones**
    August 8, 2012

    From the Fundamental Physics Prize website:

    "Two categories of prizes will be awarded for past achievements in the field of fundamental physics, with the aim of providing the recipients with more freedom and opportunity to pursue even greater future accomplishments. The Fundamental Physics Prize recognizes transformative advances in the field, while the New Horizons in Physics Prizes are targeted at promising junior researchers."

11. **Peter Woit**
    August 8, 2012

    MathPhys,

    Yes, but the problem with the analogy is, what if these large rewards went to actors for making bad movies? Where would we be then?

    Hmm, no need to answer that, I guess…

12. **srp**
    August 8, 2012

    Yes, but Jennifer A. is preternaturally, world-class adorable. Not too many physicists could make that claim with a straight face. And she once triggered a revolution in hair salons all over the world as women demanded copies of her 'do. Even Brian Greene doesn't have people copying his hair.

13. **MathPhys**
    August 8, 2012

Peter and srp

On the one hand, I definitely don't find Nima adorable (yikes), but on the other hand, I find him much more entertaining than any TV sitcom that I can think of, and what he talks about is just as real.

Go, Nima. If Jennifer A makes a Milner a year, you definitely deserve a Milner once in a lifetime.

14. **Z**
August 9, 2012

It's very important to note that telescopes such as Fermi, IceCube, Planck and JWST are _telescopes_ and not experiments like accelerators. Direct detection is something very different than observational evidence wrt the philosophy of science.

15. **Manifesto**
August 9, 2012

Be careful. This journal had a good tradition but was abandoned years ago by moderate left, degenerating into an extreme-left journal, full of debts and of nonsensical propaganda of communism and radical feminism.

Probably nowadays your blog has more readers than the Manifesto.

16. **chris bolger**
August 9, 2012

I do not understand your overly emotional rants on superstrings and on who funds physics. With the increasing lack of support by governments, the only way physics research will proceed is by private funding. Granted, it is not ideal, but any support is better than none. Milner should be applauded for this. The issues you bring up are valid, but will probably work themselves out by reasonable people over time who work on the details of giving out the prize. In other words, don't bight the hand that feeds you. This usually results in job loss, unless you have tenure.

17. **Peter Woit**
August 9, 2012

chris,

While I don't have tenure, luckily I'm in a position to be able to bite various hands that feed me and others, when I think they need some biting. So far, I think this has worked out fine.

18. **next LHC-SUSY announcement**
August 9, 2012

There have been recent press release on Higgs, but I'm not aware of one for SUSY in 2012. I infer we're talking about the 2011 null results for SUSY or something else? When will 2012-LHC SUSY or BSM results be announced, even if negative?

19. **Peter Woit**
August 9, 2012

next LHC-SUSY announcement,

CMS has already announced SUSY results using 2012 data, see

https://twiki.cern.ch/twiki/bin/view/CMSPublic/PhysicsResultsSUS#Recent_Preliminary_Results_with

ATLAS I believe will announce some next week at SUSY 2012 in Beijing, see for instance

https://twitter.com/marktibbetts/status/228834932754116608

There are many, many, many possible ways to look for SUSY signals, the situation is not like the Higgs where one was looking for something very specific, so there was one "result" which told the story. In the case of SUSY, hopes that a positive result may appear are mostly based on the fact that new and different sorts of analyses are being reported, or ones with a lot more data than was used in earlier analyses based on a fraction of the data available. Going from the 7 TeV of 2011 data to 8 TeV of 2012 data is not likely to change much, since these aren't phenomena with sharp thresholds.

20. **Q.I.**
August 9, 2012

>Chris Bolger wrote: "the only way physics research will proceed is by private funding."

While, there are some practical areas within physics that might qualify for some private funding, however, after reading the comments on this blog for some time, Woit's and Smolin's books, and a few other sources, I get an impression that physics is turning more into an insular field. And, that is not good news to qualify for already shrinking sources of private funding available these days. Few engineering and computer science students take any, if any, physics courses at all in their graduate studies, which I think is a sad state of affairs. I can understand that many areas within HEP may not be of interest to engineering and computer science students, However, as somebody who is not a physicist, I just can't bring myself to not notice a deep desire by the physics community to be seen as mathematicians. Which is a further disconnect from the reality of the technological areas, because if people in other disciplines can directly refer to math books and papers for their needs, then why consult a physicist's approach on mathematics. Especially, when the notation and technical writing used by physicists are not as consistent and good as the math community.

I could be wrong, but the way I see things is that physics should try to bridge the gap between several technological areas while offering its own perspective on the fundamental challenges. However, I'm not sure if that is the current direction.

21. **Peter Woit**
August 9, 2012

Q.I.,

"a deep desire by the physics community to be seen as mathematicians".

I don’t see this at all, other than among a very small part of the theoretical physics community that has ended up pursuing some topics that end up using a lot of mathematics. One could easily get a very wrong impression from this blog, where I write about topics in physics that correspond to my interests, which have a lot to do with mathematics. Most physicists even I meet have limited interest in mathematics, and no desire to be seen as mathematicians.

22. **next LHC-SUSY announcement**

Like some of the other posters, I don’t think you need worry about string theory and supersymmetry becoming orthodoxy despite the lack of experimental evidence. I am confident that there will be new theories forthcoming which will dramatically revise the Standard Model, and consequently lead to quite new avenues of experimental investigation. We still need to find out what gravity is, what dark matter is, why the expansion of the universe accelerates, etc. There will be answers to these questions which in hindsight will seem obvious, but the current SM does not include those answers. It will have to be revised into a form that does. People will keep working on that until they get some good results. I don’t see how things could happen any differently – even if it might take quite some time.

Interesting discussion regarding private funding of research. One might almost imagine a deliberate policy by conservative circles to reduce educational funding thus permitting private funding to fill the gap.

The problem with private funding is, of course, that he who pays the piper calls the tune. At least universities and granting agencies provide a system of oversight for granting. With private donors it’s one person’s decision.

Recently here in Canada we have seen more of this business of megadonations by rich patrons funding new research institutes. These donors don’t have to spell out explicitly what research is to be done. By funding centres to enquire into specific issues they direct the nature of research.

So while on the surface Milner’s money seems positive as an infusion into a hungry system, as Peter has said, it perverts research by directing academics in a certain direction either by allowing them the luxury to hire grad students, buy equipment or by encouraging others to enter a field so as to be eligible for the money.

We have recently come to the point where this ideological approach to academic funding has become so acceptable that comments like Chris Bolger’s are commonplace.

@ MathPhys : Don’t ever go looking at how much money professional football (soccer for you guys in the US) players make. You’d get a heart attack.

26. **ex**
August 10, 2012

@ Manifesto:

Be careful. This journal had a good tradition but was abandoned years ago by moderate left, degenerating into an extreme-left journal, full of debts and of nonsensical propaganda of communism and radical feminism.

Be careful, it was the opposite. It was Manifesto that was created to abandon the moderate left parties, because of their support to Soviet invasion of Prague (to reestablish the *order* after the happy period of self-liberation known as Prague spring).

It has a declared strong left partisanship, but it is still one of the most free newspapers in Italy – a miracle, after the Berlusconi period and in this era of Market propaganda, “single thought”, and suppression of critical voices. Take care.

Tmark48,

The world is mad.

28. **JDM**
August 10, 2012

Peter,

Like others here, my instincts run contrary to yours, although for somewhat different reasons. I do find your thoughts in the influence of that scale of private money on the field interesting and, to a degree, compelling; however, I anticipate things developing in a different direction.

You’re absolutely right that money at that scale could underwrite a generation of students, postdocs, and textbooks, and so keep an otherwise floundering branch of the discipline around past its use-by date. But I’d say that one generation amounts to the half-life of this effect.

The problem, I think, comes from taking at face value Milner’s conceit that’s he’s emulating Nobel. The Nobel Prize got to the place it currently occupies because of robust, widespread support across the scientific community. That is, it grew on the power of prestige. Sure, the money was a part of that, but not the most critical. If you look at the first few decades Nobel awards in physics, for example, you get a whose who of early 20th century physics. Moreover, that list would still be a whose who of that era if the Prize had never existed. The Nobel earned its prestige by awarding, retrospectively, the most worthy accomplishments, as judged by a broad selection of scientists.

A chunk of money, however large, can’t do the same thing on its own. It won’t be able to develop truly widespread communal support in the absence of rich theory-experiment dialogue. Milner is engaged in a much narrower enterprise. The work he’s supporting can’t be sustained indefinitely from the top down. A viable field provides support and opportunity for the workaday folk, not just the leading lights. A lucrative private prize, however, large, will not be enough to lure new students into a research area that otherwise offers few prospects. Perhaps the wave of textbooks you envision will get one generation’s worth of use, but faculty who see that these books offer the vast majority of their students little of concrete value will move away from them, or the vestiges of once-promising research programs will be excised from later editions. Once this begins to happen, Milner—assuming that he continues to award his prize on the basis of his peculiar definition of “fundamental”—will look progressively less like Nobel, and more like Templeton.

Joe

August 12, 2012

I think if you care about the money and the physics, get together a petition, or call this Yuri guy up, and say, hey, fund some experiments. I would at least FB him 🙂
In many branches of Academia, there are departments that are divided between theoretical and practical (perhaps plastic is the term, strangely enough, as in the plastic arts). And here I think a petition to department deans to create more real chairs for experimental physicists is in order. Your point about the extravagant cost is well taken, but a few ounces of sheer genius can do a lot. It may be that there are no real bargains left, such as Cavendish's torsion bar or double-slit electron diffraction, but it may also be that we need to look harder.

LEP3

August 9, 2012
Categories: Experimental HEP News

For many years now discussion in the HEP community of what might be the appropriate next machine to try and finance and build after the LHC has centered around the idea of a linear electron-positron collider. The logic has been that an electron-positron machine would provide a much better environment that the LHC for detailed studies of physics at the TeV scale. At these energies, synchrotron radiation losses when accelerating electrons are so high in a circular geometry that such a machine would have to be a linear collider to keep the power needed something plausible. The two main proposals under study have been the ILC (250 GeV + 250 GeV, later upgradeable to 500 GeV + 500 GeV) and, a less mature technology, CLIC (1.5 TeV + 1.5 TeV). These would be very expensive machines to build and operate ($10 billion and up?), requiring completely new technology, tunnels and detectors.

The operating assumption has been that initial results from the LHC would show the existence of new supersymmetric or other particle states in the region of multiple hundreds of GeV to small numbers of TeV, and the linear collider designs could then be chosen and optimized to study this new physics. The other main goal of such a collider would be detailed study of the Higgs, and knowing the mass of the Higgs is also highly relevant to what kind of linear collider to build.

The initial LHC results are now in (125 GeV Higgs, nothing new at the TeV scale) and they are rather discouraging for the linear collider idea, providing no strong motivation for studying electron-positron collisions around 1 TeV. A "Higgs Factory" capable of producing and studying large numbers of Higgs particles is an attractive idea, but the production cross-section for a 125 GeV Higgs is dominated by the process $e^+ + e^- \to Z + H$, which starts to get large around 220 GeV and reaches a maximum value around 255 GeV. So, for most Higgs studies, the right energy for an electron-positron machine is around 250 GeV, not 1 TeV.

This realization is driving a new proposal that is getting a lot of attention: the idea of going back to circular electron-positron colliders, building a new machine in the LHC tunnel, optimized as a Higgs factory, and designed to operate at 120 GeV + 120 GeV. This is being called "LEP3″, since it would be in many ways similar to LEP2, the predecessor machine to the LHC, which operated in the same tunnel, reaching an energy of 209 GeV. There would be huge cost advantages to building such a machine over the ILC or CLIC, since it can use the LHC tunnel, infrastructure, and, crucially, the CMS and ATLAS detectors (the detectors are a large part of the cost of a new accelerator).

Space was left in the LHC tunnel to allow another ring, so there are various possibilities for having a LEP3 and the LHC cohabitate. Until now, the assumption has been that the LHC would be upgraded to the"HL-LHC", operating at higher luminosity throughout the 2020s, then perhaps an "HE-LHC", operating at higher energies during the 2030s. This plan is being challenged by the LEP3 proposal, with the argument that it might turn out that Higgs physics is where the only action will be, and a long period of LHC operation at higher luminosities and modestly higher energies might be less worthwhile than building a LEP3 Higgs factory.

There's a very good article about this at PhysicsWorld. For more detail about LEP3, see here, here and here. John Ellis is one of the co-authors of the latest document proposing study of the LEP3 possibility, and the Physics World article has him arguing that, after waiting to see if LHC14 turns up anything:

> LEP3 could be a more secure option than the ILC if only a Higgs is discovered…If the LHC does not discover anything beyond the Higgs, then would you keep running it for years?

Lyn Evans, who led construction of the LHC and is now director of the linear-collider project argues against the LEP3 concept:

> The first job is to fully exploit the LHC and all its upgrades, This is at least a 20 year programme of work, so I think that it is very unlikely that the LHC will be ripped out and replaced by a very modest machine with little scope apart from studying the Higgs.

The problem is, what if, as seems increasingly likely, "studying the Higgs" is the only new physics accessible in these energy ranges? Dreams of superpartners and extra dimensions may die hard.

Comments

1. **Bernhard**
   August 9, 2012

   This is interesting, but I think Ellis is dreaming. No way the LHC will be shut down until is completely explored, the pressure to keep the machine running and achieve as high integrated luminosity (including upgrades) as possible is enormous. Building a Higgs playground would be nice but at the cost of the LHC, no way.

   Furthermore I hear the Japanese are strongly pushing for the ILC to be built (in Japan) and they are willing to pay for a considerable cost of it. In any case, before the LHC running a considerable time at design energy an luminosity these are speculations. And I believe very few people would be excited about working in a "Higgs machine" and ultimately this is a key aspect.

   The ILC running at 1 TeV can in any case still easily be defended as a discovery machine as e.g. virtual corrections from all sorts of models make the discovery reach for large range of particles (models) to be much higher than the machine center-of-mass and or even the LHC for that matter.

2. **HE-LHC vs HL-LHC**
   August 9, 2012

   If all they find is the Higgs boson up to 14 TEV by 2020, no SUSY or DM or other particles, or extra dimensions what would be the point of spending money to build a HL-LHC upgrade around 2020? What would higher luminosity offer? Couldn't the LHC continue to run at a lower luminosity but take more time to gather more data?

3. **Peter Woit**
   August 9, 2012

   HE v. HL,

   The idea of the HL-LHC is to increase the luminosity by something like an order of magnitude, and run for a decade. If you stay at current design luminosity, you'd have to run for a century to match that.

   One motivation for the high luminosity is to look for new physics via rare events. But, even just for the Higgs, higher luminosity means much better measurements. The crucial question is just how much better a LEP3 could do than this.

4. **DEQ**
   August 9, 2012

Why the idea of a muon collider not gaining traction? Is that technology just too far out right now, i.e. something 20 years away?

5. **Peter Woit**
August 9, 2012

DEQ,

Yes, muon collider technology is still a long ways off (although you'd need someone more expert than me to give a time estimate), requiring some very new technologies. LEP3 however would use what appear to be relatively straight-forward extensions of proven technologies.

6. **Tmark48**
August 9, 2012

My opinion is that the future of HEP is going to be in astronomy/astrophysics.
Space is the only environment where we can witness (with suitable detectors/telescopes) physics beyond the SM. Investing is astronomy is going to be much more productive than building a YAA (yet another accelerator) for untold tens of billions of €/$/£/Yens when we don't even know at what energy scale beyond SM physics kicks in.

As for the LHC, for pete's sake it has been in operation for what less than 4 years and we want to build another one ? LHC is going to be useful for a good decade if not 20 full years. It is going to be useful even if it throws in the dust bin all the speculative ideas that are found to have no experimental evidence.

7. **Peter Woit**
August 10, 2012

Tmark48,

The LHC was designed about 20 years ago, with approval of funding and work on starting to build magnets beginning around 1993. So, if you believe it has a lifetime of 20 years, now is about the time for starting work on whatever will be next. These projects have a very long lead time.

So far, instruments in space (which aren't cheap either…) have yet to tell us what's beyond the SM. I wouldn't be so sure this will change in the forseeable future.

The interesting thing about the LEP3 idea for a new machine is that it's not necessarily that expensive. Instead of order of magnitude $ten billion in new money, it might be doable for a lot less, fitting within the CERN budget with no significant increase. It definitely seems worthwhile to investigate the idea and produce some realistic cost estimates, as well as a serious investigation of the physics case for the machine.

8. **Mitchell Porter**
August 10, 2012

"Dreams of superpartners and extra dimensions may die hard."

In my opinion, now that there's a Higgs, the next big issue is the hierarchy problem. The economical way to test known forms of unification, would be to test their solutions to the hierarchy problem, e.g. the existence of new "partner" particles for the top. That way you test at the same time, both standard versions of supersymmetry (with light stops) and nonstandard models with top-partners. And it seems that this is what the experimental collaborations are doing…

9. **Tmark48**
August 10, 2012

The LHC was designed about 20 years ago, with approval of funding and work on starting to build magnets beginning around 1993. So, if you believe it has a lifetime of 20 years, now is about the time for starting work on whatever will be next. These projects have a very long lead time.

–
You are correct, but big projects take decades to come to completion. Even the Hubble was like this. But the thing is, the LHC was designed for one purpose, finding the HIGGS.
Even now that the LHC has found the HIGGS, we still don't know what kind of HIGGS particle it is. Further experiments are warranted.
You say we need to start considering a new accelerator. Ok, to search what ? What is the goal ? It cannot be a moving goalpost as supersymmetry is. Isn't it better to upgrade the LHC and continue using it instead a starting a wild goose chase ?

So far, instruments in space (which aren't cheap either…) have yet to tell us what's beyond the SM. I wouldn't be so sure this will change in the forseeable future.

–
Astronomical instruments are way, way, way less costly than building particle accelerators and they bring more science to the table. As technology improves, detectors improve and our ability to see and interpret high energy astrophysical phenomena gets better and better. No such thing is possibile for particle accelerators.
We simply cannot increase energy levels to tens of thousands of TeV. What if beyond SM physics kicks in at that scale ? High Energy Physicists are screwed.
We need to start considering that maybe beyond SM physics is simply unattainable here on earth.
Furthermore all interesting fundamental physics is coming from astronomy.
Dark matter ? check.
Dark energy ? Check. Particle accelerators are "in my opinion" becoming obsolete mainly because technology doesn't give us the tools to increase energy levels arbitrarily at which to probe the microscopic scale.

The interesting thing about the LEP3 idea for a new machine is that it's not necessarily that expensive. Instead of order of magnitude $ten billion in new money, it might be doable for a lot less, fitting within the CERN budget with no significant increase. It definitely seems worthwhile to investigate the idea and produce some realistic cost estimates, as well as a serious investigation of the physics case for the machine.

–
At the pace at which technology improves, astronomical instruments can become competitive with particle accelerators in the short term. Nature has no problem orchestrating high energy events in the cosmos. But we here on earth we are limited in our ability to create high energy events. This is a problem that the HEP community has to start thinking about.

10. **Bernhard**
August 10, 2012

Tmark48,

you are perhaps right, but these experiments would have to seriously deal with the problem of luminosity. The thing with accelerators is that it gives you a way to make a controlled experiment. If the next energy frontier is at the GUT scale, we are screwed, yes, but we don't know that, so we keep looking. How are you going to build detectors to look for astrophysical sources and have statistical evidence of BSM physics? And I'm not talking about dark matter, I'm talking about filtering an interesting process from huge SM background and studying a new resonance. Or are you perhaps saying that the sort of thing CAST does is the way to go? Then you need to look for a specific thing that requires a "moving goalpost", like axions.

11. **Roger**
August 10, 2012

I'd like to know what the prospects for the "desktop experiments" when it comes to falsifying the Standard Model. For example, what precision is needed on g-2 of the muon or the EDM neutron limits in order to explore the multi-TeV region ? Is it a better use of resources to invest in these types of experiments ?

12. **Peter Woit**
August 10, 2012

Roger,

Precision tests of the SM like the ones you mention can only give you very limited information about the multi-TeV region, and you're not going to learn anything at all about the Higgs from them. Definitely worth doing, but they're on a different cost scale and looking at different physics, not really alternatives to accelerator experiments.

Tmark48,

The interesting thing about the LEP3 proposal is that it does have a well-defined goal (detailed study of the Higgs), and the cost looks doable (proponents are talking about .1 x cost of a linear collider). I know of no conceivable way astrophysical observations can study this kind of physics.

As for whether astrophysics can tell you about the multi-TeV scale, Bernhard points out the problems, but in any case, that's a different issue.

13. **Roger**
August 10, 2012

Peter – I was thinking more about their ability to detect "new physics" rather than their ability to characterise it. I'm curious as to how much investment (experimentaly and theoretically) would be needed such that it would be possible with one of these experiments to get sensitivity to non-SM processes at a scale beyond the LHC.

14. **Peter Woit**
August 10, 2012

Roger,

There has been lots of work, theoretical and experimental, on these ideas. Having a convincing violation of the SM prediction would be quite interesting, some sort of clue, and people are working hard on this. But the problem is that typical BSM models are complicated, with vast numbers of undetermined parameters (more than 100 for the MSSM). So, if you see nothing, you put a constraint on a complicated function of 100 or so parameters, which is where we are now, these experiments do give non-trivial constraints (although arguably the muon g-2 value is marginally non-SM, so maybe there is something there). If you see something, and you try and interpret it as for instance SUSY, you are getting very little about the underlying theory, since you just get one number, and it's a very complicated function of the numbers you are interested in.

15. **David Nataf**
August 10, 2012

Tmark48,

There's a tremendous future in astronomy/astrophysics in terms of fundamental physics, and all competent physics departments are recognizing this: Dark matter, dark energy / modified gravity, number of neutrino species, inflation, anthropic principle, etc. However, we shouldn't make a bandwagon and pretend that this is where the entire future is going to be.

Keep in mind that if the particle physics community doesn't build another particle accelerator, the know how to build another particle accelerator will be lost. You need to have supervisors training the next generation. It is possible that the SM goes up to 1 PeV or whatever but you don't know. I'll also point out that null results are scientific results. If somebody has a proposal for a particle accelerator that is simply to see if the SM extends up to 10x the energies probed by the LHC, with no prior that they should not, I would say that this sounds like a legitimate scientific experiment.

Your proposal that funding be cut from future particle accelerators and shifted to satellites is also politically impossible. First, let's recognize that the most likely outcome is that money is going to be cut from all pure science sectors. LISA and SIM have been eliminated for example due to lack of funds. Further, they are different budgets. The astrophysics experiment budget is largely an industrial policy for the high-tech sector in the USA. The mirror in the Hubble Space Telescope is the same size as that in many spy satellites, for example. There are different corporate blocks supporting different science experiments.

16. **uiop**
August 10, 2012

The next generation astronomical observatories such as ALMA, SKA, and the thirty-metre class telescopes cost more than a billion dollars, and flagship-class satellite missions are even more expensive (even small ones cost a couple of hundred million). Are accelerators really way, way, way more costly?

17. **David Nataf**
August 10, 2012

No.

The cost of the James Webb Space Telescope is now 6 billion dollars and counting.

Anyway it's a false dichotomy. The combined costs are under 1% of the US federal budget. I think it's safe to assume that if money is cut from one column it won't be moved to the other column.

18. **Roger**
August 10, 2012

Peter
I buy the argument that such experiments are weak in many respects but they may have a crucial advantage in being able to falsify the SM at a higher energy scale than that of the LHC- I should add that I'm an experimentalist at one of the LHC experiments btw.

I've yet to see the limits in precision on calculations and measurement which we think can realistically be achieved on, eg, g-2_muon and other related experiments etc. If it turns out that there is a realistic gain to be had by using "desktop experiments" to access higher energies then investing in them that would be a punt worth taking in my opinion (we've spent a *lot* of manpower on looking for black holes and other nonsense). The key argument for me would be whether or not the SM calculations and measurement errors would be believable such that a Nobel prize could be given. Very high precision and accuracy are hard to get right.

Regarding the limits one could set on, eg, SUSY that's of small interest (to me). The key thing is, for the first time, we could unambiguously falsify the SM (ok, excluding the neutrino stuff..).

19. **Anon**
August 11, 2012

Hi Roger –The naive standard model prediction for neutron EDM is very small of order 10^{-32} ecm. This assumes just std model with say PQ symmetry to solve the strong CP problem. Experiments will probe the region 10^{-26} ecm to 10^{-29} ecm in the next few years. If it is found experimentally it would be a deviation from just the standard model + PQ symmetry that is the usual way of thinking of neutron edm. For a prediction of lower bounds on neutron EDM based on P and CP symmetries that have been used to solve the strong CP problem (in place of PQ symmetry) please see the paper http://lanl.arxiv.org/abs/1203.2772 — even if new physics is beyond collider reach — say beyond 100's or 1000's of TeV this solution still predicts a deviation from the standard model in a large region of its parameter space.

20. **Patrick**
August 11, 2012

To Peter:

The first argument that comes to mind in favour of LEP3 is certainly the cost, as well stated in your post, but the physics arguments are also numerous. Not only LEP3 can do the same measurements as a linear collider of the same energy, but it does them better. Indeed, most of the Higgs coupling and Higgs mechanism related measurements are statistically limited, and the statistics foreseen for LEP3 is about one order of magnitude larger than that foreseen at a linear collider at 240 GeV, two orders of magnitude larger at 160 (the WW threshold) and three orders larger of magnitude at the Z pole.

The much larger repetition rate and the number of detectors (up to 4), unique to circular machines, are the reasons for this extraordinary performance. If – God forbid ! – the LHC found nothing beyond the Higgs after three years running at 13 TeV, LEP3 would open the door to unprecedented and unchallengeable precision measurements, including measurements of virtual effects at the Z pole, which in the past determined the top quark mass before its discovery at the Tevatron, which a much more modest luminosity. (LEP3 could repeat the LEP1 programme in … 10 minutes!) Now that the top quark and the Higgs mass are known, very small effects due to heavy particles can be unveiled with these precision measurements, and show the direction to follow for the next-to-next machine.

21. **Bernhard**
August 11, 2012

Patrick,

but at a linear collider one could go in principle to 1 TeV of CME and this would beat LEP3 as a discovery machine. I agree with "LEP3 can do the same measurements as a linear collider of the same energy," but I guess a good argument for a linear collider is its high CME and luminosity which it´s sensitive to all sorts of very heavy virtual corrections.

I agree though that to build a "cheap" machine (and much faster, which to me is much more important the the cost) to see what makes sense to build next and at which CME makes sense too.

22. **Roger**
August 11, 2012

Patrick
If, after 3 years running at 13/14 TeV, the LHC finds nothing other than the Higgs then the last thing CERN should do is close down the LHC and replace it with LEP3. The LHC at that point will still only have delivered a fraction of the luminosity intended for that device. Limits on the direct production of heavy new particles could still be extended a lot (this is especially the case for electroweakly interacting particles).

Another point worth making is that a lot of innovation takes place with the development of new accelerator technologies. This is not a reason in itself to go for a costlier option but it is something which ought not to be forgotten.

23. **Roger**
August 11, 2012

Another point springing to mind is that LEP3 would be unique among the major facilities in recent years in being essentially a single topic machine. LEP1,2, HERA, the Tevatron, the LHC all had/have a very broad physics program in addition to their core priority areas. Given the success of LEP1,2 in measuring (very precisely) everything under the sun and the comparatively small increase in centre-of-mass energy in going to LEP3 its unclear whether or not a broad physics program would be in anyway attractive or useful. It would also perforce mean a lot of particle physics research groups moving away from collider physics. That may or may not be a bad thing but I'm pretty sure that it would happen.

24. **anonomous**
August 11, 2012

With our without the LEP3, it sounds like we will have 20 years to stew over the results of the LHC before new HEP results come. I think that astrophysics will be the hot area for uncovering new phenomena but as we have no way to control these events it will be hard to confirm models. It looks like we will have a lot of time to theorize on what BSM physics will look like.

25. **Low Math, Meekly Interacting**
August 11, 2012

Thanks in advance for humoring an utter non-expert…

How realistic is the cohabitation scenario? If it's doable, shouldn't LEP3 be a no-brainer at such a low cost compared to, say, the ILC, which is perhaps decades away from being built in even the most optimistic estimates. It's hard to see how the LEP3 would cannibalize the ILC's budget if it could be built relatively soon. I can't imagine there wouldn't be a wonderful professional symbiosis between the scientists working on two such impressive machines operating in such close proximity. Would the LEP3 somehow preclude the construction of the next generation LHC? Again, if no harm comes to the LHC, why not, BSM physics or no? Precision Higgs physics too pedestrian?

26. **Peter Woit**
August 11, 2012

LMMI,

Politically, I'd guess there's a problem that deciding to build LEP3 would put the idea of an LC on hold for many years.

Practically, even if LEP3 and the LHC can cohabit, building LEP3 would probably involved shutting down the LHC for multiple years during construction, as well as during times LEP3 is running. The cost would presumably come out of the CERN budget, forcing a delay or cancellation of plans for higher luminosity (HL-LHC) or (HE-LHC).

The machines would use the same detectors, and building and running the machines would be the same people as at the LHC now. So, it would be the same people working on both experiments. Right now, I think skepticism about LEP3 is partly skepticism that the thing could be built cheaply, without interfering with the LHC, as advertised, together with worry that it would put a stop to HL-LHC, HE-LHC or LC possibilities.

But some of the commenters here know quite a bit more about this than I do…

27. **Yatima**
August 12, 2012

Well, I didn't that Fermilab has already a website on a Muon Collider Project. I hope to see this running before I kick the bucket!

http://www.fnal.gov/pub/muon_collider/animation.html

28. **Low Math, Meekly Interacting**
August 13, 2012

Thanks for your perspective!

29. **yyy**
August 15, 2012

@Yatima
Building of full-scale Muon Collider will require the following to be built before:
1. Neutrino Factory [non-colliding beam of circa 30 GeV muons]
2. Higgs Factory [two colliding beams of muons 63 GeV each];

It will take few decades.

Short Items

Categories: Uncategorized

- There's an interview with the CERN director here.
- John Preskill and others at the Caltech Institute for Quantum Information and Mattter now have a blog here.
- The usual summer workshop on math and physics at Stony Brook is now running at the Simons Center, see videos of talks here. Videos of talks from the Simons Symposium this spring in the Virgin Islands on knot homologies and BPS states are now available here.
- Last month there was a CBMS conference on Unitary Representations of Reductive Groups in Boston, with David Vogan the main speaker. For a nice set of survey lectures and others, see here. If you find the Vogan conference too old-school, a workshop on categorical representation theory this coming week organized by David Ben-Zvi may be more to your liking, lecture notes starting to appear here.
- The only thing stopping me so far from ordering a copy of Francis Farley's novel Catalysed Fusion is that it looks like it is only available in ebook form, and I've until now avoided those and stuck to paper. According to an article in the Telegraph:

  > …a steamy new novel written by a retired physicist lifts the lid on the organisation's studious exterior to reveal an altogether more glamorous lifestyle of wild nights, adrenalin-fuelled sports and romantic trysts…
  >
  > Prof Farley describes a group of young researchers whose groundbreaking work and racy private lives intertwine as they enjoy the high life at Switzerland's top ski resorts and France's best beaches.
  >
  > Prof Farley revealed that he even based a character on himself – Ivan, a physicist and crack glider pilot who is married to a former stripper and sets up a new lab on a nudist Mediterranean island.
  >
  > He told the Daily Telegraph: "We were well paid, we had diplomatic status, no taxes. We got tax-free petrol and drinks and we went out and enjoyed life…
  >
  > "We worked hard and then some people would go home to their families but there were lots of little floozies about and other men had a roving eye, and so did some of the women."

  Perhaps things have changed a bit since the eighties in Geneva….

- Text books for graduate students on SUSY and string theory are coming fast and furious these days. Next month will see Peter West's Introduction to Strings and Branes, a few months ago there was String Theory and Particle Physics: An Introduction to String Phenomenology by Ibanez and Uranga. Even more recent is Freedman and Van Proeyen's Supergravity, which now has one review on Amazon (from "Dan"):

  > This is a must-buy for every high energy theorist who wants to know Sugra. The first nine chapters also make a great source for classical field theory and can be used as a complement for PhD students learning QFT and GR.
  > A wonderful work!

Update: A few more recent and upcoming string theory textbooks are:

- Strings and Fundamental Physics
- Basic Concepts of String Theory
- D-Brane: Superstrings and New Perspective of Our World

Comments

1. **MathPhys**
   August 12, 2012

   I really want to know who 'Dan' is, who wrote that review of Dan Freedman's and van Proeyen's book.

   I must object to this salesman-like behavior that's turning our subject into a circus act. This is science. Remember? Remember your ideals when you embarked on a career in physics? Whatever these were, they definitely were not to sell your colleagues something.

2. **Friend**
   August 12, 2012

   "Catalysed Fusion "… sounds like it might make good episode of Big Bang Theory.

   Just a joke, no offense intended.

3. **Phil**
   August 12, 2012

   MathPhys,

   I find nothing wrong with Dan's review. Salesman-like behavior? What's wrong with recommending a book?

4. **Peter Woit**
   August 12, 2012

   Phil,

   I suspect that MathPhys thinks "Dan" = book's author, and evidently the review is rather similar to the way the author describes his own book.

   I have no idea whether it's normal for authors to write 5 star reviews of their own books at Amazon, maybe it's the done thing. All sorts of odd stuff goes on there; when my book came out a Harvard faculty member was offering people $20 to write bad Amazon reviews of it….

5. **MathPhys**
   August 12, 2012

Phil,

If you don’t already know, it’s pointless to explain it to you. What happened to modesty? Is shame dead? Are we salesmen now? You write a book and let people make up their minds.

6. **Alfred**
   August 12, 2012

   Update: A nice new interview with Ed Witten: http://www.youtube.com/watch?v=sAjuG3GGjUE

7. **voice of temptation**
   August 12, 2012

   MathPhys, that’s an interesting perspective. Would you like to be a guest on our program, “The Decline and Fall of Physics in the 21st Century”? It could lead to a new career for you, as a media personality!

8. **MathPhys**
   August 12, 2012

   Please listen to E Witten’s interview that Alfred has linked above, to hear how a scientist can describe his work, and what he strongly believes in, but modesty, and without using superlatives to describe his own contributions.

9. **Phil**
   August 12, 2012

   MathPhys and Peter,

   How do you know that this reviewer is the author? I see no evidence for it. I also skimmed through the Amazon preview of the book and didn’t see the reviewer’s statement in the book. Do you know where it is?

10. **MathPhys**
    August 12, 2012

    http://www.amazon.com/Supergravity-Daniel-Z-Freedman/dp/0521194016/ref=sr_1_1?s=books&ie=UTF8&qid=1344824763&sr=1-1&keywords=freedman+supergravity

11. **Peter Woit**
    August 12, 2012

    Phil,

    I’ve heard from a reliable source that the review I quoted is very similar to the way the author describes his own book. In any case, I’m guessing that the author is not trying to hide his own identity, since he is using his own name “Dan”. If he were trying to hide behind a pseudonym, he’d use a different name. Again, I’d be curious to hear from anyone who knows more about Amazon reviews: are author self-reviews using their own name common? For all I know, there’s no rule against it. A few minutes of Googling turned up no rule of this sort.

12. **David Appell**
    August 12, 2012

    Geez MathPhys, lighten up. If a textbook author can’t give himself a little one-paragraph boost on Amazon, what’s the world coming to? In this day and age authors need all the help they can get, or before long these kind of books might not even exist anymore.

13. **Q.I.**
    August 13, 2012

    I think it is okay for authors to write a review of their own book, however, IMHO, they must identify themselves as authors. It appears “Dan” has not done that. Reviewer rating is an important consideration for me to buy books from Amazon and I think I should know if the person writing the review is actually an author.

14. **Nadja Summer**
    August 13, 2012

    I´m still dreaming to visit the CERN in Switzerland, you may also check out this interesting interview with Dr. Paul Jackson on http://tinylink.net/75367

15. **MathPhys**
    August 13, 2012

    Q. I.

    Definitely. An author can say “I wrote this book and I think it’s the best book that x, y and z can buy for this and that reason”. All above counter, and nothing at all wrong with that.

16. **Chris Oakley**
    August 13, 2012

    > when my book came out a Harvard faculty member was offering people $20 to write bad Amazon reviews of it

    With (approx) 1,000 String theorists maybe it was his inability to pay the $20,000 bill that caused Lubos to flee the country. I do not remember seeing that many reviews, though.

17. **Christian**
    August 13, 2012

    I’ve gotten all curious. Is the book any good? I already skimmed the Amazon preview, but that does not tell me whether the book is pedagogical and the exercises useful. I’m a PhD student in accelerator physics, and would like an introduction to the subject.

18. **MathPhys**
August 13, 2012

Christian,

I personally expect that Freedman and van Proyen will be a standard reference work on supergravity. I don't know of any other textbook on the subject, except Peter West's which hasn't appeared yet. At 600 pages and $65, it's reasonably priced (for a CUP hardcover) and clearly geared towards students.

19. **KK**
August 13, 2012

If that Farley in the fifth bullet is the Farley from g-2, then he is the guy who in the 60s-80s was well known for participating in the ladies program ("accompanying persons" were ladies then). And I know ladies who found him a nuisance. So I guess that "his steamy new novel" contains his dreams rather than reality.

20. **Hugh**
August 13, 2012

Ive read Catalysed fusion. It's quite fun rather a mish mash. Quite a bit of male fantasy sex. The physics while clearly impossible (involving very low mass high spin leptons) is also fun and coherent. Some of the experimental stuff is well described. It's not Proust but may be almost a male equivalent of 50 shades of grey with added physics (and gliding).

21. **SteveM**
August 13, 2012

Having worked about half way through Freedman's book this year I can honestly say it is a truly excellent and beautiful textbook. Very well written and organized with everything laid out and explained very clearly and precisely, in what is generally a difficult subject that can often become messy and confusing. As you progress through the chapters, you see it all coming together before your eyes and the basic universal structure of SUGRA becomes apparent. The material in the first half of the book alone is worth the asking price. Excellent treatments of field theory, Clifford algebras and fermions, Rarita-Schwinger fields, basic SUSY, gauge symmetries, differential geometry, spin connections etc. etc. Highly recommended.

22. **Gilgit**
August 14, 2012

Since you are talking about text books I wanted to ask a question. I have started going through various physics text books again after a long time away and have reached quantum mechanics. I have plenty of Quantum Mechanics books to choose from, but I always planned to skip anything on String Theory since it seemed so half baked.

But in a few posts a week or two back, Peter commented on how String Theory, when stripped of all the hype, "that there's a case to be made for string theory research based on other things it has led to", spin-offs he called them (this was in response to Bob Jones comment quoting Witten saying: string theory has helped us better understand theories we already have).

I must admit to being totally ignorant of this. Do any of the text books you've listed or can buy on Amazon on String Theory cover these areas? I had assumed the texts were all about untestable unification theories combined with ridiculously advanced math and so never intended to look at them.

I've been slowly covering a lot of physics and math and expect to keep going till I've covered a whole lot more and at some point I might run into these areas so I thought I'd ask what some of these 'spin-offs' are called. I'm not looking for an in depth description of them, just some terms and maybe: this QM book talks about such and such or this ST book actually mentions something useful.

Or is this a dumb question and all the introductory string theory books cover this? Or is the only way I'd encounter any of these topics is if I read dozens of advanced research papers that only 50 people in the whole world can understand?

Thanks

23. **MathPhys**
August 14, 2012

It's too bad, but all stringy textbooks that I know of are devoted to perturbative physics, model building, etc. Some discuss blackholes in string theory and so forth, but that's not the sort of thing that Peter W had in mind.

24. **Peter Woit**
August 14, 2012

Gilgit,

Mostly the string theory textbooks don't cover the mathematically interesting parts of the subject, but focus on trying to explain the failed unification stuff. One of the most interesting areas of spinoffs from string theory is work on 2d conformally invariant qfts. There are several advanced graduate level textbooks that focus on this, one example is

di Francesco, Mathieu, Senechal Conformal Field Theory

Two other good books covering some of this math/physics are

Fuchs, Affine Lie Algebras and Quantum Groups
Gannon, Moonshine Beyond the Monster

For a different interesting area of mathematical physics coming out of string theory, see
Vafa and Zaslow, eds. Mirror Symmetry

Fuch

25. **Bob Jones**
August 14, 2012

Gilgit,

I'm glad you brought this up again because I think there's a lot of confusion among the general public about this aspect of string theory. Unfortunately, popular books and string theory textbooks don't help the situation because they focus primarily on unification. The only exception I know of is the book by Vafa, Zaslow, et al. that Peter mentioned, but you'll need to know a bit of quantum field theory and algebraic geometry before you'll be able to read it.

I don't think it's a good idea to dive into string theory without the proper background. There are so many other fascinating topics to learn about which are much more firmly established than string theory. I would start by learning quantum mechanics (the book by Griffiths is the standard text) and then try to learn some basic quantum field theory and relativity (see for example the book by Zee and the one by Baez and Muniain). Eventually you'll be able to read more advanced books on quantum field theory and string theory (like the two volumes published by the IAS).

If you just want to learn more about applications of string theory, there several accessible introductions on the internet. For example, see

http://www.nature.com/news/2011/111019/pdf/478302a.pdf

http://www.sns.ias.edu/~malda/sciam-maldacena-3a.pdf

http://www.sns.ias.edu/~malda/Published.pdf

http://www.sns.ias.edu/~witten/papers/KnotsandPhysics.pdf

http://physics.berkeley.edu/events/Colloquia/movies/col.streaming.3-12-12.mov

http://media.scgp.stonybrook.edu/video/video.php?f=20120411_2_Arkani-Hamed_qtp.mp4

26. **Gilgit**
August 15, 2012

Hey, that's nice of you guys. I appreciate the references and links.

And I certainly plan on going through many different Quantum Mechanics/Field Theory books. I've spent the past year on Amazon poking around. An amazing resource – the reviews (taken with a grain of salt) will let you know which are the most popular books, which are the classics, what are the other books at the same level as this one, comparing several books on the same topic, etc.

And the lists Amazon has – one guy taught himself General Relativity and then wrote up 7 lists comparing books on General Physics, Math for Physics, Special Relativity, General Relativity, Differential Geometry, Tensors… specifically from the point of view of a self learner.

And the internet has a fair number of solutions manuals – either written by grad students or official ones – to many physics texts (including Griffiths, Sakurai, and a few other QM books).

In fact one professor in France wrote the solutions, in English, to every problem in "A First Course in General Relativity" (Schutz) and posted it for anyone to download. He even added a few more intermediate problems designed to help students figure out how to do the more complicated problems.

The reason I brought it up (boy am I off topic now) is that I kind of figured there would be lots of people who posted solutions to popular texts. Kind of like how in the olden days people would write commentaries on Greek Philosophers or on Confucius and then other people would write commentaries on commentaries, etc. Seems like an easy way to get noticed. Similar to budding programmers writing useful open source programs… but it hasn't happened so maybe what I think is a good idea isn't as good as I thought.

At least there are quite a few published problem books out there – books with hundreds of problems with full solutions. I'll bet there are at least 5 or 6 Quantum Mechanics books like that now. Plus others on Field Theory, Differentiable Manifolds/Riemannian Geometry – searching on Amazon I even found "Problem Book in Relativity and Gravitation" with hundreds of GR problems from 1975! Who knew?

So if I really get stuck I believe there are resources out there to get me going again. I'm sure it will take only 5 or 10 years or so to learn all of this, but at least I think it's possible.

Thanks again.

’t Hooft on Cellular Automata and String Theory

August 13, 2012
Categories: Uncategorized

Gerard ’t Hooft in recent years has been pursuing some idiosyncratic ideas about quantum mechanics; for various versions of these, see papers like this, this, this and this. His latest version is last month’s Discreteness and Determinism in Superstrings, which starts with cellular automata in 1+1 dimensions and somehow gets a quantized superstring out of it (there are also some comments about this on his web-site here).

Personally I find it difficult to get at all interested in this (for reasons I’ll try and explain in a moment), but those who are interested might like to know that ’t Hooft has taken to explaining himself and discussing things with his critics at a couple places on-line, including Physics StackExchange, and Lubos Motl’s blog. If you want to discuss ’t Hooft’s ideas, best if you use one of these other venues, where you can interact with the man himself.

One of ’t Hooft’s motivations is a very common one, discomfort with the non-determinism of the conventional interpretation of quantum mechanics. The world is full of crackpots with similar feelings who produce reams of utter nonsense. ’t Hooft is a scientist though of the highest caliber, and as with some other people who have tried to do this sort of thing, I don’t think what he is producing is nonsense. It is, however, extremely speculative, and, to my taste, starting with a very unpromising starting point.

Looking at the results he has, there’s very little of modern physics there, including pretty much none of the standard model (which ’t Hooft himself had a crucial role in developing). If you’re going to claim to solve open problems in modern physics with some radical new ideas, you need to first show that these ideas reproduce the successes of the estabished older ones. From what I can tell, ‘t Hooft may be optimistic he can get there, but he’s a very long way from such a goal.

Another reason for taking very speculative ideas seriously, even if they haven’t gotten far yet, is if they seem to involve a set of powerful and promising ideas. This is very much a matter of judgement: what to me are central and deep ideas about mathematics and physics are quite different than someone else’s list. In this case, the central mathematical structures of quantum mechanics fit so well with central, deep and powerful insights into modern mathematics (through symmetries and representation theory) that any claim these should be abandoned in favor of something very different has a big hurdle to overcome. Basing everything on cellular automata seems to me extremely unpromising: you’re throwing out deep and powerful structures for something very simple and easy to understand, but with little inherent explanatory power. That’s my take on this, those who see this differently and want to learn more about what ’t Hooft is up to should follow the links above, and try discussing these matters at the venues ’t Hooft is frequenting.

Comments

1. **Robert Smart**
   August 13, 2012

   I hope you’ll also comment on Alain Connes new paper. It does try to be consistent with the standard model, but apart from that it’s too hard for me.

2. **Gerard 't Hooft**
   August 13, 2012

   Even though my work is here sketched as “not even wrong”, I will avoid any glimpse of hostility, as requested; I do think I have the right to say something here in my defense (One positive note: “Not even wrong” sounds a little bit better than “Wrong wrong wrong” on another blog …).

   First, I agree that cellular automata doesn’t sound very sexy; those who have seen Wolfram’s book will certainly be discouraged. But I want to stress as much as I can that I am striving at a sound and interesting mathematical basis to what I am doing; least of all I would be tempted to throw away any of the sound and elegant mathematics of quantum mechanics and string theory. Symmetries, representation theory, and more, will continue to be central themes.

   I am disappointed about the reception of my paper on string theory, as I was hoping that it would open some people’s eyes. Perhaps it will, if some of my friends would be prepared to put their deeply rooted scepsis against the notion of determinism on hold.
   I think the mathematics I am using is interesting and helpful. I encounter elliptic theta functions, and hit upon an elegant relation between sets of non-commuting operators p and q on the one hand, with integer, commuting variables P and Q on the other. All important features of Quantum Mechanics are kept intact as they should.

   I did not choose to side with Einstein on the issue of QM, it just came out that way, I can’t help that. It is also not an aversion of any kind that I would have against Quantum Mechanics as it stands, it is only the interpretation where I think I have non-trivial observations.
   If you like the many world interpretation, or Bohm’s pilot waves, fine, but I never thought those have anything to do with the real world; my interpretation I find far superior, but I just found out from other blogs as well as this one, that most people are not ready for my ideas. Since the mud thrown at me is slippery, it is hard to defend my ideas but I think I am making progress.

   They could well lead to new predictions, such as a calculable string coupling constant g_s, and (an older prediction) the limitations for quantum computers. They should help investigators to understand what they are doing when they discuss “quantum cosmology”, and eventually, they should be crucial for model building.
   G. ’t H

3. **Peter Woit**
   August 13, 2012

   Prof. ‘t Hooft,

   Thanks for writing here with your reaction to and comments on the blog posting. I hope you’ll keep in mind that I often point out that “Not Even Wrong” is where pretty much all speculative ideas start life. Some of the ideas I’m most enthusiastic about are certainly now “Not Even Wrong”, in the sense of being far, far away from something testable.

   While my own enthusiasms are quite different than yours, and lead me to some skepticism about your starting point, the reason for this blog posting was not to launch a hostile attack, but to point others to what I thought was an interesting discussion, one which many of my readers might find valuable to know about.

   Good luck pursuing these ideas, may you show my skepticism and that of others to be mistaken…

4. **Anonymous**
   August 13, 2012

   Prof. ‘t Hooft,

   While I am not familiar with your particular work, I am familiar with previous explorations on the theme of interpretations on quantum mechanics and determinism, particularly with old things such as de Broglie-Bohm's theory, Bell's contextual ontological model, Kochen-Specker's model, and newer things such as Harrigan & Spekkens classification of ontological models, Lewis et al. psi-epistemic model, Hardy's excess baggage theorem, etc. But after studying them with interest for a while, I gradually developed the opinion that they have no good motivation, use uninteresting mathematics, and have been generally fruitless. Since then I have stopped paying attention to this area of research.

Since you seem to be interested in defending your work and, furthermore, in publicizing it, I would be very interested in knowing what's the difference from these previous explorations and, more importantly, what's the motivation for you to begin work in this area (since you claim not to be motivated by an aversion to Quantum Mechanics).

I do hope you can convince me to study your work, and perhaps an answer could be useful to other researchers as well.

5. **Tim May**
August 13, 2012

I think it's great that Prof. 'T-Hooft (hope I got the capitalizations and apostrophes right) is commenting here. This site is in many ways much less hostile than other sites we could all name easily.

I started out (well, in terms of blog years, not my physics education several decades ago) as a string critic. I didn't find Brian Greene's first book very persuasive (nor a book from the 1980s, I forget who wrote it). I was receptive to Lee Smolin's "Three Roads to Quantum Gravity" and to this blog, even before the book came out.

However, partly as a result of reading this blog for about half a dozen years (I think), I've gradually warmed to a lot of the string stuff. Not the Kaku stuff, but the Arkani-Hamed types of stuff.

The fact that we may be 10-15 orders of magnitude away from probing the energies needed to test some of these theories is, of course, daunting. And I think both Woit and Smolin were basically right to warn of the "We are only interested in hiring string theorists" situation a while back.

However, things seem to be on a somewhat better keel today. Or so is my perception from this blog and others. And of course the stuff coming out of cosmology and observational astronomy is just plain exciting.

How it links with math is also exciting, albeit probably decades or even centuries off in terms of real experimental links.

Exciting times. And I think "Not Even Wrong" is useful for reminding its readers to doubt some popular theories. Sort of like the guy the Romans used to hire to ride behind the triumphant god-king warrior to remind him he is not really a god.

As for CAs, I'd've thunk (a technical term 🙂) that Kochen-Specker and other no-go results rule out strictly local (as CAs seem to be) theories. But I look forward to seeing Prof. 'T-Hooft enter this arena of debate.

–Tim May

6. **Bernhard**
August 14, 2012

Prof. 't Hooft,

I think the key point in all this is in your last paragraph:

"They could well lead to new predictions, such as a calculable string coupling constant g_s, and (an older prediction) the limitations for quantum computers. They should help investigators to understand what they are doing when they discuss "quantum cosmology", and eventually, they should be crucial for model building."

Regardless of what people think about your ideas (most of the people probably just dismiss it without reading it after hearing about what you are claiming) the key point with new interpretations of Quantum Mechanics is suggesting an experiment where it can predict something new (OK, saying this to a Nobel prize professor sounds perhaps very pretentious, but I just want to express my deepest concern about your message). A new paper based on this one, but concentrated only on the "what's measurably different" in all of what you are saying, would (I suppose) attract attention and perhaps put skepticism on hold for a while. I confess I find difficult to digest your paper but if I could understand better where could it measurably matter then this would be a different story. Otherwise it will probably stay as a curiosity.

Let me finish saying I deeply admire your courage on working with fundamental problems in QM and as I semi-young physicist I even more deeply envy the freedom you have to pursue your own ideas.

7. **Anonyrat**
August 14, 2012

Prof 't Hooft is in exactly the right situation to play with highly speculative ideas that a young postdoc. cannot afford to do.

8. **Neil**
August 14, 2012

If anyone has "earned the right" to engage the profession with speculative ideas, it is Professor 't Hooft with his track record of brilliant theoretical insights. I look forward to learning more about this.

9. **Anonymous***
August 14, 2012

't Hooft,

Could you explain why you think the Bohm theory is rubbish? It seems to me that it has already done exactly what you are trying to do — provide a perfectly consistent alternative to the standard approach in quantum mechanics.

I also don't think that you are siding with Einstein on quantum mechanics. Einstein made clear that he did NOT think something like Bell's inequality could exist, but it DOES! He was very clear that his thinking would change if something like a Bell inequality was discovered, in particular it would lead to something along the lines of a Bohm interpretation.

10. **anonII**
August 14, 2012

At first, I did not believe it was GT – but doing the ('t) correctly (twice even) gave it away. Thanks for posting.

11. **Yatima**
August 14, 2012

I posted this before and I will post it again!

Ray Streater on Bohmian Mechanics:

http://www.mth.kcl.ac.uk/~streater/lostcauses.html#XI

12. **Peter Woit**
August 14, 2012

Unless Prof. 't Hooft himself wants to answer and discuss the topic, enough about Bohmian mechanics, please.

13. **Danny**
August 14, 2012

`t Hooft is one of the good guys, an incarnation of Dirk Foster and a physicist of the highest calibre. This deterministic programme seems Just Possibly True, and should probably serve as inspiration for the sort of paradigm-shifting research everyone seems to advocate (but no-one pursues). My humble opinion.

14. **Jeff**
August 14, 2012

I think the biggest issue here is that 't Hooft (clearly a brilliant physicist) ignores Conway/Kochen, who clearly prove, given three axioms, that the universe *can't* be deterministic. Actually, they prove it isn't "random" in the usual sense either. And the axioms one needs to assume are essentially completely straight QM and relativity, together with the inability to influence past events.

15. **Peter Orland**
August 14, 2012

Though I don't necessarily accept 't Hooft's scenario, I am a little surprised by some of the criticism. The no-go theorems mentioned above are not relevant.

There is no contradiction for quantum evolution to occur in a deterministic system. A cellular automaton, for example, can be regarded as a transfer matrix with a special property. This property is that given any initial (basis) state, the matrix element is not zero for a unique choice of final (basis) state. Such transfer matrices can be unitary, hence identified with quantum evolution.

I don't know whether the scenario is useful or not. It is certainly not, however, ill-conceived.

16. **Bob Levine**
August 14, 2012

There are two problems with Jeff's dismissal of 't H.'s approach; Peter Orland has touched on one. For the other, see

http://philsci-archive.pitt.edu/8437/1/WuthrichChristian2010PhilSci_IndeterministicWorld.pdf

Wüthrich's observation that even Conway and Kochen's scenario depends on access to information about—in fact is a *function* of—prior events (which, NB, has nothing to do with influence over prior events) seems like a huge analytic challenge to C&W's core thesis. Obviously, the game is still in play, and meanwhile, you can't appeal to C&W as any kind of decisive refutation of what 't H. is proposing.

17. **Peter Orland**
August 14, 2012

… and it is not the same as DeBroglie/Bohm mechanics. Or Nelson's for that matter.

18. **Jeff M**
August 14, 2012

Peter O,

I'm a bit confused about why you feel Conway/Kochen isn't relevant. Prof. 't Hooft is more than a good enough mathematician to understand that his system somehow violates one of their 3 axioms, but I can't from his writeup figure out which one it would be. Then again, if you read his paper, he seems to be ducking the issue "The philosophy used here is often attacked by using Bell's inequalities[1]—[3] applied to some Gedanken experiment, or some similar "quantum" arguments. In this paper we will not attempt to counter those (see Ref. [16]), but we restrict ourselves to the mathematical expressions." Since the discussion in [3] is a valid mathematical proof, I can't understand ignoring it.

19. **Peter Orland**
August 14, 2012

Jeff,

't Hooft's model does not specify values of observables. It has deterministic evolution of basis states. That is why the theorems you quote do not apply.

20. **Jeff**
August 14, 2012

Peter o

Thanks, been too long since I thought like a physicist. :-). I'm reading as a mathematician, and assumed "deterministic" had the usual meaning.

21. **Raisonator**
August 15, 2012

Just another link, which may be helpful in this context:

http://www.youtube.com/watch?v=lGB3oVxivhE

22. **Maynard Handley**
August 15, 2012

"Though I don't necessarily accept 't Hooft's scenario, I am a little surprised by some of the criticism. The no-go theorems mentioned above are not relevant.

There is no contradiction for quantum evolution to occur in a deterministic system. A cellular automaton, for example, can be regarded as a transfer matrix with a special property. This property is that given any initial (basis) state, the matrix element is not zero for a unique choice of final (basis) state."

This (cellular automaton as a transfer matrix) may or may not be true but it's not interesting. The problem of interest here is not alternative computational models of QFT (ie alternative ways to solve PDEs or calculate path integrals). The problem of interest is WHY DOES SOMETHING LIKE COLLAPSE OF THE WAVE FUNCTION OCCUR?

The deterministic answer, in all its forms, whether Bohm or many universes or whatever, is to claim that this "collapse" is a misunderstanding, that if you define the problem properly, then some deterministic combination of initial conditions plus minor perturbations along the way lead you inevitably to the specific state that you measured.
The nice thing about this world view is that it's compatible with relativity — it doesn't bring up any (so far completely unresolved IMHO) questions about "when" does this collapse occur, bearing in mind that "when" is a relative concept and so does the collapse "propagate outward" at the speed of light from some initiating point (very problematic) or does it happen "simultaneously" (hmm, that's not a very relativistic word) (perhaps simultaneously over some especially blessed world surface?).

OK, so determinism is nice. Only problem is that it appears to be wrong wrong wrong. Bell's inequality is one version of why it's wrong, but the deeper reason it is wrong is that it uses a broken mental model of the relationship between probability and QM.
Probability is based on the idea of underlying space \Omega, a sigma field of events, and a measure associated with the sigma field. On top of this we construct random variables which (and this is the important part) are all COMPATIBLE. That is, for any random variables X and Y, the concept of a joint distribution,say F(X, Y) is well defined. At root, this is because the sigma fields defined by X and Y are subfields of the underlying \Omega sigma field, and we can construct an intersection of them. Even more fundamentally, this is because the "building up" operator we're working with is set union, and set intersection plays nicely with set union.

Now we switch to the world of operators and vector spaces.
Given one particular operator O, this has a set of eigenvalues.
Associated with each set of eigenvalues (-\infinity, \lambda] is a vector space,call it V_\lambda.
IF in addition we are given a vector \psi, we can now associate a real number with V_\lambda, namely the length of the projection of \psi into V_\lambda.
This in other words gives us a monotonic increasing function (a measure) associated with increasing \lambda.
This may look unfamiliar, but it's really not scary, it's the usual stuff you are familiar with — an eigenvalue and associated with a "probability" for that eigenvalue given by , only made a little more rigorous and described in the language of probability.

This monotonic increasing function associated with increasing \lambda is just like the cumulative distribution function associated with a random variable,and because of that, people have for almost a hundred years being slipping informally between operator language (eigenvalues, eigenspaces, "probability associated with an eigenvalue") to an implicit assumption that we are dealing with full-blown probability theory and random variables. We are NOT.
Things fall apart if we consider now a second operator, call it Q, which does not commute with operator O. Whereas two random variables ARE always "compatible" in the sense that I stated earlier, specifically, that they have an associated joint distribution (and an associated underlying set of points \xi \in \Omega each of which represent "initial conditions" which might lead to a particular joint outcome of X=x and Y=Y; this sort of thing is no longer true for non-commuting operators O and Q.
Q (and vector \psi) generate another spectrum of eigenvalues, each with an associated weight, and so can also, apparently, be thought of as random variable.
But there is no "compatibility" between these two random variables. More specifically, there IS NO finer sigma algebra which contains both the sigma algebras generated by the O-"random variable" and the Q-"random variable".
At root, this is because the fundamental "points" we are dealing with when we treat O as having an associated random variable are not simple points, they are vector spaces, and the building-up operation as we aggregate these is not a union of sets of "simple points", it is a cartesian product of vector spaces. But the cartesian product does NOT play nicely with intersection the way union does (we don't have the full set of De Morgan laws).

Or to put it slightly differently, given a set \Omega, the set which is actually relevant to QM is C^\Omega, and the measures defined by operators apply to this set C^\Omega "sliced by cartesian product" along different angles for different operators. This is different from standard measures which derive by slicing \Omega "by union". The union slices, when intersected, still give useful sets. Cartesian product slices, when intersected, simply give the set {0}, not useful structure.

I know this sounds like a whole lot of weirdness, but there's nothing unorthodox here — it's just standard probability theory, and standard Hilbert space theory interpreted as measure theory. But, IMHO, this conceptualization is, once you understand it, extremely powerful in revealing where the true weirdness of QM lies. In particular, again IMHO, it's as powerful a mathematical argument as we're ever going to get that the underlying idea of many-world theories. I've never seen a real mathematica formulation of a many-world theory, so I've no idea what the proponents actually mean; but as far as I can tell, what they mean is essentially a probabilistic model: the multiverse consists of some unfathomably large set \Omega of points \xi, each \xi corresponding to a universe, with some sort of measure tied to subsets of \Omega, and our universe is the deterministic unfolding of one of these \xi. As I've tried to explain, you just can't get this to work, because the model only works when you "aggregate points by union", and QM doesn't do that.

23. **Peter Orland**
August 15, 2012

Maynard,

Bell's inequality is not violated in 't Hooft's model. It is just a way to formulate quantum mechanics. It is deterministic in the way that one basis vector is sent to the next, during some discrete time interval. This is a linear unitary map (both vectors are normalized), hence just quantum mechanics. Nothing is any different concerning collapse or no-collapse of wave functions.

A trivial example of this kind of model (much simpler than what 't Hooft considers) can be done with two spin states, s1 and s2. The transfer matrix sends s1 to s2 and s2 to s1. It therefore has the representation of the Pauli matrix sigma1. Well, that is a unitary evolution operator. A slightly less trivial example is a permutation of N objects, with N>2 (which can have complex eigenvalues, with unit norm). Any permutation can be represented as a unitary N X N matrix. Hence it can be written as the logarithm of i (sqrt of minus 1) times the time interval times a Hamiltonian (also an N X N matrix). The Schroedinger equation is satisfied, in the sense that at its solution is the state vector. The eigenvalues of the transfer matrix do not have to be real numbers (though its components are real).

This kind of model is not a traditional hidden-variable theory in the sense of De Broglie, Bohm, Nelson or anyone else. Unlike those theories, you cannot specify all observables simultaneously. You can specify certain observables at discrete time intervals, but the uncertainty principle is intact.

I am not saying you should accept the idea, just that you need to see it for what it is.

24. **Peter Orland**
August 15, 2012

Anyway, I would prefer not spending time defending this. I wish I did not get incensed when I see people's work criticized for the wrong reasons.

25. **Peter Orland**
August 15, 2012

I meant to say Bell's inequality is violated. It is just QM.

26. **Maynard Handley**
August 16, 2012

Thanks, Peter.
I don't want to thread jack, but how does what you say fit in with Peter's statement about "One of 't Hooft's motivations is a very common one, discomfort with the non-determinism of the conventional interpretation of quantum mechanics."

I will admit I have not yet this particular 't Hooft's paper (though I have pretty much always been pleased with when I have read something by him) but I assumed, from that, that this WAS the point at issue. Hence my long attempt to summarize the issues in play and my views on them.

If all we have is "deterministic evolution of the wave function" then why is Peter saying what he is saying?

27. **Peter Woit**
August 16, 2012

Maynard,

If you read my posting, you'd notice that its point is to explain why I'm not trying to seriously understand exactly what 't Hooft is doing. So, I'm not in any position to participate in a discussion of this sort. Actually, neither are you, since you admit you haven't read his paper. Enough about this.

28. **jim**
August 16, 2012

Here's a more concise rebuttal of Streater: http://www.ilja-schmelzer.de/realism/BMarguments.php

29. **Peter Woit**
August 16, 2012

No more Bohmian mechanics. At all, ever.

30. **Sandro**
August 26, 2012

Prof 't Hooft, don't get discouraged by the opposition to your cellular automota approach to QM. Computer science is still in its infancy, and it's impact on mathematics and physics has only just begun.

I think your approach via minimalistic cellular automota is very promising, and the recent anti-determinism bias is just a fad. QM has equally expressive deterministic and non-deterministic formulations, and an exploration of the limits of deterministic formal systems given the current empirical evidence is essential. There seems little reason to posit non-determinism if it is not necessary to do so, as deterministic explanations invariably have more explanatory power.

SUSY 2012, and Strassler on the String Wars

August 15, 2012
Categories: Uncategorized

This post was originally going to be just about the latest SUSY exclusion results announced at SUSY 2012 and their significance, but I realized there's nothing much new to say, and it would be tedious to just write the same things. ATLAS new results are here, including some using this year's 8 TeV data. As before, not a hint of SUSY in the CMS or ATLAS data. Now that the expected places to find SUSY have shown nothing, emphasis is on how to search more obscure corners of the 100 + parameter space of the theory which are accessible at the LHC, but hard to study. For a good recent survey of this effort, see Matt Reece's recent presentation here.

SUSY 2012 featured a plenary talk by Gordon Kane, promoting his string theory "predictions". As usual, the gluino is right around the corner. Back in 2000, it was supposed to be around 250 GeV, with SUSY discovery at the Tevatron in 2001-3 (see here). Last summer the "prediction" was 600 GeV, just above the 500 GeV limits. Last December, the gluino discovery was imminent, by summer 2012. The latest news is that the gluino mass prediction is now 1 TeV, just above the 800 GeV limits according to Kane. You can watch the gluino move by comparing the same "prediction" plot on slide 22 here and slide 34 here. Kane now claims in bold face that "**String/M theory prediction is that no gluino signal expected so far**" (page 35) referring (I think) to this paper, which seems to say nothing of the kind. This is just getting more and more bizarre.

Matt Strassler (described here as "the chief US theoretician") has rarely been critical of string theory hype (although he did in a comment refer to Kane's claims as "garbage and propaganda"), preferring to see prominent blogging critics of string theory and SUSY hype as the bigger problem to deal with. Today though he took a dramatic and rather admirable step, with a posting about string theory that starts off with:

> …the theory's been spectacularly over-hyped, and the community's political control of high-energy physics in many U.S. physics departments has negatively impacted many scientific careers, including my own.

He goes on to cast himself as a lonely moderate surrounded by two teams of extremists, arguing that

> it is high time the ball were grabbed by the referee and placed quietly in the middle of the field where it belongs.

His refereed position in the middle of the field would have acknowledgement that "string theory cannot be tested at present, and that situation might continue for a very long time, perhaps centuries", while lauding string theory for providing a range of important insights into other problems than unification. This refereed position seems to me already pretty much the mainstream position of string theorists I know. My problems with it are that it still allows the heavy promotion of a failed idea (string unification as "our best bet", even if mysteriously "hard to test"), and the over-hype problem is also prevalent among discussion of string theory applications to other parts of physics.

Strassler gives an interesting example of how some ideas from string theory ended up providing inspiration for advances in amplitude calculations, although the main heros of the tale are the phenomenologists who have done the hard work behind these advances (see his exchange with the anonymous "dude" in the comments).

Oddly enough, what seems to have motivated Strassler to take this new public stand are the recent $3 million prizes awarded to his colleagues down the road at Princeton. He devoted this recent posting to attacking me and *Nature News* for quoting me about the prizes, but ended up agreeing with some of my concerns, specifically:

> What upsets me is that there is a long, long list of deserving scientists, some of whom have received little recognition despite their important work, and some of whom could really use some research money and/or time off from teaching — and Milner overlooked them all…
>
> Philanthrophy needs to be done with the consent and participation of the beneficiaries; otherwise it generally fails, and sometimes it causes complete disasters. For instance, you can completely destabilize an organization that is functioning well if you just hand one of its members a million dollar check without understanding the implications…
>
> Anyway, as far as I can tell, the Milner prize is one thing our field didn't really need. I can think of a few things we really do desperately need, at least in the U.S.

It's pretty clear where Strassler thinks the money should have gone:

> we have too many string theorists teaching at the top U.S. universities, and not enough theorists doing other aspects of high-energy physics, including Standard Model predictions…

He explained in the earlier posting that he has been trying to raise private money for an LHC Institute, but that this has failed because of the recession. I don't know any details of this, but I do know that about five years ago he and Arkani-Hamed were proposing something like this to the NSF, with the two of them as co-directors. This foundered not because of the recession but because reviewers didn't much like the idea of giving a lot of new money to well-funded theorists at Princeton and Rutgers, largely to retool string theory groups into LHC phenomenology groups.

That proposal advertised the likelihood of discovery of SUSY or something equally dramatic about a year after first beams at the LHC, with a large group of theorists needed to sort out the "LHC Inverse Problem" of how one was going to figure out the underlying physics responsible for the confusing plethora of non-SM signals the LHC would be seeing. Perhaps a reason for finding it hard to get funding for a theory LHC institute these days is not the recession, but the lack of any such advertised signal. On the other hand, with $12 million of cash in their pockets now, the IAS theorists should be able to themselves privately fund the proposed Arkani-Hamed/Strassler center, if they still think this a good idea.

Comments

1. **anon.**
   August 15, 2012

   Gordy's backup slides are still touting the Fermi-LAT 130 GeV gamma ray line as a possible signal of wino dark matter. This is a superficially attractive idea that is *completely* incompatible with the data from continuum gamma rays, among other bounds. He also is quoting out-of-date LHC bounds, which now put gluinos decaying through off-shell third generation particles above 1 TeV, not just 800 GeV.

   It's frustrating for those of us who sympathize with some of his arguments against other popular approaches to model-building that he's so overzealous in promotion of his own ideas that no one takes him seriously anymore, and attempts to argue along similar lines are treated as presumptively not worth listening to….

2. **Bernhard**
   August 15, 2012

   Does anyone know if there was any audience reaction to Kane´s claims? He went to the biggest BSM conference to tell those lies? I fear that if he says enough times people will start believing he did what he claims (predicting the Higgs mass with gluinos always around the corner, despite of what he said the day before).

One could say nobody take him seriously anymore, but then again, he was invited for a plenary talk in one of the most disputed conferences in HEP…

3. **Bernhard**
   August 15, 2012

   Sorry, for two comments, but I can´t resist: "Physicists at CERN believe that we'll probably first encounter supersymmetrical particles in early 2015, when the power of the Large Hadron Collider will have increased by a factor of two."

   We are back in time, it´s 3 years ago again and we juuust need to turn on the machine to find SUSY! It´s hilarious!

4. **SteveB**
   August 15, 2012

   I had read Strassler's comments before your post. I didn't get the impression that he was claiming to be "the" referee, but was using the sports analogy to hope for more middle ground. (I believe he would say he is in this middle ground.) I don't think you should get on his case (even though you did it rather mildly) for only recently commenting on the over-hype. He hasn't been doing a public blog that long, and it has mostly been educational rather than commentary. Even when doing commentary, it isn't a requirement that one must speak out on all one's positions, knowing that attacks will be coming. I could not do what you do — my skin is not nearly thick enough to endure the responses — so thank you again for this blog. But not everyone is so willing.

5. **Peter Woit**
   August 15, 2012

   SteveB,

   I was quite serious when I described as admirable his finally criticizing the over-hype problem. Would have been even more admirable if he'd done it earlier. The situation in the particle theory community for decades has been kind of grotesque, with most people privately agreeing that the situation with string theory was problematic, few willing to say so publicly for fear of retribution. I hope we're seeing a change in this environment, towards one where people can have honest conversations about the issues, without fear that someone is going to come after them personally for disagreeing with them about a scientific issue.

6. **mhm**
   August 15, 2012

   So we want the ball in the middle of the field. Ok. The teams playing are string theory, and who else exactly? More garbage on random BSM model building?

7. **Eric**
   August 15, 2012

   I think it should really be pointed out that the most likely scenario involving SUSY at this point is that with R-parity violation. In SUSY with R-parity violation, the LSP is no longer stable and so there are no MET signals. All current SUSY searches to date have looked for these MET signals assuming R-parity is conserved. So, R-parity violating SUSY is basically unconstrained by any of the current data from LHC.

   It should also be mentioned that R-parity was only added ad-hoc to the MSSM in order to eliminate operatorators which allow rapid proton decay. In certain extensions of the MSSM, it is possible eliminate the problem of rapid proton decay in other ways. In particular, if there are extra local U(1) factors which couple to either baryon or lepton number, then the B and/or L violating operators can be eliminated, also stabilizing the proton from rapid proton deay. In this scenerio, it is not necessary to invoke R-parity, and models of this type are basically unconstrained by LHC limits on superpartners.

8. **physicsphile**
   August 15, 2012

   Eric,

   Isn't R-parity also needed for the MSSM to provide a sufficiently stable dark matter candidate?

9. **APP**
   August 16, 2012

   Eric,

   The experimentalists are well aware of RPV SUSY and many searches have been done for the modified MET-free signals (typically multi-jets or multi-leptons). The limits on sparticle masses are almost as stringent as the R-parity conserving case — 1st/2nd generation squark mass lower bounds in range 700 to 760 GeV (ATLAS 7 TeV data), and gluino mass bounds in range 760 GeV to 1.77 TeV (ATLAS 7 TeV data). In other words RPV doesn't buy you very much, unless one sits at rather special points where other things happen as well (like significant displaced vertices, see recent paper of Peter Graham etal http://arxiv.org/abs/arXiv:1204.6038). If low-energy SUSY is somehow hiding within the LHC data it is doing it in a much cleverer and more subtle way than straightforward RPV.

   Physicsphile,

   You are correct that R-parity conversation can give a dark matter (DM)
   candidate, but in fact it has been known for many years, at least 10, that standard SUSY neutralino DM is quite finally-tuned. In much of R-parity conserving SUSY parameter space one does NOT get a successful DM candidate. The SUSY-DM connection is one of those things that has been way overhyped. Many of us working in the field have thought that the Peccei-Quinn-Weinberg-Wilczek axion (with suitable axion decay constant—there is disagreement about the "best" value) is more likely as the DM.

   Peter,

   Many of us working in high-energy particle theory have for years argued against the domination of particle theory by string theory, especially at the "top" US/European universities which train the majority of the next generation of theorists (there have been exceptions, especially Berkeley, MIT, U Wash, Oxford, Pisa, but even these are under threat). However, like Matt, we have chosen to do this behind the scenes believing this the strategy more likely to succeed. It's certainly true that we haven't been all that good in resisting/reversing the takeover by string theory! This continuing takeover is greatly assisted by a) the books by Lisa and Brian which persuade many very bright students that the most exciting area is string theory, and b) the prize- and grant-giving bodies which still greatly favor string theory, partially because the older generation of famous theorists who make the decisions are dominantly strong supporters of strings. Among the most famous US theorists, probably only Frank Wilczek has publicly argued that too many resources were going into ST (though others have done so behind the scenes). The Milner Prize probably makes this whole situation worse so I can understand Matt's frustration. I should say that I'm happy for ST to get reasonable support. The problem, as you've said, is that too many resources have gone into an area that isn't really physics because most of the answerable questions are purely theoretical and have no relation to any conceivable experimental probe (Kane's "predictions" are not predictions at all but reflections of many special choices he's made—no one outside his small coeterie takes him seriously). Sadly for all the students who decide to work in ST the field is in a bad way with very little interesting work going on—witness the growth AdS/CFT "condensed matter" physics which most condensed matter physicists view as not having anything to do with real systems and having discovered no new phenomena.

10. **Bernhard**
August 16, 2012

mhm,

ST is not playing at all, is has its own separate game and it doesn't invite outsiders to play with. Luckily nobody else wants to play with it anyway.

11. **Peter Woit**
August 16, 2012

APP,

Thanks for the comment about RPV theories!

That string theory has been heavily overhyped isn't at all a controversial claim, with even most string theorists privately agreeing this is the case (and complaining that they are now suffering from the backlash due to hype they weren't responsible for). It's remarkable though how few physicists have been willing to be quoted about this publicly. One reason is fear of retribution, but I think a bigger reason is that "string theory" has become such a complex topic that few people (even few string theorists…) feel comfortable making any broad statements about its problems.

I've found it highly problematic over the years that when journalists talk to me, and ask: "OK, you seem to make sense, but name a bunch of other theorists who we can talk to who agree with you about the overhype problem", there are few people I can send them to. Matt believes that it's an atrocity that journalists quote me since I don't have the right credentials. At least now, since he's "the chief US theorist" in the media, and is willing to acknowledge the overhype problem, that should help. Having others say something publicly would help too.

At least in the US, the problem of string theory influence has changed a bit. Few places (except Princeton) will hire string theorists at the tenure-track level, with physics departments well aware of the overhype problem. But the top institutions are still largely filled with senior string theorists, providing few opportunities for the best students to get trained in other areas. These same people also have outsized influence on grants, prizes, etc., with the new money from Milner just exacerbating that problem.

12. **anon.**
August 16, 2012

APP, can you provide links to the limits you're quoting? The latest CMS search for RPV gluinos in 3-jet resonances (through the UDD operator), for instance, is setting a limit below 500 GeV on the gluino mass. I imagine limits are stronger for the lepton-number violating processes, but I don't know where to find the strong bounds you're quoting. In the hadronic case I'm also not aware of a search for, e.g. gluino -> neutralino with the neutralino decaying to a 3-jet resonance through UDD. I was under the impression that most of the RPV parameter space is not constrained — or at least, not directly constrained in quoted limits, but maybe constrained by theorists' re-analysis of the data. I would be happy to be corrected, though….

13. **Bob Jones**
August 16, 2012

"Few places (except Princeton) will hire string theorists at the tenure-track level, with physics departments well aware of the overhype problem."

I don't know much about the job situation in physics, but this statement seems wrong to me. The work on amplitudes and twistor string theory is currently one of the hottest topics in theoretical physics. Over at the University of Chicago, a string theorist was recently given the position of "university professor":

http://news.uchicago.edu/article/2012/08/08/physics-initiative-launches-hiring-dam-thanh-son

14. **Peter Woit**
August 16, 2012

Bob Jones,

The tenure-track particle theory job market is well-covered by the Rumor Mill at

http://particle.physics.ucdavis.edu/rumor/doku.php

This year the only string theorist I see getting a job offer is Simone Gombi at Princeton.

The "amplitudes" business is not string theory and with rare exceptions the experts in it are not string theorists. People are making progress in computing QFT amplitudes, which are not string amplitudes. In some cases they have gotten some inspiration from techniques and calculations in string theory. Matt Strassler's post telling the story is specifically, as he explains, trying to highlight cases of influence from string theory (although you'll see in the comments, an expert takes him to task for this). The "twistor string" business is a small part of this story, although twistors themselves are a big part. But twistors really have nothing to do with strings: it was Roger Penrose who developed them as good variables for handling questions of 4d conformal invariance in GR.

While string theorists are not getting hired at the crucial tenure-track level, the generation that got tenure in the late eighties or so is very heavily loaded with string theorists, since you almost had to be doing that to get a job at the time. These are now old enough to be the grand old men and university professors of the field, with honors and prizes of all sorts coming their way as they get to the right age. This doesn't mean their non-string theory colleagues think that what they do has much future….

15. **APP**
August 16, 2012

anon: As I'm sure you know extracting the limits on RPV SUSY is a complicated business as there are so many parameters, one must be careful to impose all the flavor constraints on the RPV couplings/sparticle masses, and the final states (and whether they pass experimental cuts) are highly spectrum dependent. The limits I quoted are for CMSSM+RPV, so not 2 new things going on at once, in particular NOT also a "natural SUSY"/"effective SUSY" spectrum where all the superpartners not directly tied to electroweak symmetry breaking are made heavy. There are also certain assumptions on the RPV couplings that dominate motivated by flavor considerations, and most importantly NOT involving the UDD operator that you correctly mention as an exception (which is dealt with in the most challenging "natural SUSY" case by Raman Sundrum etal in http://arxiv.org/abs/arXiv:1206.2353 and which has significantly lower limits). In any case the limits can be extracted from the early figures of the Peter Graham etal paper I quoted together with ATLAS note http://cdsweb.cern.ch/record/1472934 (also useful to look at is https://cdsweb.cern.ch/record/1432202). Both Raman's and Peter's papers investigate tricky cases where RPV SUSY can be hiding, but as I'm sure you appreciate my point was that "vanilla" RPV doesn't help much in weakening the sparticle mass limits and more complicated/clever things must be going on to have a SUSY spectrum without large fine-tuning. Hope this helps.

16. **Bob Jones**
August 16, 2012

“The ‘amplitudes’ business is not string theory”

This is why the whole argument against string theory seems silly to me. In order to say that string theory has ruined theoretical physics, you take an extremely narrow view of the subject. You’re saying that the study of N=4 SYM amplitudes is not string theory even though it is equivalent to string theory by duality.

“with rare exceptions the experts in it are not string theorists”

I am not an expert myself, but I believe that many of the experts do conduct research in string theory (examples that come to mind are Arkani-Hamed, Bourjaily, Cachazo, Elvang, and Volovich). Many of these people are very young and have gotten tenure-track jobs within the last ten years.

“the generation that got tenure in the late eighties or so is very heavily loaded with string theorists… These are now old enough to be the grand old men and university professors”

Dam Thanh Son is actually a pretty young guy; it looks like he got his tenure-track job at Columbia in 1999.

“This doesn’t mean their non-string theory colleagues think that what they do has much future…”

Just look at the article I posted for evidence that this is not the case.

17. **APP**
August 16, 2012

Peter,

I agree that many tenured theorists privately share, in whole or in part, your views. The problem with going public, and I can only speak for myself, is that I don’t want to become a public figure. I went into physics for the fun/excitement and privilege of research itself and I want to devote as much time to that as possible–I know that may come across as selfish but I don’t even like going to conferences if I can avoid them (even if they are in exotic locales)! Even more importantly I’m very disturbed how uncivil the atmosphere and nature of the discussion typically is in the press/blogsphere (very often not driven by the correspondents themselves, but by troll comments or by certain unsympathetic reporters wanting a personalized, and hence “dramatic” conflict). As I’m sure you appreciate very well it is hard to have one’s nuanced position not misreported or distorted out of all recognition, and even more upsetting, in a way that makes it seem like a personal attack. I’m sure we share the greatest respect for the achievements, intellect, and seriousness of the leading string theorists, and I think it would be wrong, and in the end counter-productive to allow opinions to be misrepresenated as personal attacks on them of their research. (Personally I feel that research is such a crazy thing to which to devote one’s life, the only real criterion is whether it makes the person him/herself happy! The rest of us don’t have the right to judge what a person does with their time—especially as the old Hollywood dictum “Nobody knows anything” is almost certainly right.) The primary issue that bothers me is that many very bright young students go into strings with a fantasy of what it’s going to be like and what they will work on and achieve, when in fact they would have been far happier and more productive with physics that is closer to experiment. It’s sad to see young talent and enthusiasm misdirected…

Anyway, I’m sure you know my real-life identity, and I guess I’m OK for you to tell journalists that I’m one of the many (I could probably name a hundred other theorists) who have not too dissimilar views to you, but unfortunately my name is *off the record* . Sorry. Anyhow, Glashow, Georgi, & Wilczek are rather more substantial figures that would also support a sensible re-balancing of the field.

18. **piscator**
August 16, 2012

Dam Son is not a string theorist. Look at his publication history and what he has worked on. He is a field theorist who has, at times, used ideas coming from string theory.

19. **Peter Woit**
August 16, 2012

Bob Jones,

I should have looked more carefully and seen who this was about, I just assumed it was a Chicago string theorist you were talking about. Yes, Son is of a later generation, he’s also (as piscator points out) not a string theorist, not even an HEP theorist (he’s a nuclear physics theorist, which is somewhat different). I’m sure some of the connection of his work with AdS/CFT gets him support from string theorists, but I’d guess the desire to hire and reward him has a lot to do with universities wanting to hire outside HEP and outside string theory.

My argument with string theory has always been with it as an idea about unification, and I continually repeat that to make it clear. The relationship between string theory ideas and N=4 SYM is an extremely complex subject, my comments earlier were specifically about perturbative amplitudes and Witten’s twistor string. I don’t see any point to highly oversimplified claims about N=4 SYM and string theory being the same thing. That’s neither an accurate nor an interesting statement.

20. **huh?**
August 16, 2012

Just to keep things accurate here: you have repeatedly attacked attempts to connect string theory to nuclear physics or condensed matter physics as vastly over-hyped. Son, a virtuoso field theorist and many-body theorist, is certainly by far best known for his work on the holographic viscosity bound and related connections of holography to nuclear physics. His other most famous papers are on holographic models of QCD. Your last post is not accurately portraying your previous descriptions of string-related work, and the opinions of excellent physics departments (including evidently Chicago’s) are in genuine opposition to your own, regardless of what you choose to state on your blog. This has been reflected in hiring in the past, and will likely continue to be in the future. (I personally know of several top 10 physics departments on the lookout for promising young faculty who work in string theory or cognate areas with high overlap).

21. **Peter Woit**
August 16, 2012

APP,

I understand your feelings pretty well I think. One of my motivations for getting involved in this is that I’m in an unusual position in a math department, in a position such that I don’t need to worry about grants and about a lot of things most people have to worry about. I’m well aware of this, and it’s one reason I thought I should speak up publicly, since I could do so without worrying about a lot of the things other people would have to. I hope the blog and the book provide a resource for students to hear a different point of view than they might otherwise get, giving them something to think about. A lot of the hostility I find rather bizarre: I have plenty of friends who are string theorists and have never had trouble discussing the subject, about which we almost always agree on much more than we disagree. On the few occasions people have invited me to "debate" a string theorist, they have ended up sorely disappointed by the lack of fireworks.

22. **APP**
August 16, 2012

Bob Jones,

I know Dam Son somewhat and he would certainly not describe himself, or be described by others even in outside fields like condensed matter theory, as a string theorist. He's a very sharp and creative *quantum field theorist* who happens to sometimes use string techniques, especially AdS/CFT, to answer interesting questions about strongly-coupled theories in certain limits. His collaborators are a bit closer to paid-up string theorists. Overall I think that Peter is correct in saying that the vast majority of tenure-track jobs nowadays are going to Standard Model/beyond-the-SM/astro-particle theorists. Also many of the best people working in the amplitudes field would not at all fit inside traditional string theory, Nima included. Never trust the blurb written by university administrators, or publishers' PR departments to judge what people do!

23. **Peter Woit**
August 16, 2012

huh?

Yes, I've definitely written about how string theorists have engaged in outrageous hype about the connections between string theory and serious work in nuclear physics, QCD and heavy ion physics, work of people like Son. Son himself has never engaged in this sort of hype from what I have seen, which is one reason people want to hire him, and not string theorists. As for your claims about departments wanting to hire string theorists, you should keep in mind that it looks like you're at the one department in the world people think of as more fanatical about the subject than Princeton. We'll see what the rumor mill says in coming years, the number of string theorists getting jobs in the US pretty much has to go up, it can't get any lower.

I suspect that you're thinking of the condensed matter theory area of active research supposedly overlapping with string theory. Sure, as with Son, many departments would love to hire a good condensed matter theorist who has done AdS/CFT-related research that has had some success. Few however are going to be interested in people trained as string theorists who have moved on from overhype about its importance for particle theory and cosmology to now make overhyped claims about its importance in condensed matter theory.

If string theorists retool themselves, become experts in another field, and make real advances in that field using some tools they learned as string theorists, that's great. If they keep generating outrageous hype about string theory unification, the multiverse, etc, and try to justify themselves with dubious claims about how important their ideas are for other fields, they're not going to get far.

24. **APP**
August 16, 2012

Peter,

I also find a lot of (all?) the hostility bizarre. I really wish everyone took others' views more seriously and less personally. Theorists and their groupies are, more so than the average, an arrogant bunch of people with fragile egos!

25. **anon.**
August 16, 2012

Thanks, APP, I hadn't followed the details of applications of multilepton searches to bounding RPV parameter space. I guess we can summarize it as part of the bigger picture that the only allowed way to hide new strongly produced particles below a TeV is if they decay to multiple jets with very little missing energy and not many leptons or photons in the final state….

26. **APP**
August 16, 2012

anon,

yes that's my understanding too. glad to be of help—good luck in your research!

27. **Bob Jones**
August 16, 2012

"He is a field theorist who has, at times, used ideas coming from string theory."

"He's a very sharp and creative quantum field theorist who happens to sometimes use string techniques"

If you want to call him a field theorist and not a string theorist, that's a terminological point and not a substantive one. I understand that Son does not work on string theory for its own sake, but his most famous work is on applications of string theory. I see no problem with calling such a person a string theorist.

I think there's a pretty good mathematical analogy here. Let's say you have a mathematician who works in algebraic geometry and uses schemes to prove interesting results on algebraic varieties. Is this person a classical algebraic geometer or a modern algebraic geometer? I think most mathematicians would agree that this is a silly question.

"My argument with string theory has always been with it as an idea about unification, and I continually repeat that to make it clear."

I realize this, and I actually agree with a lot of the points you make. But honestly, I find it strange that this is being framed as a debate over the legitimacy of string theory. The term "string theory" is a broad, ill-defined thing with lots of different connotations, and you really ought to use different terminology. Instead of string theory, why don't we just say "multiverse" or "landscape" or "string phenomenology"?

"I don't see any point to highly oversimplified claims about N=4 SYM and string theory being the same thing."

I agree that I'm oversimplifying, but the point is that you can't really separate string theory from quantum field theory. The two frameworks are so inextricably related that it's hard to say what counts as string theory and what doesn't. Again, I think the mathematical analogy is a good one. Saying you can do quantum field theory without string theory is like saying you can do algebraic geometry without schemes. Sure you can do it, but string theory is a natural extension of quantum field theory in the same way that the notion of a scheme is a natural extension of the notion of a variety.

28. **Sam**
August 16, 2012

There is a huge difference as to whether one is a "consumer" of the results of a particular field versus a "producer" of results in the field. For instance, in some of my research I have used extant "off the shelf" results concerning elliptic operators to answer certain questions in geometry. I am a geometer, but in no way would I consider myself, based on this line of research, an analyst.

A more substantive discussion of whether one is a "string theorist" could be based on whether the person in question is actually producing new results in string theory. One can of course simultaneously be both a consumer and a producer of a particular theory. Has Son's work produced new techniques, insights, results in string theory proper (beyond the insight that its methods can be used in the manner to which he used them?) The research can be great regardless of an answer of "yes" or "no".

But finally, it is odd to argue as to what category another person's research belongs. I realize hobby horses need to be ridden here, but at the end of it all it is only the person in question whose opinion matters and it is likely that they don't really have an opinion- they are just busy prosecuting their research.

29. **Peter Woit**
August 16, 2012

Bob Jones,

Actually, the distinction between QFT and string theory is not just a terminological one. For one thing, we know what QFT is, whereas "string theory" is not a well-defined term (which is one problem with your string theory = schemes analogy).

The campaign to make Son a string theorist and all quantum field theories string theories is an ideological one, basically an attempt to define away the problem of the failure of the main string theory research program. Better to keep different words for different things, as well as keep track of what ideas work and which ones don't.

30. **Bernhard**
August 17, 2012

Seiberg's prophecy fulfilled

""Most string theorists are very arrogant," says Seiberg with a smile. "If there is something [beyond string theory], we will call it string theory."

(http://www.guardian.co.uk/science/2005/jan/20/science.research)

31. **piscator**
August 17, 2012

Bob Jones:

The way I see it is more as follows. As I work on string compactifications I use various results on Calabi-Yau manifolds in my work. However by no reasonable classification am I a mathematician or an algebraic geometer.

I agree that terminology is just terminology. However I think it begins to matter when encountering statements like 'string theory has dominated hiring', 'there are too far many string theorists around' etc. The way to support this statement is classifying everyone who was worked on anything related to string theory as a string theorist. You can do this, but it is misleading, as in most cases people work on string theory because they want to learn about some particular problem and string theory provides tools to address this problem.

>>The campaign to make Son a string theorist and all quantum field theories string >>theories is an ideological one, basically an attempt to define away the problem of the >>failure of the main string theory research program.

It is statements like this that make terminology important. If the `main string theory research program' means a program involving particle physics-susy-unification-strings I can think of a total of one, possibly two, faculty hires in total in the US in this area in the last ten years. There are not that many people in the US doing this and, really, there never have been.

32. **Bob Jones**
August 17, 2012

"we know what QFT is, whereas 'string theory' is not a well-defined term (which is one problem with your string theory = schemes analogy)."

You make a very interesting point here, but of course perturbative string theory is a fairly well-defined thing which can be formulated without reference to a dual QFT.

"I agree that terminology is just terminology. However I think it begins to matter when encountering statements like 'string theory has dominated hiring'"

I guess I'm just not sure what point was being made. If the point is that people are not getting hired to do string theory and particle physics, then I agree. If the point is that string theory is dying/becoming irrelevant, then I disagree for the reasons I gave.

33. **Peter Woit**
August 17, 2012

Bob Jones,

Yes perturbative string theory is a well-defined structure. But it's not a QFT, and QFTs are definitely not perturbative string theory.

34. **anon**
August 19, 2012

Hi Guys,

I was reading your comments about RpV in SUSY and I would like to mention a talk by Pavel Fileviez Perez about R-parity Violation at SUSY2012. It looks like there are well-motivated theories where one can expects RpV in a nice way. See:

http://www.phy.pku.edu.cn/~susy2012/resources/conf_day3/plenary/4_Pavel-Fileviez-Perez-SUSY2012.pdf

what do you think?

35. **anon**
August 19, 2012

A comment about G. Kane. I do not understand why him can be invited to major conference such as SUSY2012, his work is affecting the reputation of high energy physics, he should retire and allow a young person to get his place at UMich. Most of the people disagree with his papers, but since he is a political figure still the people invite him. There are no opportunities to young people and he is going around talking about these stupid results.

36. **Roger**
August 20, 2012

anon
A scientist should never be forced to step down because others disagree with his papers. The tenure system (such as it is these days) is properly designed to support academic freedom.

I'm certainly no supporter of Kane's ideas btw.

37. **Mitchell Porter**
August 21, 2012

anon, Gordon Kane isn't a one-man show. There might be a dozen or more people working on M-theory phenomenology in that general framework (G2-MSSM). It's actually one of the more bold and interesting things I can see going on in phenomenology, because it does try to make connections to fundamental theory, and I don't blame Kane for being excited that he can get a 125 GeV Higgs, 145 GeV dark matter particle, and so on, without finetuning.

LHC News

August 17, 2012
Categories: Experimental HEP News

The LHC is operating well, hitting record peak luminosities, with integrated luminosity for the year over 11 fb^{-1}. By the end of the year there may be 25 fb^{-1} per experiment or so. Current plan seems to be to update the results on the Higgs in December, much like last year, so there may not be much news until then.

This week the LHC Machine Advisory Committee was meeting, slides here. The current schedule has this proton run ending mid-December. After a heavy-ion run early next year, the machine will go into a long shutdown starting in March, with main goal to fix the magnet interconnections and commission the machine to run at nearly design energy, 6.5 TeV/beam. First beams at this energy will not be until April 2015, with maybe 20-25 fb^{-1} of integrated luminosity in the first year's run.

With no sign of SUSY so far, and little reason to believe it will show up in the rest of the 2012 data since nothing has shown up already, the rallying cry of SUSY enthusiasts is now "Wait Until 2015", or, maybe more like 2016, since early 2016 may be when analyses of a significant amount of 6.5 TeV data start to appear. I'd been wondering whether David Gross has been getting discouraged at the prospect of having to pay off on his SUSY bets. Someone asked him this recently, with the results here on YouTube. He says he's still willing to take 50/50 bets on SUSY, but "with the right conditions", which are 50 fb^{-1} of analyzed data/experiment (he says this will be "years from now I think", roughly 2017 maybe if all goes well), and he adds "then we need a judge, because it won't be so obvious I think". So, it looks like it's going to be quite a while before we get to see Gross pay up…

Comments

1. **RalphB**
   August 17, 2012

   2017? No problem, I'll still be here reading my favorite physics blog (assuming you're still writing it).
   A naive question. Is this bet about finding no other particles by 2017? Because if any particles are found, isn't there some conceivable susy framework that could be said to predict it?

2. **Peter Woit**
   August 17, 2012

   RalphB,

   Gross's bet is about SUSY, not just "there will be a new particle". The reference to "then we need a judge" refers to the fact that if a new particle is found, it may be very unclear whether it is a superpartner, because of the problem you refer to of lots of SUSY possibilities.

3. **John**
   August 17, 2012

   A rather amateur question: What happened to the theory of large extra dimensions and Randall-Sundrum model?
   At what point are these theories supposed to show up at the LHC?
   Have they found them yet?

4. **Christian**
   August 17, 2012

   No extra signs of Randall-Sundrum gravity has been found, nor has any other signs of extra dimensions. See here: http://arxiv.org/abs/1112.2194 for a quite recent one, but just google with keywords such as ATLAS, CMS, randall sundrum, 5 fb^-1 and so on.

5. **Shambler**
   August 17, 2012

   An interesting article from Matt Strassler here, about the ATLAS trigger, and how it relates to the search for new physics:
   http://profmattstrassler.com/articles-and-posts/lhcposts/triggering-advances-in-2012/data-parking-at-cms/

   Not news to anyone here I'd say, but interesting to consider just how narrow the parameters of the search are at the LHC, and what unpredicted (and unprogrammed-for) events may go unobserved.

6. **Shambler**
   August 17, 2012

   ^^ Make that, CMS trigger 🙂

7. **John**
   August 17, 2012

   Christian,
   thank you very much indeed. I also found these two: http://arxiv.org/abs/arXiv:1110.6452 and http://arxiv.org/abs/arXiv:1202.3827
   One wonders if their theories have proven to be wrong, what's all the publicity about?

8. **APP**
   August 17, 2012

   John,

   You ask a very pertinent question. The truth is that the absence of any sign of deviation from Standard Model (SM) predictions in pre-LHC precision tests of the SM (such as searches for new forms of transition among "flavors", ie, types, of quarks or leptons, or subtle changes in the relationship between the very accurately measured Z and W boson masses), disfavoured in a big way large extra dimensions, and also to a lesser but still significant extent Randall-Sundrum theories. That's part of the reason why the theory community had a preference for SUSY—not that this theory was any near perfect in this regard either! With 20/20 hidsight this lack of evidence in precision tests should have told us that all new beyond-the-Standard-Model physics was at a much higher (factor 10 to 100, maybe more) energy scale than the optimists hoped. Certainly it's seeming that way if you dispassionately consider the apparent lack of any truly new physics in the LHC data. Christian is right that this applies equally to large extra dimensions, Randall-Sundrum, and SUSY theories (and even more, technicolor, little higgs, composite higgs, higgsless models, and the plethora of other ideas theorists have cooked up over the years!).

So when should we give up with these theories? Well with SUSY it's getting pretty
clear that we are on the edge of what's allowable, at least in versions of SUSY that
don't have some new clever ingredient, or maybe two new clever ingredients…
With RS or LEDs it's harder to judge where the acceptable boundary is because of a feature of these theories—unlike SUSY models they are "strongly-coupled" theories, which means in simple terms that the usual approximation techniques we use to do calculations fail. This failure is especially severe in the electroweak symmetry breaking, ie, Higgs, sector, and we really have a very poor idea of how high an energy one could push up RS or LEDs theories and still solve the hierarchy problem for the Higgs. (I spoke to one of the world experts on these theories a few weeks ago and he had no good estimate apart from an informed "guess" based on dimensional analysis!–an estimate which would already kill off RS and LED theories given the LHC bounds mentioned by Christian).

All this is part of the reason why the big majority of particle theorists are either very confused about what to work on, or very defensive of their favorite theory. It looks like Nature has chosen the "…something we haven't been bright enough to think of…" option—that or semi-anthropic reasoning along the lines of Arkani-Hamed–Dimopoulos Split SUSY theories and their ilk (which personally I *do*
think are an option despite the hatred of the vast majority of the physics community for this approach).

Anyway, that was a long, not very numerically precise answer to your very good question.

9. **Former string theorist**
August 18, 2012

It turns out that I like this video of D. Gross. He did solid pre-string theory work (obviously), and is an important contributor and advocate of string theory, but his reputation does not depend on SUSY nor strings. So….. he made a bet, which he may likely lose, OK. He is not prone to hype and recently I admire his stance against the landscape's implications. Nevertheless, the outcome of the bet is keeping me on the edge of my seat!

10. **Garrett**
August 19, 2012

My $1K SUSY bet with Frank Wilczek gets called on July 8, 2015. Looks like that may be before the second run data gets analyzed, which isn't really fair, but that was the date Frank chose. It was timed to be during a FQXi conference, with Max Tegmark as our judge. I've already won a SUSY bet, but it was against two string theory grad students who subsequently left academia. I wonder if SUSY will get less popular as the strongest proponents pay out these bets.

11. **Phil**
August 19, 2012

Peter,

Let me ask you a question. Which of these two scenarios for the LHC do you prefer:

1. No new physics discovered at all for the entire lifetime of the LHC aside from a Standard Model Higgs.

2. New physics discovered, but the only new physics is SUSY.

Thanks!

12. **Primate**
August 19, 2012

What Phil is asking you, Peter, is: would you prefer to be a monkey, or a Bishop of the Church of England? My advice is to choose the monkey, as Huxley did.

13. **Peter Woit**
August 19, 2012

Phil,

I'd just like to know what the LHC can find out about the real world, would prefer that it find something that gives us a hint about how to do better than the SM. I don't have any preferences that the world be one way or another. Of the two alternatives you mention, one seems much more plausible to me than the other.

14. **MathPhys**
August 20, 2012

Phil's question ws not directed to me, but it's such a good question, so I wish to volunteer an answer. I want to see as much as possible discovered at LHC, or anything at all in addition to the Higgs, whatever that may be.

SUSY, no-SUSY, weirdo things, whatever works and of course, the weirder the better. I only wish to know that the money that taxpayers put into the LHC has not gone down the drain because we could have used it for some other very urgent purposes (I hear that unemployment in Spain and Portugal has hit some ridiculously high levels).

15. **Phil**
August 20, 2012

In other words, since you prefer the LHC to "find something" that can take us beyond the SM, you would prefer senario 2 over scenario 1. A SM Higgs, and nothing else, would tell us nothing about how to do better than the SM because of the plethora of SUSY models you mentioned — both low and higher energy ones — as well as all the other models people have cooked up, all of which could be compatible with a SM Higgs at 125 GeV. So, out of those two possibilities, you'd surely want the SUSY one. Is this correct?

The reason I'm asking is because I've been getting these strong vibes from you that you not only think SUSY is not plausible and won't be discovered, but you don't WANT SUSY to be discovered at the LHC. For example, I'm sure you'd agree that quantum gravity effects at LHC energies is not very plausible, but you'd definitely WANT the LHC to discover them. However, in the case of SUSY, you neither expect nor WANT SUSY to be discovered at the LHC. In fact, you want every single model that's been getting media attention to NOT be discovered at the LHC. If SUSY doesn't get discovered, you'll feel incredibly vindicated,you'll gloat on your blog and say "I told you so!", and all the SUSY proponents will look like fools. And that's precisely what you want. Also, you'd love for quantum gravity effects to show up at the LHC, as long as those effects are NOT string theory effects, for the same reasons as why you don't want SUSY to show up, even if it means light would be shed on how to go beyond the Standard Model. Is this correct?

So which one of those two assessments above for you are more accurate? I just want to understand you a bit better before I invest my time in reading your blog because there are many many physics blogs out there and I surely cannot read them all! 🙂 Cheers!

16. **Yatima**
August 20, 2012

“I just want to understand you a bit better before I invest my time in reading your blog.”

I think this world has some people that really feel entitled.

17. **Peter Woit**
August 20, 2012

Phil,

If you’re honestly interested in my motivation here, it’s pretty simple: I want to understand fundamental physics better, so am very carefully paying attention to what is going on at the LHC and what it is telling us. The motivation for paying a lot of attention to the negative SUSY results is not that I personally want to gloat (this isn’t unexpected, most theorists were expecting this) , but that it seems to me this is one of the discoveries of the LHC, and there’s an active campaign in many quarters to deny this. You’ll note that I’m paying about zero attention to “gloating” about or discussing negative LHC results about extra dimensions, black holes, quantum gravity, strings. Virtually no one ever seriously thought the LHC would see such things, and it’s not at all surprising or interesting that the results of such searches are negative.

18. **tt**
August 20, 2012

why does it matter what anyone WANTS ? it’s nature, it doesn’t care what you WANT.

19. **dark matter**
August 20, 2012

what are the prospects of directly creating and observing dark matter at these energies and luminosities? not necessarily SUSY. Has there been any reports of dark matter, and if not, what are the ramifications of a null result for both SUSY and CDM cosmology?

20. **Peter Woit**
August 20, 2012

dark matter,

The LHC experiments are certainly looking for new particles that would explain dark matter, SUSY or not, but haven’t found anything. The problem with dark matter is that you so far have really only observed it via its gravitational interactions, but have no idea what its other interactions with known particles are (although you know a lot about what they aren’t: can’t be strong, EM, etc…)

If you see evidence for a new particle at the LHC consistent with a dark matter candidate, that would be a fantastic breakthrough. Unfortunately, if you don’t see this, that doesn’t tell you that much, just gives more constraints on what possible interactions a dark matter particle might have.

21. **MathPhys**
August 20, 2012

Can someone kindly recommend something to read for the not-exactly-layman but knows nothing about astrophysics on the status of dark matter. Something straightforward.

22. **David Nataf**
August 20, 2012

MathPhys,

There are way too many seemingly independent lines of evidence pointing to dark matter to have a simple explanation for a non-expert: galaxy rotation curves, velocity dispersions of galaxies in clusters, lensing behind the bullet cluster, the velocity anisotropy of stars in the solar neighbourhood, and the growth of structure in the universe.

For a non-expert, I’d recommend focusing on just one of these, the Galactic rotation curves to get started, and the Wikipedia page seems good:
http://en.wikipedia.org/wiki/Galaxy_rotation_curves

You might also want to check out the bullet cluster paper:
http://arxiv.org/abs/astro-ph/0608407

23. **Friend**
August 20, 2012

This should be an easy question for some of you. I don’t know a lot about particle detection techniques, so I have to wonder… As I understand it the LHC takes a lot of data, and one has to employ sophisticated algorithms to wade through all this data to see if there is a signal corresponding to a particle with certain properties. OK, is it possible that we might not be aware of a new particle if we’re not looking for it? If we don’t program the right algorithm, could we miss the detection of some kinds of particles at the LHC? Or would any new particle always slap us in the face and there would be no way we could miss it? Thanks.

24. **Peter Woit**
August 20, 2012

Friend,

The answer completely depends on the properties of the conjectured particle, which will determine how often if it produced, in conjunction with what other particles, and what it decays into. Some sets of properties will make a particle easy to see, others extremely hard to impossible.

The LHC is colliding strongly interacting particles, and if your conjectured particle has strong interactions, it will get produced relatively copiously. Right now the LHC null results for SUSY are mainly for the superpartners of strongly interacting particles, since these must be strongly interacting. Particles with only weak interactions (such as conjectured dark matter particles) are produced relatively rarely, so much harder to see. Still, even if something is produced rarely, it may be observable if its production and decay involve some very unusual, distinctive signal. Of course,then the problem is that you need to be looking for that unusual distinctive signal. There's a legitimate worry that the LHC is producing some new particle with properties that make it observable in principle, but no one has been looking for the right signal.

25. **Friend**
August 20, 2012

It's beginning to look as though they have been looking in the wrong place… no sign of SUSY or Strings. And it sounds like anyone with a new theory will have to convince a lot of Ph.Ds before they will even look for those new signals. Or can the data be searched in restrospect for signals predicted by a new theory?

26. **Peter Woit**
August 20, 2012

Friend,

These experiments have not just been looking for SUSY or strings, but also much more generically for the kinds of signals you expect from production of an unknown particle, or from some other deviation from the Standard Model. If they're missing something, it's going to be something with quite unexpected properties.

The data from the experiment is stored and will be available to try out different analyses for many years to come. As time goes by and the obvious searches and searches for SUSY get done, I suspect any plausible suggestion for what else to look for in the data will start to be able to get a hearing. The real worry is the triggering: only a small fraction of the data is stored, that which satisfies some conditions that indicate it's possibly interesting. The nightmare is some un-thought of new phenomenon which shows up only in events that the trigger is now dropping. But people do worry about how to avoid this nightmare, and the LHC is going to be around gathering data for many, many years, with many opportunities to try different triggers if someone comes up with a good reason.

27. **MathPhys**
August 21, 2012

@ David Nataf,

That's great. Thank you.

28. **Peter Woit**
August 21, 2012

A reminder,

I'm afraid I don't have the time or interest to run a general discussion board about physics, so please don't submit comments unrelated to the posting. Physics Stack Exchange is one of several examples of a better place for such discussions.

29. **SteveB**
August 22, 2012

@Friend,

Just want to point out that Matt Strassler has recently written a long article about which events are recorded in LHC (what triggers an event as worth keeping) and why and how they are now storing some different data that will only be analyzed later during the upgrade shutdown as compute resources become available. See:

http://profmattstrassler.com/2012/08/13/the-trigger-and-the-parking-lot/

This Week's Hype

August 21, 2012
Categories: This Week's Hype

> The Higgs suggests that there could be more dimensions of space-time than we previously thought.

From a New Yorker piece this week (subscription required) about Joe Incandela of CMS and the Higgs discovery.

Even the famed New Yorker fact-checkers are no match for extra-dimensional hype. Will someone tell them they've been had?

Comments

1. **Hamish**
   August 21, 2012

   I look forward to reading that when my copy of magazine arrives this week. The New Yorker seems to have embarked on a series of in-depth biographical pieces with the likes of Bruce Springsteen and Paul Ryan being covered lately. Good to see a physicist in the mix.

2. **Peter Woit**
   August 21, 2012

   Hamish,

   Unfortunately it's not an in-depth piece, but one of the short "Talk of the Town" pieces. It's well-done in terms of giving some atmosphere for a day in the life of Joe Incandela, but the theme is more bemusement at the incomprehensible things those physicists are up to at CERN than attempt to explain anything.

3. **former mathematician**
   August 21, 2012

   Reading the sentence in the context of the article, I believe "dimensions" was meant as "complications," rather than anything geometric.

4. **Peter Woit**
   August 21, 2012

   former mathematician,

   "complications of space-time" is no better than "dimensions of space-time". The Higgs appears to be a spin-zero, scalar particle, with nothing even slightly unusual about its relation to space-time.

5. **worse**
   August 21, 2012

   The New Yorker has done worse. In 1962 Jeremy Bernstein wrote an article in the New Yorker about Lee and Yang
   http://www.newyorker.com/archive/1962/05/12/1962_05_12_049_TNY_CARDS_000270950
   The article implied that the parity violation idea was more due to Lee than Yang. Yang was really upset. The article was the direct cause of the end of the collaboration between Lee and Yang. It had been a tremendously fruitful collaboration. Bernsteon's article did far more damage to to physics than any confusion to readers about a minor statement about the Higgs and space-time dimensions.

6. **Peter Woit**
   August 21, 2012

   worse,

   I don't mean at all to suggest this does any damage to physics. As for Lee and Yang, my impression is that they were headed for some sort of conflict, no matter what Bernstein wrote about them. But that's really far off-topic…

7. **Samuel Kerckhoff**
   August 21, 2012

   Hello, I was wondering if some one could enlighten me i.e. Peter Woit 🙂 or anyone with info.
   I've read the LHC has not detected any new physical phenomena that is not already predicted by the standard model, while operating at its current energy level. Is there a possibility that new things, not predicted by physicist, will be detected when the LHC is operating at the maximum energy level that it was designed for?

   Thanks

8. **Samuel Kerckhoff**
   August 21, 2012

   Or at least the LHC detecting new things that would show physicist what steps to take beyond the standard model.

9. **former mathematician**
   August 21, 2012

   How about "complications in the universe"? Which would fit the context equally well.

10. **Peter Woit**
    August 21, 2012

    Samuel,

Sure, when the LHC goes from 4 GeV to 6.5 GeV/beam in a couple years, that will make accessible any new phenomena in the energy range just above the current LHC limits. Maybe there's something unexpected there. However, there's no good argument for why something new should show up in this new energy range, but not in the range now being explored at 4 GeV/beam

11. **Peter Woit**
    August 21, 2012

    former mathematician,

    I really don't think the problem here is the writer's word choice. There has now been a long tradition of physicists hyping the idea that "extra dimensions may be seen at the LHC", and it's not really surprising that a writer exposed to this would get the mistaken impression that the Higgs discovery has something to do with this.

12. **Don Murphy**
    August 21, 2012

    Peter Woit:However, there's no good argument for why something new should show up in this new energy range, but not in the range now being explored at 4 GeV/beam

    I'm not sure I understand this statement. Does it mean the LHC is going to operate at higher energy only to confirm what is already known at the lower energies; or do you really mean to say there is no good argument for why something new should show up and therefore that is not the reason for the LHC going to higher energies? Can you clarify. Thanks

    Don

13. **Peter Woit**
    August 21, 2012

    Don Murphy,

    By operating at higher energy, the LHC will explore a new, previously inaccessible region, and if there's a new particle accessible in this mass region, it should find it and will study it.

    The point I was trying to make though is that this is unlike the case of the Higgs, where we had excellent arguments (from the nature of the Standard Model) that a new particle HAD to be in the region accessible to the 3.5 TeV/beam LHC., going to the 6.5 TeV/beam LHC, the SM says there won't be anything new there. We're all hoping though that the SM isn't all there is, that there really is something unexpected going on, and that it will show up in careful study of this new energy region. Only way to find out is to do the experiments…

14. **David Nataf**
    August 21, 2012

    Peter,

    Will there be new, independent tests of the SM at these higher energies?

    Will other branching components of the Higgs manifest themselves at these energies, or will the focus still be on photons, electron/positrons, bottom, and tauon decays from the Higgs?

15. **Peter Woit**
    August 21, 2012

    David,

    Good question. I don't recall seeing a good discussion of this anywhere, but I'm sure it's available somewhere. Maybe an expert can point to this.

    At higher energies the Higgs cross-sections increase, but you also get increases in background, and have pile-up problems to deal with, so I don't know what happens to the sensitivity in the various channels they are looking at. At higher energy you may also get some new channels that open up.

16. **Mike**
    August 21, 2012

    I know we don't have the article to read, but do you think they are justifying "extra dimensions" based on the excess in the diphoton channel or branching ratios that are different than theorized by SM?

17. **Peter Woit**
    August 21, 2012

    Mike,

    I have no idea where the writer picked up this particular piece of hype. Maybe there are people out there claiming the diphoton excess as suggesting extra dimensions, but if so until now their hype hadn't made it into mainstream media.

18. **John**
    August 21, 2012

    What's wrong with writing a paper (or giving an informal talk) suggesting that the diphoton excess and other deviations can be due to extra dimensions or other exotic things? That's not hype. What is your definition of 'hype' ? If it hadn't made it into the mainstream media yet, is it still hype?

19. **John**
    August 21, 2012

    Also, Peter, in response to:

    "We're all hoping though that the SM isn't all there is, that there really is something unexpected going on, and that it will show up in careful study of this new energy region."

Is any SUSY model one of the things you are personally hoping for? I know you'd bet against SUSY, but is there one version of the theory you are praying shows up at the LHC? (Not that you pray! 🙂 I mean figuratively.)

20. **Peter Woit**
August 21, 2012

John,

If "The Higgs suggests that there could be more dimensions of space-time than we previously thought." isn't hype, I don't know what is. Again, I have no idea who fed this to the writer or why, no reason to believe it was someone promoting their diphoton excess model.

I think there's something fundamentally wrong with all SUSY extensions of the SM on the market: they're complicated and ugly (because of the necessity of SUSY breaking, with no known good way to do it), you have to go to great lengths to explain why no evidence at all for them has shown up, and they don't really explain anything about the SM that needs explaining.

That said, the abstract mathematics used in SUSY models is interesting, and maybe there's some such thing as a SUSY QFT that really does work. The mathematically interesting SUSY models often involve a "twisted" version of SUSY. Maybe there's some way of using that to get an interesting model, but that's purely speculative, I personally know of no way of doing this.

I wrote a whole book chapter about SUSY in NEW, the book, and don't want to rewrite that here. I haven't looked at it recently, but as far as I know there's nothing much I'd change if I were rewriting it today (other than reporting that the experimental evidence against SUSY is much stronger…).

21. **Emanuel Derman**
August 22, 2012

Maybe the experimentalist had thought that there were only two dimensions to space time, and now, having discovered the Higgs, he realizes that there are four.

22. **P**
August 22, 2012

@ Samuel, John:
Peter is expressing his opinion when he says that SUSY doesn't address anything in the standard model that needs explaining. As I'm sure he would admit, many top notch, highly cited theorists disagree with him here – they would say that the hierarchy problem is in fact a problem, which has been the source of many arguments on this blog, Peter essentially the only dissenter. (No disrespect Peter, just stating facts). Those experts would claim that if any physics solves the hierarchy (perhaps SUSY) it should appear near LHC energies, perhaps at the next energy level in a few years.

@ Peter:
This is hype of a different sort, I think! Many good theorists think strings are a good idea for various reasons, perhaps unrelated to unification, and overhype it. I cannot think of a single reason to think that anything about the Higgs implies extra dimensions. Can you? This is a serious question . . . hype (SUSY, e.g.) is usually attached to some physical idea, which people may disagree with, but I don't even know what the physical idea is here that links these two (a la the idea potentially linking SUSY and the hierarchy).

23. **Igor Khavkine**
August 22, 2012

@P:
Just a remark. It's hard to put an upper bound on the number of dissenters withot a representative sample. And here one should keep in mind that there are quite a few physicists informed enough about QFT to have an opinion, but do not work on beyond SM physics. It might also shock you to learn that there are physicists who think that the cosmological constant problem is not a problem either.

24. **John**
August 22, 2012

Peter,

Would you be disappointed if SUSY showed up at the LHC?

Also, in response to, "If 'The Higgs suggests that there could be more dimensions of space-time than we previously thought.' isn't hype, I don't know what is."

That wasn't what I meant. I meant suppose there's a theorist who takes a possibly observed small deviation from a Standard Model Higgs and writes a paper about how an extra dimensional model can produce such an effect. Nothing wrong with that, is there?

25. **John**
August 22, 2012

Also, in response to,

"That said, the abstract mathematics used in SUSY models is interesting, and maybe there's some such thing as a SUSY QFT that really does work. The mathematically interesting SUSY models often involve a "twisted" version of SUSY."

So, are you hoping this shows up at the LHC?

26. **Peter Woit**
August 22, 2012

John,

I'm not sure if you're the same person who submitted about a dozen comments to the last posting demanding to know what I wanted the LHC to find about SUSY. See that posting for the answer to this.

Yes theorists can write any papers they want, they shouldn't hype their results to New Yorker reporters.

P.

It's just not true that I'm the only dissenter about the hierarchy problem, as anyone who looks at the previous discussion here can tell. In any case, the LHC has pretty much shown experimentally that the hierarchy problem argument for SUSY to appear at the electroweak scale is wrong.

27. **chris**
August 22, 2012

David Nataf,

"Will there be new, independent tests of the SM at these higher energies?"

yes, and the prime example is the detailed study of the Higgs decay amplitudes. These are all very precisely predicted by the SM and their measurement will constitute a very nontrivial check of the SM in a previously inaccessible sector.

28. **Peter Woit**
August 22, 2012

chris,

Yes, but do you know of a source explaining which channels will be accessible at 6.5 TeV/beam, and what the expected accuracies are for the signal sizes in these channels (for plausible luminosities)?

29. **P**
August 22, 2012

Peter,

I'd be impressed if you could find a well-known highly cited professor at a top university who would claim that there is no fine tuning problem related to the Higgs mass. Some (Nima, e.g.) these days are willing to abandon naturalness and say that maybe nature is fine-tuned, but I haven't heard anyone say that there isn't a fine-tuning, i.e. that the hierarchy doesn't exist. SUSY is very constrained, indeed (I agree!), but it is far too early to say that it's fully ruled out at low energies or that nature doesn't provide another solution visible at LHC which solves the hierarchy. See Matt Strassler on related issues, with a more informed opinion than mine.

On the part of my comment I addressed to you – I suppose the idea they're using to link extra dimensions and this Higgs mass is Randall-Sundrum? Is there another obvious candidate?

30. **John**
August 22, 2012

Peter,

I checked the last posting and if you're referring to 'Phil', he and I are not the same person. I read your response to him, but I'm not sure how your response answers the question I asked. I wanted to know if you are hoping for that particular SUSY model involving twisters you mentioned to show up at the LHC. I know you're betting against all forms of SUSY, but I was wondering if that version of SUSY is something you are personally wishing for. Is this true?

Also, I don't think SUSY as a solution to the hierarchy problem has been completely ruled out, but I could be wrong.

"Yes theorists can write any papers they want, they shouldn't hype their results to New Yorker reporters."

Well, perhaps the reporters went to THEM first. Perhaps the theorist(s) explained their work without any hype, and the reporter turned it into hype in order to sell more papers.

31. **Peter Woit**
August 22, 2012

P,

You're just starting up precisely the same argument we had here in great detail before about fine-tuning, actually discussing the science. This is just tedious and a waste of time. Now you want to just make it an argument from authority which is both tedious and dumb. If anything is clear about the story of particle theory in the last 30 years, it's that the endlessly repeated ideology about BSM physics isn't working so has some flaw in it. I see no point in arguing about how many prominent people share this ideology, to what degree.

P. and John.,

As I keep repeating, I have no idea where the New Yorker writer got that particular piece of hype from, would be curious to know, as well as curious to know how it got past their fact-checkers.

John,

The "twist" of SUSY I'm talking about has nothing to do with "twistors", and, as I said, I don't know of a viable model. That was just a speculative comment about the logical possibility of a more successful very different kind of model that still in some sense has "supersymmetry". As I wrote to "Phil", what I want from the LHC is to learn something about how the world works. I don't have a model that I "want" the LHC to find, and as for known SUSY models, there just is no good argument for them, lots of reasons why you expect not to see any evidence for them.

32. **John**
August 22, 2012

Peter,

Oops, I confused twisted with Penrose's twistors.

You seem to have a strong, let us say, aesthetic doubt against SUSY. True, SUSY can be quite "ugly" generically, with lots and lots of free parameters, and no good or well-motivated way of breaking it. I'm sure everybody wants something incredibly beautiful to emerge at the LHC. Given that perspective on aesthetics, are you hoping more for a nightmare scenario at the LHC if it meant that perhaps a much more beautiful and exciting theory were just (or at a much higher energies) above the LHC's reach, or are you more inclined (than the previous possibility) to hope for ANYTHING, even something ugly like SUSY, if it meant that particle theory has a greater chance of progressing based on actual concrete discoveries and nature shedding a brighter light on what particle theorists may work on next?

33. **Peter Woit**
August 22, 2012

"John"
You sure do sound a lot like "Phil" and all the other pseudonymic comments I deleted from the same person that kept asking me tendentiously what I "wanted" from the LHC. For the last time, all I (and I think this is true of most physicists) want from the LHC is for it to tell us something new about nature. This may just be that the SM holds up to and above a TeV. Something non-SM, anything non-SM, would be great since this would be handing us a wonderful new puzzle of the highest order. I'm not going to argue with whoever/whatever is responsible for the design of the physical world by "wanting" them/it/whatever to do it a certain way or I won't be happy.

I point out the ugliness of viable SUSY models purely because, since there is no experimental evidence of any kind for them, the only possible argument in their favor is one from aesthetics.

34. **Bob Jones**
August 22, 2012

"Oops, I confused twisted with Penrose's twistors."

John, why don't you go read about some of the serious applications of SUSY instead of continuing with this silly argument? Peter has given you a fascinating example of why SUSY is interesting and valuable even if it doesn't show up at the LHC.

35. **John**
August 23, 2012

Peter,

Thanks for your response. And no, I'm NOT Phil.

36. **Joey**
September 5, 2012

I find your comment about this being hype amusing. First of all, if there is a Higgs and it is a scalar, then it means it's mass is stable either by means of some new physics or by a really incredible fine-tuning of the parameters of the Standard Model. Sure, it's possible but nature, in our experience so far, has mostly found balance via equilibrium so it seems very reasonable to assume there is some new physics we have not seen that creates the balance. It is a rational assumption, not a guarantee. So following this line, there are a couple of possibilities. It is either a spectrum of new particles (a new dimension in the sense that we have a new symmetry and a new array of fundamental states) or the Planck scale is not what we think it is, and perhaps String Theory with its additional dimensions can be a motivator for this idea. Yes, these are big ideas, but I would not call them hype.
Frankly, I think you have to be a really arrogant twit to just call them hype unless you have really something useful to bring to the discussion.
Anyway, such glib comments do not inspire me to read this blog. Hopefully you can improve in future.

37. **Peter Woit**
September 5, 2012

Joey,

You're behind the times, submitting comments about last week's hype, when this is old news, with fresh hype for this week already available.

38. **fuzzy**
September 8, 2012

P. & Peter,

in my view the "naturalness problem" is not a problem concerning the physics but perhaps the philosophy (why things are as they are and not as they are not?) or the sociology (why, even in science, some priviledged thinkers have a hierarchical position rather than ideas?).

I do not know any serious discussion of it in the literature; I believe that ether theory has been not worshipped as this "problem" or "principle" has been in the recent years.

The hype that you pointed out proves, once again, that we need critical discussions of what high energy physics became.

Bill Thurston, 1946-2012

August 22, 2012
Categories: Obituaries

Bill Thurston passed away yesterday, at the age of 65, after a battle with melanoma. Thurston was for many years the dominant figure in the study of 3 dimensional topology and geometry, winning a Fields medal for this work in 1982. His “Geometrization Conjecture” classifying the topology of 3 manifolds was finally proved by Perelman as part of his work on the Poincaré Conjecture.

For an exposition of some of his work, see *The Geometry and Topology of Three-manifolds*, which exists as a set of unpublished notes here, and a book covering the first few chapters of the notes here. Thurston was sometimes criticized for not writing up full proofs of his results, making it difficult for others entering the field (and sometimes students were advised not to enter the field since Thurston was so good the danger was he would just solve all open problems). He wrote a truly wonderful essay On Proof and Progress in Mathematics, responding to this and laying out part of his vision of how to do mathematics.

My first encounter with Thurston was in the early eighties, when I was a physics graduate student at Princeton. I was working on the problem of defining the topological charge of a lattice gauge field, and it became clear that one approach to do this would require computing the volumes of “spherical tetrahedra”, the 3d analog of the problem of computing the areas of spherical triangles. I’d had some experience trying to talk to mathematicians about the problem I was working on, with the usual result a baffling response about principal bundles, sections, characteristic classes, and all sorts of what seemed to be abstract nonsense (which later on of course I learned was the right way to think about the problem…). So, I was pretty convinced that mathematicians were uniformly experts in a lot of abstract, high-powered technology, surely no longer conversant with the kind of more concrete formulas of the mathematics of earlier centuries.

This was before the days of the internet, so the answer to my problem couldn’t be found via Google, and a bit of library research got me nowhere. So, I stopped by to see a friend who was a math grad student and asked him my volume question. He said that while he didn’t know, he knew someone who could surely help me, and took me over to the math lounge, where Thurston could often be found. After I asked my question, Thurston immediately knew the answer, explained it to me on the blackboard, and gave me the proper reference of where to read more (you break them up in a certain way and then get an answer in terms of things called Schläfli functions, see here). I realized that my views of how much the best research mathematicians knew about concrete calculations and lore from previous centuries had been rather naive.

Thurston’s death at such a relatively young age is a loss for us all. My condolences to his family, including his son Dylan, a very talented topologist in his own right, who has been my colleague here for the last several years.

Update: Terry Tao has more about Thurston and his work here.

Update: More here, here and here. Also worth the time is seeing what he had to say on MathOverflow.

Update: Jordan Ellenberg has something here.

Update: The New York Times has an obituary here.

Update: There’s a Cornell site here, Scientific American has a piece by Evelyn Lamb here, John Horgan here.

Update: Jonah Sinick has put together a memorial slideshow here.

Comments

1. **Anonymous**
   August 22, 2012

   Very sad news and a great loss to science. My condolences to all bereaved.

   However, Peter, did you manage to define the topological charge of the gauge field for the general gauge group case ? Also, if you solved it in the lattice case, did your definition carry over to the continuum limit ?

   The question of defining topological charge carried by gauge fields seems very important to me, because gauge field theory *is* the theory of interaction of these charges, and empirically the bound states of gauge charges, in the limit, yields gravitating bodies.

2. **Peter Woit**
   August 22, 2012

   Anonymous,

   I didn’t use the volume formulas that Thurston told me about, that’s too hard. What I did do was just for SU(2), and was easy to compute, made sense in the continuum limit. It only worked for SU(2), where things come down to computing degrees of maps. Lots of other people have worked on this over the years, a long story, maybe for another time, since the only relation to Thurston I know of is our one conversation in the common room.

3. **Jeff M**
   August 22, 2012

   OK, as a mathematician I fell somehow obliged to tell my Thurston story. I never actually met him, though I know several of his students pretty well. When I was an undergrad at Hampshire in the early 80’s Thurston came to give a talk at Smith about his work with 3-manifolds. My advisor, Ken Hoffman, took me to see him. Didn’t really understand all that much, but the way he explained things really made the basic ideas understandable, even to an undergraduate who was at the time a physics major and hadn’t even taken modern algebra yet. In grad school I spent hours (days, weeks…) with a xerox of his lecture notes, beautiful doesn’t really even begin to describe how wonderful they are. I spent some time a few years ago with Steve Kerchoff at a conference, he was one of Thurston’s first grad students, and was the advisor of a friend of mine. Kerchoff was at the lectures which turned into the notes, he described how amazing it was to see all this stuff when it was brand new, and totally out of the mainstream.

4. **Scott Carter**
   August 22, 2012

   In the era, 1982-1985 both Bill Thurston and Mike Freedman would often visit the University of Texas at Austin. The visits were so frequent, in fact, that it was difficult to do anything other than attend the seminars, dinners, and after dinner parties. Once, at Cameron Gordon’s house, some of started to play with a toy motor cycle (wind up, hand held thing) that Cameron's son Andrew had. Bill reved the thing up (rrr-rrr-rrr) I think he even added his own sound effects, and he got the thing to fly across the diagonal of the den. This feat impressed me — not as much as his mathematics — but I always think of him as being playful.

5. **Wayne Collier**
   August 23, 2012

   I feel about Bill Thurston's passing much as I feel about the death of great spiritual leaders. Profane though he was like the rest of us, his mind was sacred. Thurston conceived, manipulated and illustrated the texture of God.

6. **Gil Kalai**
   August 23, 2012

   I did not have the privilege of knowing Bill Thurston personally, but his immense influence, the beauty of his ideas, and his special personality give me now a feeling of a great personal loss. Of course, it is a great loss for mathematics.

7. **Bernard Chazelle**
   August 24, 2012

   Bill and I were colleagues for many years at Princeton
   and at the Geometry Center. The joke there was, Why is Bill
   so involved in producing software to make high-dimensional geometry visible
   when the last person in the world who needs any such tool is Bill?
   His geometric intuition was beyond belief (I have fun anecdotes about that).

   But I am too sad today to talk about anything that's not, well, sad. His 60th b'day
   conference at Princeton would be one such occasion. Marvelous talks and
   a sweet personal note when Bill told me he followed my political
   activism on the web and added "We have no choice but be active."
   Bill was the guy who turned down an endowed chair at Princeton
   because the name attached to it was a rightwing militarist.
   What's so sad about all that? Well, the last two people I talked
   to at the conference were Bill and his former student Oded Schramm,
   both of them gone way too soon. Leaves a knot in one's stomach.
   Bill approached math with a touch of magic. A very sad day.

8. **Richard**

   Danny Calegari wites.

9. **Timothy Riley**
   August 24, 2012

   Bill Thurston is ever so missed here at Cornell. There is a page up in tribute. It includes a place for posting remembrances and a selection of quotes assembled by Dylan.

10. **Cam Scott**
    August 26, 2012

    Brought to my attention via this blog, I always have in mind Thurston's laudation on the Award of the Millennium Prize to Grigoriy Perelman For Resolution of the Poincaré Conjecture and hope that it is worth reviewing at this apposite time. Here it is in part: "Perelman's aversion to public spectacle and to riches is mystifying to many. I have not talked to him about it and I can certainly not speak for him, but I want to say I have complete empathy and admiration for his inner strength and clarity, to be able to know and hold true to himself. Our true needs are deeper – -yet in our modern society most of us reflexively and relentlessly pursue wealth, consumer goods and admiration. We have learned from Perelman's mathematics. Perhaps we should also pause to reflect on ourselves and learn from Perelman's attitude toward life."

    We should learn too from Thurston's own exemplary attitude toward life.

Linde on Inflation and the Multiverse

August 25, 2012
Categories: Multiverse Mania

Andrei Linde is one of Yuri Milner's $3 million dollar men, best known for his "chaotic inflation" version of inflationary theory, as well as being one of the main proponents of anthropic multiverse mania. There's a long piece based on a conversation with him up now at the Edge web-site.

Much of the piece is just a retread of the usual heavily-promoted ideology of the past 30 years of fundamental physics research: we must have SUSY, so must have supergravity, so must have string theory, so must have the landscape, so must have a multiverse where we can't predict anything about anything, thus finally achieving success. Linde claims he pretty much had this picture 30 years ago back in 1982, with the string theory component in 1986, with others coming around to his point of view in the last 10 years, partly because of the KKLT work he was co-author of in 2003.

Besides the tired Stanford pseudo-scientific ideology, there's also a wonderful history of the subject of inflation, from a Moscow point of view, which is rather different than the Western, Alan Guth-oriented, point of view from which the story is often told. Linde's description of Hawking's visit to Moscow is not to be missed:

> The next morning after I gave a talk at this conference, I found myself at the talk… oh, my God, this is going to be a funny story… I found myself at the talk by Stephen Hawking at Sternberg Institute of Astronomy in Moscow University. I came there by chance because I have heard from somebody that Hawking was giving a talk there. And they asked me to translate. I was surprised. Okay, I will do it. Usually at that time Stephen would give his talk well prepared, which means his student would deliver the talk, and Stephen from time to time would say something, and then the student would stop, and change his presentation and do something else. So Stephen Hawking would correct and guide the student. But in this case they were completely unprepared; the talk was about inflation. The talk was about the impossibility to improve Alan Guth's inflationary theory.
>
> So they were unprepared, they just finished their own paper on it. As a result, Stephen would say one word, his student would say one word, and then they waited until Stephen would say another word, and I would translate this word. And all of these people in the auditorium, the best scientists in Russia, were waiting, and asking what is going on, what it is all about? So I decided let's just do it, because I knew what it's all about. So Stephen would say one word, the student would say one word, and then after that I would talk for five minutes, explaining what they were trying to say.
>
> For about a half an hour we were talking this way and explained to everyone why it was impossible to improve Alan Guth's inflationary model, what are the problems with it. And then Stephen said something, and his students said: "Andrei Linde recently proposed a way to overcome this difficulty." I didn't expect it, and I happily translated it into Russian. And then Stephen said: "But this suggestion is wrong." And I translated it… For half an hour I was translating what Stephen said, explaining in great detail why what I'm doing is totally wrong. And it was all happening in front of the best physicists in Moscow, and my future in physics depended on them. I've never been in a more embarrassing situation in my life.
>
> Then the talk was over, and I said: "I translated, but I disagree," and I explained why. And then I told Stephen: "Would you like me to explain it to you in greater detail?" and he said, "Yeah." And then he rode out from this place, and we found some room, and for about two or three hours all the people in Sternberg Institute were in panic because the famous British scientist just disappeared, nobody knew where to.
>
> During that time, I was near the blackboard, explaining what was going on there. From time to time, Stephen would say something, and his student would translate: "But you did not say that before." Then I would continue, and Stephen would again say something, and his student would say again the same words: "But you did not say that before." And after we finished, I jumped into his car and they brought me to their hotel. We continued the discussion, which ended by him showing me photographs of his family, and we became friends. He later invited me to a conference in Cambridge, in England, which was specifically dedicated to inflationary theory. So that's how it all started. It was pretty dramatic.

Addressing the question of "what evidence is there for any of this?", here's what Linde has to say:

> Usually I answer in the following way: If we do not have this picture, then we cannot explain many strange coincidences, which occur around us. Like why vacuum energy is so immensely small, incredibly small. Well, that is because we have many different vacua, and in those vacua where vacuum energy is too large, galaxies cannot form. In those vacua, where energy density is negative, the universe rapidly collapses, and in our vacuum the energy density is just right, and that is why we live here. That's the anthropic principle. But you cannot use anthropic principle if you do not have many possibilities to choose from. That's why multiverse is so desirable, and that's what I consider experimental evidence in favor of multiverse.

So, the main experimental evidence for the multiverse is that an anthropic argument works. Some might not find this completely convincing.

About 5 years ago, the field of "string cosmology" was quite active, with even a graduate-level textbook appearing. My impression (contrast the tone of this review, with those of 5 years earlier) is that there's much less interest in this area during recent years, since it became obvious that no predictions about physics were going to emerge from it. Late this year or early next year the Planck experiment will finally report what it sees in the CMB. I'm curious to know whether Linde and other string cosmology proponents have any predictions for what Planck will tell us.

Update: The Annenberg Foundation funds Annenberg Learner, a site designed to provide information to high school teachers. Their Physics course includes a unit from Stanford's Shamit Kachru, which is pretty much pure hype, unadulterated by any skepticism that string theory might not be the way the world works. Physicists may have lost interest in string cosmology, seeing it as a failure, but that's no reason not to teach it to high school students…

Update: Historian of science Helge Kragh has a new article Criteria of Science, Cosmology, and Lessons of History discussing the Multiverse, philosophy of science, and the dubious use of historical analogies. About the Multiverse: "it explains a lot but predicts almost nothing".

Update: Tonight's arXiv listings include The Top 10^{500} Reasons Not to Believe in the Landscape from Tom Banks, which starts off with:

> The String Landscape is a fantasy.

He goes on to claim co-credit with Linde for the anthropic explanation for the value of the CC (in inflationary models), as well as to argue that it is wrong:

> Linde and I were the first to suggest an anthropic explanation for the value of the c.c. based on inflationary models , but within the context of the string landscape, or most any contemporary view of global EI , I don't think anthropic reasoning leads to good phenomenology.

Comments

   August 25, 2012

Hi Peter,

As I understand it there isn't a unique prediction for Planck from string cosmology or from inflation in general. The main hopes would be that Planck eventually shows some evidence for gravitational waves or primordial non-gaussianity. Either of these should considerably narrow down the possible types of inflation that could have occurred. But unfortunately, if no such evidence is seen the results will still be compatible with many other forms of inflation from and not from string cosmology.

2. **Shantanu**
August 26, 2012

Peter and others,
just to give credit where its due, want to draw attention to Demos Kazanas paper in
1980 in ApJ which contained the same ideas of inflation. Its sad that not many people
cite this paper.
http://adsabs.harvard.edu/abs/1980ApJ…241L..59K

3. **Mike**
August 26, 2012

Will Planck be able to show evidence of gravity waves from the gravitational lensing of CMB measurements and will Planck actually confirm inflation predictions to a high degree of accuracy?

4. **paddy**
August 26, 2012

Peter sorry for being repetitive and either speaking to the converted or to deaf ears. Any invocation of (or recourse to) a multiverse/anthropic argument is suspect on so many different levels: (a) philosophically it begs the question, (b) logically/probabilistically it makes the inverse gambler's fallacy, and (MOST IMPORTANTANTLY) (c) scientifically it runs the gamut from being moot to being meaningless.

5. **Peter Woit**
August 26, 2012

paddy,

I basically agree, although one has to look in detail about exactly what claims are being made in each "anthropic" case. The underlying problem here is not so much the anthropic business, but that people are trying to mask the fact that their fundamental theory is a failed, vacuous theory predicting nothing. They're invoking a multiverse of different possibilities, but when you ask what their theory says about what these possibilities are, the true answer is that it says nothing, so they are making ad hoc assumptions that things are "equally likely".

For a different point of view, Linde basically compares opposition to anthropics to Stalinism:

" But what is important is that when we studied inflationary theory, we started asking questions which seemed to be metaphysical, like why parallel lines do not intersect, why the universe is so big. And if we had said, "Oh, my God, these are metaphysical questions, we should not venture into it," then we would never have discovered the solutions. Now we're asking metaphysical questions about anthropic principle, about stuff like that, and many, many people tell us, "Don't do it, this is bad, this is the "a" word (anthropic). You should avoid it."

We shouldn't avoid anything. We should try to do our best to use the simplest explanations possible, or what proves simplest, and if something falls into your hands as an explanation of why cosmological constant vacuum energy is so small, and you decide not to accept it for ideological reasons, this is very much what we had in Russia long ago. That ideology told me which type of physics was right and which type of physics was wrong. We should not proceed this way. Once you have multiple possibilities, then you can have scientific premises for anthropic considerations, not just philosophically talking about "other worlds". Now we have a consistent picture of the multiverse, so now we can tell: "this is physics, this is something serious." That was about multiverse and different versions of it."

6. **paddy**
August 26, 2012

Peter,
Your last point (with the quotes) actually frightened me when I realized that the implication is that some might then think that there should have been in my post another clause: (d) "politically" ……

7. **physicsphile**
August 26, 2012

Mike,

If inflation happened at around the GUT scale or higher, Plank may be able to detect the gravitational waves by B-modes in the polarization anisotropy of the CMB. Ground based and balloon experiments are trying to detect gravitational waves on smaller scales which involves trying to remove the B-modes generated by lensing.

The simplest models of inflation predict a red spectral index and a flat Universe. Planck should be able to confirm these to very high precision.

8. **Shantanu**
August 26, 2012

physicsphile,
from what I understand, GUT-scale inflation is already ruled out (or constrained) by WMAP limits. The whole idea of GUT is just a daydream.
shantanu

9. **physicsphile**
August 26, 2012

Shantanu,

WMAP constrains the tensor to scalar ratio to be r less than 0.36 at the 95 percent confidence level. The energy scale during inflation is 3*10^(16)r^(1/4) GeV and so is constrained to be less than 2*10^(16) GeV by WMAP. The GUT scale is around 10^(16) GeV and so WMAP has not ruled out GUT scale inflation.

I should also mention that the simplest model, ie canonical single field inflation predicts that Planck should not detect non-gaussianity, isocurvature perturbations, running of the spectral index or departures from flatness. It predicts that there should be a red power spectrum of perturbations which should be confirmed at the 5 sigma level.

10. **anonymous**
    August 26, 2012

    Tsujikawa's talk exhausts most of the single-field models people discuss. Shantanu will be pleased to see Kazanas very clearly cited.
    http://www2.yukawa.kyoto-u.ac.jp/~jgrg20/invitedata/I18_tsujikawa.ppt

    For more details on this parameterization, consult e.g. Seery & Lidsey.
    http://arxiv.org/abs/astro-ph/0503692v2

    The bottom line is that f_NL has to be small in any of these models with c_s=1. Unobservably small. The best you can get from the usual CMB methods is f_NL~3. (On paper, Planck is supposed to be sensitive to f_NL~5.) To put that into perspective, you'd have to have f_NL~100s before you could tell it's there just by looking at the maps. Anything with an observable f_NL would be really weird and tell us a lot. On the other hand, if that happens and we still want to stick to these classes of models, c_s<1 will mean it's that much more impossible to measure appreciable tensor-to-scalar ratio r without an ultra deep delensing survey maybe 10-15 years from now. Large-field inflation like chaotic inflation is actually the experimentalists' best hope right now.

11. **P**
    August 26, 2012

    "My impression (contrast the tone of this review, with those of 5 years earlier) is that there's much less interest in this area during recent years, since it became obvious that no predictions about physics were going to emerge from it"

    One of the difficulties in superstring cosmology is that there are many scalar fields, and thus many possible cosmologies – depending on which scalar is the inflaton, there are different predictions. But it's too strong and ultimately just wrong to say that any one of those candidate inflation scenarios doesn't make predictions. Axion monodromy, e.g., is a large scale inflation model which is very well motivated in type II string compactifications. This scenario predicts observable tensor modes – see McAllister, Silverstein, and Westphal.

    http://arxiv.org/abs/0808.0706

    Planck data will be out soon and could rule out or in this possibility.

    Cheers,
    P

12. **SUSY**
    August 26, 2012

    "Much of the piece is just a retread of the usual heavily-promoted ideology of the past 30 years of fundamental physics research: we must have SUSY, so must have supergravity, so must have string theory, so must have the landscape,"

    The chain of reasoning presented above seems "convincing" if SUSY does exist.

    You've expressed your skepticism of SUSY extension of SM in BSM physics. Are you also skeptical of supergravity? If researchers and papers are published that shows that supergravity is perturbatively renormalizable, isn't that strong evidence that SUSY is needed (and leads to the above chain of reasoning).

    BTW Eva Silverstein claims her research on string theory and SUSY would imply SUSY would NOT be found at LHC energies. So it's little wonder her husband promotes it without any skepticism. I can provide a link if you want.

13. **chris**
    August 27, 2012

    What is so special about perturbative renormalizability? Ordinary gravity is close to being proven renormalizable nonperturbatively, i find this equally appealing.

14. **Peter Woit**
    August 27, 2012

    SUSY,

    If supergravity by itself makes sense, that's one way (another would be chris's nonperturbative renormalizability of conventional gravity) to break the chain of arguments leading to the string theory anthropic multiverse. I don't want to start yet another discussion of the problems of quantum gravity. The point is just that if you have a long chain of arguments that leads you to something vacuous, what you have is a reductio ad absurdum, showing that there is some flaw in those arguments. There are plenty of possibilities for the flaw, including the starting point of SUSY.

15. **CU Phil**
    August 27, 2012

    Chris,

    By "Ordinary gravity is close to being proven renormalizable nonperturbatively", are you referring to the searches for an RG fixed point that are usually referred to as the asymptotic safety program?

    My understanding of the current state of things there is that there is numerical evidence based on truncations of the ERGE for certain actions, and with certain restricted field content. I think the program is an interesting one, but this seems to be somewhat far from having a proof of a fixed point in 4D for gravity in the presence of matter fields. Am I mistaken about the state of things there?

16. **Peter Woit**
    August 27, 2012

    CU Phil, Chris,

    I'm sorry, but this isn't a physics discussion board, and I'm not going to moderate yet another discussion of quantum gravity that has nothing to do with the posting. Best to take this sort of thing to Physics StackExchange or somewhere else.

17. **Bernhard**
August 27, 2012

There is nothing new in Linde´s anthropic argument for the vacuum energy but every time I hear it it amazes me how obvious it is that is can in principle "explain" any number. Anomalous magnetic moment of the electron? Forget a brilliant theory like QED that actually predicts it with exquisite precision. You just need some crap theory where you have a zillion solutions for the magnetic moment and when you realize you just can´t explain the number with your crap theory you invoke anthropic reasoning, after all, the electron must have that anomalous magnetic moment in this universe so that we can exist etc, etc. Really …

18. **theoreticalminimum**
August 27, 2012

On a completely different note: I wanted to throw this out for general interest. Cédric Villani has a book out this month, "*Théorème vivant*" (Édition Grasset). Villani has by now become a household name in France when it comes to the common perception of the (eccentric) mathematician and the popularisation of mathematics, and this book has been greatly expected by many. He's also the latest Fields medalist to start a new blog-like website. His colleague at the CMS (Cambridge), Clément Mouhot, also has a blog.

19. **Ly**
August 27, 2012

Roger Penrose once pointed out that there should still be a "horizon problem" for EWSB, since most inflation models postulate that inflation ceases well before the universe cools below the electroweak critical temperature. He seemed to think that large-scale defects left over from that era ought to occlude the light of distant galaxies, contrary to observation. Is it reasonable to expect EWSB defects to behave this way, or be otherwise dramatically visible? The papers I've looked at have invariably been irritatingly vague on the subject, when they raise it at all.

20. **John**
August 28, 2012

Peter,

"Much of the piece is just a retread of the usual heavily-promoted ideology of the past 30 years of fundamental physics research: we must have SUSY, so must have supergravity, so must have string theory, so must have the landscape, so must have a multiverse where we can't predict anything about anything, thus finally achieving success."
Granted, SUSY is the assumption. But if SUSY is discovered at the LHC, then doesn't it follow that supergravity should be more likely? If gravitons exist, and since every particle has a superpartner, it follows that the graviton must have a superpartner. Hence, supergravity. Now, I'm no expert, but I thought string theory is the UV completion of supergravity. And string theory predicts a multiverse. Though it's most likely experimentally unverifiable, it's a prediction nonetheless. And it has the potential to explain the smallness of the CC. That's why some people are taking the idea seriously. They would absolutely LOVE to test the idea, but they can't. But that doesn't mean they'll stop working on it. They believe string theory is the most promising approach to quantum gravity. What's wrong with that?

"So, the main experimental evidence for the multiverse is that an anthropic argument works. Some might not find this completely convincing."
But it's still a possibility that has the potential to explain the size of the CC. For a long time, there was no experimental evidence of planets outside the solar system. Now we've detected many of them, and an anthropic argument for the fine tuned conditions for life on our planet makes sense. Certainly, there is no conceivable way to test the multiverse, but it's still a possibility. Now suppose, in the distant future, we somehow find a way to conduct tests of a future quantum theory of gravity (not necessarily string theory) that has the multiverse as a consequence. Suppose we still have no idea how to test the multiverse portion of the theory. Suppose it pasts all those tests. Doesn't that mean the multiverse portion gains much more credibility? Gravitational waves haven't been detected yet, but nobody doubts their existence because GR has been tested so well.

According to the Annenberg Learner website, the course explores the "frontiers of physics." One definition of "frontier" that I've found defines it as "An undeveloped area or field for discovery or research." Doesn't string theory fit that description? According to the website: "The goal is to make the frontiers of physics accessible to anyone with an inquisitive mind who wants to experience the excitement, probe the mystery, and understand the human aspects of modern physics."

What's wrong with that? Frankly, when I was in high school, I wanted to learn more about string theory than condensed matter physics. Also, you can't exactly teach your interests, Peter, to these kids: representation theory applied to QFT. It may be exciting research on the frontiers, but nobody at that level will understand it and it won't entice them to study physics. Every section of that course, not just speculative string theory, can encourage the students' wonder for physics.

From the ST part of the course: "…theoretical effort to develop a "theory of everything" that brings all four forces under the same conceptual umbrella." What's wrong with talking about the "effort" to produce a theory of all forces? He doesn't mention whether it's been successful or not, just that it's an "effort". He also says, "the string concept has stimulated a great deal of theoretical excitement even though it has no connection to experiment so far." Is this not true, Peter? He even tells us that there's no experimental evidence for it so far. He's misleading nobody. He calls ST "the most promising approach", implying that there are others. What's wrong with that? (And yes, ST is the most promising approach so far.)

Therefore, Peter, when you comment about this description on the website with, "which is pretty much pure hype, unadulterated by any skepticism that string theory might not be the way the world works." you are dead wrong.

21. **Peter Woit**
August 28, 2012

John,

I don't see any point in repeating here the same arguments again about why the string theory multiverse is pseudo-science. Others can make up their own minds about whether teaching failed untestable speculation to high school students as the "frontiers of science" is in either their interest or the interest of the field.

22. **John**
August 28, 2012

Bernhard,

"Anomalous magnetic moment of the electron? Forget a brilliant theory like QED that actually predicts it with exquisite precision. You just need some crap theory where you have a zillion solutions for the magnetic moment and when you realize you just can´t explain the number with your crap theory you invoke anthropic reasoning, after all, the electron must have that anomalous magnetic moment in this universe so that we can exist etc, etc."

QED isn't a candidate for a quantum theory of gravity/fundamental theory, isn't it? If, in the distant future, a fundamental, well-defined theory is found that agrees with the experiments done in that future, AND predicts a multiverse, wouldn't that mean the multiverse has more credibility? It may not completely validate it because you can imagine a fundamental theory that agrees with the experiments and does not have a multiverse, but the conjecture at least gets a little more credible.

23. **John**
August 28, 2012

Peter,

Do you not agree with the definition of "frontier" that I gave you? If you don't, why not? If you do, then string theory fits nicely with that definition, wouldn't you say? QM has been with us for almost 100 years and has been very well tested and is in everything from TVs to smartphones. So it's not really "frontier". But string theory is, wouldn't you agree?

Also, do you not agree that the quotes I took from the ST unit website contradicts your claim that the page contains information "which is pretty much pure hype, unadulterated by any skepticism that string theory might not be the way the world works." ? Let me repeat those quotes, in case you forgot:

"…THEORETICAL EFFORT to develop a "theory of everything" that brings all four forces under the same conceptual umbrella." He also says, "the string concept has stimulated a great deal of theoretical excitement even though IT HAS NO CONNECTION TO EXPERIMENT SO FAR."

And, for all we know, the ST program is not dead yet. There is much work to be done to discern what M-theory really is. Correct?

24. **John**
August 28, 2012

"I don't see any point in repeating here the same arguments again about why the string theory multiverse is pseudo-science."

Peter, please don't leave me hanging. I wrote so much in those first two paragraphs. I did my best! Please direct me to the pages that show how wrong I am. If SUSY is detected, and if gravitons exist, supergravity should exist, right? And if supergravity needs a UV completion, and if string theory is the only UV completion for supergravity, hence string theory. And if string theory predicts the multiverse, then the multiverse is something worthy of more study. And if a fundamental theory in the future passes all test and it predicts a multiverse, wouldn't you say the multiverse gains in credibility? (I even heard Steven Weinberg give this argument.) Yes or no?

Please, Peter, don't leave me hanging here. Yes, or no?

Don't you appreciate the relation between the anthropic multiverse and the fact that many many planets exist? It's another anthropic argument.

25. **John**
August 28, 2012

Also, Peter, if a high school student gets so excited by string theory that he/she decides to major in physics, but then decides he/she wants to do condensed matter theory and he/she makes significant progress in condensed matter theory, isn't that a good thing? And, again, the course is about "frontiers" in physics, and string theory is definitely part of the frontiers of physics.

26. **Peter Woit**
August 28, 2012

John,

Yes, amidst the pages and pages of hype, one hype-filled sentence ("A GREAT DEAL OF THEORETICAL EXCITEMENT") does have one clause admitting no connection to experiment ("SO FAR"). Whether one clause buried in the pages of hype for failed ideas salvages the whole thing as a responsible project aimed at high school teachers is up to people to decide for themselves.

And yes, as you argue with Bernhard, if string theorists all of a sudden calculate accurately all the parameters of the SM, using a string theory landscape calculation that implies a multiverse, that would be good evidence for a multiverse. It's also true that if I discover tonight a wonderful TOE which explains everything perfectly and has no multiverse, that will be evidence against the multiverse. At this point, both of those eventualities seem equally irrelevant: I'm a lot more likely to get run over by a truck on my way home tonight.

As for your speculation about the smart high school student, what if he or she instead of getting excited about the hype sees it for what it is, decides "frontier science" is BS, and decides to become a lawyer instead of a scientist? I think a lot of that has been happening in recent years….

I can tell you have a deep and abiding love for this hype. Enjoy, but I'm already wasting too much of my life discussing it, enough for now.

27. **John**
August 28, 2012

"decides to become a lawyer instead of a scientist? I think a lot of that has been happening in recent years…."

Can you give me evidence of this? How many high school kids do you know?

"Yes, amidst the pages and pages of hype," Pages and pages? Can you send me a link to all those "pages and pages"?

"And yes, as you argue with Bernhard, if string theorists all of a sudden calculate accurately all the parameters of the SM, using a string theory landscape calculation that implies a multiverse, that would be good evidence for a multiverse. "

So it's no impossible, right? It's still possible for this to someday happen. So what are you complaining about?

"It's also true that if I discover tonight a wonderful TOE which explains everything perfectly and has no multiverse, that will be evidence against the multiverse."

I totally agree with you.

"I can tell you have a deep and abiding love for this hype." I don't love the hype. I'm just trying to show you that you are wrong. If I'm not allowed to do this, then why have a comments section for your blog?

Also, Peter, you didn't tell me whether or not you agree with my definition of 'frontier' and whether string theory fits that description.

You also haven't given me the websites that goes over the flaw in the logical progression of SUSY –> supergravity —> ST —-> multiverse. Do they exist?

28. **John**
August 28, 2012

"As for your speculation about the smart high school student, what if he or she instead of getting excited about the hype sees it for what it is, decides "frontier science" is BS…"

But the description of this class specifically says that there is so far no experimental evidence for it. It also specifically says that it is a "theoretical effort". That's not hype, that's honesty. If a high school students decides not to pursue physics even after those disclaimers, that's his/her problem. Are physicists not allowed to study this? And are people not allowed to show this to high school students? If such a unit is presented in that way (emphasizing lack of experimental support and that it's still very speculative), it's much more likely to excite students than turn them off.

Again, please link to me all those "pages and pages" of hype you saw.

29. **John**
August 28, 2012

"I can tell you have a deep and abiding love for this hype. Enjoy, but I'm already wasting too much of my life discussing it, enough for now."

But most of your blog posts are about String Theory hype! And now, suddenly, after responding twice to my comments, you decide that you're wasting too much of your life? Until the next obscure thing you find on the web that strangely convinces you is hype? I mean, where did you even find this course website? It's like you're purposely seeking out this stuff. If you're wasting too much of your life with this stuff, then just stop posting about string theory hype. I mean it's like it's so bad, you're posting stuff you THINK is hype, when it really isn't, as I showed above in this particular example (see the quotes from the website). I just don't get it.

30. **Anonyrat**
August 28, 2012

I'll give a a course in astrology, that hasn't been proven yet, but conceivably could be a guide for each and every human being on this earth, and lead them to their true destiny. And maybe some of the high school children will become interested in astronomy instead. Peter, oh , Peter, what is wrong with that?

31. **John**
August 28, 2012

Anonyrat,

Astrology HAS be shown to be incorrect. You know that. So your example makes no sense.

32. **John**
August 28, 2012

Peter,

I guess you have no rebuttal for me? Let me know. 🙂

33. **Typhoon**
August 30, 2012

Consider the spherical high-school student . . .

All this pure speculation about what a hypothetical high school might or might not choose after being exposed to ST is analogous to arguments for the multiverse and vice versa.

34. **Chris W.**
August 30, 2012

Astrology HAS be shown to be incorrect.

No it hasn't, because it can't be. Why? Because it doesn't lay any hard predictions on the line. It always has an excuse. That sounds kind of familiar…

(It doesn't mesh well at all with successful theories that *do* lay any hard predictions on the line, so it is certainly incorrect in that sense, and it makes only trivial use [at best] of mathematical arguments. Obviously astrologers don't care about any of that.)

35. **John**
August 30, 2012

"Because it doesn't lay any hard predictions on the line."

Astrology does have a prediction. It predicts that your life and/or personality is dictated by the positions of the stars relative to the earth. It has been tested: Take any two people born under the same sign. If their life and/or personality is different from each other, astrology is wrong.

String theory does have a prediction: it predicts SUSY, though not the energy scale at which it is broken.

36. **DrDave**
August 30, 2012

IF I were to say the following (and I'm not): "There are other universes in the multiverse where astrology has been proven to be correct, and eventually we may be able to detect these other universes. You just need to be patient." You might be skeptical. The problem is that there is no logical determinant in an open-ended, adaptable universes that is different from the above quote. Once you assume that any universe in a multiverse can be constructed to adapt to data which which is contra-indicative, there is a logic problem which is essentially: no argument can be proved or disproved. People who are tired of the argument simply want some rules, and if "no rules" is the game, then there is basically just an endless loop.

37. **scientific responsibility to the public**
September 2, 2012

"The Annenberg Foundation funds Annenberg Learner, a site designed to provide information to high school teachers. Their Physics course includes a unit from Stanford's Shamit Kachru, which is pretty much pure hype, unadulterated by any skepticism that string theory might not be the way the world works. Physicists may have lost interest in string cosmology, seeing it as a failure, but that's no reason not to teach it to high school students…"

If, by 2020, the LHC at full design energy and luminosity (14TEV) finds no evidence of SUSY after collecting sufficient data, and no other evidence of SUSY is forthcoming, do you think Stanford's Shamit Kachru and other popularizers (i.e Brian Greene, Michio Kaku, Stephen Hawking) have a public responsibility to say string theory should be treated with skepticism?

38. **Peter Woit**
September 3, 2012

scientific responsibility,

Actually I think it's now been a long time that string theory unification is something that should be presented skeptically to the public. I don't think the failure to find SUSY (or anything else for that matter) is going to make much difference to the people promoting string theory to the public. The Kachru material for high school teachers avoids claiming LHC-scale SUSY as a string theory prediction, and everyone still promoting string theory is now careful to do this, since it is now clear what the experimental bottom line is likely to be.

Nothing is going to stop continuing attempts to mislead the public, but the physics community is not so easily misled, and is already very skeptical about string theory unification. The negative LHC results will have an impact among physicists.

Simons Foundation and the arXiv

August 28, 2012
Categories: Uncategorized

Via the Quantum Pontiff, news that the Simons Foundation will be providing up to \$300,000 in financial support to the arXiv for each of the next five year. Last year, the arXiv announced a \$60K planning grant from Simons. Now the Foundation is stepping in with a much bigger contributions, for details see here.

This kind of support for open-access publication is an excellent way for Simons to use its resources. Perhaps this will be the beginning of a larger effort to buy back control of the math and physics literature from commercial publishers and set up a viable model for making this literature available to all going forward. This may be an expensive undertaking, but Simons (and other math/physics-friendly financiers) have resources on the scale necessary to do this.

Comments

1. **MathPhys**
   August 29, 2012

   If the Simons Foundation or any other with money to spend on science can make, for example, pre-arXiv papers that appeared in Nucl Phys B available to all of us, quite a few of us would be really grateful.

2. **chris**
   August 29, 2012

   a big thank you to all the responsible people. this is a way of donating money that really helps the entire scientific community.

3. **David Nataf**
   August 29, 2012

   Of course we shouldn't need to be helped. A lot of scientists choose to submit to corporate journals and to submit to the ArXiV.

4. **David Nataf**
   August 29, 2012

   Sorry, I meant to write "not to submit to the arXiv".

5. **Sakura-chan**
   August 29, 2012

   It's really frustrating when a journal paper is archived online, but the publisher does not let individuals purchase access to single papers. And then when they do allow individual purchase, it is usually around \$20 to \$30 for a single paper. Even the big libraries that I am affiliated with don't have complete journal coverage, so I am left to sheepishly cold e-mailing the author to see if they have it on hand.

6. **P**
   August 29, 2012

   This is great news. The Simons foundation is doing wonderful things for mathematics and physics.

   My friends in fields outside of physics can't believe that we have such a nice centralized preprint archive. Are there any archives in other fields similar to the scale of arXiv.org?

7. **Shantanu**
   August 29, 2012

   Peter this is off-topic , but have you watched the panel debate on future of physics @aspen this month moderated by Lisa Randall?
   it has some interesting stuff.

8. **Peter Woit**
   August 29, 2012

   Shantanu,
   Just took a look, but there seemed to me little there about the actual topic of the future of physics beyond a lot of self-satisfied general comments. For those interested, see
   http://vod.grassrootstv.org/vodcontent/11072-1.wmv
   but I'd rather not start a discussion of it here.

9. **Av**
   August 29, 2012

   Not precisely on-topic for this thread, I recognize, but:

   http://arxiv.org/pdf/1208.5715v1.pdf

   I'd be interested in Peter's views on these "Top 10^{500} Reasons Not to Believe in the [String] Landscape".

10. **Peter Woit**
    August 29, 2012

    Av,

    That topic belongs in the previous posting, where I yesterday added an update about it to the posting…

11. **Allan Rosenberg**

August 30, 2012

arXiv is great, but if the goal is to make scientific results free to everyone, we still need peer review. Shouldn't there be a PLOS journal for physics, too?

12. **open access**
August 30, 2012

I regularly contact authors to ask for a pdf copy. Nothing to be sheepish about it. Note that the arXiv is more than open access. It is also non-peer review. Open access in the sense of the arXiv does not imply quality control. It is also true that authors post rejected papers on the arXiv. A friend of mine once told me about a paper he saw posted. The description seemed familiar. I looked it up and recognized it as a rejected manuscript I had refereed, but now with my referee comments mixed in. So this is all good, what the Simons foundation does, but don't expect quality of publications to improve. Indeed, I have no doubt the ST gang (and many others) love the arXiv.

13. **Chris Austin**
August 30, 2012

I would also like to thank the Simons Foundation for its support of arXiv.org.

The arXiv quality control model seems to me to be similar to the quality control model used in manufacturing industry, where the most effective quality control is the control workers apply to their own work. For competent production workers, the knowledge that a small, random sample of their work will be checked by supervisors is sufficient to ensure that all their work meets the required standard. Conversely substandard workers receive a period of intense scrutiny and coaching, during which their work either improves to the required standard, or they lose their jobs, which would correspond to losing arXiv submission privileges.

When submitting a paper to arXiv, I take far more care with it than I would if I were just submitting it to a journal, because I know that submitting an unacceptable paper to arXiv could result in permanent loss of submission privileges.

Another reason that papers submitted to arXiv but not to a journal may be better written than papers also submitted to a journal, is that if authors know that a journal editor might alter what they write, they might be less motivated to take care with the presentation.

14. **open access**
August 30, 2012

What is "unacceptable?" Is this unacceptable?
http://arxiv.org/abs/0901.2564

I know for a fact that the authors did not lose their arXiv posting priveleges. Do you know anyone who has lost their arXiv posting priveleges?

15. **Peter Woit**
August 30, 2012

Chris is referring to authors without regular academic positions, who can have difficulty being allowed to post articles on the arXiv. For those with regular academic positions, I think not being allowed to post on the arXiv is highly unusual. One example might be Brian Josephson. Please though, I'd rather not try and moderate a discussion here and now of arXiv censorship issues.

16. **Jeff M**
August 30, 2012

Not sure if arXiv is any different for physics and math, but in math I think it's essentially unheard of for someone in an academic position to lost posting rights. Removal of papers is purely voluntary as far as I know, if someone finds a mistake in your paper you should of course remove it (and I know of times when this has happened) but I'm sure it doesn't always happen. That said, arXiv is a wonderful, amazing resource. In any case at this point many mathematicians post their papers on their own websites as well, including already published ones. Funny story about the referee finding a rejected paper on arXiv, with referee comments – I just refereed a paper which I had already read, and discussed with a colleague, since it had been on arXiv for a while. Made the refereeing process much easier 🙂

17. **MathPhys**
August 30, 2012

B D Josephson can post on the arXiv

http://arxiv.org/ftp/arxiv/papers/1206/1206.5850.pdf

18. **MathPhys**
August 31, 2012

Paul Ginsparg's arXiv is probably the most important factor in advancing research in physics in the Third World post-1992. To my mind, Ginsparg should get a Nobel Peace prize for that. If Third World scientists aren't busy doing physics, superstrings included, they could turn their supersmart minds to less peaceful endeavors with disasterous consequences.

19. **aliaspg**
August 31, 2012

"If Third World scientists aren't busy doing physics, superstrings included, they could turn their supersmart minds to less peaceful endeavors with disasterous consequences."

As in "developping toxic financial products for Wall Street?"

20. **MathPhys**
August 31, 2012

As in "developping toxic financial products for Wall Street?"

Yes. Literally.

21. **aram**
September 6, 2012

The reason not to post bad papers to the arxiv is that good researchers have reputations that they want to protect (and also some inherent pride in doing good work). The flip side is that we might not read arxiv papers from people we haven't heard of, but we would look at their papers in a journal because then we know that someone we (somewhat) trust has vouched for it being interesting.

Short Math Links

August 31, 2012
Categories: Uncategorized

Some links of mathematical interest that I've recently run across:

- The life and work of Alexander Grothendieck is one of the great stories of modern mathematics. Winfried Scharlau's first volume of a biography of Grothendieck, covering the years up to 1948 is now available in English, see here. The third volume, covering Grothendieck's life after 1970 is only available in German, see here. Leila Schneps is writing a second volume, covering his life and mathematics during the height of his career, from 1948-1970, with chapters appearing as they are written on this page. She is now up to 1952.

  The same page contains links to various wonderful articles about Grothendieck's mathematics, many by mathematicians who interacted with Grothendieck during his period of greatest mathematical activity.

- Cédric Villani joins other Fields Medalists with blogs, see here. Villani has just published in France a memoir called *Théorème Vivant*, a mix of autobiography and description of a collaboration on a mathematics problem. More about the book here, here and here, with a video here.
- Many of the talks given at this summer's String-Math 2012 conference are now available as slides or video, see here.

   Grothendick lives in the south of France with a daughter who cares for him. At least that was the case about 5 years ago.

2. **Raisonator**
   September 17, 2012

   I found this interesting link, Alain Connes goes blogging:

   http://noncommutativegeometry.blogspot.de/ – A DRESS FOR THE BEGGAR ?

   His latest paper is pretty exciting, I find.

3. **martibal**
   September 17, 2012

   Maybe off topic, or already treated elsewhere, but could someone explain a bit this idea that coupling the Higgs with a new ? or neutrino related ? (this is not clear to me) scalar field, then some instability due to the low mass of the Higgs are cured.

   This is the point of this Chamseddine-Connes paper: such an interaction term appeared in the spectral action, but was neglected. It seems that taking it into account, then noncommutative geometry can now accommodate a 125GeV Higgs (whereas the previous prediction, back to 2010, was around 170 GeV).

The Templeton Effect

September 3, 2012
Categories: Uncategorized

The Chronicle of Higher Education has a long story about the Templeton Foundation, entitled The Templeton Effect. Much of it is about various subfields of philosphy where Templeton money has been successful at bringing religion, theological concerns and religious philosophers to greater prominence. One section however describes the Templeton funding promoting a new field of Philosophy of Cosmology. Religion doesn't explicitly appear here, but the story of how this "Philosophy of Cosmology" got underway gives a good example of how money influences intellectual pursuits:

> Barry Loewer, a philosopher at Rutgers University at New Brunswick, isn't likely to turn up at a Society of Christian Philosophers meeting with Newlands and Miller. "I myself have no interest in philosophy of religion and am not a religious person," he says. For years, Loewer has been working with a group of philosophers, mathematicians, and physicists in the New York area, meeting and collaborating on papers—nothing very expensive. But about five years ago a colleague at Rutgers, Dean W. Zimmerman, told the group about the Templeton Foundation and suggested that they apply for a grant. Zimmerman, a top Christian philosopher, had already served on Templeton's advisory board and participated in many foundation-sponsored activities.
>
> The idea at first was to do a project about quantum mechanics and the foundations of physics, which was an interest of Loewer's group. Templeton had other ideas. The foundation pointed the group in the direction of cosmology, with the prospect of a much bigger grant, and the researchers jumped at the idea. They realized that cosmology encompassed the questions of time and physical laws that had concerned them all along.
>
> "You know that story of Molière's where someone discovers that he has been speaking prose his whole life?" says Loewer. "It was a little bit like that."
>
> The nearly $1-million grant his team received from Templeton last year coincided with another, slightly larger one called "Establishing the Philosophy of Cosmology," which was awarded to scholars at the University of Oxford. Despite the change of plans at Templeton's behest, Loewer stresses, "They've been really helpful, and totally noncoercive in terms of any agenda that they might have. I had my eyes open for it."
>
> Not that philosophers are especially well practiced in negotiating the terms of million-dollar grants, much less in thinking about how such money might sway them. Neither Loewer nor Mele nor Miller nor Newlands could have anticipated back when they were in graduate school that they'd be administering projects like this; their training was for armchairs, libraries, and conferences. But now that the money is coming into the field, it is being welcomed even by those who lack the foundation's spiritual proclivities. "Templeton picks some people whose Christian epistemology I might not share," Brian Leiter says, "but there's no quarreling that they're serious philosophers." Suspicions about some secret religious agenda tend to lessen the more widely the foundation's substantial sums begin to spread.

   Why evolution is true blog had today piece about Templeton funding a homeschooling course at Cambridge University. The Anthropic principle, science giving evidence for faith and so forth. All neatly packed for home schoolers. Laugh or cry, not sure which one.

   http://whyevolutionistrue.wordpress.com/2012/09/03/hey-kids-a-homeschool-course-on-accommodationism-courtesy-of-the-faraday-institute-cambridge-university-and-the-templeton-foundation/

2. **Pravda**
   September 3, 2012

   Oh, more concerns about Templeton money and Christian theology.

   It seems as though I am the only person who considers Christian theology to be rather innocuous compared to post-modernism, or the "sociology of scientific knowledge/science" which on any balanced analysis must be recognized as being far more pernicious than a belief in evolution. Need I even mention the theological aspects of string theory? Even belief in "The Singularity" a la Kurzweil has more far-reaching deleterious consequences than belief in creationism.

   One can only assume that this has got to do more with the socio-economic status of the groups in which these beliefs are prevalent, than the beliefs themselves.

3. **Peter Woit**
   September 3, 2012

   Pravda,

   When Kurzweil starts a multi-billion dollar foundation devoted to influencing fundamental physics research, I'll start paying attention to him and that "Singularity".

   In the meantime, discussion of the very large set of "things that are worse than Templeton" is off-topic.

4. **Michael Kovarik**
   September 4, 2012

   Templeton funds a lot of fundamental research in fields where there otherwise is a money drought (see FXQi, whose existance owes itself to Templeton) so that the McCarthy-esque attempts to discredit them are becomming stale.

   Templeton does not have overtly religious overtones as skeptics claim. It is an institution that feuls a lot of discussion on the relationship between the natural universe and spirituality — a topic that is both intellectually serious as well as important to many people. Once you remove the assumption of empiricism (which is, of course, necessary to formulate scientic hypothesis) from the *a priori*, truth becommes a little more blurry.

   I know you don't like nonscience parading as science, but I don't think that is what Templeton is trying to do, nor do I believe that people take what Templeton funds as purely scientific discussions.

   As for this specific project, Philosophy of Cosmology, I am glad that Rutgers is getting that grant. The physics department needs it terribly.

5. **chris**
   September 4, 2012

Templeton has its agenda – but is it so different from public funding sources?

in the US, NSF and DOE have their agenda, too. it is always determined at a very high political level which kind of research gets funded and usually the lucky ones – those who have their interest aligned more or less with the agendas – tend to just praise the decisions and take the money. scientists in other subfields largely go unnoticed because no money means no employment, less publications, no public recognition of the whole subject.

this is just the way science works as a social, human endeavor.

6. **S. Molnar**
   September 4, 2012

   "Suspicions about some secret religious agenda tend to lessen the more widely the foundation's substantial sums begin to spread." Well, my suspicions increase when that happens.

   That said, I agree with chris that government funding can be pernicious as well. I seem to recall that Norbert Wiener (and there were others) was very much against mathematicians accepting government grants for just that reason when they began in earnest around 60 years ago. On the other hand, it's hard to do research on an empty stomach and impossible to do modern experiments without a lot of money.

7. **srp**
   September 5, 2012

   Anti-materialism in a metaphysical sense seems to be the thing Templeton wants to promote. Platonists, romanticists, anthropicists, etc. would all be potentially useful to that project. To the extent that their views have any independent merit I don't mind TF throwing some bucks at them, especially if they also have the side effect of paying for good theoretical physicists and philosophers to do their thing.

Fall Course: Quantum Mechanics for Mathematicians

September 3, 2012
Categories: Uncategorized

This fall I'm teaching on quantum mechanics for mathematicians, at the undergraduate level. There's a web-page with more information here. I'll be writing up lecture notes, which should appear on that web-page as the course goes on, starting Wednesday.

We'll see how this works, but the plan is to teach many of the standard topics, although starting from a different point. Most quantum mechanics classes start out with classical mechanics, then somehow try and motivate quantum mechanics from there, following the historical logic of the subject. I'll instead start with the simplest purely quantum systems, especially the two-state, spin-1/2 system, now famous as the "qubit" of quantum computation. This is also a central example for the theory of Lie groups, Lie algebras and representations, so something that every mathematician should become familiar with. Another advantage of starting here is that there's no analysis, just linear algebra, and one can easily do everything rigorously.

Later on in the course I'll get to the standard material about wave-functions and quantum particles in potentials. The emphasis will be though not on the analytical machinery needed as a rigorous foundation for this subject in general, but on specific problems and their symmetries, and the use of these symmetries to do real calculations, ending up with the spectrum of the hydrogen atom.

We'll see how this goes, and what the students think of it. As lecture notes appear, corrections and suggestions of how to improve them would be appreciated.

Comments

1. **Jeff M**
   September 3, 2012

   Peter,

   You might want to check out anything you can find about the course Herb Bernstein has been teaching at Hampshire since the early 70's – I think Lee Smolin took it when he was there. It assumes no math at all that I remember, and no physics either, but he does QM from the operator perspective, rather than the way I (and I assume most people) first learned it. He was of course aiming at a different audience (many if not most of the students were first or second year), but it might be interesting for you to check out. Not sure what if anything has been written about it, pretty sure Herb is still at Hampshire though he must be close to retirement at this point, plus he has his institute.

2. **qm for physicists**
   September 3, 2012

   There is a good reason standard QM courses and textbooks start off as they do. The intended audience (physics undergraduates) have 2-3 years of experience with classical dynamics — Newton, then Lagrange and maybe Hamilton — also electrodynamics and relativity, also optics and statistical mechanics. It makes perfectly good sense to talk about blackbody radiation and the photoelectric effect. It also makes perfectly good sense (and is very good physics) to teach students that the equations of classical physics were derived on the basis of macroscopic objects, and now they must learn that there is no reason for thos equations to be true at the atomic level, and the fact is that new ideas (not just new equations) are needed. It is a cautionary tale that we should not assume that the equations we know apply all the way down to the smallest, and also the largest, length scales. It is the business of a physicist to recognize that there may be new physics in domains of energy, momentum, length, time, whatever, which have not been explored yet. QM at the atomic level is an example of this. Feynman has a good piece about this in the Feynman Lectures on Physics, although I cannot cite the exact page reference from memory.

   It makes sense to begin with a "free particle", then a "particle in a box", then a "particle hitting a barrier" (includes tunneling through a barrier) then a harmonic oscillator and then the hydrogen atom. These are all concepts the students can relate to, at some level, with material in their prerequisite courses. They can solve some partial differential equations. They have already solved Laplace's equation and the diffusion equation in many problems. But Lie groups? How many physics undergrads know about Lie groups? SU(2)?

3. **Mike**
   September 3, 2012

   This seems like a good perspective for mathematicians, but I really enjoyed the comparison of classical physics with QM when I took the intro to QM class. I am guessing most math majors have some exposure to basic physics problems so it's probably OK to discuss some of these great examples (potential wells, harmonic oscillators) for a good intuitive basis of comparison between NM (Newtonian) and QM.

4. **Paul Wells**
   September 3, 2012

   Peter,

   Feynman did a similar experiment in Feynman lectures vol III treating spin/rotation as central before moving onto Schrodinger's equation. Interested in your comments on his approach.

   Good luck!

   Paul

5. **Peter Woit**
   September 3, 2012

   qm for physicists,

   Undergrad math students rarely know anything about Lie groups or SU(2) either. Part of the idea of the course is to teach the theory of SU(2) and its representations, assuming no knowledge of the subject. No intention to get into the general theory of Lie groups.

   Paul Wells,

   I've gotten some inspiration from Feynman's lectures and his starting this way. He has all sorts of wonderful material about the physics of spin, and I guess was trying to get students familiar with that as a way of getting into the subject. I've heard this wasn't very successful, perhaps partially because it's very challenging stuff to absorb. Unlike Feynman, I'll be concentrating more on the mathematics (which Feynman was kind of avoiding) hoping that if students get comfortable with the mathematical ideas in this simple context, it will help them in further study of math, as well as in understanding these physical systems.

6. **Matt Leifer**
   September 3, 2012

   You should take a look at Schumacher and Westmoreland's book if you have not done so already http://www.amazon.com/Quantum-Processes-Information-Benjamin-Schumacher/dp/052187534X

7. **Emma Woodhouse**
   September 3, 2012

   Hi Professor Woit, I have little physics knowledge but very high level math skills–would I survive this course?

8. **Jeff M**
   September 3, 2012

   Peter,

   If you want a good undergrad resource for Lie Groups, check out http://www.amazon.com/Lie-Groups-Introduction-Mathematical-Association/dp/0883857596/ref=sr_1_4?ie=UTF8&qid=1346719859&sr=8-4&keywords=pollatsek
   I took algebra with Harriet as an undergrad, and she did Lie Groups the second semester, I think the book is basically taken from her teaching notes.

9. **JollyJoker**
   September 3, 2012

   The starting point seems very nice. It's for mathematicians rather than physicists, so a historical "why we needed this" view seems pointless. As a coder without any real education in QM but yet an interest in what's happening in physics, I've been thinking about reading some basics of quantum computing to get an idea of what "quantum" really means.

10. **Lowell**
    September 4, 2012

    You should look at

    Julian Schwinger, "Quantum Mechanics" Springer

11. **David Nataf**
    September 4, 2012

    My introductory QM course at McGill started off the with the Stern Gerlach experiment. We used the textbook by townsend which didn't get to the wave function until chapter 6.

12. **Sadiq Ahmed**
    September 4, 2012

    Hello Dr. Woit,

    Any way to audit this course through the internet?

    Warm regards.

15. **Tmark48**
    September 4, 2012

    @ JollyJoker : having an historical point of view is never pointless especially in Quantum Mechanics. Even if the course is geared towards students of mathematics, giving them an idea of why the things are the way they are in QM is a good way to teach the subject. Then you can go on exploring exotic topics, or even formulate QM is a purely group theoretic way. Remember QM is not mathematics, it is physics so in ultimate analysis physics provides the justification for mathematics not the other way around.

16. **Peter Woit**
    September 4, 2012

    Thanks to all for the book suggestions, most of which I wasn't aware of. The Townsend book that David mentions (A Modern Approach to Quantum Mechanics, John S. Townsend) looks quite good, starting as I'd like to try with spin. The book that Matt Leifer mentions also (like most books oriented towards quantum information theory) starts with spin, looks very interesting, although headed more in a different direction than the course I'm planning to teach. JeffM, that looks like a very nice intro book on groups and Lie algebras. I do though want to emphasize much more the representations, which that approach doesn't cover.

17. **Peter Woit**

September 4, 2012

Emma Woodhouse, Sadiq Ahmed,

The only prerequisite for the class is calculus/linear algebra. In particular no physics will be assumed (although for some later topics, some physics background would be helpful). I'll be writing up notes as I go along, anyone who wants to is invited to try following along as those appear. We'll see how far they get before I run out of steam.

One thing I'm also thinking of doing is providing a much shorter, summary version of the notes, one aimed at mathematicians with a lot of background. This would contain no explanations of the math, just explanations of the physics in terms of the math, much of which would be a translation effort.

18. **Bob Jones**
September 4, 2012

I really think this is the best way of teaching quantum mechanics. The approach that starts with wavefunctions and infinite-dimensional Hilbert spaces is just too mathematically complicated for a student seeing the subject for the first time. The only problem with this simpler approach is that there aren't many interesting physical systems. Besides spin-1/2 particles (and particles with higher spin), what systems can you study using only finite-dimensional Hilbert spaces?

When I was first learning quantum mechanics, one of the things that bothered me was the arbitrariness of the postulates. I think you can minimize the number of unmotivated postulates if you take a more mathematical approach like the one described here. For example, in the C*-algebraic formalism, you start by postulating that the observable quantities in a quantum mechanical system correspond to the self-adjoint elements of a unital C*-algebra. From this one assumption, you can derive the most of the theory. For example, it follows from the operational meaning of the word "state" that the states of a quantum system correspond to functionals on the C*-algebra. You can then recover the Hilbert space using the GNS construction, and you can derive Born's rule from the Riesz representation theorem. You can also get Schrodinger's equation from Stone's theorem on one-parameter unitary groups.

If I were teaching a course on quantum mechanics for mathematicians, that's how I would do it.

19. **Peter Woit**
September 4, 2012

Bob Jones,

Well, you can take tensor products…. You could also do the SU(3) classification of states using flavor in particle theory, but that's way beyond this kind of course. The theory of spherical harmonics and thus the classification of atomic orbitals by angular momentum quantum numbers is also essentially finite-dimensional.

At least for a course at this level, I don't want to try and set up general theory, just work out the parts of the theory and examples where most everything comes down to representation theory (i.e. not do general potentials, just quadratic and 1/r, and maybe set up perturbation theory).

20. **Scott Aaronson**
September 4, 2012

Bravo, Peter! If there's *anything* I'm confident about in life, it's that starting with qubits is the right way to teach quantum mechanics. I tried to set out the reasons in my Quantum Computing Since Democritus Lecture 9. Basically, yes, it can be great fun to keep students in suspense for an hour or so (piling on one strange phenomenon after another) before finally letting them in on a great secret (in this case, that Nature prefers the 2-norm over the 1-norm when doing probability theory). But it seems excessive to drag out such a shaggy-dog story for an entire semester!

Two other sets of course lecture notes people might find helpful, if they're interested in this approach to quantum mechanics, are Umesh Vazirani's (from his undergrad course "Qubits, Quantum Mechanics, and Computers") and John Preskill's (from his graduate quantum computing course).

21. **Bob Jones**
September 4, 2012

Peter,

Thanks for your response. Those are nice examples.

A pretty good book which formulates quantum mechanics in the way I described is

http://www.amazon.com/Introduction-Mathematical-Structure-Quantum-Mechanics/dp/9812835229/ref=la_B001JO5VSM_1_2?ie=UTF8&qid=1346783227&sr=1-2

22. **Peter Woit**
September 4, 2012

Scott,

Thanks. I've already had a link to the Preskill notes, will look at the Vazirani ones.

I liked your lecture trying to motivate quantum, especially the QM as OS line. Still though, I think the answer to the "why" questions is something like "because unitary representations of groups are a fundamental unifying structure that is all over mathematics, so why shouldn't it be fundamental for physics?

23. **Mathematician**
September 4, 2012

Excellent Peter, am looking forward to your notes!

24. **Laurens Gunnarsen**
September 5, 2012

May I suggest that you may want to introduce your students to the profoundly illuminating work of the late Itamar Pitowsky? I would in particular suggest the immediate relevance to your purposes of the fascinating and highly readable article

"George Boole's 'Conditions of Possible Experience' and the Quantum Puzzle"
Brit. J. Phil. Sci. 45 (1994), 95-125

Here one finds what is probably the most penetrating and revealing account ever written of the reasons for the existence of (and general methods for constructing) "Bell-type inequalities” — which are, of course, badly violated in the real world of elementary particle interactions.

In its essentials, Pitowsky’s exposition is readily accessible to students with the background you assume, and I find it hard to imagine how any other approach could ever hope to equal his in clarifying the precise sense in which quantum phenomena are so extraordinarily bizarre.

25. **jg**
September 5, 2012

If you’re going to start with spin then be aware of the non-relativistic origin of spin famously argued by Levy LeBlond in this 1967 paper , (free download from Project euclid) and discussed by Walter Greiner in chapter 13 of his introductory Quantum Mechanics book: Quantum Mechanics: An Introduction

(more pages viewable with ‘Look Inside’ feature at amazon)

(Greiner’s text follows the more traditional introductory course)

26. **CU Phil**
September 5, 2012

Hi Peter,

Sakurai’s book “Modern quantum mechanics” also starts with a description of spin-1/2 particles and Stern-Gerlach apparatus, and is a pretty good book on the whole (as you probably are aware).

27. **Shantanu**
September 5, 2012

Peter again slightly OT, but would be curious to know your talk on the latest HEPAP
meeting
http://science.energy.gov/hep/hepap/meetings/20120827/

(apologies if I missed it)

28. **David Nataf**
September 5, 2012

Sakurai’s book is probably much too difficult for an introductory course.

29. **Peter Woit**
September 5, 2012

Shantanu,

Thanks for the link, I didn’t know about that. But, seems to be not much news. For one thing, US federal budget prospects are likely to be up in the air until after the election.

30. **Eli Rabett**
September 6, 2012

The tell on Feynman Volume III is that the first year students (knew some) were lost, but since then many senior (was one) and graduate level quantum courses start with it to introduce the subject. I have a friend who used it as his only text for studying for and passing qualifiers. There is no doubt that its approach provides a much more sophisticated appreciation than the usual grind it out of PDEs one.

That being said, there is a strong argument that linear algebra is a much more important course for physicists than diffeq (which mostly looks like a bag of tricks to physicists) and PDE (a bag of even more tedious tricks).

For what its worth, I took quantum as a senior using Feynman III and loved it. In grad school the quantum course was taught by a Schwinger student and I found it tedious, but understandable given the foundation I had.

31. **Mobius Trip**
September 6, 2012

What is a good free online reference for the class? When does the class start?

32. **Zen**
September 10, 2012

A LaTeX suggestion: when writing your brackets don’t use > and } % bra
\newcommand{\bra}[1]{\left< #1 \right|} % ket
\newcommand{\braket}[2]{\left} % braket

Some examples:

\ket{\Psi}
\bra{\Phi}
\braket{\Phi}{\Psi}

33. **Peter Woit**
September 11, 2012

Zen,

Thanks a lot for the suggestion, will try it out.

Proof of the abc Conjecture?

September 4, 2012
Categories: abc Conjecture

Jordan Ellenberg at Quomodocumque reports here on a potential breakthrough in number theory, a claimed proof of the abc conjecture by Shin Mochizuki. More than five years ago I wrote a posting with the same title, reporting on a talk by Lucien Szpiro claiming a proof of this conjecture (the proof soon was found to have a flaw). One change over the last five years is that now there are excellent Wikipedia articles about mathematically important questions like this conjecture, so you should consult the Wikipedia article for more details on the mathematics of the conjecture. To get some idea of the significance of this, that article quotes my colleague and next-door office neighbor Dorian Goldfeld describing the conjecture as "the most important unsolved problem in Diophantine analysis", i.e. for a very significant part of number theory.

Jordan is an expert of this kind of thing, and he has some of the best mathematicians in the world (Terry Tao, Brian Conrad and Noam Elkies) commenting, so his blog is the place to get the best possible idea of what is going on here. After consulting a couple experts, it looks like this is a very interesting and possibly earth-shattering moment for this field of mathematics. In the case of the Szpiro proof, the techniques he was using were relatively straightforward and well-understood, so experts very quickly could read through his proof and identify places there might be a problem. This is a very different situation. What Mochizuki is claiming is that he has a new set of techniques, which he calls "inter-universal geometry", generalizing the foundations of algebraic geometry in terms of schemes first envisioned by Grothendieck. In essence, he has created a new world of mathematical objects, and now claims that he understands them well enough to work with them consistently and show that their properties imply the abc conjecture.

What experts tell me is that, very much unlike the case of Szpiro's proof, here it may take a very long time to see if this is really a proof. They can't just rely on their familiarity with the usual scheme-theoretic world, but need to invest some serious time and effort into becoming familiar with Mochizuki's new world. Only then can they hope to see how his proof is supposed to work, and be able to check carefully that a proof is really there, not just a mirage. It's important to realize that this is being taken seriously because such experts have a high opinion of Mochizuki and his past work. If someone unknown were to write a similar paper, claiming to have solved one of the major open questions in mathematics, with an invention of a strange-sounding new world of mathematical objects, few if any experts would think it worth their time to figure out exactly what was going on, figuring instead this had to be a fantasy. Even with Mochizuki's high reputation, few were willing in the past to try and understand what he was doing, but the abc conjecture proof will now provide a major motivation.

Mochizuki has been at this for quite a while. See this page for some notes from him about how he has been pursuing this project in recent years. This page has notes from lectures he has given on the topic, starting in 2004 with A Brief Introduction to Inter-universal Geometry. For the proof itself, see here, but this is the fourth in a sequence of papers, so one probably needs to understand parts of the other three too.

Update: Barry Mazur has recently made available his 1995 expository article on the abc conjecture, entitled Questions about Number.

Comments

   September 4, 2012

   Safari doesn't seem to like your link to the paper…

2. **Peter Woit**
   September 4, 2012

   Not just Safari, my bad… Now fixed. Thanks Andrew!

3. **Michael Thaddeus**
   September 5, 2012

   A pity he's too old for the Fields Medal! If he were 36, there would be some pressure on the Fields committee to form an opinion of his work in the next two years…

4. **Hamish**
   September 6, 2012

   The abc conjecture…surely it's easy as 123, simple as doe rae mi?

5. **Marko Amnell**
   September 8, 2012

   There is some interesting discussion of this in response to a post by John Baez on Google+. See: http://tinyurl.com/cnh5gks
   Apparently, Mochizuki declined to come to New York to discuss his work, which is interesting but there could be any number of reasons for it.

6. **Peter Woit**
   September 8, 2012

   Marko,

   With this kind of announcement, I suspect Mochizuki has all of a sudden received a very large number of invitations to give talks. From what I hear, he's not someone who likes to travel, so he's probably now turning down lots of such invitations (including the New York one).

7. **Marko Amnell**
   September 12, 2012

   You might be right that Mochizuki's dislike of travelling could have something to do with his rejection of the invitation, but I suspect another reason may be that (as his friend Minhyong Kim says) Mochizuki is in all likelihood the only person in the world who is familiar with the concepts and ideas in the purported proof of the ABC Conjecture. A talk at this point would be premature because the audience could not understand what he was saying! In a new post, John Baez provides some comments by Minhyong Kim which I would recommend to anyone interested in this subject. Here is part of what Minhyong Kim said: "How long it will take for people to evaluate the work, it's hard to say, possibly even a year or so. Among other difficulties, his work probes the very core of mathematical language such as what we might really mean by a number or a geometric figure, and how they might be interpreted in a manner quite different from usual conventions. In fact, it relies on deep relations of a geometric nature between such varying interpretations. Such questions have occupied philosophers for millennia, but are usually quite distant from the consciousness of modern mathematicians. But then, these seemingly philosophical questions have to be recast in the robust language of precise mathematics. You have to add to that some of the most sophisticated portions of 21st century arithmetic geometry. At the moment, I can fairly safely say that there is no one but the author who is familiar with all these things. Possibly his colleague Akio Tamagawa.” https://plus.google.com/117663015413546257905/posts/d1RsN4KnCUs#117663015413546257905/posts/d1RsN4KnCUs

8. **Daniel Hill**
September 17, 2012

Do we know whether Mochizuki is claiming the strong or the weak version of the conjecture?

9. **Marko Amnell**
September 18, 2012

In IUTT-IV Mochizuki writes, “In the present paper, estimates […] are applied to verify various diophantine results which imply, for instance, the so-called Vojta Conjecture for hyperbolic curves, the ABC Conjecture, and the Szpiro Conjecture for elliptic curves.” The Szpiro Conjecture is, in fact, equivalent to the strong ABC Conjecture. [cf. Bombieri-Gubler, Heights in Diophantine Geometry p. 431]

10. **Marko Amnell**
September 18, 2012

In his analysis of Mochizuki’s articles on MathOverflow, Vesselin Dimitrov says that the key inequality stated in Section 2 of IUTT-IV is “asserted up to finitely many exceptions.” Dimitrov also says that “Mochizuki’s approach […] is entirely direct, and, consequently, effective.” http://mathoverflow.net/questions/106560/what-is-the-underlying-vision-that-mochizuki-pursued-when-trying-to-prove-the-abc/106658#106658
But from what I can gather from other comments by experts, the question of which version of the ABC Conjecture Mochizuki claims to prove, and whether the claimed result is effective or not, are open questions at this point.

11. **Vesselin Dimitrov**
September 19, 2012

Mochizuki claims the strongest version of ABC that one could think of. (In particular, the effective one, and with the exponent 1 + epsilon). See Theorem A on p. 3 of his fourth paper (ABC with exponent 1+epsilon is a standard consequence of this).

As for an explicit effective statement, take a look at the inequality asserted on page 23. It concerns Szpiro’s inequality 1/6 log(D) < (1+epsilon) log(N) + Const. for the minimal discriminant D and conductor E of a (semistable) elliptic curve E. Here, log q on the left-hand side is precisely log(D). The f on the right-hand side is our conductor N, and the other term is a constant since we are concentrating on the single number field Q. In section 2, the full ABC conjecture is deduced, in an effective manner (by the paper [GenEll]), from this effective (Szpiro) inequality.

12. **Marko Amnell**
September 19, 2012

Vesselin,

Thanks very much for clarifying those points of your analysis. And sorry if the snippets I quoted from you may have misrepresented what you said. I found your analysis of Mochizuki’s articles on MathOverflow very interesting and helpful.

13. **Nick Nazari**
September 20, 2012

If Mochizuki theory is proven right then will it also bring another proof of FLT? It is very interesting to see how long will take to confirm or infirm this new mathematics. Taking into account that in the past Mochizuki proved other deep theorems there is a great hope for a major math revolution.

14. **Vesselin Dimitrov**
September 21, 2012

@Nick Nazari: If Mochizuki’s work is correct (and this is a pretty big “If”…), it would certainly yield a new proof of FLT.

This Week’s Hype

September 5, 2012
Categories: This Week's Hype

BBC Horizon this week is running an episode How Small is the Universe? with a description that features the usual sort of hype about modern physics:

> It is a journey where things don’t just become smaller but also a whole lot weirder. Scientists hope to catch a glimpse of miniature black holes, multiple dimensions and even parallel Universes. As they start to explore this wonderland, where nothing is quite what it seems, they may have to rewrite the fundamental laws of time and space.

Access to the video is restricted to IPs in the UK, so I can’t watch the thing, and should avoid being too critical. One of the two clips though advertises The landscape of String Theory and somehow I doubt that the clip explains why this is pseudo-science. Associated with the show is this article by Andy Parker of ATLAS, which gives the idea that ATLAS is looking for strings:

> Strings can vibrate, and this allows us to explain all of the strange fundamental particles which we see as different vibrations of the strings – different notes from a cosmic violin.
>
> So far, so simple – but to explain the particles we know about, the strings have to vibrate in lots of different ways.
>
> Superstring Theory allows them to vibrate in a bizarre space with 11 dimensions – up, down, sideways, “crossways” and 7 other ways!
>
> Experiments at the LHC are looking for evidence that you can move “crossways”. If we can, there could be whole universes, as big and marvellous as our own, sitting just down the road “crossways”.

No mention is made of the fact that the LHC has seen zero evidence for any such thing, or that few if any physicists ever thought there was any real chance it would.

The other experiment invoked is the MAGIC gamma ray telescope, presumably in the context of the search for Lorentz-violating dispersion of gamma rays from gamma ray bursters. This was discussed in an edition of This Week’s Hype from five year’s ago, which featured a Slashdot report that Gamma Ray Anomaly Could Test String Theory. At Scientific American, the story was Hints of a breakdown of relativity theory?, which was about this paper, and contained the news:

> Another co-author, string theorist Dimitri Nanopoulos of Texas A&M, writes to me: “I am very excited about this, because as you know we suggested this effect about ten years ago and we have follow through with several analyses and/or improvement on theory. Notice that the 0.4 x 10^{18} GeV is the typical string scale!!!!”

Since 2007 there have been a series of much more sensitive results from Fermi ruling out the quantum gravity interpretation of the MAGIC observations (see e.g. here, here, here and here.)

Since I can’t watch the video, I don’t know what the BBC has to say about MAGIC’s results, in particular whether the show explains the story of the 2007 claims and how they were later shown not to have anything to do with space-time structure by the newer Fermi observations.

Update: I did just get a chance to watch the program. It was very well made, with the first half quite interesting, featuring the LHC and some atomic-physics scale experiments I would have loved to hear more about. About half-way through though, it started to go off the rails, with the usual kinds of problems. The extra dimensions at the LHC stuff made no mention of the fact that even string theorists see no good reason for them to show up at this scale, and the results to date confirm this. The Mike Green segment was pretty much pure string theory/multiverse hype. Reference to the “mind-boggling predictions” of string theory misses the main problem, that there are no predictions. In particular, no predictions about the gamma-ray dispersion MAGIC is looking for, which ended the show. The 5 second discrepancy described at the end in MAGIC 2005 observations I suspect has been shown to not be plausibly due to such dispersion by later Fermi results which went unmentioned.

Comments

1. **Agreed**
   September 5, 2012

   Darn, when will these guys finally learn to NOT mention any tabood s-words in public ! Just stop talking to any science journalists, in publicly available videos, on TV, in newspapers, etc about such things and the world, in particular the blogosphere, will be much more peaceful and constructive …

2. **Shantanu**
   September 6, 2012

   I thought these Magic/Fermi results about searches for violation of lorentz invariance etc test loop quantum gravity and related models. I didn’t know they are a test of string theory.

3. **Ash**
   September 6, 2012

   I live in the UK and follow “Not even wrong” I also watched the program. The BBC does try to look at all angles, the program by enlarge is looking at the topic as a whole and was overall quite good. I would recommend trying to obtain a copy of the program somehow and bear in mind the program is televised on a nation channel and therefore has to be accessible. I would need to watch it again to pass any real comment as I often ignore/block out conjuncture on string theory.

4. **Matt Leifer**
   September 6, 2012

   Overall the programme was OK, but there was a distinct failure to separate solid science from speculation, as is often the case. There was no dissenting voice on the possibility of mini-black holes at the LHC, the string theory landscape was treated credulously and there was no mention Fermi in the context of the MAGIC results.

5. **Mike Mathison**
   September 6, 2012

   I watched the Horizon programme yesterday. The usual science-doc guff of louche theorists sipping coffee in agreeable European locations, but tempered by a refreshing emphasis on experimental verification with a lot of footage of serious looking hardware, and even people actually measuring things. The theorists were given a generous platform, but weren’t treated with complete reverence.

Here's some of the commentary on string theory (your favourite, I know): "*It's a beautifully neat idea […] There are, however, one or two problems […] These strings are so small that no one has ever seen anything remotely stringy*." On the landscape: "*If they could find the right solution [ironic pause] the right one out of one followed by five hundred zeros [another ironic pause] we'd have a neat explanation for everything in our universe*." Summing up string theory: "*For now, string theory remains a theory, with no experimental evidence for any of its mind-boggling predictions […] To stand a chance of seeing strings we'd need a particle accelerator one million billion times bigger than the LHC*" (at this point the camera sweeps away into footage of distant cable cars as we leave Michael Green, apparently stranded in some rarefied cloud-shrouded alpine idly, like some well meaning guru condemned endlessly to shuffle the arcane symbols of his beautiful but otherwise utterly unworldly theory).
Lots of stuff on MAGIC in the context of the QG segment – no mention of other (Fermi) measurements. To be as generous to the programme makers as possible you could say they were using MAGIC as an *illustration* of how to indirectly test theories (QG in this case) that operate on scales so stupefyingly small they could never be tested directly. As an illustration of the *ideas* involved I think this worked rather well, and kept in touch with their emphasis on experiment and testing… but it's a shame they didn't mention what the actual observation (now) appears to be!

6. **jg**
September 6, 2012

The comments above are accurate, I also watched the programme on Monday night and thought it was a reasonably accurate popularisation (*"…for now, String Theory remains a theory, with no experimental evidence for any of its mind-boggling predictions"*). But as others have mentioned, no recent results challenging the original 2005 MAGIC results were presented, (I was sufficiently confused that I had to go check references afterwards regarding gamma ray dispersion results)
