My guess is that they should be compatible with things like the LEP lightest chargino bound ~104GeV, the LSP should be neutral and such that the relic density is within the experimental bounds. The”right” spectrum should result in radiative EWSB as well as precision gauge coupling unification at two-loops. It should give the correct value for the Z-boson mass, etc.

84. **Peter Woit**
June 19, 2007

alex,

In other words the “right values” are the ones compatible with experiment? OK, hard to argue with that…..

85. **Karla**
June 19, 2007

I think what’s meant by the ‘right’ values are the experimentally measured superpartner masses, once they have been found by LHC. Presumably, the spectrum of superpartner masses is calculable within the model given a set of input parameters (the soft terms), and the correct superparticle masses may or may not be obtained for some value of these input parameters.

86. **alex**
June 19, 2007

Sure, if your model predicts, for example, gluino LSP then it’s obviously not the “right” spectrum. But apart from experiments, the standard precision gauge coupling unification and REWSB should also be naturally realized in the model, according to my biased opinion.

Imposter String Theorist at Stanford

June 6, 2007
Categories: Uncategorized

In recent years many people in the particle theory community have been wondering what's going on with the Stanford theory group, as it has become dominated by work on things like the anthropic landscape. It turns out that, for a while now, there was someone there who even they were wondering about. Her name is Elizabeth Okazaki, and evidently for the last four years she has

attended graduate physics seminars, used the offices reserved for doctoral and post-doctoral physics students and — for all intents and purposes made the Varian Physics Lab her home

this despite the fact that she has no formal affiliation with the university. Some press stories about this are available from [The Stanford Daily]() (more [here]()) and the [San Francisco Chronicle]().

According to the Stanford paper, students interviewed said that Okazaki:

claimed to be a visiting scholar in the humanities, looking to provide an interdisciplinary perspective on string theory. On several instances, she has said that she was working with Physics Prof. Leonard Susskind, one of the world's most respected string theorists.

but

Susskind told The Daily that Okazaki was not officially associated with him or his lab in any way.

"As far as I know, she has no official connection with anyone in the physics department," Susskind said. "In fact, as far as I can tell, she has a very limited knowledge of physics itself."

The story in The Stanford Daily on-line has a long associated comment thread, containing (besides a lot of nonsense) some comments from people in the Stanford physics department that provide more insight into the situation.

The San Francisco Chronicle article quotes Stanford graduate student Surjeet Rajendran about the situation as follows:

A university has a lot of weird people… Some of the faculty are weird, some of the grad students are weird. So you don't really know who's who. And you feel rather, I guess, rude asking them, 'What the hell are you doing?'

For another perspective on this, see Scott Aaronson's posting on [The Groupies of Science](), where he makes the point that "Science Needs More Groupies, Not Less", and argues that:

When we discover a stowaway on the great Ship of Science, why throw her overboard when we could make her swab the decks?

Comments

1. **island**
   June 6, 2007

   Swab the decks???… Imposter???… Hell, she's bound to be the closest thing to a real physicist in the whole department… and they should put her in charge of it… 😉

2. **Professor Doctor Fatrear**
   June 6, 2007

   I find the title of your post completely disingenuous. This woman was the typical friendly crackpot/nutjob that can be found in the halls of every math/physics department in which I have ever spent even a few days. To call he an `impostor string theorist' suggests that string theory has something to do with her situation, which it clearly doesn't in any serious sense.

   These people survive because people's hearts are mostly kind and no one feels like going to the (sometimes considerable) effort of driving away a mostly harmless occassional nuisance.

   The nutjobs with tenure are different matter.

3. **Michele**
   June 6, 2007

   Dear Peter,
   I would you like to thank You for Your advices. I've determined to read Your new book.
   I'm now writing you because I want ask You with regard the "Loop Quantum Gravity", You think that it can be a good alternative theory as regards the string theory?

4. **Peter Woit**
   June 6, 2007

   PDF,

   The title of my post is not "completely disingenuous", it is only partly disingenuous. Sure, I'm making a bit of fun of the Stanford string theorists, perhaps somewhat unfairly. On the other hand, given Susskind's behavior over the past few years, I don't think it's a coincidence that this woman without a firm grasp on reality decided to claim affiliation with him, or that she gravitated to string theory rather than some other subject.

   Not knowing the details of the Stanford situation, I'm not expressing any opinion about what they should have done or not done, or criticizing them about this. Academia's tolerance of eccentricity and various hangers-on is a good thing and I see nothing wrong with this, quite the opposite. People like Okazaki do put one in a difficult position about what to do about them.

5. **Peter Woit**

June 6, 2007

Michele,

LQG is really off-topic here and I don't want to start up a discussion of it. Personally I choose to concentrate on particle physics, not quantum gravity, since only in that case does one have good hopes of testing one's ideas if they're successful. Among approaches to quantum gravity, LQG seems to me a very interesting one, with some appealing features. But again, this is another topic, and the last thing I want to do is have another bout of LQG vs. string theory warfare going on here.

6. **Professor Doctor Fatrear**
June 6, 2007

I've seen a woman without a firm grasp on reality gravitate to singular integral operators and a scrawny man who understood them very well. I remember a departmental stalker who was very into Penrose tilings, convinced half the department had it in for him, and spent a lot of time promoting basic physics on the web. These people are complicated, show up everywhere and in all disciplines, and have their good points as well as their bad ones. What happens in math and physics is that we can tell the difference between crackpots and people with wild ideas because we have some more or less objective criteria to work with (fortunately there are no objective criteria in music). On the other hand, you seem to be implying that Susskind also does not have a firm grasp on reality, and that seems a bit extreme; even were he a pathologically lying sycophant of the dean citing himself in every one of his two hundred repetetive articles, his behavior would be well within academic norms, and I guess he is not that bad.

7. **Aaron Bergman**
June 6, 2007

I've seen a woman without a firm grasp on reality gravitate to singular integral operators and a scrawny man who understood them very well.

I've seen things you people wouldn't believe. Attack ships on fire off the shoulder of Orion. I watched C-beams glitter in the dark near the Tannhauser gate. All those moments will be lost in time, like tears in rain. Time to die.

(sorry)

8. **Peter Woit**
June 6, 2007

PDF,

I don't disagree with your characterization of the various types that inhabit academia. But yes, I happen to think that Susskind and other promoters of the anthropic landscape (quite a few of whom are based at Stanford) don't have a firm grasp on reality, not in their everyday lives, but in the specific research program they have chosen to pursue. Sure, this is not really out of academic norms, which involve tolerating some degree of research of dubious sanity. But (see previous posting), the fact that this stuff is becoming increasingly influential and popular at the very center of the field is pretty disturbing.

9. **Stanford grad student**
June 6, 2007

There's been a bit of a mischaracterization in the media, I think, of Elizabeth Okazaki's situation. It's been made to sound as if she was a crackpot looking to rub elbows with the string theorists, hoping to push her theories. In reality, I think that her interest in science, if she even has one, was entirely peripheral to her actual goal, which was to live in the building. This was a point that the news reports tended to underemphasize, that she lived in, as in literally slept in and ate in and occupied space in, the physics building for four years, and that this was what was freaking out the grad students. She is a homeless person, and she saw a great opportunity to take up residence in a building full of people who, as we saw, wouldn't bother her, so she did. (And frankly, who can blame her? If I had to choose between the streets and the student lounge of the physics building, I'd do the same thing she did.)

Anything to do with string theory or attending seminars or claiming to work for Lenny Susskind was just part of her cover story. "Wait, who are you? What are you doing here?" "Oh, I, uh, work for Lenny Susskind, yeah, that's it." "Hmm, all right, carry on."

This is why I found it amusing that Lenny would focus on the fact that "she has a very limited knowledge of physics itself." He, like many others, missed the point entirely; she wasn't there for the physics, she was there for the roof.

10. **jhk**
June 6, 2007

Quite entertaining, but really nothing out of the ordinary. When I was at Stanford there were much weirder people hanging around the department.

If you're ever at Stanford, be sure to go to the physics library and look up a Ph.D. thesis by a Mr. Kenneth Uzo. And be sure to look at which faculty members signed off on it.

11. **anon.**
June 6, 2007

'Some of the faculty are weird, some of the grad students are weird. So you don't really know who's who.' – Surjeet Rajendran

All faculty and graduate students should wear suits (as was the case until the 60s hippy culture came in). Better still, they should be forced to wear a beard and smoke a pipe (as occurred a century ago).

12. **lostsoul Ph. D.**
June 6, 2007

I have always depended on the kindness of stringers

13. **stevenm**
June 6, 2007

From the article:
"If she were a large, intimidating man, there's no doubt that something would be done," he said. "There's a huge bias against appearances and it's prevented people from taking action. I can't see any reason why our department is special. This could really happen all over the place."

I can testify to this. My hobbies have always been weightlifting and weight training and when I studied in the US I slept in the offices overnight for a while at one point (with permission) while trying to find an apartment. Then one night I had an encounter with two security guys who were doing their rounds about 2am, and who quickly called for backup. I did have the appropriate ID and explained the situation. After that on subsequent nights they did'nt bother. I think they assumed I had something to do with the football team. This was a private university within the top 10 in the US and they had resources, and so security was quite tight. This was also back in the 90s before 9/11 and the paranoia that followed. There were also signs on the outside doors (and which you needed an electronic key to open) saying that anyone on the premises who had no right to be there would be prosecuted and probably jailed. The tolerance in the Stanford situation only persisted because it involved a small asian woman who no-one perceived to be a threat. A man of middle-eastern origin, a black man or scary white men (like myself :)) doing the same thing would be very quicky dealt with.

14. **Coin**
June 6, 2007

…so, um, is it bad that when initially confronted with a story about someone just persistently showing up at grad student seminars and pretending as if they belonged there, my initial response is "Whoa! That sounds like a pretty good idea! I wonder if I could get away with that?"

^_^;

I do want to agree with "Stanford grad student" that it is really important here to distinguish between what Scott Aaronson is calling "Groupies of Physics", and someone who is simply a homeless person pretending to be a student in order to gain access to the facilities. The distinction is important because the latter aren't fundamentally interested in science, just not freezing. I also think the latter are more common than most people realize (though I don't think most aim as high as Ms. Okazaki did)– I knew of at least one at my college who I eventually figured out was literally living in the 24-hour computer lab…

15. **anon**
June 6, 2007

I think Scott Aaronson's opinion is quite shallow. If academia wants to forge honest ties with society, they can do no better than to collaborate with private industry and entrepeneurs, so that real jobs, in the periphery of physics, are created. Scott wants groupies, and he wants to hire them to "swab the decks". Only someone who thinks he is so special he should have serfs to serve him would think that way. College Professors already have a bunch of poorly paid workers(graduate students) who write papers for them. Do these aristocrats need an additional class of poorly paid servants

16. **lostsoul Ph. D.**
June 6, 2007

Stevenm

She could have been a ninja in drag. Way back, when I was a post grad in Cambridge UK, a dude used to crash out at a course I attended. He was middle aged, smelly and, as the young might have it, gross. And he snored. And yet he took the whole course; he was given the benefit of the doubt. And, no, it wasn't Perelman. If it were not for the fear instilled by those who hope to govern us, we could all kick back and make , within reason, a little bit of space for others.

17. **Puny Geek**
June 6, 2007

Stevenm says: "The tolerance in the Stanford situation only persisted because it involved a small asian woman who no-one perceived to be a threat."

I generally agree with the comment above, except that #1 Asian women are not always small (but generally are). and #2 If she was a young attractive white woman, she wouldn't have been annoyed by others, much less getting kicked out.

I have seen so many cases when an attractive white/caucasoid woman was treated much better than an attractive asian woman, unless the asian woman is an object of fetishism. From my observation, the attitude towards women in male-dominated society seems pretty harsh, unless the women is super smart, "HOT" by their standard, or submissive to the males.

Of course, I cannot make a judgement about the case without knowing all the details, and I think a stranger *living* in a department is rediculous.

18. **Changcho**
June 6, 2007

Yes, I've met Susskind and I think the post was a just a little bit unfair to him. I believe I've seen situations similar to this in LeConte as well. The situation seems pretty much to be like what "stanford grad student" wrote.

To A. Bergman, that was great! Those lines from Blade Runner have always stayed with me ever since I saw the movie for the first time.

19. **Peter Woit**
June 6, 2007

jhk,

Googling out of curiosity turns up the following from the Palo Alto newspaper in 1997

"OUT OF THE CLOSET . . . When a Stanford math professor smelled smoke as he prepared students for a midterm exam last week, he followed its source to a nearby closet. Inside was a man sitting, smoking a pipe. "Can I help you?" the man asked as the math professor opened the closet door, according to Stanford police captain Raoul Niemeyer. The man–37-year-old Kenneth Uzo of Fremont–asked the professor if he would please close the door. The professor did so and then called the police. Niemeyer said that Uzo, who graduated from Stanford in 1992 with a Ph.D. in physics, is known to Stanford police as a habitual trespasser. He has been issued with a stay-away letter, Niemeyer said."

I wouldn't criticize anyone for signing off on the Ph.D. thesis of a problematic student. Put yourself in their position: you look at the thesis, you have some sort of thesis defense. Even if it's pretty bad, you then have two choices.

1. Pass the student, at which point the department has no more official connection to them and you can reasonably expect them to leave and not be heard from again.

2. Fail the student, in which case they'll presumably continue as a student, working on an "improved" thesis, and you'll have to keep dealing with whatever their undesirable behavior was.

20. **LDM**
June 6, 2007

Educators in academia who typically are supported by our tax dollars should be reminded that they are role models and one of their jobs outside of research is to develop the minds of their students. They are not being paid to exploit groupies… and encouraging and/or recruiting groupies would be ethically questionable.
NOW, to put this in perspective, some years ago, a young man named Steven Spielberg did a similar thing at Universal Studios. He would show up everyday and pretend to be an employee so that he could study his craft by watching films being made and by associating with people who were already doing what he wanted to do. The guards assumed he was an employee as did everyone else. And eventually, his knowledge of film making impressed Universal Studios sufficiently that he was given a seven year contract, before the age of 21. I don't think he was ever called a groupie.

21. **Ron**
June 6, 2007

I hope these two incidents back to back (Elizabeth Okazaki and Azia Kim) don't create a backlash to make Stanford a less trusting and open community. I attended as an undergraduate between '84 and '90, stopping out every other six months to work my way through school. Their policies were very student-friendly: one could leave at any time and return at any time, no questions asked. While working, I still spent a fair bit of time on campus between being enrolled. It is easy to see how Okazaki and Kim were able to take advantage of the situation. I've done so myself in other circumstances. http://www.PacificT.com/Story Stanford's trust in and respect for its students are a good thing.

22. **Fabien Besnard**
June 7, 2007

I also have some anecdotes about strange people in academia… One that I have witnessed myself is about a guy at Jussieu campus. He was always in the library whatever the hour, whatever the day. Nobody I talked to could tell me who he was. He read all kind of books, generaly in few minutes only… He had been nicknamed the ghost of the library. Someone told me, but I can't vouch for that, that he was seen someday on his knees in the middle of the street, holding a sing reading 'je veux une femme !" (I want a woman !).

23. **J**
June 7, 2007

Interesting. What is more interesting is that we have a similar guy here in China, a guy named Jia-zhong Chen. He stated that he is a professor of Harvard and somehow managed to get a position in one of the top universities (Zhejiang University) in China as a visiting scholar. He also claimed that he had published several "important" papers in PRL, which is not true. There are some other fake stuff that he has used for his cheating behavior. Oh, by the way, he even has never been accepted by any graduate school.

24. **jhk**
June 7, 2007

From the comments to the Stanford Daily article: " it sounded like she was regularly getting in and out of relationships with different guys around Varian as well as SLAC." I know being a grad student or postdoc can get pretty lonely, I wonder how many guys took the bait.

25. **Jonathan Vos Post**
June 7, 2007

Though Scott might not repair washing machines to keep groupies around, I suspect that he would repair Turing machines.

Are science fiction authors a kind of "science groupies"? Science fiction readers? People who subscribe to Scientific American? People who blog about science? People who watched "A Beautiful Mind" or "Goodwill Hunting" or "A Brief History of Time" or the hit CBS-TV show "NUMB3RS?" People who attend lectures for the free coffee and cookies beforehand?

Some "science groupies" — a small fraction, but not zero — become productive scientists. The outstanding examples include Fritz Zwicky.

There is an overlap between "science groupies" and crackpots. Howveer, it can be NP to distinguish these. One generation's crackpots includes the next generation's pioneers of the paradigm. Crackpots know this.

Living 5 miles from the Caltech campus, where I earned my first degrees, I visit campus at least once a week, attending seminars, chatting with professors, students, staff. Since I am not currently a professor (have been, in 2 fields) — does that make me a groupie?

Secretaries at Caltech, especially Math and Physics are trained to handle crackpots who walk in with manuscripts on proving Einstein wrong, squaring the circle, classifying solutions of Fermat's Last Theorem, and the like. The secretaries tell me that the crackpots sometimes explain that they hope, by dropping off their manuscripts, to instantly become professors, when their genius is recognized, a la Ramanujan.

Is any nonscientist who dates a scientist actually a science groupie? How do you know that?

The last time that I saw people living in a dorm who were not students, they turned out to be a pair of rogue cops doing an unauthorized undercover recreational drug sting, and busted an essentially innocent senior the day before he graduated, having had to have his parents, just arrived in town for the ceremony, bail him out of jail.

Which reminds me. Tomorrow is the simultaneous Caltech Presidential Inauguration and graduation, with Jared Diamond as commencement speaker. Dr. Jean-Lou Chameau, who has served as Caltech's president since September 1, 2006, will be inaugurated in a simple ceremony at the start of Caltech's 113th annual commencement on June 8. This bucks the tradition of university presidential inaugurations that involve a week of lectures and dinners, capped off with a large inauguration ceremony. Chameau felt his inaugural should reflect his priorities. Within the audience, how many of the people should one characterize as groupies?

Groupies? Drugs, sex, rock & roll, and quanta.

26. **Brain Greeen**
June 7, 2007

Clearly Peter is a string groupie, someone who tries to put meaning in his own life from string theorists' reflected glory.

27. **Michael**
June 7, 2007

The story would have been much more relevant (cooler) had Okazaki actually been interested in the physics at Stanford. Still, her situation is, though unknown to most, a minor but definitely important breach of a very expansive and secretive contingency within the halls of America's most heralded institutions:

Here we are then, countrymen. Artists who would be starving and homeless as well, we work by day in research-and we've come to love science: i do-but i am no scientist of your trimmings, Peter Woit. And yet the title hangs on my door as i type.

But what business do "they" have here?? Here? In this well-fenced depot of creativity? One might surmise they have merely been fortunate enough to mistake the gatekeeper for a teacher.

And so it goes that science brains reduced are, simply, obsessively objective artist brains who choose to model their reality with quantities over colors, tones, and words. Perhaps you will see it other way around. Modelers of observation. All of us. Just happens to be that the spies are justifiably more eager to spray their notings rudely, if even astutely on the walls of the Colluseum. Good clean, class penetrance I suppose. Wait. Is that what we're afraid of?

28. **MathPhys**
June 8, 2007

I liked very much the statement that "A university has a lot of weird people… Some of the faculty are weird, some of the grad students are weird".

How true. In fact, universities that have policies that one way or another bans such people, are not universities. They are businesses or something, but not seriously academic universities.

29. **Chris W.**
June 8, 2007

More or less in this vein, read and listen to Ron Avitzur tell "The Graphing Calculator Story," about developing software at Apple (for the first Power PC Macs) as an unpaid former contractor who had to sneak into the building in which he was working.

(By the way, Avitzur is a Stanford graduate; he was a physics major who subsequently moved into software engineering.)

30. **Ron**
June 8, 2007

While working sixteen hour days, seven day weeks, months on end, unpaid, folks at Apple occasionally said to me: "I see you here when I get in in the morning. I see you here when I leave at night. And I'm working twelve hour days! What are you doing?!" I looked them in the eye and said in a deadpan voice: *I'm in training for physics graduate school.*My Stanford experience prepared me for working at Apple. My fellow undergraduates had a theorem regarding the difficult nature of our studies: either we had been through worse already and could handle it, or if we had not been through worse before this would set the standard by which all future troubles would be compared so that after this nothing would phase us.

31. **More Asian Female Squatters, please.**
June 8, 2007

The Okazaki girl was kicked out as a byproduct of the A. Kim dorm-squatting case, i.e., people contacted the Stanford student newspaper about her case once the Kim story broke.

32. **Stanford grad student**
June 8, 2007

The Okazaki girl was kicked out as a byproduct of the A. Kim dorm-squatting case, i.e., people contacted the Stanford student newspaper about her case once the Kim story broke.

Well, it was the perfect opportunity. There had been complaints about Okazaki for years, and the department dragged its heels like hell.

33. **Chris W.**
June 9, 2007

*..nothing would **phase** us.*

That should have been "faze," but "phase" is an understandable substitution for a physicist or engineer. Perhaps it was a double entendre. 🙂

(No knock intended; as you'll see from his narrative, Ron is an excellent writer.)

34. **what?**
June 10, 2007

I've read every comment in this post and I still don't understand what a homeless girl living in the Stanford physics building has to do with string theory.

35. **Peter Woit**
June 10, 2007

what?

Instead of reading the comments, you might try readng the posting where I quoted part of the article that explained that this woman was passing herself off as a visiting scholar in the humanities, in the physics department because she was working on string theory with Susskind.

36. **MathGirl**
June 12, 2007

Better still, they should be forced to wear a beard and smoke a pipe (as occurred a century ago).
Oh yes, like in the good old days, when women weren't allowed at universities at all…

37. **surlygrad**
June 12, 2007

I totally understand the part about why no one bothered her. We had a student who, for reasons not to be discussed, lost his funding, and decided to just move into the grad student offices (eat, sleep, etc.). The rest of us really had no idea how to react or deal with the situation. It was unpleasant and there were hygiene issues

Eventually things got straightened out (the student got funding again), but it was very very weird and awkward for about six months.

38. **a.k.**
June 28, 2007

one could wonder if anyone was interested what happened to Okazaki after she had been 'kicked out' of the department, it is interesting to note the low degree of 'solidarity' (in a yet to be defined way) with her situation reflected in the above postings, whether she had been actually interested in physics from any valid viewpoint or not or did academic work in any valuable way in these four years or not- her fate (and those similar cases described described above) exemplifies what in europe would be cosidered as 'the darker side of america' and explains why hardly anyone, for instance in germany, tends to deny the value of certain achieved social standards, i.e. to formulate certain rights concerning appartment and minmum social funding.

39. **kathleen_conformal_strings**
July 12, 2007

Hmm…

I think someone like that could be a nice addition to any physics or math department… Her funny presence could be a form of relief as well as mourn all bundled up with a bit of curiosity, compassion, and disgust.

I've seen her in the department myself. I can't speak of this lady as being very distinct from any weirdo to whom I would go to interact with… There are others which appear and disappear with changing mood.

She's a confused person herself and it's remarkable how she tries to be as ecstatic as possible in that confusion. Alas, her confusion has seeped into the minds of all the geeks there and turned their being from inside out, rather unnecessarily.

Why oh why, just leave her alone, guys. Is it surprising that such people with their wierd (but reasonable) sets of intrigues exist? Don't let this dueling go on for decades, coz' who knows it wears someone out. Otherwise, let's just commit to confusion and see if it all can be reasoned necessary.

It all just leaves me laughing…

Back to quantum conformal gravity, Pontrjagin, and superpotentials…

Dispute Chez Les Physiciens

June 7, 2007
Categories: Uncategorized

Yesterday evening there was a public debate about string theory held in Paris, between Lee Smolin and Thibault Damour. So far, accounts of the debate have appeared in Le Monde and at Fabien Besnard's blog Mathephysique.

The Le Monde article is not very informative, but indicates that Damour defended string theory against charges that it was not testable by claiming that it predicted "possible classes of experimentally testable phenomena" at the LHC. Besnard gives a more detailed account, describing how Damour answered these charges of lack of testability with: "Lee, a subtle thinker, surely doesn't believe himself the naive Popperian position he is defending". He also evidently claimed that string theory was testable because it would be confirmed if a violation of the equivalence principle was found (he really should talk to Lubos, see here). Remarkably, he also claimed that observation of the kind of DSR dispersion relations that Smolin thinks LQG leads to would not be a problem for string theory, since one could also get them out of string theory (here I think he needs to talk to both Lubos and Jacques Distler).

Update: I hear that the event was recorded, and audio should be available by the end of the week at the web-site linked to above.

Comments

1. **Aaron Bergman**
   June 7, 2007

   This translation is from google, so I apologize if it gets it wrong:

   > LS explained why certain violations of the relativistic relation of dispersion were predicted by the quantum theory with loops, and that if they were not observed, that would refute the theory,

   Strange, isn't it, how Lee always leaves that (incorrect) impression.

   It's worth pointing out that while most of the scientific community works by some combination of positivism and falsificationism (which isn't nearly as contradictory as historically indicated), the philosophy of science has moved beyond both as I understand it. There's a lot of stuff out there about the problems with "naive falsificationism", for example — I'd guess that's what Damour is referring to.

2. **Peter Woit**
   June 7, 2007

   Aaron,

   The way string theorists are hiding behind philosophy of science is just ridiculous and less than honest. String theory makes no predictions, that's all there is to say about it right now. You can honestly argue that maybe once we understand non-perturbative string theory, this will change, but invoking subtleties about the philosophy of science to claim that string theory really is testable is just dishonest. And claiming that string theory can be tested by looking for violations of the equivalence principle is just absurd.

3. **Aaron Bergman**
   June 7, 2007

   And here I thought I was just clarifying a point of philosophy….

4. **anon.**
   June 7, 2007

   Babelfish translations: Le Monde and Mathéphysique.

5. **Lee Smolin**
   June 7, 2007

   Aaron,

   Please listen to the recording. I was quite precise. I said that LQG pointed to possible new phenomena which were characteristic quantum gravity effects. I gave as an example of such a possible phenomena, DSR , but I also said that there were no agreed upon precise predictions. I also said that I had written a paper deriving such an effect at a semiclassical level, but without a precise coefficient, and I also emphasized that my more rigorous colleagues were as yet unconvinced by this. I also said at least one other time that neither string theory nor LQG had so far made precise predictions by which they could be falsified.

   Lee

6. **Coin**
   June 7, 2007

   > **The cords of the discord agitate the cosmologists**
   >
   > C ' is a scientific argument with old. A controversy as the time offers any hardly any more. Wednesday June 6, in the City of sciences, in front of several hundreds of researchers, students or simple curious, two scientists of high flight discussed one of most attractive – and more inaccessible for the common run of people – constructions of physics: the theory of the cords. For the charge, the American Lee Smolin, researcher in Institut Perimeter of Ontario and signatory of the lampoonist *Nothing goes any more in physics* (Dunod, 2007).

   Oh, how I love Babelfish. I think their new name for Smolin's book is maybe actually an improvement.

7. **Aaron Bergman**
   June 7, 2007

   I don't know what you said; there doesn't appear to be a recording available yet. What I was commenting on is the continuing propensity (and the above is far from the only instance of this) of your listeners to come away with the impression that deformed dispersion relations are a prediction of LQG.

It seems odd, no?

8. **Yatima**
June 7, 2007

Babelfish serendipity:

…and signatory of the lampoonist ***Nothing goes any more in physics*** *(Dunod, 2007).*

That is actually the correct translation for the french title "Rien ne va plus en physique". Far stronger than "The trouble with…".

"lampoonist", however, is clearly wrong – "pamphlétaire" has the meaning of "written by a firebrand".

In other news, one can detect despondency at [Slate](), whereby the tought of the Standard Model soon being buttressed by a Higgs sighting and not much happening thereafter causes depression. Strings only feature on page 2:

But what happens if the Higgs turns out to be just right? Well, then the standard model predicts that you'd need a machine roughly a quadrillion times more powerful than the LHC to find anything new. (…) Though some theorists—proponents, for instance, of string theory—speculate about what such an accelerator might find, few other physicists take them seriously.

9. **Coin**
June 7, 2007

Yatima: Ah, thanks for clarifying.

10. **Garbarge**
June 7, 2007

"And claiming that string theory can be tested by looking for violations of the equivalence principle is just absurd."

I dont think that is absurd, I actually believe that is a very important venue. If GR is *wrong*, and not just due to higher order curvature effects, then we will know for sure ST, in its current form, cannot be right. The same about Lorentz Invariance, unitarity and analyticity.
The quibble though lies on how big of an effect can this be and whether can it be measurable. To attack the building blocks of a theory, otherwise adjustable to 10^500 different scenarios, sounds like the only possible route to success (or failure depending on which side you want to jump on). What's wrong with testing the only few properties all these vacuum solutions actually share!

Of course, violations of these sacred principles will radically modify our views and intuition about the world, but as a side dish will put the ST community on stage for a big change whereas LQG people may even celebrate after all 😉

11. **Peter Woit**
June 7, 2007

Garbage,

My objection is to what I take to be Damour's claim that an observation of a violation of the equivalence principle would be evidence for string theory. If you believe Lubos, string theory predicts no violation of the equivalence principle, if you believe Damour, it predicts a violation. They need to get their story straight, but can't, because string theory can accomodate virtually anything.

12. **theoreticalminimum**
June 7, 2007

I have a problem with this rhetoric:
"*"le désaccord sera toujours nécessaire à l'avancée de la science"***"** ["disagreement will always be necessary for the advancement of science."]
This statement is, I believe, vacuous and incorrect. I think that, within a community consisting of different groups of people motivated in exploring different ideas, disagreement will always naturally occur when these ideas are confronted with each other, or with any form of philosophical discussion. What really counts as progress in science is that, at some point, repeated confrontations bring the members of the community to realise that they have to agree on the correctness or incorrectness of an idea. This agreement is the advancement. Unless we can all agree that some theory is right or wrong, we can spend decades disagreeing, and science will not take a definite step forward. In other words, disagreement is necessary for the exploration of ideas, but ultimately, we have to agree on what makes sense so that we can move on.

13. **Fabien Besnard**
June 8, 2007

Lee, I wish I were more precise about your statements on my blog. Indeed you emphasised that LQG does not yet make precise predictions everyone agrees about, and I'll make an update. Still, I think the point is not really there, it is more a matter of principles. If I understood well, you wanted to show that in principle LQG is falsifiable, and when you asked Damour about the impact of DSR, should it be observed, on string theory, his answer was that ST could accomodate both DSR and no DSR. Would you agree with this version ? This is why I said that in principle, supposing some consensus is reached in the LQG community about DSR and supposing GLAST experiment sees it, one would be a in strange situation with in one hand a falsifiable theory passing a popperian test and on the other hand an incompatible, non-popperian one, claiming it does not care…

14. **Fabien Besnard**
June 8, 2007

I must also say that Thibault Damour never said that String Theory could be confirmed by some experiments at the LHC, contrarily to what the Le Monde article says. In fact, if I correctly recall, TD said he was not optimistic about this.

15. **Bee**
June 8, 2007

Hi Peter,
thanks for the links, should listen to that audio. Reg DSR, this is quite ironic. I am reasonably sure there is a comment of mine from last year somewhere in the blogosphere that says I'm waiting for a string theorist to claim they can have DSR as well. I'm just done with the String Pheno conference, giving a talk (half-ways) about

DSR – can't say I had the impression anybody was particularly interested in it (but then, it was before the first coffee break…). Best,
B.

16. **Brett**
June 8, 2007

The claim that string theory can't violate the equivalence principle or Lorentz invariance isn't justified either. It's very hard to study nonperturbative effects in string theories, but in off shell string field theory, there are operators that certainly could give rise to spontaneous breaking of these symmetries. In the twenty-six dimensional bosonic version, it seems that this does not actually occur, but at the same time, there doesn't appear to be a fundamental reason why this is so; it's just a matter of which local minimum happens to the global extremum of the effective potential. And for more "realistic" string theories, the question is still open.

17. **Question for Aaron**
June 8, 2007

Aaron Bergman wrote:

"I don't know what you said; there doesn't appear to be a recording available yet. What I was commenting on is the continuing propensity (and the above is far from the only instance of this) of your listeners to come away with the impression that deformed dispersion relations are a prediction of LQG.

It seems odd, no?"

I assume Aaron is just as scandalized by, and as prone to criticize, the much larger number of instances where string theory papers or lecture(r)s leave their audience with the impression that string theory makes predictions comparable to the above. That should go without saying, right?

18. **Aaron Bergman**
June 8, 2007

Everyone can be prone to overstatement, but string theorists haven't gone out writing books trashing their colleagues and setting themselves up as standard-bearers of scientific virtue.

19. **anon.**
June 8, 2007

'… but string theorists haven't gone out writing books trashing their colleagues and setting themselves up as standard-bearers of scientific virtue..' – Aaron

That's the problem! Instead of going out and trashing not-even-wrong hype and 'setting themselves up as standard-bearers of scientific virtue', they do the opposite…

20. **Question Answered.**
June 8, 2007

So the "overstatement" of LQG predictions is not different from string theorists' numerous overstatement of stringy predictions, but Aaron finds other reasons for criticizing only the first? Thanks for confirming that the diss was bullshit.

21. **woit**
June 8, 2007

QA,

I think I see what Aaron is saying. He's attacking someone from outside his group for doing something that he wouldn't criticize if it were done by someone inside his group, because that outsider accused people in his group of engaging in "groupthink" behavior.

Sorry Aaron, I know the above is a bit unfair. But, you know, string theorists would get a lot more sympathy if there were evidence of significant internal criticism by string theorists of the excesses going on in their own community. Some days I feel like sending a bill to some leaders of the string theory community for doing work that they should be doing.

22. **Aaron Bergman**
June 8, 2007

Actually, it seems to me that you're acceding that it was perfectly legit.

If your only response is that, well, string theorists make overstatements too, then perhaps we're all kinda the same. There are people who are overly enthusiastic and curmudgeon's all around. Nobody is more blinded by groupthink than anyone else, and there are mountain climbers and valley crossers everywhere. Lots of people are doing their best to figure out hard problems, and there's no monopoly on virtue centered in Ontario.

Which was sort of my point.

HTH!

23. **Aaron Bergman**
June 8, 2007

To PW: I don't like to criticize my colleagues in public because I generally don't think it's, well, collegial. LS, on the other hand, has chosen to write an book, a fair fraction of which, his protestations to the contrary, is precisely attacking his colleagues. I think that makes his own hypocrisies fair game, and I don't feel particularly collegial towards him.

24. **Chris Oakley**
June 8, 2007

Aaron & others,

The important issue for the select group to which most of you belong — a group financed by tax dollars — is to carry out your mission of discovering the workings of nature with the maximum of energy and integrity. If anyone wants loyalty, they should get a Cocker Spaniel. This so-called quality is totally contrary to the spirit of scientific enquiry and leads to the kinds of closed shops that Peter W., amongst others, has been justifiably complaining about all along.

25. **Aaron Bergman**
June 8, 2007

I don't think exposing the private fights of science (not all of which are substantive) to the public helps anyone.

(Of course, with the recent recording of talks at conferences and the like, the line between public and private has been somewhat blurred.)

26. **Coin**
June 8, 2007

I don't think exposing the private fights of science (not all of which are substantive) to the public helps anyone.

As a member of the public, I kind of have to say I disagree.

The public of course shouldn't be *settling* scientific disagreements or whatever, but I think keeping people informed is an unqualified good unto itself.

27. **tomj**
June 8, 2007

Here is an idea: when physicists use ordinary language, and pretend that the ordinary meaning somewhat applies to what they are talking about, then ordinary idiots which understand the ordinary meaning have every right to ask questions.

My main complaint with much of modern physics is that common words (not phrases or sentences) are used to describe or tag new ideas. The effect is very similar to teenagers overusing common language for new (private) meanings. Forget about the philosophy of science, how about the philosophy of language? People who call themselves scientists and who can't get these basic philosophies right probably shouldn't be proposing theories.

A philosophy is a framework, it contains principles, ways of comparing more concrete frameworks. Even theories are frameworks, but they are of a more concrete nature. String Theory and the Landscape bs appear to be meta-frameworks, above theory, similar to a philosophy. Viewed in this way, it is easy to see why you cannot disprove it: it is above theory. Only theory deals with data.

The problem with these meta-frameworks is that they use mathematical language as a means of definition. The effect is to mismatch the language with the level of use. Example: if the general principle of relativity can be described as a result of assuming that the laws of nature are the same in any inertial frame (as defined in GR), which is a pretty simple philosophical principle, how can a heavily mathematical theory be somehow above this? Mathematics is not going to be above philosophy. Experiment and the resultant data is not going to be above theory. And by above, I don't mean more important. Experiment and data are the foundation. You cannot throw out data based upon a new theory or philosophy. This is exactly what is happening with ST, etc. These are frameworks, above theory, somewhere near philosophy.

But the problem: philosophy and the resultant frameworks are relatively easy to describe, even if the implications are difficult or impossible to appreciate. ST, etc. somehow fail this test in a huge way. Somehow the details are chased around in an attempt to connect them with experiment or even theory. Unable to catch up with the facts, with data, the only thing left is a repudiation of the theories which are based upon the known facts. It is almost like concluding that the speed of light is infinite because nothing can catch up to it.

28. **Lee Smolin**
June 8, 2007

Dear Fabien,

Check the recording when it is available, but what I remember Thibault said is that string theory could accomodate broken lorentz invariance, as there are many vacua that have this property. Given that this was a non-technical debate in front of a popular audience I choose not to belabour the difference between broken and deformed lorentz invariance (which I suspect he understands well.) From what I know, no one has demostrated a form of interacting string theory consistent with deformed lorentz invariance, although Magueijo and I found evidence for consistent free bosonic string theories with this property. I know of string theorists who are now working on this problem, and from a much deeper point of view, but so far as I know they have not published yet.

Aaron, your whole discussion assumes that I exaggerated. I insist that a listen to the tape will show what I said was quite precise and true, indeed I went out of my way to emphasize that 1) many of my colleagues do not think there is strong enough theoretical evidence for the conclusion that 3+1 LQG is DSR and 2) even me who thinks there is agrees that I can only calculate the effect semiclassically up to an undetermined dimensionless constant.

29. **Aaron Bergman**
June 8, 2007

I insist that a listen to the tape will show what I said was quite precise and true

That may be true, but it's not my point. As I have already stated said point in multiple threads, I won't belabor it any further.

30. **M**
June 9, 2007

Aaron, around 1995 the LSND collaboration published a paper claiming a new discovery and one young member of the collaboration, instead of signing the collegial paper, published another single-author paper explaining why he did not believe in the result.

In the same years, no young string theorist questioned the mono-vacuistic ideology of string gurus, or complained about how the theory was irrealisticaly presented to the public.

Sometimes good science needs a departure from loyalty.

31. **Bee**
June 9, 2007

Hey Tomj,

philosophy and the resultant frameworks are relatively easy to describe, even if the implications are difficult or impossible to appreciate

Whether or not you think philosophy is 'relatively' easy is a very relative statement. I happen to think maths is much easier than philosophy for the 'simple' reason that it only deals with well defined objects and not to a considerable amount with interpretations of words or juggling with undefined things. I have no idea what you want to say with your comment, do you think physicists should not use words from the 'ordinary language' to describe objects because it might confuse the public?

Forget about the philosophy of science, how about the philosophy of language? People who call themselves scientists and who can't get these basic philosophies right probably shouldn't be proposing theories.

Well, the problem is that 'the public' most often doesn't understand that the theory is not made out of words but of equations. Every description that tries to avoid these equations might seem simpler but is never quite as accurate, and rarely manages to capture the elegance of an idea (my opinion). The obvious way to avoid this is just to learn the 'language' of mathematics, instead of accusing scientists to abuse 'ordinary' language. 'Reading' maths is neither a mystery nor complicated to learn (definitely not more complicated than, say, Polish), it's just a way to decipher equations. Whether you learn how to 'speak' it, is another issue. I'd wish the prejudice that maths is a nerdy thing (whereas French isn't) would end up in the trash bin. This trend however is supported by dropping equations from pop sci books, and articles etc. because it 'scares' the readers.

Best,

B.

32. **Bee**
June 9, 2007

Oh, and regarding DSR and so on, see e.g.

DSR
The Minimal Length Scale

or the slides to my yesterday's talk. Currently too tired to repeat what I've written there. The point is instead of understanding st as a theory of an extended object with standard SR, I am considering a model of 'standard' point particles with the additional property of reproducing the presence of a minimal lenght alias UV regulator or generalized uncertainty relation respectively. Thus, strings with standard SR are instead described by point particles with funny special relativistic properties (applies off shell). Plus point is, it's not necessarily an string-only approach (the only assumption I make is that the underlying theory has something like a minimal length). Differences to DSR Lee is talking about can be found in hep-th/0603032 (there are several, the most important one being my modification is offshell only, see also gr-qc/0412004 cmp. section IV about the Snyder basis and note that p^2 is the square of the four- not the three momentum). With greetings from Warsaw,

B.

33. **Aaron Bergman**
June 9, 2007

M — do please note the word "public". If you think there haven't been disagreements over just about every point of theory by string theorists young and old, then you haven't hung around string theorists very much (or physicists in general for that matter.)

The other point people seem to have missed is the difference between criticizing one colleagues and criticizing their *work*. There are papers on the arXiv contradicting other papers every day. A common pastime at lunches in various string groups is to try to figure out why the papers of the day are wrong without reading more than the abstract :). This is a good thing. Similarly, if someone wanted to write a book about the problems with string theory, I'd probably disagree on some of the substance, but I wouldn't throw a huge fit. Lee, on the other hand, isn't just disagreeing with string theory; he's attacking string theorists as scientists. Criticizing one's colleagues in this manner in a book aimed at the public is something I find extremely objectionable.

34. **anon.**
June 9, 2007

'… he's attacking string theorists as scientists. Criticizing one's colleagues in this manner in a book aimed at the public is something I find extremely objectionable.' – Aaron Bergman

You just need to lighten up a bit, Aaron. Ridicule is a tradition:

'Oh, my dear Kepler, how I wish we could have one hearty laugh together! … And to hear the professor of philosophy at Pisa labouring before the Grand Duke with logical arguments, as if with magical incantations, to charm the new planets out of the sky.' – 1610 letter of Galileo Galilei to Johannes Kepler, http://www.catholiceducation.org/articles/science/sc0043.html

35. **Chris Oakley**
June 9, 2007

Aaron,

I find your attitude to be a little too convenient. I see neither LQG nor String Theory as providing any insights other than the limited utility of signposting blind alleys, but whereas Smolin expresses himself with invariable politeness and tolerance, your own Motl throws insults around like they are going out of fashion. Why is Smolin "extremely objectionable" and Motl not? I would be interested to know.

36. **nardex**
June 9, 2007

Peter,

I've read that "the study of strings has boosted a great amount of study in many areas of mathematics and of mathematical QFTs, and has revealed very beatiful truths belonging to these areas".
Thence, for You this is not important for the string theory itself?
This is the "because" that you says that the string theory is "not even wrong".
I think that any theory that "has boosted a great amount of study in many areas of mathematics" is a useful theory.
Looking forward to receiving your kind answer

All my esteem

37. **Aaron Bergman**
June 9, 2007

Chris, why not do a little googling?

38. **Eric Mayes**

June 9, 2007

I'd like to propose the following theorem:

Any theory of quantum gravity which provides the UV completion of quantum field theory will have a landscape of consistent vacua.

The reasoning behind this is that quantum field theory can incorporate a large number of consistent models, and so it follows that a theory of quantum gravity which incorporates QFT will do the same. Thus, even if Lee's loop quantum gravity is able so someday encompass QFT, it will have the same landscape problem of string theory.

39. **Chris Oakley**
June 9, 2007

Hi Aaron,

OK.

Search #1A: "Smolin" "Insult"; top match

> In the debate, Michael said that "to put Stephen Hawking on the same page as Lee Smolin is an insult to the people of this audience" (which was more of an insult to Lee Smolin), yet even Hawking no longer believes there are singularities, and for the very same reason Smolin does not, and the very same reason Barrow does not, and the very same reason I gave in the debate: every going theory of quantum gravity, including Hawking's, eliminates them.

Search #1B: "Smolin" "Scorn"; top match

> Smolin points accurately to some of the real problems with the sociology of university life, and seems filled with scorn for those who think that nothing can be done about it.

Search #1C: "Smolin" "Vituperation"; top match

> It seems to me that the RANCOROUS VITUPERATION is confined to the minor figures.
>
> I don't see Smolin or Witten as rancorous squabblers at all, or David Gross…or JB for that matter. They all seem to be above the squabble.
>
> Smolin had some serious points about policy and science in general, which he made politely and respectfully (I thought)

Now let's try

Search #2A: "Motl" "Insult"; top match (on this blog 9/11/2005)

> Happy birthday Peter. I've enjoyed reading your blog, with the exception of Motl's insult-laden comments, and I look forward to buying a copy of your book when it comes out.

Search #2B: "Motl" "Scorn"; first relevant (also on this blog)

> Now that it's available again, the Rumor Mill has the striking news that Harvard has chosen for a faculty position one of its postdocs: Lubos Motl. Lubos is well-known as undoubtedly the most rabidly fanatic string theorist around, always willing to heap abuse and scorn on anyone who questions the idea that string theory is the language in which God wrote the world.

Search #2C: "Motl" "Vituperation" ; find the same as with "Smolin" – then this:

> lubos motl has published is objections to loop quantum gravity which lee smolin responded to.
>
> what are some common objections to string theory, esp in NEW, what do string theorists think of these objections? lubos motl calls peter's book crap, gives it 1 star on amazon. (then it got deleted).
>
> ——————————————————————————————–
>
> marcus08-27-2006, 04:30 PM
> what good does animosity and vituperation do?
>
> I don't think it does much good.

Need I say more?

40. **Aaron Bergman**
June 9, 2007

Say more? I have no idea what your point is. It's certainly not relevant to mine.

41. **The man**
June 9, 2007

Perhaps a fitting cousin of string theory for which "not even wrong" also applies:

http://itre.cis.upenn.edu/~myl/languagelog/archives/000024.html

42. **Kris Krogh**
June 9, 2007

Aaron,

The point seems clear enough and Googling was your idea. What can you come up with?

43. **Aaron Bergman**

June 9, 2007

Chris asked why Smolin was objectionable and Lubos was not. Seems to me that that's assuming facts not in evidence.

44. **Kris Krogh**
June 9, 2007

Hi Aaron,

Maybe Google is attesting to some facts here.

45. **Kris Krogh**
June 9, 2007

Are you agreeing now that Smolin is not objectionable?

46. **mclaren**
June 9, 2007

Haven't these people ever heard of Occam's Razor? The claim that some fabulously elaborate conjecture which makes no testable falsifiable predictions is nonetheless verifiable because the simpler proven theory of physics (The Standard Model) to which it reduces in the limit is testable, is just breathtakingly ignorant and shockingly foolish.
If we accepted this crackpot reasoning, then every crank conjecture without a shred of evidence would be considered "testable" because the standard physics on which the crazy conjecture gets piled (without a shred of evidence to justify it) is known to be testable.
Ridiculous but obvious example: ESP is good solid science because it's based on conjectured "ESP waves" (whose precise nature remains conveniently undefined — as undefined as the actual nature of the alleged strings in string "theory") which follow the familiar laws of physics, and since the familiar laws of physics are testable, ESP must be solid verifiable science too.
Other examples of this gross abuse of Occam's Razor in physics are so obvious it's insulting even to discuss them, but since these Ivy League physicists seem to persist in this bizarrely defective reasoning, I guess someone has to point out the obvious.
History is littered with elaborate conjectures that reduced to familiar solid physics in the limit, but which turned out to be unnecessary idle speculation. The most obvious example is the luminiferous aether. As late as 1925 reputable physicists were giving lectures abou "the crisis in the ether." Experiments were being done to try to detect the ether as late as the mid-1920s. None succeeded in showing any evidence of the ether. That was the crisis. The solution to the crisis turned out to be simple — throw out the ether as an unnecessary conjecture. Use Occam's Razor. Do not multiply superfluous entities. Problem solved.
It's getting unutterably wearisom to hear all this talk about string "theory." It's not a theory, people, it's a conjecture _at best_. Let's call it what it is: the String Conjecture. It's not a theory since it hasn't even advanced to that stage yet. It's not even an hypothesis yet. It's just people blwoing mathematical smoke up our asses.
Moreover, the String Conjecture is a baseless conjecture. There's not a single shred of evidence in all of physics for the conjecture that we live in a universe with more than 4 physical dimensions. There's not the merest scintilla of evidence in the entire history fo physics that there exist any universes other than our own, let alone that multidimensional "branes" can come into contact with one another in 11 (or 26) dimensional space and set off Big-Bang-type events.
There's not the smallest tincture of evidence from any physics experiment ever done that ultra-tiny strings exist in 11 (or 26) dimensions and give rise to all the elementary particles with their vibrational modes.
All this stuff is science fictional conjecture. There's no evidence for any of it. The science ficitonal part isn't fatal — after all, the notion that particles are also waves is science fictional conjecture, but that weird wave/particle duality conjecture was forced upon us by overwhelming masses of evidence. The string conjecture isn't required by any evidence, it's just some neat math. At this point, the string crowd will predictably point out there was no evidence for the neutrino when Fermi hypothesized it. But that analogy is fatally flawed. Fermi based his hypothesis on a rock-solid law of physics, the conservation of momentum. If we throw that out, we're all in trouble. So a strange conjecture like the neutrino was preferable to the much more unpalatable conclusion that momentum conservation was violated. This is the same principle David Hume used in his reasoning. Choose the conclusion that requires the least miraculous operation of the universe, and you're usually correct
But unlike the case of the neutrino, no such rock solid principle of physics requires us to posit the string conjecture. 11-D strings are just idle speculation, with no hard evidence to back it up.
Well, the problem is that 'the public' most often doesn't understand that the theory is not made out of words but of equations.
Once again, this string speculation is **not** a theory. It's a *conjecture*. It's a ***baseless*** conjecture, derived from no physical evidence, just math.
Anyone can make a wild conjecture from elegant mathematics and then posit outlandish disconnected results. For example:
"Green's Theorem requires that we live in an 11-dimensional universe in which all elementary particles are made up of vibrating strings." No it doesn't. Green's Theorem is just a set of equations, and they don't require that strings or higher dimensions exist, they're just empty mathematics which makes no predictions about observed reality. So how is that different from string "theory"? Like the vacuous nonsenical conjecture above, string 'theory" doesn't require that strings or higher dimensions actually exist, string "theory" only describes such hypothetical constructs **IF THEY DO EXIST.** Like my absurdly meaningless Green's Theorem example, string "theory" makes no testable falsifiable predictions about observed reality. Like my ridiculous example involving Green's Theorem, no basic physics requires us to make that conjecture.
Really, too many supposedly educated physicsts suffer from a weirdly superstitious awe of mathematics. Just because you write down an equation, however elegant, doesn't mean it has any necessary relationship with reality. The math can be true and beautiful and yet flagrantly contradict observed reality. The Banach-Tarski paradox is the most obvious example of beautiful and indisputably true mathematics which completely contradicts observed reality, but you find these kinds of weird results littered throughout mathematics. The kind of naive Platonism we get from the string conjecturists is just bizarre. Don't any of these string people know that there exist other options beyond naive Platonism? Did John Dewey and David Hume not exist? Where were these people during Philosophy 101? Asleep?
Wake up, people! There's nothing magical about equations, they're just mental models — not reality itself. Just because someone writes down a beautiful series of interlocking equations doesn't mean they must be true. Keats' claim "Truth is beauty and beauty truth, that is all ye know and all ye need to know" may sound passable for art or poetry, but it fails disastrously in science. A physics theory is NOT a set of equations, it's a testable hypothesis with a rational mechanism behind it that happens to be embodied in equations. The equations are not always required for a theory to be solid science, as the second laws of thermodynamics demonstrates. That law of physics was valid for quite a long time before Boltzmann and later Maxwell put the second law of thermodynamics on a firm mathematical footing.

47. **Peter Woit**
June 9, 2007

nardex,

You've already asked that off-topic question under another name and it has been discussed here. String theory is "not even wrong" as an idea about unification in physics, this has nothing to do with whether it is useful in mathematics or in other areas of physics.

All,

The comments here have gotten pretty much completely off-topic, not to mention not making much sense. If you have something substantive to say relevant to the posting, please do so, but otherwise please just stop it with the pointless argumentation, rants, etc.

48. **Eric Mayes**
June 9, 2007

Dear Mclaren,
This are many compelling reasons for introducing strings and it is far from being 'baseless conjecture'.

This really sad thing about this debate is that there are so many ignorant people out there who are easily manipulated by these fallacious arguments. If we're honest, you have to admit that what is being peddled is us-against-them -ism. In this picture, string theorist are elitists who live in their Ivy League ivory towers telling the common-folk who really no better what to believe, while the populist heroes Woit and Smolin are the defenders of rationally and common sense. The truth is that the serious people who are really doing physics will continue to study string theory because it offers the best chance to make progress, by far.

49. **Peter Woit**
June 9, 2007

Eric,

In blog comment sections you'll find some examples of uninformed populist nonsense, but neither Smolin nor I, with our Harvard and Princeton backgrounds are this kind of populist. I freely admit to a certain elitism, and work at an Ivy League institution (something there are problems with, but they don't have to do with the level of science and math done here).

My last comment trying to stop the flow of off-topic comments doesn't have seem to have succeeded, so I'll just start deleting such comments now. This may be elitist of me, but I'm not going to tolerate having the comment section here taken over by arguments so dumb that no informed person is going to read it or participate in it.

50. **Aaron Bergman**
June 9, 2007

Are you agreeing now that Smolin is not objectionable?

No.

51. **vicar**
June 9, 2007

Aaron said: "A common pastime at lunches in various string groups is to try to figure out why the papers of the day are wrong without reading more than the abstract :). This is a good thing."

Oh yes, that's a really good thing.
In reality, this sort of attitude is exactly what Smolin means by groupthink. You look at the abstracts and if they do not agree with your preconceptions you have a good laugh and move on to the next victim. The only papers you actually look at are those by names you recognise as being a member of the gang. I have heard some unbelievably naive things being said on the basis of this "let's just glance at the abstract and decide that the paper is wrong" procedure. This is essentially LM's approach, and it has led him to write some things that gave me a very bad case of vicarious embarrassment. As for example what he has said about equivalence principle violation over the years, things that would not be tolerated in an undergraduate in any respectable university.

52. **Aaron Bergman**
June 9, 2007

Here it was that I thought groupthink meant mindlessly agreeing with the status quo and not questioning things said within the group. Now, apparently disagreeing with papers counts as groupthink, too. I'm so confused.

(I hasten to add that the subject of such lunchtime conversations is most often string papers, but now, of course, string theorists will be accused of only looking at string papers and nothing else. Groupthink! And so it goes on….)

53. **mclaren**
June 9, 2007

Eric Mayes remarked:
There are many compelling reasons for introducing strings and it is far from being 'baseless conjecture'.

Compelling mathematical reasons. Not compelling experimental evidence. If I'm wrong, please provide the title, volume number, issue number and page numbers of the peer-reviewed HEP journal that has published experimental results confirming the predictions of string theory that would compel us to believe that string theory is the next necessary step in HEP.

This really sad thing about this debate is that there are so many ignorant people out there who are easily manipulated by these fallacious arguments.

Show me the evidence. That's all that counts. Show me the HEP experiments providing evidence for string theory. Everything else is irrelevant. The two biggest pieces of experimental evidence in HEP in th last 20 years, dark energy and oscillating neutrinos, weren't predicted by string theory.

If we're honest, you have to admit that what is being peddled is us-against-them -ism.

People are asking for hard experimental evidence. You can't have experimental evidence for or against a scientific theory if the theory doesn't even make testable predictions. Without testable predictions or experimental evidence pro or con, the "theory" is **not even wrong**.

In this picture, string theorist [sic] are elitists who live in their Ivy League ivory towers telling the common-folk who really no [sic] better what to believe, while the populist heroes Woit and Smolin are the defenders of rationally [sic] and common sense. The truth is that the serious people who are really doing physics will continue to study string theory because it offers the best chance to make progress, by far.

At some point, you have to recognize that a theory isn't making predictions and no one knows how to squeeze or tease it into making testable predictions. At that stage, the whole project has become what Hubert Dreyfus calls a degenerating research program. From the nonsensical philosophical arguments now being offered in favor of string theory and judging by its persistant inability to make testable falsifiable prediction, string conjecture seems to be a degenerating research program.

Eric Mayes' claim here is the same as Sean Carroll's faulty argument — string conjecture is valid science because physicists are still working away at it. That's faulty because it doesn't matter how many people work at an area of investigation if it produces no tangible results. Thousands of physicists worked worldwide investigating the ether in the 1920s but no results came from that line of investigation. It was a degenerating research program. Physicists eventually abandoned it.

It doesn't matter how many people investigate string theory if it continues to fail to produce testable falsifiable predictions. If you're not making predictions that can eventually be tested in a laboratory, you're not doing science. It's just that simple.

54. **CapitalistImperialistPig**
June 9, 2007

Peter,

You said *"My objection is to what I take to be Damour's claim that an observation of a violation of the equivalence principle would be evidence for string theory. If you believe Lubos, string theory predicts no violation of the equivalence principle, if you believe Damour, it predicts a violation. "*

Doesn't a dilaton violate the equivalence principle? I thought it had to be massive to confine the violation to short distances.

55. **CapitalistImperialistPig**
June 9, 2007

Aaron,

Your assertion that theoretical physicists should keep their disagreements private is pretty darn medieval. It's not in keeping with the history of physics or science generally, and it's dishonest to hide such disagreements from the people paying the bills.

56. **Aaron Bergman**
June 9, 2007

My god, does nobody read what I say? Or am I really that unclear?

Let me quote it again: *The other point people seem to have missed is the difference between criticizing one colleagues and criticizing their work.*

57. **Bee**
June 10, 2007

The other point people seem to have missed is the difference between criticizing one colleagues and criticizing their work.

hum… I wonder how the 'sociological' part of the book had been discussed had it not been written by a physicist but by someone working in, say, the sociology of sciences? I suspect, then the criticism would be it was *not* written by a 'colleague' who knows the field?

Hi Vicar,

In reality, this sort of attitude is exactly what Smolin means by groupthink. You look at the abstracts and if they do not agree with your preconceptions you have a good laugh and move on to the next victim.

nah, you're mixing up cognitive biases, what you're talking about is called confirmation bias:

`a tendency to search for or interpret new information in a way that confirms one's preconceptions and avoid information and interpretations which contradict prior beliefs. It is a type of cognitive bias and represents an error of inductive inference, or as a form of selection bias toward confirmation of the hypothesis under study or disconfirmation of an alternative hypothesis.'

and is btw also exactly what Polchinski criticizes about Lee's book *Regarding group-think: you interpret the reaction of string theorists to your book as more evidence for your point of view.*

Entertaining, eh? We can probably spend the rest of our days accusing each other of faulty thinky, or other logical and formal fallacies. I esp. like the Texas sharpshooter fallacy, anybody wants to write a book about it?

Sorry, Peter, couldn't resist – this comment section has just gotten too silly.

-B.

58. **Peter Woit**
June 10, 2007

Some of the most common automated spam robots operate by posting comments consisting of a generic phrase of indeterminate reference, or a snippet from a previous comment, followed by such a phrase. I'll just point out that the comments from some people here recently are indistinguishable from those of the spam robots (just that they don't have a link to a web-site trying to sell something in the "web-site" field).

59. **Peter Woit**
June 10, 2007

CIP,

In general, massless moduli fields can give violations of the equivalence principle. That's why some string theorists say "string theory predicts violations of the equivalence principle". But we don't see such long-range forces, so string theorists argue that the fields must be massive and short range, and concentrate recently on models where this is true. Some like Lubos, then start going on about how "string theory predicts no violations of the equivalence principle." The whole thing is kind of ridiculous.

US Particle Physics Planning

June 11, 2007
Categories: Uncategorized

Last week both SLAC and Fermilab hosted "Users Meetings", providing a forum to discuss the current status and future plans of the two laboratories. The SLAC agenda is here, and talks from previous years are available here, with this year's perhaps available later.

The Fermilab meeting was also celebrating the 40th anniversary of its first Users Meeting, which was held back in 1967 at a time when Fermilab was under construction, with plans for a 200 GeV fixed-target machine underway, led by director Robert Wilson. This year's talks are available here. The status of the Tevatron is described in Roger Dixon's talk. Already the machine has delivered nearly 3 fb^{-1} of luminosity to the two experiments there, half of this over the last year. They are projecting to have 6-7 fb^{-1} by the end of FY 2009 (a bit more than two years from now). The current plan calls for operation of the Tevatron only until the end of FY 2009, and a year or so ago there was even some discussion of shutting it down before then. With the machine operating well, a healthy US HEP budget, the LHC startup now not until 2008, and some cautious optimism that that the Tevatron might be able to accumulate enough data to see the Higgs under some scenarios, it looks like no one is about to shut the Tevatron down early, rather the question will be how much extra time to give it. There seems little point to shutting it down as long as the LHC is not producing results that make it obsolete, and no one knows yet how long that is going to take. While those running Fermilab would like to know what they will be doing several years in advance so that they can plan and budget, it may be difficult to do this since no one knows what will happen with the LHC.

Fermilab is in the middle of a long-range planning exercise, with a Steering Group meeting trying to put together a plan by August 1. They have many of their materials available on-line. Some of the discussion revolves around the question of the ILC, with talks showing that in principle it would be possible to start construction of the ILC in 2012 and have it built by 2019, but few people believe that things will happen this fast. Whether building the machine makes sense will depend on what is seen at the LHC. Other scenarios are under discussion, for example see here. Other than the LHC, the main things one could conceive of building at Fermilab would be a more intense proton beam (proton driver), or accelerating muons to provide a "neutrino factory" and perhaps ultimately a muon collider.

While US HEP has a difficult task ahead to figure out what to do after the Tevatron shuts down and the energy frontier moves to CERN, at least the budget situation is looking a lot better than it was a few years ago. At the Users Meeting, there was a presentation by the DOE's Robin Staffin showing budget figures that included a 6.8% increase planned for FY2008, after a 5.9% increase from FY2006 to FY2007. For some reason the federal government seems to have decided to put significantly more money into fundamental physics research, and HEP is benefiting from this. For more about the general situation with the Federal science research budget, see this recent talk by John Marburger, the director of Office of Science and Technology Policy.

For the budget situation in mathematics, see this report in the latest Notices of the AMS about the NSF budget numbers. After flat budget numbers for the past couple years, there was a 3.3% increase for mathematics research in FY2007, and the proposal for FY2008 has a 8.5% increase. Math is cheap compared to HEP, with the NSF spending on math (which is the bulk of federal math research funding) only about a quarter the size of the HEP budget. The AMS Notices article also computes numbers for what fraction of the NSF budget goes to different fields, noting that in FY2004 18.3% was for math, 20.9% for physics, while the FY2008 proposal goes 17.8% to math, 23.6% to physics.

Update: Also at SLAC, this week the DOE is there to review the lab. Presentations prepared for the DOE are on-line. Michael Peskin gave a presentation about the work of the theory group. He highlighted (besides hopes about the LHC) the work of SLAC's Lance Dixon on computing perturbative QCD amplitudes, including its relation to N=4 supersymmetric Yang-Mills and to the conjectural finiteness of N=8 supergravity.

Comments

1. **Eric**
   June 11, 2007

   Peter, Thurston is celebrating 60th birthday at Princeton
   http://www.math.princeton.edu/Thurston60th/

2. **DB**
   June 12, 2007

   Isn't it interesting that while the US is the undisputed world leader in string theory research, it has not led the way in experimental HEP since the 1970s.? Remember that the only reason the Tevatron is currently the world's most powerful collider is because CERN's LEP was shut down to build the LHC. Oh, and just before the LEP shutdown we were also told about events that "might" indicate that the Higgs had been seen there. MiniBoone was interesting, but a pale shadow of Kamiokande and Sudbury. By substituting "cheap" math for real physics, is it such a surprise that we end up with string theory?

3. **alex**
   June 12, 2007

   You say the NSF spending on math is only a quarter of the HEP budget, but go on to quote figures making the NSF budget for math not much smaller than for physics as a whole (17/18 % compared to 21/24 %). Are you talking about a different budget the second time?

4. **Peter Woit**
   June 12, 2007

   alex,

   Math is funded mainly by the NSF, and the NSF gives comparable amounts to math and physics. But HEP is mainly funded by DOE, and it is this funding that is much greater than math.

   DB,

   The US HEP problems can be traced back to the SSC debacle. I don't think that's something that can be blamed on the string theorists…

5. **Zathras**
   June 12, 2007

   Within physics, is HEP getting a smaller portion of the pie? Any other areas that are getting significantly more than they had before?

6. **Intellectually Curious**
   June 12, 2007

"By substituting "cheap" math for real physics, is it such a surprise that we end up with string theory?" -DB

Now, I understand why math is cheap, since one needs only paper and pencil (and usually a trash can) to do pure research. But what is "cheap math"?

7. **John H.**
   June 13, 2007

   Peter, with so much money being spent on HEP research, if neither LHC nor ILC provides new and meanigful data this may summon the end for particle physics… atleast for some time to come. Then what?! What will all those who devoted half of their lives (and sometimes more for senior researchers) do? What will they have to show for their lives' efforts…

   Just a thought…

8. **Coin**
   June 13, 2007

   Peter, with so much money being spent on HEP research, if neither LHC nor ILC provides new and meanigful data this may summon the end for particle physics

   Even if this is so, is it at all possible that this would be not the end of experimental particle physics, but just the end of collider experiments?

   I mean, if it were ever absolutely, truly necessary to do so, surely there's *some* way to do frontier fundamental particle research even if there's no funding for new ubercolliders.

9. **John H.**
   June 13, 2007

   Sure, HES [High-Energy Speculation]… 😉

10. **DB**
    June 13, 2007

    Experimental HEP research is increasingly using the astrophysics channel – which has a long and distinguished history of discovery from the muon (Anderson, 1936) to the charged pions (1947) to the neutrino oscillations at Kamiokande and Sudbury. Expect continued growth in the placing of sophisticated detectors in orbit – why the ISS is not being better exploited for this purpose is a mystery to me.
    The US remains the world leader in astrophysics with the infrastructure to design and deliver the best in class detectors so if, as I expect in maybe ten years time, non-terrestrial HEP once again becomes the dominant mode of particle physics research, it is perfectly placed to retake the lead. However, when I look at Nasa's funding priorities, its scaling back on its science budget, Europe and Japan's resolve, I just wonder.

11. **Peter Woit**
    June 13, 2007

    John,

    It's not the experimentalist's fault if it turns out Nature has decided to look exactly like the Standard Model up to 1 TeV or more. Finding out about Nature is what experimentalists do, and they have been and are doing it. Sometimes what they find out is dramatic and unexpected, sometimes not, but it's still valuable to know what actually happens. The fact that the Standard Model is so good is in itself a very interesting experimental result.

    What is worrisome about the post-LHC future is that, if the SM still holds, no one has a plausible idea about how to do what physicists have always done: keep trying to find out what happens at higher energy and shorter distance scales. The LHC will provide a jump of a factor of 7 in energy, but there's no affordable technology out there that could give us another such factor anytime soon.

12. **Matteo Martini**
    June 15, 2007

    Peter Woit wrote:
    " The LHC will provide a jump of a factor of 7 in energy, but there's no affordable technology out there that could give us another such factor anytime soon "

    What about the Super LHC?

    The maximum integrated luminosity increase of the existing options is about a factor of 4 higher than the to the LHC ultimate performance, unfortunately far below the LHC upgrade project's initial ambition of a factor of 10

13. **Matteo Martini**
    June 15, 2007

    Sorry,
    I did not write the sentence was quoted from Wikipedia:
    http://en.wikipedia.org/wiki/Super_Large_Hadron_Collider

14. **Thomas Larsson**
    June 16, 2007

    Matteo, SLHC gives higher luminosity, not higher energy. More collisions, but at the same energy.

15. **Matteo Martini**
    June 16, 2007

    Thomas,
    thanks for your reply.
    What about the VLHC?
    200TeV, instead of 7+7TeV?
    http://en.wikipedia.org/wiki/Very_Large_Hadron_Collider

16. **Peter Woit**
June 16, 2007

Matteo,

As the Wikipedia article mentions, the "VLHC" idea would require a machine hundreds of kilometers in size, and the cost would likely be prohibitive. There's little chance of such a thing being built within the next few decades.

17. **Matteo Martini**
June 16, 2007

Peter,
thanks for your comment.
I have read something the VLHC, in this file, http://vlhc.org/Limon_seminar.pdf, written by P. Limon, and, it is stated that:
1) the technology needed to build a VLHC, is available today; and
2) if we can afford a linear electron collider, we can afford a VLHC (do not understand the exact meaning of this sentence, though..)

What do you think?

18. **Peter Woit**
June 16, 2007

Matteo,

The problem with the VLHC is not the technology, but its size. It would be bigger than the failed SSC project. Given that the SSC was going to cost more (in constant dollars) than the ILC is supposed to, I suspect the VLHC would be significantly more costly than the ILC to construct.

19. **Matteo Martini**
June 16, 2007

OK
Let` s hope something completely new comes out from LHC, then.
Than, there will be maybe hope that the world` s governments could decide to go ahead, one day, with a bigger Hadron Collider.
Please, not that, last year the defense budget of the U. S. alone was over USD400 billions (http://www.whitehouse.gov/omb/budget/fy2007/defense.html)
Since the estimated cost of the ILC is around USD5 billions (http://www.linearcollider.org/pdf/RDR_Machine%20Overview_v5-1.pdf), I think there is still room, if there is any compelling reason for governments, to go ahead, and build a machine significantly larger than the ILC.
Note, that world powers did not have any problem to pop out some USD95 billions for the Space Station (http://www.space.com/news/spacestation/gao_iss_inquiry_010619.html).
I did not really read of any real practical outcome and scientific progress, from that expensive program.
Please, note that the figure I gave above (USD$400 billions+), is the budget of only 1 year, and, of only 1 country.
The cost of building any machine, such as the VLHC, would have to be split in many calendar years, therefore, reducing the cost per year to a fraction.
Also, collaboration and splitting costs between nations, would provide a further reduction of the expenses for each nation.
The bis point, in my opinion, is: will we really find something new next spring?
Will some theorist, come out with a brand new theory that requires a 50 TeV machine to be proven, but, that could change our lives and spur progress?
If yes, there could be reasons, in the near future, to work for an even bigger Collider.
If not, maybe, we will be stuck with the Standard Model for another 100 years.

20. **Nuttata**
June 17, 2007

>If not, maybe, we will be stuck with the Standard Model for another 100 years.

No reason to complain, it could have been much worse. Look at high Tc superconductivity, for example. Those guys have been stuck for more than twenty years, and they don't even have a theory. At least the SM does work.

But there's no way the LHC could possibly leave us entirely empty-handed. Some kind of EW symmetry breaking must be there, and/or some unitarity-restoring sector. "Nothing" is not in the menu, as soon as the experiment is up and running.

21. **Matteo Martini**
June 17, 2007

As far as I can see, human progress of the last 100 years, has been mainloy driven by breakthroughs in elementary physics.
The inventions of the:
– semiconductors (in the early 70s), which lead to the birth of the modern electronic and informatic business (Intel, AMD, Microsoft, Google and the modern IBM);
– the discovery of the DNA, in the early 50s (at the basis of genetics and modern biochemistry);
– laser optics (which lead to the development of current optical cables, and made it possible the birth of companies like Cisco systems and of the internet);
– the future quantum computing?
were, almost all, based on the discoveries of the behaviour of the atom, and, based on general relativity and quantum mechanics

If you look at the " old " industries (such as: avionics, rocket industries, car business, machines of all kinds), there has been nothing really new in these fields, in the last 40 years, at least.
The car engine, it has been the same in the last 100 years, and, after the man in the moon, in 1969, no big advancement in space exploration too.
Planes, are not inherentically new, after the invention of the jet engine (made in the sixties).
This is because, all the " old " mechanical industries, basically, use the 3 laws of physics, discovered by Newton in the late 1600s.

The same is happening with the " new " industries (informatics, semiconductor business, ..), there is still a lot of innovation, there, but, for how long??

In my opinion, if we do not advance, to the next level of knowledge of particle physics, human progress will probably, reach a halt in 20-30 years..

Just my opinion, though..

22. **sinus**
June 18, 2007

> The car engine, it has been the same in the last 100 years, and, after the man in the moon, in 1969, no big advancement in space exploration

I beg to disagree. It is true that the most basic ideas involved in the explosion engine have not changed. But today's cars, and their engines, are very different from those of 100 years ago. The technology involved in those differences is highly non trivial and, in many ways, revolutionary.

Regarding outer space exploration, we've been living a golden age of cosmology for more than ten years now. Cosmological and astrophysical knowledge has undergone many revolutions in the last two decades or so, due to enormous advances in space exploration which produced large amounts of high quality data. To quote but one example: several dozen extrasolar planets have been discovered, whereas none was known during the XX century.

23. **Matteo Martini**
June 18, 2007

Sinus wrote:

Matteo:
Yes, there have been many substantial innovations in the car engine, as well as in the commercial aviation business (look at the A380), but, the basic structure of the car engine, as well of that of the plane, has not changed in the last decades.
Current car engines use the Otto cycle, or the Diesel cycle, to provide energy, and, these cycles have been discovered more than 100 years ago.

Sinus wrote:

Matteo:
I beg your pardon.
I meant human space exploration.
There is nothing revolutionary, in this field, since the man on the moon, dated 1969.
If we have to go to Mars today, we would still use rockets, and a lot of fuel.

Random Collection of Stuff

June 14, 2007
Categories: Uncategorized

Pretty much everybody in the math community seems to be getting a blog. Many of the new bloggers are quite good research mathematicians (including even some Fields Medalists). Two very new ones are:

Secret Blogging Seminar: Named after a “Secret Russian Seminar” at Berkeley, a group blog of several ex- and current Berkeley math graduate students (Ben Webster, A.J. Tolland, Scott Morrison, Noah Snyder and David Speyer)

Math Life: The blog of UT Austin’s number theorist Fernando Rodriguez Villegas

A few things I learned from the Secret Blogging Seminar postings and following associated links:

The Microsoft Research group at UCSB working on “topological quantum computation” is now known as Station Q, and has a web-site.

Googling “Secret Russian Seminar” led to the web-site of Scott Carnahan, a student of Richard Borcherds who will be a postdoc at MIT this fall. Carnahan has some interesting sets of notes there, including notes from Borcherds’ 2004 course on QFT. Back in 2001, Borcherds had taught an earlier version of this course, and notes taken by Alex Barnard are available. According to Carnahan, Borcherds began the 2004 course with the comment:

Some of you might remember I gave a class a few years ago on the standard model. It ran into a few technical problems, the main one being the fact that I didn’t know what I was talking about. I’ve learned a thing or two since then, and I’m going to try again.

I’ve finally been making some progress in understanding some mathematics associated to BRST; if this keeps making sense I hope to get something written about it this summer. I recently noticed that the pretty much incoherent Wikipedia entry on the BRST formalism, has been joined by another incoherent one on BRST quantization. Both entries contain the warning at the top “This article or section may be confusing or unclear for some readers”, which is an understatement.

A new issue of Symmetry Magazine is out, and it contains a report on the recent string theory debate in Washington between Brian Greene and Lawrence Krauss. An editorial noted how amazing it is that this sort of thing drew 600 people willing to pay $25. There’s lots of interest out there in fundamental physics in general, and this controversy in particular.

Can’t remember where I saw this earlier today, but there’s a famous quotation I hadn’t heard before from economist John Kenneth Galbraith which seems to apply well to the current situation in string theory:

Faced with the choice between changing one’s mind and proving there is no need to do so, almost everyone gets busy on the proof.

Update: One more. Adrian Cho at Science Magazine has an article about the debate going on over how long to run the Tevatron. The chair of the P5 panel is saying that they will recommend running through 2009, but that “It would take some unusual circumstances to justify running beyond 2009.” But, if the LHC takes longer to get working correctly than planned (there’s a history of this with new accelerators), and Tommaso’s Dorigo’s rumors of sightings of a Higgs at the Tevatron ever start to firm up, it’s going to be hard to justify starting to tear the machine down…

Update: Yet one more about math blogging. Lieven le Bruyn has changed his blog from NeverEndingBooks to Moonshine Math (also known as NeverEndingBooks, v. 2). He begins with a wonderful blog posting about the j-function which explains one of my favorite remarkable facts about numbers:

$$e^{\pi\sqrt{163}}=262537412640768743.99999999999925\ldots$$

Comments

1. **Aaron Bergman**
   June 14, 2007

   One thing that all this time on the internet has made clear to me is that physicists have done a pretty poor job of communicating that our understanding of QFT has changed. Renormalization is still communicated as this form of black magic that we do only because it gets the right answer. I would say that we now have a good understand of how it works. We even have a reasonable conjecture (see the previous discussion with Peter Orland) of how one might going about defining a quantum field theory via path integrals, and how the process of renormalization relates to that definition. Maybe someone should write a popular science book about effective field theory…

   On another note (again from reading the notes on Borcherds’s lectures), as I understand it, the idea of using the nonisomorphism of Pin(1,3) and Pin(3,1) to distinguish the signature of spacetime is wrong. There are eight ways (IIRC) to extend the Spin group to deal with the full orthogonal group of which two are the Pin groups. I don’t know of any physical reason to distinguish the various choices.

2. **anon.**
   June 14, 2007

   Regarding BRST: recently I was trying to understand the old paper by Thierry-Mieg that interprets the ghosts as vertical components of the connection on the principal bundle. The antighosts are still ad hoc. After this the literature appears to bifurcate in several directions, and I can’t tell which if any of them give a clear explanation of the full BRST structure with both ghosts and antighosts. Can you point me in the right direction? Is there one authoritative reference?

3. **Chris Oakley**
   June 15, 2007

   Aaron,

   I would love to be able to regard renormalization at something other than black magic, but it really does not help when someone of Borcherds’ standing comes out with a statement like this:

   > In general, renormalization is used to cancel out the terms you get from poles. This is a rather bizarre process by which terms are inserted that depend on the coupling constant, so that the resulting poles exactly cancel out the poles you get from the analytic continuation. The main justification for why it works is that the answers you get agree with experiment to some absurd number of significant figures.

(See the previously-linked lecture notes).
I nominate you to write this book on effective field theory. I will look forward to reviewing it on Amazon.

4. **matteoeo**
   June 15, 2007

   I think Michel Le Bellac "Des phénomènes critiques aux champs de jauge" (don't know the english name), part II (from chapter V on), is a great introduction to path integrals, renormalization and effective field theories ad could be studied in a QFT course (obiously also part I should be studied to undersand the statistical mechanical basis, but part II is pretty much independent).

5. **Thomas Larsson**
   June 15, 2007

   The canonical reference is [Henneaux and Teitelboim](#).

6. **Johan Couder**
   June 15, 2007

   Aaron Bergman says: "…Maybe someone should write a popular science book about effective field theory… "
   Chris Oakley says: "…I nominate you to write this book on effective field theory. I will look forward to reviewing it on Amazon."

   I second that. There is more than one book on quantum mechanics out there at an "intermediate level", i.e. in between the puerile pop science books and graduate level textbooks.
   But as for QFT ? Feynman wrote a nice book on QED for the math-disabled, and Schumm did his best to explain the Standard Model [at least better than Peter did 😉] to the lay person without using too many silly analogies (as in say Randall's "Warped passages"). Some of us laypersons have asked MacMahon to write a "QFT Demystified" book (he wrote fairly good ones on QM and GR.), but he seems more interested in doing a "String Theory Demystified" version.J :-))

7. **Peter Woit**
   June 15, 2007

   anon,

   Thomas is right that Henneaux-Teitelboim is about the best there is. But they don't have much to say about the geometrical interpretation of the formalism they are working with, that's what has always remained obscure to me.

8. **A quantum diaries survivor**
   June 15, 2007

   Hi Peter,

   please fix the link to Adrian Cho's article (need to remove one extra http). Curiously, he did not cite me in his piece although he interviewed me on the issue, while you do cite me in the same paragraph when you cite him. Your psychic powers at work ? :-°

   Cheers,
   T.

9. **Peter Woit**
   June 15, 2007

   Thanks Tommaso, fixed. I guess I do have psychic powers…

   This whole discussion about the Tevatron seems a bit odd. From Cho's article, the cost of running the thing is 4% of the US HEP budget. It's the only thing in the US producing HEP data at the high energy frontier, and it's not like anyone has an obviously better idea for an HEP experiment that is not getting funded. I'm not seeing why the plan is not to just keep running it, only starting to shut it down after the LHC has definitively started producing the kind of results that would make the Tevatron data of little to no interest.

10. **anon.**
    June 15, 2007

    Thomas, Peter: Thanks, I have heard of that book but I haven't obtained a copy yet. I am hoping to find something explicitly geometric, though.…

11. **A quantum diaries survivor**
    June 15, 2007

    Peter, I think the money issue is only part of the deal. By keeping the Tevatron alive, the US HEP program maintains that it is a good idea to invest on an alternative to LHC, while a lot of effort has been done and is currently ongoing to try and make the US participation in ATLAS and CMS as visible and clear as possible.

    There is thus a contradiction between keeping the Tevatron on the scene indefinitely and putting money and effort in the CERN endeavour. That is only embittered by the fact that scientists that could be useful at CERN are enticed into continuing to work at the Tevatron.

    From the outside, the choice of spending some 30-50M$ a year for a few more years of Tevatron running beyond 2009 is a no brainer – there are even things that the Tevatron is better at doing than the LHC at full power. But from the point of view of dictating the strategy of US HEP, it looks like the decision is a bit tougher.

    Cheers,
    T.

12. **Hendrik**
    June 15, 2007

    Dear Peter and Thomas, concerning BRST, a few remarks;-

    The classical (geometric) version of BRST is mathematically in good shape (cf. e.g. Stasheff arXiv:hep-th/9112002v1) and even connects with quantum theory through geometric quantization, cf. Duval e.a. in Commun. Math. Phys. 126, 535-557 (1990).

However a purely quantum BRST constraint reduction procedure
cannot rely on the classical theory (due to the problems with quantization maps – check out Gotay e.a. on Groenewald-Van Hove obstructions). For quantum BRST the theory is in much worse shape, with only a few sporadic rigorous papers, e.g. by Horuzhy.

There is not one BRST in method in heuristic physics, but several.
Broadly speaking, there is the Hamiltonian version (as in the book by Henneaux and Teitelboim or in the Russian BFV school), and the Lagrangian version (as in the papers by Kugo and Ojima), and these come in several different flavours.
The Hamiltonian version starts from a set of quantum constraints and give an algorithm for constructiong the BRST charge Q, whereas the Lagrangian version starts from a set of gauge transformations and "replaces" the gauge parameters by anticommuting ghost fields to obtain the BRST graded derivation d.

Whilst on the surface these two methods seem quite similar, (with an obvious connection in d = graded commutator with Q) there are subtle differences in the actual constructions involved. The Hamiltonian version is the more problematic one of the two;- it is quite easy to produce quantum constraint systems where Hamiltonian BRST produces different results from the usual Dirac method, or is inconsistent, e.g. by producing a nonpositive physical space, or the wrong physical observables. This has been noted in a number of places in the heuristic literature, but usually an ad hoc "fudge" is invoked to get out of such tight spots. In the rigorous literature the failure of BRST has also been noticed, cf. e.g. Landsman and Linden, Nuclear Physics B Vol 371, 415-433 (1992) or McMullan, Commun. Math. Phys. Vol 149(1), 161-174 (1992). I also have an (unpublished) preprint on the breakdown of Hamiltonian BRST which I can email to you if you're interested.

On the other hand, the Lagrangian BRST is applied almost exclusively to gauge theories (i.e. where there is a gauge potential, not just a nonphysical degree of freedom), and closely follow Kugo and Ojima. A good example is e.g. the book by Scharf "Quantum Gauge Theories: A True Ghost Story" where their threatment of QEM can be made rigorous, and it produces the correct results. Whether Lagrangian BRST can be made into a general quantum constraint reduction procedure still remains to be seen (but I have not followed the recent literature on BRST so might have missed it).

I am aware that the real appeal for BRST comes from the path integral approach, but from the operator point of view I still cannot see how quantum BRST is an improvement over a simple Dirac constraint approach. Unnecessary and problematic formalism.

13. **Hendrik**
June 15, 2007

Dear anon, I think that Bonora and Cotta-Ramusino in Commun Math Phys, 87(4), 589-603 claim to have an improved version of Thierry-Mieg's paper on BRST. This is fully geometric (hence classical).

14. **Scott Carnahan**
June 15, 2007

It's a bit surprising to see that those QFT notes got publicity – I had mostly intended them for fellow grad students who didn't feel like taking notes. Most of the comments that I took down (e.g. Allen Knutsen's remark about Pin groups) were basically off-the-cuff, so they should be taken with a grain of salt.

I should mention that I don't think Borcherds' ending comment about renormalization is completely representative of his viewpoint, and he may have been just tired and cynical. He is aware of effective field theories (and they are mentioned in the 2001 notes), and he has said several times that all of the ingredients for making perturbative quantum field theory (and in particular renormalization) mathematically rigorous already exist in the published literature, but that writing them down together is highly nontrivial.

Tao's blog entry on the Fields medalist lectures has a shorter but more recent representation of his work.

15. **theoreticalminimum**
June 16, 2007

For anyone who wants to have a look at the "Quantization of Gauge Systems" book, a djvu copy can be downloaded here.

16. **Chris Oakley**
June 16, 2007

Scott,

Borcherds' comment about renormalization may have been unguarded, but that does not mean that it did not accurately reflect what he thought. The argument about rigour is one that no-one ought to have. The rigour of a scientific theory one ought to be able to take for granted. Certain assumptions lead to certain consequences. The consequences may not be in accordance with experiments, but there should never be an issue about whether they connect with the underlying assumptions or not. Can you imagine a distinction being made between axiomatic and non-axiomatic classical mechanics? I once got an e-mail from an "axiomatic" field theory post-doc saying that I was trying to be "holier than the pope" in requiring rigour in quantum field theory, but why am I being unreasonable? Is there any mathematical cheating going on in going from Newton's universal law of gravitation and the derivation of elliptical planetary orbits obeying Kepler's laws, or between Maxwell's equations and the calculation of the force between two current-carrying wires? Why should there be two sets of standards, one for QFT and one for everything else?

17. **Thomas Larsson**
June 16, 2007

Hendrik, I would be interested in your preprint. You can find contact information on the arxiv.

When you talk about problems, is it the BRST method that breaks down, or do people make mistakes when applying it? One need to honor certain regularity conditions, but it is nevertheless possible to make subtle errors. E.g., thm 17.2 of H&T is flawed already for the harmonic oscillator, because it only works as stated if you say that the oscillator has a gauge symmetry. The reason is that there are "Noether identities" of the form (17.8) due to the fact that the equations of motion has solutions. The difference is that the index &alpha runs over a (d-1)-D manifold for solutions, and over a d-D manifold for genuine gauge symmetries.

18. **Hendrik**
June 16, 2007

Dear Thomas, expect my email on Monday. Regarding:

“When you talk about problems, is it the BRST method that breaks down, or do people make mistakes when applying it?”

I do mean the stronger statement;- if you take Hamiltonian BRST (as expressed in the book by H&T) seriously as a constraint algorithm, then it fails when applied to some simple constraint systems. To get the right answer additional assumptions are necessary (which of course means that you know the right answer by other means).

The input of a quantum constraint system is simple,- it is a *-algebra A of operators (on Hilbert or Krein space with some common dense domain), together with a set C of distinguished elements which you want to set to zero (constraints). It is easy to generate such pairs (A,C) for which the Hamiltonian BRST fails.
Dynamics (i.e. a one-parameter automorphism group of A) is independent from this;- just assume a dynamics which preserves the constraints. In any case Hamiltonian BRST is a kinematic procedure, dynamics adjustment is not part of it.

It is not even clear to me that if you start from equivalent constraints (i.e. they produce the same physical state space) that Hamiltonian BRST will produce the same physical algebra.

I have to emphasize again that Lagrangian BRST (which is closer to the classical geometric version) is not a general constraint algorithm, it is just for gauge theories. For these (at least the ones which can be analyzed rigorously) it seems to produce the right result.

19. **Johan Couder**
June 18, 2007

for those who thought i was kidding … McGraw-Hill is releasing David MacMahon’s “String Theory Demystified” on December 24, 2007. (search for the title at McGraw-Hill’s website if you like)
Apparently: “Using the proven Demystified format, this book elucidates the highly mathematical and complex topic of string theory, covering key topics such as particle physics, quantum field theory, D-brane physics, and different types of strings. YOu will learn the mathematical tools necessary to truly decipher string theory.”
How mainstream can you get ? Eagerly awaiting the “ST for Dummies book” 🙂

20. **anon.**
June 18, 2007

> David MacMahon’s “String Theory Demystified” on December 24, 2007.

Brilliant. I’m writing Santa for a copy for the book as part of my next Christmas present, plus a sexy supersymmetric partner and hopefully also an extra dimension (just to the new supersymmetric partner and I achieve perfect unification at high energy). 😉

21. **Chris Oakley**
June 18, 2007

Achieving perfect unification with your supersymmetric partner on an uncomfortable Planck scale must be very hard.

22. **Prestito**
June 18, 2007

Well, really a nice idea make a blog about this argument. My best compliment about that.

23. **Matthew**
June 18, 2007

“Is there any mathematical cheating going on in going […] between Maxwell’s equations and the calculation of the force between two current-carrying wires?”

As a matter of fact, there is. It’s a bit hazy in my mind, but I do know there’s all sorts of problems in defining various “fundamental” things in classical E&M. For example, the radiation-reaction problem. Fuzzy things like pre-acceleration.

All the same sorts of problems that show up in QFT as a matter of fact. It’s just that, as Aaron pointed out, we know a lot more about their origin and how to solve them.

24. **anon.**
June 19, 2007

It’s a bit hazy in my mind, but I do know there’s all sorts of problems in defining various “fundamental” things in classical E&M.

Put current into a transmission line (pair of wires) by connecting them to a battery, and you get a continuous flat-topped logic pulse propagating along the transmission line at light speed for the insulator.

This violated Ampere’s law of circuits because the current pulse doesn’t know in advance if there is a complete circuit at the far end of the line, or an open circuit.

Maxwell’s whole genius was adding an ‘extra current’ to Ampere’s law which can flow across space between the two wires (even across a vacuum), completing the circuit while a transient flows into an open circuit!

What happens when you do the experiment with sampling oscilloscopes is you find that the energy reflects back from the far end of the transmission line. If it’s an open circuit at the far end, the reflected current adds to the energy flowing in, so the transmission line charges up, a little like a capacitor.

All the same sorts of problems that show up in QFT as a matter of fact.

Maxwell’s extra current was supposed to be due to the displacement of virtual fermions in the vacuum, which polarize in an electric field. The vacuum ‘displacement current’ consequently flows in direct proportion to the rate of change of the electric field, dE/dt.

Nice theory, and it predicts light. Problem is, QFT involves a vacuum polarization due to pair production of virtual fermions, only at high energy (above Schwinger’s electric field strength threshold for pair production, or the IR cutoff energy for particle scatter). So below the IR cutoff, Maxwell’s displacement current mechanism is in difficulty. However, the correction is easy to see: electrons are accelerated by electric fields in the conductors, so they radiate transversely. Each conductor behaves as an antenna radiating an inverted version of the radio signal from the other one. At large distances from the power line, the superimposed radio signals cancel out perfectly. The conductors are therefore just swapping this radio energy, and the resulting effect of the swap is equivalent to having a ‘displacement current’. So you still justify the Maxwell equations when you dig deeply, though his original theory is wrong.

25. **Peter Woit**
June 19, 2007

Enough about E and M, this is completely off topic.

26. **Scott Carnahan**
June 19, 2007

Chris,

I think mathematical rigor in a physical theory is an admirable thing, but history seems to indicate that it is not strictly necessary for progress. In particular, your example of celestial mechanics illustrates that people like Newton could make useful physical predictions using the theory of fluxions without the precision of epsilons and deltas that appeared two hundred years later. For another example, much of early quantum mechanics used objects like the Dirac delta, which was not made mathematically precise until Schwartz formulated the theory of distributions in the late forties. Quantum field theory is currently in the intermediate stage, like Kepler's laws in the early 1800s.

I don't think this sort of work should be rejected for a lack of rigor, because in the end, physicists are communicating ideas and calculational heuristics to other humans, not a proof-verifying computer. If an idea allows us to build a simpler mental picture of a process, or a heuristic consistently yields answers that agree with experiment, I think it increases our understanding of the universe, and some sloppiness should be tolerated. It is also occasionally useful for mathematicians who require rigor to have some bold theoretical leaps charted by people who aren't burdened by such restrictions.

27. **Intellectually Curious**
June 19, 2007

Scott,

If I understand your comments correctly, you seem to suggest that mathematicians are "proof-verifying computers," and that they should occasionally make some "bold theoretical leaps." But mathematical proofs require imagination and creativity as well as rigor in thought, and mathematicians are far from the automatons that you seem to depict they are. They are more like poets in this regard. And in order to do creative research, they do have to take bold theoretical leaps sometimes.

Arghh, I guess even some physicists (assuming you are one) misunderstand the nature of the mathematician's work. Well, at least you didn't think – as many members of the public do – that their work involves crunching numbers all day long. 🙂

28. **Chris Oakley**
June 19, 2007

Scott,

The important thing is that, when have a botch-up, you recognise it as such. The problem is that most QFT books & lecture courses sell renormalization like dishonest salesmen, harping on the miraculous achievements and hardly drawing attention to the caveats (such as my comment #461 here).

29. **Hendrik**
June 19, 2007

Peter, following on from your quote:

"Faced with the choice between changing one's mind and proving there is no need to do so, almost everyone gets busy on the proof."

There is a recent article in "Reason" supporting this exact point: http://www.reason.com/news/show/120455.html

30. **Peter Woit**
June 19, 2007

Hi Hendrik,

Thanks for pointing to the "Reason" article.

Also, thanks a lot for the comments on BRST, quite helpful and interesting. I think you're right that Hamiltonian BRST has a lot of problems with it, and in its present state is a very unsatisfactory formalism.

It's closely related to Lie algebra cohomology, and there's the same philosophical issue there: why not just look at the invariant part of a representation, what's the point of looking at a complex, whose 0-cohomology is the invariant piece you want?. Anyway, Lie algebra cohomology has had some real uses in representation theory, I've been trying to understand those for quite a while, only recently have some promising ideas that seem to connect to BRST, we'll see what that leads to.

Mathematicians have some really interesting theorems under the slogan of "quantization commutes with reduction", but the connection of this to BRST remains unclear.

31. **emyl**
June 19, 2007

>"quantization commutes with reduction"

but that is not true, as far as I know. At least, not in gauge theories.

32. **Peter Woit**
June 19, 2007

emyl,

Not sure what you have in mind. I was being too telegraphic perhaps, here's a survey article about exactly what I meant:

http://www.ams.org/bull/1996-33-03/S0273-0979-96-00661-1/S0273-0979-96-00661-1.pdf

33. **emyl**
June 20, 2007

peter,

thanks for the reference, looks quite interesting. What I had in mind were some examples quite similar to the one given in that paper after the statement of the central “theorem”, as they call it. Regards.

The Triple-Scoop

June 15, 2007
Categories: Uncategorized

Experimenters at the Tevatron have released data showing the existence of a new baryon, built out of a down, strange and bottom quark, and having a mass of 5.774 +/- .019 GeV. It has been given the name "Ξ_b". The FNAL press release is referring to this as a "triple-scoop" baryon, since it contains one quark from each of the three generations. Tommaso Dorigo has a new posting about this.

Postings on this blog tend to involve a certain amount of discussion of bad behavior by theorists, so I guess I should point out here that this story comes with some accusations of less than good behavior by experimentalists in the way this was announced. The press release is all about the announcement of this discovery by the D0 experiment, and about their paper, which was submitted to the arXiv Tuesday night. It turns out though that D0's competition, CDF, also has had the same result for a while, and it had already been "blessed" but not officially announced. So CDF was "scooped" at the last moment for the "triple-scoop", and I imagine there are dark accusations going around about how D0 might have found out about this and rushed out the paper and press release. Supposedly there is an informal one-week notification period that the two experiments normally observe to keep this kind of thing from happening. Anyway, looks like they're trying to fix it up a bit: the FNAL web-site contains a "special announcement" of back-to-back seminars about this, D0 at 1pm, which will "immediately be followed" by a CDF seminar. The D0 seminar is called

First observation of a new b-baryon, Ξ_b

whereas the CDF seminar is entitled

Observation of a new b-baryon, Ξ_b

Comments

1. **Chris**
   June 15, 2007

   It should be down, strange, and bottom quark.

   Best regards,
   Chris

2. **Peter Orland**
   June 15, 2007

   I remember similar behavior concerning the upper bound on
   the number of light neutrinos in the late 80's. The SLC (sort of
   the ILC scheme, except the two beams came from the same machine)
   at SLAC had a very small number of events (I think less than 30). Some people at Fermilab were also working at the SLC detector (I forgot the official name) and made sure to get their results out first. Shortly
   therafter the SLC was dismantled.

3. **Peter Woit**
   June 15, 2007

   Chris,

   Thanks! fixed.

4. **Coin**
   June 15, 2007

   I guess I'm trying to figure out exactly what the result or relevance of finding this particular particle was. I think I get what they found, and I get that it's historically impressive, but I'm not sure what it means for physics.

   Is the idea that the fact this particle exists is a surprise, and gives theorists some new work in explaining how it's possible? Or was this something they were hoping or planning to find, which validates a prediction of some previous bit of theory? Is the idea that now that this weird crossgenerational baryon has been found, they can do some experiments to explore its properties and thus maybe learn something new about the exact nature of the mysterious quark generations? Or is the spirit just "Golly gee gosh, look at this weird-looking thing that we got to come out of the accelerator"? (Note that I'm *not* saying this last possibility is at all a bad use of research time.)

   Also, does the existence of this thing mean they have to modify any of those nonets or decuplets or whatever that they use to classify hadrons?

5. **stefan**
   June 15, 2007

   Coin,

   the place of this "cascade-bottom" in the baryon multiplets has been known since long – see at Physics News Graphics for a graphical representation of the respective multiplet:

   http://www.aip.org/png/2006/270.htm

   I would be surprised if anything had to be modified in this scheme. The point is, of course, that most of these baryons have not been observed yet, although probably no one doubts that they exist.

   Interestingly, the Particle Data Group already lists the Cascade-bottom, if only as a "1-star" particle (meaning "Evidence of existence is poor" – see pdg.lbl.gov/2007/listings/s060.pdf). These first hints at its existence were found about ten years ago in the DELPHI and ALEPH experiments at CERN, but there seems to have been no mass determination at that time. It would be interesting to know how the Fermilab results fit to these earlier data.

I don't know if this is possible in practice, but it may be interesting to compare the now measured mass of the Xi_b with lattice calculations – for the bottom-charm meson B_c, there has been a quite spectacular agreement between lattice results and experimental data (see e.g. Physics News Update 731, May 2005). Moreover, all kinds of quark potential models used to describe the properties of hadrons work best for heavy quarks such as the bottom. So, it may be possible to check some predictions of these models against experimental data.

6. **ObsessiveMathsFreak**
June 15, 2007

To paraphrase Tom Lehrer

> And then I write
> By morning, night,
> And afternoon,
> And pretty soon
> My name in Dnepropetrovsk Fermilab is cursed,
> When he finds out I published first!

Although, D0 is at Fermilab too….

7. **Coin**
June 15, 2007

Stefan, thanks!

8. **csrster**
June 20, 2007

Hmm. Triple-scoop. Must have ice-cream.

9. **andy**
June 20, 2007

I hope that you tolerate an off topic post, Professor Woit.
Someone claiming to be Lubos Motl says that he is leaving science. In the comment area on Tommaso Dorigo's blog
http://dorigo.wordpress.com/2007/06/19/a-small-peter-woit/
I apologize if it turns out to be a hoax. I think that I have always been surprised by the vitriol from this man. But at the same time I think that the criticism against string theorists should have always sound more like "you thought outside the box on a tough problem but you are a valuable scientist and you should move on to another approach" and less like "we think you are an idiot."

10. **Peter Woit**
June 20, 2007

andy,

Lubos has been saying for a while that he was leaving Harvard after this academic year, and I gather that that's what's happening. I don't know what he intends to do, but perhaps he'll keep doing physics, just not at Harvard.

11. **A quantum diaries survivor**
June 21, 2007

Yes, Lubos is "retiring", but he will continue to think about science. And I bet a dime or two he'll continue blogging about it too!

T.

12. **Jim**
June 21, 2007

So does this mean that Lubos was denied tenure at Harvard?

13. **woit**
June 22, 2007

Jim,

Lubos is leaving a tenure-track job at Harvard, but he hasn't been there long enough to have reached the point where they would have to decide about tenure.

14. **JC**
June 22, 2007

Peter,

I thought assistant professor jobs at Harvard were NOT tenure-track? (ie. To get tenure at places like Harvard, one has to actually apply and compete for a separate tenured job opening? At other less prestigious places, it's largely an administrative change of job title after a committee review.)

15. **woit**
June 22, 2007

JC,

I don't know exactly how things work at Harvard, but I was under the impression that assistant professor position's like Lubos's are nominally tenure-track, although mostly they don't lead to tenure, and people who accept them are well-aware of this. There are several highly prestigious places in the US like Harvard where most senior hiring is done from outside, but typically there is a tenure-track system in place, even if most people in it don't actually get tenure.

Assorted News

June 22, 2007
Categories: Uncategorized

Yesterday Sean Carroll and I appeared on the BBC Radio 4 program The Material World, in a segment on String theory – knot good enough?, about the controversy over string theory. The segment started with a piece from the play Humble Boy by Charlotte Jones, in which the main character is working on string theory. I don't think anything either of us said was particularly controversial or would be in any way surprising to a regular reader of either of our blogs. The same program had a segment on the multiverse three weeks ago.

Some more titles of talks at next week's Strings 07 have appeared. Witten's talk is entitled "Three-Dimensional Gravity Revisited" and presumably will be about the new ideas described here. So, at least one talk there will be about a non-string theory approach to quantum gravity more along the lines of the LQG program. The schedule doesn't seem to include any discussion session like the one at Strings 05 where the audience voted against the anthropic landscape.

A competing conference to Strings 07, Loops 07 will be taking place at the same time next week, but in Mexico, not Madrid. It's much smaller, with less than a third as many participants. There will be one plenary talk on string theory, Moshe Roszali speaking on "Background Independence in String Theory".

As the hunt for the Higgs is heating up at Fermilab, and CERN has officially announced the delay of LHC startup until next May, there's a group of filmmakers who may be well-positioned if something exciting is found at the Tevatron. For the last few years 137 Films has been making a film to be called The Atom Smashers, following scientists working at FNAL. Filmmaker Clayton Brown is keeping a blog about this.

Yet another bogus "possible signature for string theory". Even Lubos doesn't seem to believe this one, so I'll just quote his argument:

My personal guess based on our work on the weak gravity conjecture is that the black hole bound is also satisfied in string theory for localized macroscopic objects, up to small corrections. This belief of mine is supported by the observation that Gimon & Hořava don't have any explicit solution for their "superspinar".

Christina Sormani tells me she has created a Wikipedia article on the proof of the Poincare conjecture, see here. For the latest on Perelman, see here.

Comments

   June 22, 2007

   'String Theory – knot good enough?

   'Radio 4 Drama's science season continues on Saturday with Charlotte Jones' play Humble Boy. In it, a young physicist turns to String Theory in an attempt to unite the irreconcilable in his life. But is he doomed to failure?'

   Sounds fairly realistic … will have to listen in tomorrow.

2. **Michael**
   June 22, 2007

   hehehe

   http://xkcd.com/c171.html

3. **Aaron Bergman**
   June 22, 2007

   So, at least one talk there will be about a non-string theory approach to quantum gravity more along the lines of the LQG program.

   ???

4. **Peter Woit**
   June 22, 2007

   Aaron,

   If Witten is talking about the same thing I heard him talk about, it's an approach to quantum gravity that involves non-perturbative quantization of the 3d version of Ashtekar variables, no strings anywhere to be seen.

5. **Aaron Bergman**
   June 22, 2007

   I think it's unseemly to speculate on what other people are working on, so I probably should just be quiet. I'll just say that it's silly to frame this as a LQG vs. string thing. Witten invented the Chern-Simons quatization of 2+1D gravity way back when.

6. **Christine**
   June 23, 2007

   For the latest on Perelman, see here.

   Well, I know next to nothing of the russian language, but tried one of those online translators, and giving some discounts to the usually terrible literal translations and other funny effects, I did not like what I read. Ridiculous.

7. **AGeek**
   June 23, 2007

   Tried Babelfish. They are making fun of him for riding the subway in sneakers rather than driving a Lamborghini in Guccis, after he turned down a million dollar reward?

How profound.

8. **anon.**
June 23, 2007

[Babelfish translation]

9. **Peter Woit**
June 23, 2007

Aaron,

The LQG comparison may be silly (but only very slightly so…), but I think it's remarkable that for the second year in a row Witten's talk at Strings XXXX will not be about string theory. And, I strongly suspect his talk will be by far the one with the most interesting new ideas.

10. **Kris Krogh**
June 23, 2007

Peter,

Your Perelman link — how would you feel if people followed you with cell phone cameras and posted it to the web?

11. **Peter Woit**
June 23, 2007

Kris,

I don't think it would bother me, if it was a rare event. A lot of it would certainly get annoying. Perelman may feel quite differently, I have no idea. I couldn't read the Russian comments, and if they're stupid and disrespectful, that's a shame.

12. **Viri**
June 23, 2007

[in English via google language tools]

Can someone who actually knows russian translate this?

13. **Eugene Stefanovich**
June 23, 2007

Here is my try at translation of the Perelman "news".

Almost forgot. Recently I met Perelman in St. Petersburg subway. Yes, that same crazy scientist who proved the Poincare conjecture. They wanted to give him Fields medal and 1 million bucks, but he told everybody to fuck off.

He boarded at subway station Kupchino and left at Victory Park. During that time I discreetly took pictures of him on my cell phone. The picture quality is bad, but that's all I have.

He looked like an accomplished tramp; he also had a huge fingernail on his little finger that he used to constantly probe in his mouth. Terrible. Nobody recognized him except myself, that was somewhat strange. However, my surprise disappeared when I tried to tell about this encounter to my acquaintances: less than one out of five heard anything about Perelman. Although he was shown on TV many times.

14. **Aaron Bergman**
June 23, 2007

How'z'bout we wait for the talk and then see what's in it?

15. **Pavel Krapivsky**
June 23, 2007

Here is a translation of a note about Perelman:

I almost forgot! A few days ago I met Perelman in St. Petersburg's metro. Yes, that crazy scientist who proved Poincare conjecture. They wanted to give him a Fields medal and 1,000,000$, but he said — go fuck yourself. So Perelman got in on "Kupchino " station and he got off on "Park of Victory" and all the time when he was in the car I was recording him on my phone. Quality is poor, but it is what it is.

He looks like a homeless. He has a very long nail on his pinky, and he pecked in his mouth with this nail. Awful. Apart from me, nobody recognised him which was sort of odd. Yet I am not surprized anymore — when I described the story to my friends, at most one out of five ever heard about Perelman. Although there were many programs about him on TV.
%%%

Overall, the author uses quite illiterate Russian, and I am not surprised that it is hard to translate mechanistically. The following comments are totally useless, and many are indeed stupid and stinky, so after reading such comments one may want to take a shower.

16. **Peter Woit**
June 23, 2007

Aaron,

Well, I heard him give a talk with pretty much the same title a few weeks ago here in New York. During the talk he brought up the question of LQG, noting that in 3d you could covariantly express gravity in terms of a gauge theory, that the way this was done in 4d (LQG) was non-covariant. I'm not sure I really understand this point, maybe he will elaborate at Strings or in a paper.

In the question session afterwards someone asked him about whether what he was doing could be embedded in string theory. His only answer was to note that recent arguments claiming to show that you can't decouple supergravity completely from string theory in a limit failed in 3d, implying that even if you embedded what he was doing in string theory, it could be completely decoupled from the string theory. There was nothing at all about string theory in his talk. Perhaps he has come up with an important connection to string theory in the last few weeks, perhaps there is some less important connection to string theory which he'll mention in Madrid but didn't mention in New York. But, as far as one could tell from his talk here, the important new idea he has about 3d gravity doesn't have anything to do with string theory.

17. **Richard**
June 23, 2007

Not even having the benefit of the translation yesterday, I thought that these pictures and the picture taker — not Perelman himself — were a bit creepy.

18. **gunpowder&noodles**
June 24, 2007

I wonder who decides the list of invited speakers. There are some pretty odd choices there — some people whose recent papers have hardly been cited, and others whose talks are clearly going to be re-runs of talks given many times before……the only novel-looking talks are those of Verde and Vafa.

19. **Chris Oakley**
June 24, 2007

Er … Pavel, what was wrong with Eugene's translation?

To tell the truth, I am a bit disappointed with Perelman. I was hoping that he would be wearing a T-shirt with "F*** the IMU" on it.

20. **Viri**
June 24, 2007

«Er … Pavel, what was wrong with Eugene's translation?»

I think Pavel meant that the article's author used "illiterate Russian" not Pavel and thats why machine translations of it suck even more than usual. (seems clear to me)

Regarding the 1 in 5 ratio who knew of Perelman, I bet all of them know who Paris Hilton is. She achieved so much after all…

21. **Chris Oakley**
June 24, 2007

Eugene is a Russian speaker!

22. **Peter Woit**
June 24, 2007

gunpowder,

I presume the speakers are chosen by the "International Advisory Committee"

http://gesalerico.ft.uam.es/strings07/020_organization07_contents/021_international_ac.htm

Have you considered that the very small number of talks that sound like they'll have novel ideas might be due to something other than the advisory committee not doing the best possible job of coming up with speakers?

23. **Aaron Bergman**
June 24, 2007

Well, the paper is out, and it's about finding dual CFTs for 3D gravitational systems. So, I suppose it depends on whether you call AdS/CFT string theory or not.

24. **LDM**
June 24, 2007

The Pavel Krapivsky and Eugene Stefanovich translations are correct… with Eugene capturing just a little more correctly (for examples Eugene gives the translation "bucks", which is what the author wrote, whereas Pavel gives "$", normally understood as dollars, which is not what was written.

However, both I think did not capture the true flavor of the obscenity, because while there are a variety of ways to say "**** you" in Russian, the one chosen was one of the strongest…so strong in fact that some Russians will not utter it and will prefer a euphemistic, watered down form. It is also doubtful that a machine translation would get the obscenity, because нахуй correctly written should be two words, на хуй…which I will not translate here for reasons of decorum.

What is NOT correct is the statement that Perelman appears often on Russian TV. I get 16 channels of Russian and Ukrainian TV, and have yet to see Perelman on the news.

25. **Peter Woit**
June 24, 2007

Aaron,

Invoking the letters AdS/CFT doesn't make it string theory. This isn't string/gauge duality since there are no strings on the AdS side.

People have looked a lot at exactly this AdS_3/CFT_2 correspondence, trying to relate string theory on AdS_3 to 2d CFT. This gets very complicated and ugly from what I can tell. What Witten has done is throw out the strings on the AdS side, making things much simpler, and it seems, much more interesting.

26. **Aaron Bergman**
June 24, 2007

Strangely, most string theorists don't feel the need to live in such pigeonholes.

27. **Kea**
June 24, 2007

On page 37, Witten does mention the possibility of embedding this into a string theory.

28. **gunpowder&noodles**
June 24, 2007

“Have you considered that the very small number of talks that sound like they’ll have novel ideas might be due to something other than the advisory committee not doing the best possible job of coming up with speakers?”

I really wouldn’t presume to judge that. What I do know is that, if I were on that committee, I would find some diplomatic way of telling the invitees, in the strongest possible terms, that we don’t want to see the nth re-hash of a talk claiming that eternal inflation is absolutely guaranteed to work, that 3-dimensional gravity is really cool despite the abundant evidence that it is utterly unlike 4-d gravity, etc etc etc.

29. **M**
June 25, 2007

sorry Peter: I stopped after reading the 1st sentence of the abstract, because it looks one more paper that studies irrelevant physics in order to find interesting mathematics.

Is this recent theoretical trend healthy for physics? Please search “FIND A WITTEN AND TOPCITE 500+” on SPIRES: how many of these 46 super-papers should an experimentalist read? And what about other theorists that do Witten-style research without being Witten?

30. **joe**
June 25, 2007

There was a New Yorker article about Perelman, Yau & others pursuing the Poincare Conjecture proof:

http://www.newyorker.com/archive/2006/08/28/060828fa_fact2?currentPage=10
http://www.newyorker.com/archive/2006/08/28/060828fa_fact2?currentPage=11

> … and said that he was dismayed by the discipline’s lax ethics “It is not people who break ethical standards who are regarded as aliens,” he said. “It is people like me who are isolated.”
> …
> As for Yau, Perelman said, “I can’t say I’m outraged. Other people do worse. Of course, there are many mathematicians who are more or less honest. But almost all of them are conformists. They are more or less honest, but they tolerate those who are not honest.”
> …
> The prospect of being awarded a Fields Medal had forced him to make a complete break with his profession. “As long as I was not conspicuous, I had a choice,” Perelman explained. “Either to make some ugly thing”—a fuss about the math community’s lack of integrity—“or, if I didn’t do this kind of thing, to be treated as a pet. Now, when I become a very conspicuous person, I cannot stay a pet and say nothing. **That is why I had to quit.”** We asked Perelman whether, by refusing the Fields and withdrawing from his profession, he was eliminating any possibility of influencing the discipline. “I am not a politician!” he replied, angrily.
> ..
> Mikhail Gromov, the Russian geometer, said that he understood Perelman’s logic: “To do great work, you have to have a pure mind. You can think only about the mathematics. Everything else is human weakness. Accepting prizes is showing weakness.” Others might view Perelman’s refusal to accept a Fields as arrogant, Gromov said, but his principles are admirable. “The ideal scientist does science and cares about nothing else,” he said. “He wants to live this ideal. Now, I don’t think he really lives on this ideal plane. But he wants to.”

!!

He quit his job as a mathematician, because of his discovery..because his notoriety would force him to deal with the unethical idiots.

You now understand Perelman’s MIND (totaly Ideality, VS Reality=Corruption), which accounts for his isolation. The latter is perceived as eccentricity, the extreme language FU!.

This reminds me of the quote:

“An unreasonable man tries to Change the World, a reasonable man adapts to it..we need more unreasonable men”
— Revolution VS Evolution

“Captain Pike has an illusion, and you have reality. May you find your way as pleasant.””
— [“The Menagerie”](#)/Star Trek, Talosians final message to Capt. Kirk

Perelman changed the world of mathematics, & has “retired” into a world of mathmatical-ideality (“illusion”..mathematics is said to be imaginary by a famous mathematician)

ST is an “illusion” (all math, no connection with real-world experiment), & after 20 years needs to be “retired”. The Star Trek quote refers to 2 paths: Reality & Illusion. “Not Even Wrong” is accentuating that the Illusion is going no where.

31. **Thomas Larsson**
June 25, 2007

I am confused about what Witten tries to do. Wasn’t CS theory for general group G solved 20 years ago, with all correlators being framed knot invariants which can be readily computed from G. Why not just put G = SO(2,1) and be done with?

In my understanding, the difference between a spin connection and a SO(2,1) gauge connection is that you have a vielbein which can be used to write down the Einstein-Hilbert action,. But the CS action does not depend on the vielbein, so I don’t see what special about spin connections in this case.

Anyway, it is striking that there are two unphysical assumptions: D = 3 and a negative cc. Witten suggests in section 1.2 that a world with positive cc (like the one we may be living in) is always at best metastable, which is pretty close to the anthropic worldview.

32. **Peter Woit**
June 25, 2007

M,

I agree the Witten paper has no direct physical relevance, and there’s no reason experimentalists should be reading it. But it’s a fundamental new idea about gauge theory, gravity and mathematics, and as such it may some day lead to something directly physically relevant. I think a lot of Witten's best work should be thought of as analogous to some of the best work of experimentalists developing new detector technologies and acceleration techniques. There's no reason a theorist should be reading the papers of people who are making advances on using lasers to accelerate particles, and this work is not of any immediate use in HEP, but it is very important that someone is doing this kind of thing, and it is the sort of thing that may lead to important breakthroughs in the future.

Thomas,

CS theory is just not well understood at all for cases like this of non-compact space and groups. One of the interesting things about Witten's work is that I think it shows how little we understand about what many people think of as simple gauge theory QFTS which are completely understood.

33. **Peter Woit**
June 25, 2007

Aaron,

I was making no comment at all about string theorists, I was making comments about string theory. You seem a tad defensive…

I won't be surprised a few years from now when string theorists are working on 4d gauge theory approaches to quantum gravity using Ashtekar variable, insisting what they are doing should be called "string theory". I think Nati Seiberg made the comment to a reporter a couple years ago that whatever theorists had some success with in the future, they would call it "string theory".

34. **urs**
June 25, 2007

Classical Einstein gravity may be formulated as a theory of SO(n,m)- and/or ISO(n-m)-connections. This basic fact underlies the approach of LQG just as well as many developments in the study of supergravity, which is usually best understood as a gauge theory for the super Poincare Lie algebra.

The crucial point of LQG is 2-fold

1) conceive the space of all these gauge connections as a space of holonomy functors

2) pass from the space of ordinary (smooth) connections to the larger one of "generalized connections" (essentially dropping smoothness and continuity of the holonomy).

It is mainly the second point here which makes LQG different from other approaches of quantizing gravity. I don't think that Witten is talking about quantizing Chern-Simons using "generalized connections".

But I do very much agree that it is good that attention is being paid to understanding gravity as a theory of gauge connections. Of smooth connections, in particular. One look at the LQG program anew, without passing to generalized connections.

35. **urs**
June 25, 2007

> One look at the LQG program anew […]

One should look at […]

36. **Aaron Bergman**
June 25, 2007

I was making no comment at all about string theorists, I was making comments about string theory.

I just think it's amusing that anything you think is interesting you define to not be string theory. I think most of the rest of world would consider AdS/CFT as part of the circle of ideas generally called "string theory".

You seem a tad defensive…

Are you really going to play the "defensive" game? It doesn't put you in very good company.

37. **Pavel Krapivsky**
June 25, 2007

There is nothing wrong with Eugene's translation, I just submitted mine before I saw his. LDM rightly says that it is hard to "capture the true flavor of the obscenity".

38. **Peter Woit**
June 25, 2007

Aaron,

Most of the world considers AdS/CFT to be "string theory" because the AdS side of the correspondence is a string theory. I seem to be repeating myself, but it's a simple fact that in Witten's paper the AdS side of the correspondence is NOT a string theory. Claiming that what Witten is doing in this paper is "string theory" is simply dishonest.

39. **Aaron Bergman**
June 25, 2007

And I think that's all there is to say on the subject.

40. **marcus**
June 25, 2007

Peter said:
Claiming that what Witten is doing in this paper is "string theory" is simply dishonest.

Urs said:
One look at the LQG program anew, without passing to generalized connections.

One convenient way to do that—combining a fresh look with an illustrative comparison—is to follow Laurent Freidel's recent online seminar talk of 15 May.

Matter coupling to 3d quantum gravity and effective field theory

The link to the series of online LQG seminars is at

http://relativity.phys.lsu.edu/ilqgs/

The direct link to the PDF of Laurent's slides is
[url]http://relativity.phys.lsu.edu/ilqgs/freidel050807.pdf[/url]

The direct link to the MP3 audio of his talk is
[url]http://relativity.phys.lsu.edu/ilqgs/freidel051507.mp3[/url]

A key point which Laurent makes at the outset is that because matter is present the system has infinitely many degrees of freedom and that he is intentionally restricting himself to using analytical tools which apply to the 4D case (with matter) as well. He explicitly excludes AdS/CFT.
In the work described in the talk, the authors get Feynman diagrams of matter out of spinfoams (the "paths" of spacetime geometry evolving in a path-integral picture).

Since both talks are recent and concern 3D gravity, they make an interesting side-by-side comparison and allow the fresh look that Urs mentioned.

41. **Changcho**
June 25, 2007

Perelman is a very intriguing character. I liked the quote from joe about needing more "unreasonable men" to change the world.

LDM: I have been studying a bit of the Russian language, but strangely enough I could not find the insulting expression in my russian textbook ;-), thanks! However, from your post I should be very careful about that insult as you imply that it is very strong…

42. **urs**
June 25, 2007

Why is theoretical physics harder than mathematical physics? Witten gives a good explanation on p. 10:

> We make at each stage the most optimistic possible assumption. Decisive arguments in favor of the proposals made here are still lacking. The literature on three-dimensional gravity is filled with claims (including some by the present author [6]) that in hindsight seem less than fully satisfactory. Hopefully, future work will clarify things.

😉

43. **M**
June 25, 2007

Peter, I do not understand your analogy: nobody would worry that people who develop lasers might have lost contact with the reality. On the contrary, the physical relevance of a certain kind of theoretical work looks questionable, even taking into account that sometimes progress comes from unexpected directions. I wonder what Newton would have achieved by studying topological supergravity in lower dimensions.

44. **urs**
June 25, 2007

> One convenient way to do that—combining a fresh look with an illustrative comparison—is to follow Laurent Freidel's recent online seminar talk of 15 May.

What I meant is that it is still an open (though possibly also still intractable) problem to find the quantized configuration space of *smooth* connections in the case of either Yang-Mills theory or of Einstein gravity, or of any other non-trivial nonabelian gauge theory.

I am talking about the analog of the "LOST theorem

href="http://de.arxiv.org/abs/gr-qc/0504147

or the analogous result be Ch. Fleischhack

http://arxiv.org/abs/math-ph/0407006

by CH. Fleischhack — but for *smooth* connections.

In fact, this has been done in the case of abelian (but possibly higher) connections by Freed, Moore and Segal. They find a couple of very interesting — and very subtle — quantum effects. Precisely *this* kind of analysis ought to be done for Yang-Mills and/or Einstein gravity in Palatini form.

Clearly nonbody can do it right now. But that's the interesting problem to solved. I would appreciate if people started looking into this problem more seriously. Freed-Moore-Segal demonstrate that there is gold to be found here…

45. **elzorro**
June 25, 2007

Not sure if it has been mentionned on this blog already but there has been a quantum gravity school in Poland last march organized by John Barrett and Hermann Nicolai covering some string theory, some LQG, and some stuff related to noncommutative geometry and to quantum groups. Some of the lectures notes are online, all the talks being available as mp3s http://www.fuw.edu.pl/~kostecki/school.html

46. **LDM**
June 25, 2007

M:
The history of the laser is the opposite. Some very great physicists did think it was crazy. When Townes met Niels Bohr in Denmark and explained to him the idea behind the maser, he said "but that is not possible". Townes never could convince him.

Von Neumann had the same reaction (but later changed his mind).
Noted Columbia theorist Llewlen Thomas said flatly it could not work, and stopped talking to Townes. All this is recounted by Townes in chapter 5 of his book "How the laser happened".

So in some sense, the laser analogy is not too bad, but contrary to Peter's opinion, the theorists can learn a lot from experimentalists, as the laser history shows.

If I cared to refute Peter's analogy, I would prefer to cite an observation of Ulam's in regard to Von Neumann:
"Von Neumann was the master of, but also a little bit the slave to, his own technique. When he saw that something could be done, he let himself be carried away on tangents. My own feeling is that some of his work on classes of operators or on quasi-periodic functions, for example, is very interesting technically, but to my taste not terribly important; he could not resist doing it because of his facility." – Adventures of a Mathematician, pg. 78.

Witten results are technically interesting to mathematicians, but to my taste, not terribly important for real physics.

47. **Peter Woit**
June 26, 2007

M,

Another way of saying my analogy is that every scientific field is limited in what it can do by the limits of its tools. What Witten is doing is trying to come up with new understanding of the basic tools of fundamental physics, QFTs. Personally I think a deeper understanding of the relation of math and QFT may lead to new tools that might ultimately allow the solution of fundamental problems in HEP. Sure, this hope is very speculative and maybe wrong, but I think it's as promising a speculative idea as any others out there at the moment.

It's hard to tell where new ideas like Witten's will lead, maybe nowhere. But at least he's coming up with new ones, not endlessly working on the same tired ones that don't work like most people.

48. **M**
June 26, 2007

LDM, I didn't know this history, but I insist that inventing the laser might have been successful physics or unsuccessful physics. In any case, physics.

Peter, in some speculations I see the effort to come back with results (e.g. today the arXiv:0706.3688 paper by Chamseddine and Connes), while a too large fraction of hep-th now looks disconnected from reality.

Anyhow, let's wait 30 more years to see if we will better understand physics by studying things like gravity in 2+1 dimensions, the SM landscape in 2+1 dimensions, etc.

49. **Kea**
June 26, 2007

Witten's criticism of the gauge theory approach, mentioned by Distler (who was at the talk), would seem to apply to both strings and Woit's favoured QFT thinking.

50. **anon.**
June 27, 2007

Kea, I note that you quote Lubos' remark on your blog:

"Well, I happen to think that if Edward Witten started to work on loop quantum gravity, as defined by the existing contemporary methods and standards of the loop quantum gravity community, it wouldn't mean that physics is undergoing a phase transition. Instead, it would simply mean that Edward Witten would be getting senile. We all admire him and love him, if you want me to say strong words, but he is still a scientist, not God." – Lubos Motl

This kind of gives the impression that Ed Witten risks being deemed as "senile" and "not God" but merely "a scientist" if he did take more interest in Loop Quantum Gravity. Maybe that's why he doesn't?

51. **LDM**
June 27, 2007

M:
Since that particular laser history is not taught in the textbooks, it is safe to say more than a few physicists are unaware of it.

Regarding your comment:
Anyhow, let's wait 30 more years to see if we will better understand physics by studying things like gravity in 2+1 dimensions, the SM landscape in 2+1 dimensions, etc.

Well of course, there's no need to wait 30 years, you can simply decide now that these approaches are sterile, and so strike out on your own…and if these approaches are not likely to go anywhere in terms of physics, you have *drastically* increased your chances of discovering something interesting by not studying them.

52. **evankeane**
June 27, 2007

Ah i noticed this paper on the violation of the Kerr bound while perusing the arXiv … was wondering if you would mention it!

Evan Keane

Strings 2007

June 25, 2007
Categories: Strings 2XXX

Strings 2007 is starting today, and already there seem to be a large number of different laptops connecting to this blog from wlan.uam.es. I'm hoping that some of their owners will write in here with news of how the conference is going. I'll also try and add links here to any blog and press coverage of the conference that I see or hear about.

Witten's new 83 page paper entitled Three-Dimensional Gravity Revisited appeared on the arXiv last night and presumably this is the detailed version of what he'll be talking about in the first of tomorrow's talks at the conference. It corresponds pretty much to what he talked about here in New York a few weeks ago, which was described here. I assume many of those laptops at the conference are being used to download and read copies of Witten's paper. At his blog, Clifford Johnson notes that he won't be at Strings 2007, and hopes that this will ensure that there will be an exciting breakthrough announced there, just like what happened when he decided not to attend Strings 1995.

As I write this, I see that string theorist Jacques Distler is there live-blogging. Here's the first of his reports.

Update: Some of the slides of the talks are already on-line. The slides for Witten's talk are available here.

Update: There's an interesting posting here by Jacques Distler about the Witten talk, and, for those who enjoy such things, quite a rant from Lubos here, prompted by my comment that in this case Witten is investigating quantum gravity using non-perturbative QFT, not strings.

I've been reading Witten's paper a bit more carefully, and it raises all sorts of interesting issues. He makes the point that even in 3d, we really don't know exactly what "non-perturbative pure quantum gravity" is. He uses the Chern-Simons formulation of 3d gravity in terms of gauge theory to motivate his guess at the correct boundary CFT, and then once he has that he has something much more well-defined to study.

This is a bit reminiscent of the compact, non-gravitational situation. There Chern-Simons theory works fine perturbatively, but to understand the non-perturbative theory one connects it to a CFT on the boundary, in this case the Wess-Zumino model (this is the story that got Witten a Fields medal).

Update: B. Yen has set up a video-blog for Strings 2007, where there will be iTunes podcasts of the conference available.

Update: Latest report from Jacques Distler is that, since Witten's one, which he got to write about:

*there have been some **very** cool talks*

(emphasis in the original), but he can't tell us even which ones they were since his laptop is malfunctioning. Slides of the talks are available here. I've looked through them and, besides Witten's, don't see anything I would describe as "**very** cool", but maybe that's just me.

Update: All the talks are on-line now and I just looked through the last of them, and watched the summary talk by Gross. Lisa Randall discussed recent calculations of black-hole production at colliders, with the bottom line being that even in the unlikely event the gravity scale is within reach of the LHC, existing bounds already pretty much rule out the possibility of seeing the kind of dramatic effects from black hole production that have been widely advertised as something that might be seen at the LHC.

Gross noted that the conference was much less mathematical than last year's, possibly because Yau was not involved in organizing it. He was most enthusiastic about describing the many talks on AdS/CFT, especially the Beisert talk which told about recent progress in getting an exact solution of N-4 SYM. Some talks referred to possible applications of AdS/CFT not just in QCD and heavy-ion physics, but in condensed matter physics (using the duality to get info about relevant CFTs). He told about Polchinski's speculation that "maybe AdS/CFT will solve high T_c superconductivity", but dismissed it with "sounds great, but seems unlikely to me." He dealt with the landscape talks by flashing them by quickly, in a lower and less enthusiastic voice, noting that they made up at least a quarter of the talks at the conference. He dealt similarly with the cosmology/anthropic talks, describing Bousso's as "an attempt to make the anthropic principle precise if not respectable."

After the summary, he gave his own take on the state of string theory, saying that one had to be honest about the lack of falsifiable predictions and that now he had a slide headed "The Failures of String Theory". He continues to feel that the main failure is because we "don't know what string theory is", that something is missing, some principle that would pick out not a "vacuum" but a "cosmology", one perhaps using new ideas about what space and time are. He said he was not too upset by the landscape, because "we don't know what the rules are" in string theory, so one can't argue that string theory implies the landscape. He appeared to feel that he is losing the debate, complaining that this used to also be the opinion of his colleagues, but that they were going over to the other side because of the cosmological constant, saying that if another explanation of the CC was found 90% of the anthropicists would come back to his side. He tried to minimize the size of the CC problem, measuring it with respect to a supposed 1 TeV SSYM breaking scale and working in energy, not energy density units, so it is only too small by a factor 10^{16}. He compared this to Dirac's famous large number problem (which Dirac tried to solve not anthropically, but by time-varying constants, leading to a prediction that was falsified), which was finally "explained" by asymptotic freedom. His message to the anthropocists was "just because you don't know an explanation doesn't mean it doesn't exist".

Finally he mentioned that Strings 08 will be at CERN, Strings 09 in Rome, and no one has yet agreed to host Strings 10. He argued that the series of Strings conferences "must go on", because they are "like the canary in the coal mine", and if they stop that would be a very bad sign for string theory.

I'm curious to know what those in attendance thought of this; it wasn't exactly a rousingly optimistic portrayal of the state of the subject…

Update: There's an article in El Pais about the conference and about the state of string theory. My Spanish isn't perfect, but as far as I can tell the piece was pretty much pure unadulterated hype, of the sort that it is one goal of the Strings XX bashes to generate.

Update: Jacques Distler finally got his computer fixed, and posted about one example of what he considered a "**very** cool talk" with exciting new ideas. Unfortunately, it seems the ideas are not that new, since a commenter wrote in to his blog to point to papers from four and a half years ago that do pretty much the same thing.

Comments

1. **A quantum diaries survivor**
   June 26, 2007

   Hi Peter,

   I wonder why three international conferences dealing with strings one way or another are being held at more or less the same time around the globe. I of course would not have dreamt of going to Strings 07, while I am indeed going to Pascos next week, which has some strings flavor but admittedly is also devoted to particles and cosmology. But die-hard stringers might have had to make a difficult choice.

   By the way, I will try to report from there, but I will be there only for a couple of days so I can't really promise anything…

Cheers,
T.

2. **marcus**
June 26, 2007

here is a sample exerpt from the talk by Witten, slides 14 – 16:
==quote==
First of all, I am only going to consider the case of negative cosmological constant.
Currently there is some suspicion that quantum gravity with Lambda > 0 doesn't exist non-perturbatively (in any dimension) with positive cosmological constant. The reason for this is that it does not appear to be possible, with Lambda > 0, to define precise observables. This is natural if it is the case that a world with positive cosmological constant (like the one we may be living in) is always unstable.

If that is so, then a world with Lambda > 0 doesn't really make sense as an exact theory in its own right but (like an unstable particle) must be studied as part of a larger system.

Whether that is the right interpretation or not, since I don't know how to define any precise observables, I don't know what it would mean to try to solve 2+1-dimensional gravity with Lambda > 0, since it isn't clear what we'd want to compute.
==endquote==

Unfortunately this sounds like a rationalization. Perhaps it is a question of what tools one uses, as you suggested in comment to your previous post:
http://www.math.columbia.edu/~woit/wordpress/?p=570#comment-26394
If one set of tools for studying the world fails to provide observables, then before declaring the world we "may be living in" to be "like an unstable particle" it seems a sensible reaction would be to look around for better technical means. Am I missing some essential part of the message? Maybe others would comment on this passage.

---

3. **Thomas Larsson**
June 26, 2007

Marcus,

Witten's argument is exactly what leads to anthropic principle: if our dS universe is only a metastable vacuum, it is probably an ugly mess from a landscape of possibilities, and there is no beautiful selection principle to guide us. Declare defeat, and work on mathematically nice but physically wrong things, like 3D and AdS.

This is a unavoidable problam if all observables in QG are global, because dS space lacks the right asymptopia where the global observables can live. AFAIU, the only way around this dilemma is if there are local observables in QG after all; then we don't have to worry about the lack of global observables.

Indeed, we know for sure that there are local observables in classical GR – Rovelli's GPS coordinates. Now, these are only partial observables, but we could make them complete by reading a local clock. Without leaving my car (if I had one), I could use my fancy GPS equipment to read off my GPS coordinates, and read off the dials of my watch to get proper time, and get a local, complete observable. This observable is local, because I don't have to visit a holographic screen in an AdS region of the multiverse (i.e. outside our visible dS universe) to make this observation; I can stay in my car.

4. **Peter Woit**
June 26, 2007

Marcus,

I think this debate over dS observables is completely irrelevant to the Witten paper. All he is doing is referring to that debate and noting that the arguments in his paper involve the AdS case, and don't apply to the dS case. He's not making any claims in this paper of any new ideas or understanding about the dS case.

5. **Jim Clarage**
June 26, 2007

If I were still in theoretical physics I'd eagerly await next year's Strings 2008. For it will mark the 175th anniversary of Hamilton's article on optics and planetary motions where he invokes the spirit of Bacon:

In every physical science, we must ascend from facts to laws… and unity arises from variety: and then from unity must re-deduce variety, and force the discovered law to utter its revelations of the future.

Or if I can quote again with inlines relevant to science nearly two centuries later:

In every physical science [even string theory], we must ascend from facts to laws… and unity arises from variety: and then from unity must re-deduce variety [i.e., must reproduce the standard model], and force the discovered law to utter its revelations of the future [i.e., make novel and testable predictions of future experiments].

6. **Peter Woit**
June 26, 2007

Hi Tommaso,

One reason there are a lot of string theory conferences (20-30 a year) is that there are a lot of string theorists. And conferences are concentrated in the summer months when people don't have to teach. Typically there are a few smaller "satellite" conferences organized before and after the main Strings conference, at locations not too far away. I gather there are some of these going on around now. Will look forward to your reports from PASCOS!

7. **Eugene Stefanovich**
June 26, 2007

Jim Clarage:

I don't think that string theory should be blamed exclusively for the stagnation in modern theoretical physics. I think that the fundamental problem was best expressed by Mark Srednicki in his reply to Chris Oakley on Cosmic Variance

And I don't agree at all with your statement that while "it would be very nice to explain SM parameters, but establishing a mathematical framework free of inconsistencies has to be done first." Historically, progress in physics has almost never been made this way. It almost always came by somebody futzing around with some not-fully-baked theory, until something interesting popped out.

This “futzing around with some not-fully-baked theory” was very successful until 1960’s. But, apparently, it doesn’t work anymore. I think that the chance that something will “pop out” is close to zero. Maybe it is time to stop relying on random attacks and switch to a methodical and organized siege: Decide which physical principles are truly important (the principle of relativity? laws of quantum mechanics?…) and build a rigorous axiomatic mathematical framework around these principles.

8. **hmmm**
June 26, 2007

> Decide which physical principles are truly important (the principle of relativity? laws of quantum mechanics?…) and build a rigorous axiomatic mathematical framework around these principles.

Well that’s the whole problem isn’t it. That’s like saying *“…to become a gazillionaire we need to decide which business idea is the right one and build a rigorous business around that…”*

9. **Eugene Stefanovich**
June 26, 2007

hmmm,

That was my point. I have an impression (please correct me if I am wrong) that there is no much interest in designing a sound plan and building the “business” from ground up. Just look at talks at String 07 or any other similar gathering. People are trying to prove theorems without even knowing what their axioms are. These are conjectures based upon previous conjectures. Using your analogy, they try to become gazillionaires by gambling in a nearby casino. Srednicki thinks this is the way to go. I respectfully disagree.

10. **Coin**
June 26, 2007

Using your analogy, they try to become gazillionaires by gambling in a nearby casino.

Well, they have to. It’s the only game in town.

11. **Coin**
June 26, 2007

So I’m afraid a lot of this is beyond my current level of understanding, but I’m trying to figure out– it’s been commented several times that Witten’s Strings 2007 paper here doesn’t seem to have much to do with string theory. However, it does seem like it has a lot to do with AdS/CFT correspondence. In fact, it seems like he’s *using* the AdS/CFT correspondence; as I understand this he’s analyzing black holes in 3-dimensional AdS spacetime by reasoning about the equivalent 2-dimensional conformal field. That’s AdS/CFT, right? So here is basically what I’m trying to figure out:

1. This paper seems to somehow be using AdS/CFT without talking about strings. I didn’t actually realize you could *do* that. Is there anything “special” about CFTs that correspond to spaces with strings, or is it just a matter of whether you choose to describe the space as containing strings?

2. Although the paper doesn’t explicitly talk about strings, would it make sense for the ideas in this theory to be followed up, in either a later paper by Witten or somebody else, by linking these ideas to string theory or simply adding strings to the toy model described here? If so, what would that look like? Like, would it make any sense to drop strings into the toy model here and analyze their interactions with a BTZ black hole?

12. **Peter Woit**
June 26, 2007

Just a reminder. If you want to have general philosophical discussions about physics, please find some other forum. If you have something substantive to say specifically about the topic of this posting, String 2007, please do so.

13. **Peter Woit**
June 26, 2007

Coin,

When people talk about “AdS/CFT” duality, they normally are talking about a relationship between string theory on five-dimensional AdS space (really AdS times a 5-sphere, the strings need 10 dimensions) and a supersymmetric gauge theory on its 4d asymptotic boundary. More generally, one hopes that this string-gauge duality works for different sorts of geometries. One could try and do this with 3d AdS space, and people have worked on that.

But this is just not what Witten is doing. He’s not looking at string theory on the AdS space, he’s looking at pure gravity, and at a Chern-Simons gauge theory, and trying to understand their relation. Pure gravity and string theory on AdS are just two very different theories. What Witten is doing just isn’t a string/gauge duality. I don’t see what you’re going to achieve by adding string theory to this story, and I suspect if Witten thought one could get anything that way, he’d certainly be mentioning it in his paper or talk at the conference. Strings are mentioned zero times in his talk

14. **ori**
June 27, 2007

Let us leave alone for a moment the question of whether the recent paper of Witten has anything to do with String theory or not.

What it clearly implies, is that variable changes as those promoted by Ashtekar and used in LQG can not be correct, and have nothing to do with the quantum version of gravity (which is expected to have black holes to start with). Thus, in the most well understood situation of 3d gravity, where the variable change is clean and covariant (unlike 4d) Witten shows that this avriable change is menaingless in quantum level.

Should we still expect that 4d LQG tricks do makes sense ? certainly not. This is a complicated non covariant version of the 3d case, and one should not expect any conclusion besides that LQG has no meaning after quantization.

Thus, one of the conclusions of Witten’s paper is that LQG does not make any sense.

15. **Peter Woit**
June 27, 2007

Ori,

Witten does not claim that using gauge variables and the Chern-Simons action has nothing to do with quantum gravity. He actually uses these to produce the correct central charge of the boundary CFT. Here's what he actually does say about this:

> We know that Chern-Simons gauge theory is useful for perturbation theory, as was explained in that section, and we hope that it is useful for understanding some nonperturbative questions. We used the gauge theory approach to get some hints about the right values of the cosmological constant (or equivalently of the central charge) simply because it was the only tool available.

The variables that do seem to be useless for non-perturbative quantum gravity in 3d are string variables. Witten doesn't mention strings at all in his talk and gives no indication that he thinks they have anything to do with this problem.

Unfortunately I don't think this tells us anything one way or another about 4d, but if one could have the kind of success there starting with Ashtekar variables that Witten seems to have starting with Chern-Simons in 3d, that would be quite spectacular.

16. **Ori**
June 27, 2007

Peter,

I want to avoid misunderstanding and confusion. Forget for a moment how Witten derives whatever he derives, this is a matter of taste. The invariant physical conclusion is that the non perturbative complition of 3d gravity has nothing to do with the gauge theory !

Similar conclusion is expected to hold for the 4d case, where there would not be enough dof in the gauge theory to create black holes, as in the 3d case.

Most of the people here are laymen, and I want to make sure that they understand that Witten's conclusion is that the gauge theory variables are bad. This was known to Seiberg for some time, apparently. This leaves no hope that any interesting insight can be derived from gauge theory formulation of 4d gravity, for obvious reasons. Thus, LQG seems to have been falsified.

Unrelaed comment for experts : The way Witten derives some central charges does uses gauge theory variables. This is, however, incorrect since the gauge theory variables dont make much sense. Witten admits this is the case, and wishes he had a better way to derive the central charges. He could, as well, guess the correct values by some factorization and absence of gravitational anomalies requirements. This is the second way he motivates these charges, which is much more convincing.

One should not confuse the physics conclusion (which is that the Chern-Simons formulatoins have nothing to do with gravity) with the technical details (which is an incorrect derivation of some central charges, which is as good as a guess). Note that the reason CS has nothing to do with gravity is independent of the ability of disability to derive these central charges.

17. **Ori**
June 27, 2007

Another comment is that Peter is correct that there are no stringy variables in the story. However, the construction of the paper is a very particular example of something which was well known is string theory : AdS/CFT. This also shows that the results obtained in string theory in this context are much more general, because similar techniques can be applies in non supersymmetric non stringy cases.

18. **gunpowder&noodles**
June 27, 2007

"Thus, LQG seems to have been falsified."

Oh, come. It's extremely clear that all of Witten's [brilliant] work on this is strictly dependent on the 3D context. There is not a clue about how to extend *any* of this stuff to the enormously different 4D case. I have no time for LQG, but enthusiasts for it could quite legitimately point out that 3D gravity has been studied intensively for years, and so far it has told us exactly nothing about 4D physics. There's no reason to suspect that this is about to change.

For all my admiration for EW, and gratitude to him for the way he has changed the subject, I have to summarize the situation as follows: he has shown that gravity with the wrong sign of the CC in the wrong dimension is wrongly described by Chern-Simons. Next talk please.

19. **Peter Woit**
June 27, 2007

Ori,

Your claims that Witten has shown that "gauge theory variables are bad" etc. are directly contradicted by what Witten actually wrote, including the part I quoted above. You're putting lots of highly tendentious claims in his mouth which are not in his paper and were not in his talk (or in the one I heard here in New York). I think Witten is someone who is very careful to say precisely what he means. In this case he is being very clear that the question of how to properly understand 3d non-perturbative quantum gravity is very much still up in the air. Here's what he writes:

> We make at each stage the most optimistic possible assumption. Decisive arguments in favor of the proposals made here are still lacking. The literature on three-dimensional gravity is filled with claims (including some by the present author [6]) that in hindsight seem less than fully satisfactory. Hopefully, future work will clarify things.

This is very different than claiming that he has shown that "the non perturbative complition of 3d gravity has nothing to do with the gauge theory !" and falsified the whole idea of using gauge theory variables.

20. **Ori**
June 27, 2007

The conclusion from your comment is that you have misunderstood the paper completely. You have picked some quotations out of context, and that is it.

Witten clearly write that the CS theory can not be the correct non perturbative complition, he said it explicitly in strings and it is written in the paper. This is the whole point of the paper, if you claim otherwise, you have misunderstood the paper and the talk. Let me quote for you :

"There is, however, an even more serious problem with the idea "gauge theory=gravity in 2+1 dimensions"…. "

He has couple of such arguments against the 3d description via CS theory, which in the overall sum to what I said.

You may keep thinking whatever you want, I am the last to care, I was only willing to make sure that readers of this blog will be aware of the correct statements.

To gunpowder&noodles :

If you had read the paper, you would have understood that the arguments against the gauge theory description are completely general, and can be extended to 4d as well. Witten also says that theories with positive cosmological constant probably have no non perturbative complition (unless embedded in a more complete model), so it is not clear what is the point in trying to quantize de sitter backgrounds, without a stable ads ground state

21. **Ori**
June 27, 2007

Another way to proceed, is that u answer a question (Instead of putting more and more out of context quotes to defend yourself).

There are BTZ black holes in 3d. If CS is the correct way to quantize gravity than there should be extremely many states in the topological CS theory. What are they ? 🙂

Of course, there are no such states (since CS is a topological theory), which is the main point in Witten's paper (and the strings talk). This means that CS has nothing to do with the full quantum theory of pure gravity.

22. **dont be misleading!**
June 27, 2007

I would like to recall ori that is possible to written the BTZ black hole as a solution of CS theory. It was done many years ago by Malrof and other people. Look at ArXives.

Thus, the quantum CS theory also contains BH, as is part of they are part of its classical spectrum.

23. **woit**
June 27, 2007

Ori,

I certainly don't claim that Chern-Simons is the "correct way to quantize gravity". For one thing, as Witten states, non-perturbatively the situation of 3d gravity remains unclear. The problem is not necessarily even well defined: maybe there is more than one consistent non-perturbative theory that has the right classical limit. Witten has made a very interesting proposal about a distinguished boundary CFT that might deserve to be called the "right" boundary CFT for non-perturbative pure gravity. I don't think he claims at all to know what if any 3d variables and Lagrangian treated non-perturbatively with conventional path integral techniques would lead to this theory.

This problem corresponds to something that has always bothered me in the simpler compact Chern-Simons-Witten theory. The standard thing people say there is that, even non-perturbatively, the theory is defined by "integrating [tex] e^{ikCS[A]} [/tex] over the space of connections A". This is kind of nonsense. Try actually doing this integral, e.g. by putting it on a lattice, and you start to see what the problems are. While the CS action is fine for generating a perturbation theory, non-perturbatively it doesn't completely define the theory. What Witten does in that case is use the CS action to motivate what the boundary theory is (WZW), and then uses that to actually do computations. Even in that case, the CS action isn't the full story about the non-perturbative theory, but it definitely is true that you want to be using gauge theory variables.

Anyway, there's a very interesting story going on here, and gauge theory variables are definitely part of it.

24. **Peter Woit**
June 27, 2007

Thanks dbm,

I was wondering about Distler's claim that "We would not, for instance, ever see the BTZ blackhole from the gauge theory", which didn't seem to make sense since the gauge theory gives the same classical equations and the BTZ black hole is a classical solution.

25. **A quantum diaries survivor**
June 27, 2007

Peter,

your links to lubos' blog get dumped to a unwelcoming page, you should know this by now, or is it an attitude to ignore the fact ? 😉

This time though I will second the auto-embargo of Lubos. I intended to read his rant, but now I changed my mind… He is probably happier that way.

Cheers,
T.

26. **Peter Woit**
June 27, 2007

Tommaso,

I'm not ignoring it, just figure it adds to the entertainment value…

27. **Aaron Bergman**
June 27, 2007

What I think Jacques meant (although I haven't asked him) is the microstates of the BTZ black hole — it's hard to imagine where they are in a topological theory.

28. **urs**
June 27, 2007

> microstates of the BTZ black hole — it's hard to imagine where they are in a topological theory.

The Einstein-Hilbert action functional can be rewritten as a Chern-Simns action functional in 3d. So if the former has an extremum somewhere (like a black hole solution), the latter must have, too. After all, they are *equal*. No? What am I missing?

29. **urs**

June 27, 2007

> it’s hard to imagine where they are in a topological theory.

One more thing:

consider pure gravity in any dimension d. Consider a d-dimensional topological space, possibly wtih boundary. Suppose you could make sense of the EH path integral over all metrics on that space, possibly with prescribed boundary data. Shouldn’t the answer depend solely on the topology of the chosen space? Shouldn’t it in fact give you a functor from d-dimensional topological cobordisms to some flavor of vector spaces? Wouldn’t that be exactly as for Chern-Simons theory?

The only real distinction which I can see between the EH formulation and the corresponding gauge theoretic (Palatini) formulation of gravity is that the former vaguely suggests not to include degenerate metrics, while the latter vaguely suggests to include them.

30. **Aaron Bergman**
June 27, 2007

No? What am I missing?

Microstates. You’re thinking about the classical solution which is a macrostate.

31. **urs**
June 27, 2007

> No? What am I missing?

Microstates. You’re thinking about the classical solution which is a macrostate.

Hm.

Suppose I did the CS path integral over connections with the constraint that the vielbein be invertible.

What would be the difference between using the EH action functional in the path integral from using the CS action functional? Both are equal. Both are defined on the same domain. What’s the difference?

32. **urs**
June 27, 2007

(Sorry, there is a blockquote missing. The comment preview did correctly show the nested quotation which I did include.)

33. **Aaron Bergman**
June 27, 2007

Isn’t that question aking to, suppose I did the path integral for the EH action in 4D? Do you know how to quantize CS theory with that constraint?

(Witten talks about this in his original paper, BTW.)

34. **urs**
June 27, 2007

> Do you know how to

Right, of course I don’t.

The only thing I really know here (beyond knowledge of folk lore and plausibility arguments that all get so confusing after a while) is this:

for every modular tensor category, I can construct

A) a 3-dimensional TQFT

B) a 2-dimensional rational CFT

C) such that they are holographically related.

If that tensor category happens to be the representation category of loops in G, then

A) is G-Chern-Simons theory

B) is the WZW model on G

C) is the fact that states of Chern-Simons are conformal blocks (precorrelators) of WZW.

It is strongly assumed that this can be extended beyond rational CFTs. But only for rational CFTs this has been done in detail.

In any case, there should be other modular tensor categories, or variations thereof, and there should be other realizations of A,B,C. I would like to see if what Witten is talking about could be (classes of) other realizations of this. It ought to be, since he is in effect arguing that A should be defined in terms of B.

35. **joe**
June 27, 2007

The videos seem to be working for me (USA, west coast). Somewhere else, someone mentioned some download bandwidth issues.

I need to contact the program chair (name & email) to get permission to do some tests with their videos. Can’t find it on the Strings ’07 website, just the webmaster emails. Help? (I went to the IFT sponsor site, but the Miembros section has a generic list of staff.)

36. **ori**

June 27, 2007

Hi, “dont be misleading!”

You seem to completely misunderstand the point. It is correct that the classical BTZ solution was written long time ago, as any other classical solution (eg gravitons near the boundary). However, the BTZ entropy can not be accounted for by the quantum CS theory in any reasonable way (and here Witten says “although there were some attempts in the past…”).

Thus, the CS theory does not appreciate the thermodynamics of black holes and can not explain their entropy. Hence, CS can not describe in the quantum level anything like gravity (this is a correct invariant physical conclusion which means that the gauge theory variables are meaningless after quantization and can at best serve for some unmotivated guesses).

A similar thing happens in 4d as well, where the gauge theory variables of LQG dont make sense after quantization.

37. **ori**
June 27, 2007

Urs,

>”The only real distinction which I can see between the EH >formulation and the corresponding gauge theoretic (Palatini) >formulation of gravity is that the former vaguely suggests not to >include degenerate metrics, while the latter vaguely suggests to >include them.”

You are correct, and this difference is very very crucial !! if not this difference the theories were equivalent. In all known examples in string theory the non perturbative formualtion has never included degenerate metrics. Also here, this is the fundamental reason for the failure of CS variables in the quantum level. Similarly, in 4d, the gauge theory variables (and LQG) break down for the same reason.

38. **Arun**
June 27, 2007

In 4D, LQG has enough degrees of freedom to account for black hole entropy, therefore I do not buy Ori’s *A similar thing happens in 4d as well, where the gauge theory variables of LQG dont make sense after quantization.*.

It may very well be that LQG does not make sense for other reasons.

39. **dbm**
June 27, 2007

hi uri,

I think that despite phylosphical considerations, facts are facts.

And the first fact is that you don need to consider the CS formulation of GR to admit configurations wih a degenerated vielbein, is enough to consider the first order formalism in which the vielbein and the spin connection are regarded independent fields, this theory, automatically, admits a solution where all the fields are zero. Furthermore this first order formulation of GR can be done in any dimension.

The second fact is that it has been proved, long ago, that the first order formalism, is off shell equivalent to the usual metric formulation, that is: the set of configurations where the vielbein is not inverible is of measure zero.

I would say that all this bla bla, of witten and the degrees of freedom of GR, and that in string theory the invertibility of the metric is a serious thing, contradict not only his paper on the soulbility of GR, but also his papers on topological quantum field theory, and topological gravity of the 80’s.

I really dont like his arguments and I even think that his last paper deserve further analysis, for instance is no possible that the guy doesnt obtain the right value for the entropy for BH of mass=2 and says, ok, for larger k a better agreement will be obtained.

Come on!

40. **Carol**
June 27, 2007

I want to live in the dimension where a story can earn you a Fields medal, and shouting loud enough releases a graviton.

41. **ori**
June 28, 2007

dear dbm,

The entropy for k=1 is not expected to match since you compare a semi-classical entropy given by the BH formula to an exact calculation of microstates.

In this regime, semi classical analysis makes no sense since the black hole is very small and gravity is strongly curved. Therefore, the fact the results are similar is a good surprise.

The fact that for larger k there is a better and better agreement is a strong indication that what Witten did is correct.

Of course, this is correct regardless of you liking or disliking this.

42. **Arun**
June 28, 2007

How do black holes form in 2+1 classical gravity? (i.e., with no gravitational radiation)?

43. **dbm**
June 28, 2007

Dear ori,

So, please explain me, why in every realistic situation in which we can actually compute the entropy beginning with the microscopical description it COINCIDE with our thermodynamical result.

Thanks!

44. **ori**
June 28, 2007

Dear ori,

>So, please explain me, why in every realistic >situation in which we can actually compute the >entropy beginning with the microscopical >description it COINCIDE with our >thermodynamical result.

>Thanks!

I assume you refer to systems which are not gravitational. The explanation is trivial : The result coincides with the thermodynamic result in the limit where the system is large. For example, even in the system of free spins which contains N spins the result will not coincide with the thermodynamic result for finite N, there are logarithmic corrections (Stirling's formula) etc.

Note that to count states correctly one also needs to have a weakly coupled description of the degrees of freedom, and for the word thermodynamics to make sense there needs to be a classical description of the system.

In the case k=1 the black hole is very small, so it is not a macroscopic system and also the system has no good classical description. Thus, you basically extrapolate formulas illegaly and you should not be surprised that you get a somewhat different result.

I don't have any idea what you meant by your comment, anyone who has ever studied statistical physics know that there is never agreement with thermodynamics beyond the strict limit of infinite number of dof, sorry.

45. **dbm**
June 28, 2007

Ori,

You are right, in the theormodynamic limit.

However, I still insist in my point of the offshell equivalence of CS theory, and 2+1 GR, I mean the facts that I previously mentioned.

The first fact is that you don need to consider the CS formulation of GR to admit configurations wih a degenerated vielbein, is enough to consider the first order formalism in which the vielbein and the spin connection are regarded independent fields, this theory, automatically, admits a solution where all the fields are zero. Furthermore this first order formulation of GR can be done in any dimension.

The second fact is that it has been proved, long ago, that the first order formalism, is off shell equivalent to the usual metric formulation, that is: the set of configurations where the vielbein is not inverible is of measure zero.

46. **ori**
June 28, 2007

I am happy you agree (and you should withdraw your "come on" comment).

The mistake in your other statement is the sentence

"the set of configurations where the vielbein is not inverible is of measure zero."

Nobody knows how to formulate the non perturbative gravity path integral (it is not necessarily the naive one with Haar measures)
and hence, you can not deduce the measure of degenerate metrics correctly, sorry.

In fact the work of Witten CLEARLY shows that the effect is not a measure zero one, and leads to substantial non perturbative differences in the two theories (which naively differ by measure zero).

47. **ori**
June 28, 2007

btw, one should expect this set of non invertible metrics to be very important also in higher dimensions.

48. **dbm**
June 28, 2007

But, consider the paper gr-qc/0303113. My argument is as follows, if the first order, palatini, formalism admit naturally a degenerated viebein, and these people has shown that it coincide, off shell, with the second order metric formalism. ..

There is some level of tension between that paper and your last setence!

btw, thanks for the discussion, is fun.

49. **ori**
June 28, 2007

I will study the paper, perhaps tomorrow. I don't wanna give sloppy answers.

50. **amuseds**
June 28, 2007

Meanwhile at the pinnacle of the 'Superstringy Universe' edifying discourse on the subject can be found, such as

…. So PW is basing his monster conjecture on a single footnote! Well, I’ve always been leery of a man with a foot fetish. Such a man reminds me too much of a gay shoe saleman several years back who kept marveling at my feet as though I was Cinderella in the flesh trying on glass slippers. I swear, I recall feeling both deeply annoyed and genuinely embarrassed by the whole ordeal!

And since then I’ve come to realize that it takes a real man to become captivated by the more noteworthy parts of my body. In a way, I suppose, PW is nothing more than that faggot shoe salesman at Nordstrom’s.

….PW’s site would have already petered-out (no pun intended) if it weren’t for a few top contenders, such as Aaron. That being said, I must make mention that Lubos was (and always will be) Peter’s toughest challenger – without having a single close second coming from behind him!

Now I’m totally clueless when it comes to military matters, but it seems pretty obvious to me that the only sure-fire way to stamp out PW’s site is to battle it out of existence, not to simply let it fizzle out – like an open can of coke. Moreover, I’ll go out on a limb and say that because his site is essentially limited to a single narrow issue, this severe handicap will work to hasten its demise.
…

Now back to the discussion of the relevance of gauge theory to quantum gravity…

51. **hmmm**
June 28, 2007

> …. So PW is basing his monster conjecture on a single footnote! Well, I’ve always been leery of a man with a foot fetish. 52. **Peter Woit**
June 28, 2007

Please, Lubos’s craziness is bad enough, but if you start discussing here the commenters on his blog, that way lies madness…

53. **gunpowder&noodles**
June 29, 2007

Ori declaims:

“If you had read the paper, ”

No need to remind us that you’re a string theorist…..

“you would have understood that the arguments against the gauge theory description are completely general, and can be extended to 4d as well.”

Wow. Do tell us, in mathematical detail, how to perform that feat. Or at least refer us to EW’s paper. Chapter and verse please. And no “clearly a similar argument” stuff please.

54. **ori**
June 29, 2007

Dear “gunpowder&noodles”,

Gauge theory decriptions contain in their path integral solutions which correspond to degenerate metrics in the gravitational description. These are not measure zero, as was previously thought (the absence of degenerate metrics gives rise to a different non perturbative complition).

You may or may not be convinced, it is not important. There will certainly be people who will keep thinking in the gauge theory variables direction although it was proved incorrect for d=2 and d=3. I presume that sensible people understand this point very well and will take it into account.

The situation has changed, since previously one could argue that the change of vairables is regular apart from a measure zero set of configurations. The same argument was presented for both 3d and 4d (in the 3d case even Witten himself was actually incorrect). Now that this argument is known to be incorrect for 3d and 2d it is most conceivable that the 4d case, which has the same singular locus , and essentially the same ambiguities, should not be described by gauge theory variables

55. **Peter Woit**
June 29, 2007

ori,

Can you point me to somewhere where anyone has actually done the Chern-Simons integral non-perturbatively (in a non-abelian theory)? As far as I’ve ever been able to tell, this integral is just inherently ill-defined, you’re integrating a phase over an infinite-dimensional space, and there is no “measure” here with any reasonable properties that would allow you to talk about some configurations being “measure zero”. The problem is very fundamental, it exists even in simple QM analogs of the CS theory. If you actually try and discretize the Chern-Simons functional integral and do the the (finite) integral, it appears that there is no way to get an answer which is not completely dependent on how you do the cutoff.

56. **urs**
June 29, 2007

> somewhere where anyone has actually done the Chern-Simons integral non-perturbatively

I [this lecture](), Mike Hopkins hinted at a way how to do it. But didn't really explain it.

57. **Peter Woit**
June 29, 2007

urs,

That's not at all what I'm talking about, since that kind of very abstract "integral" has no notion of "measure" or "measure zero". What I don't believe exists is the kind of standard integral used to define path integral quantization: an honest measure in the cut-off theory that, when you integrate appropriate quantities against it gives well-defined answers when you remove the cut-off.

58. **urs**
June 29, 2007

> that kind of very abstract "integral" has no notion of "measure" or "measure zero".

Yes, as I said. He hinted at a way how to do it, but didn't explain it.

59. **Arun**
June 29, 2007

Very brash out of ignorance, I'd say that in 2+1 pure gravity black holes have no way to evaporate (or to form) perturbatively, there being no radiation. So perturbation theory cannot take you from a non-black hole sector of states to a blackhole sector of states. I would guess that in 3+1 pure gravity neither condition holds.

60. **Yatima**
June 29, 2007

The presentation PDFs really need abstracts.

An LHC status report This I can understand more or less.

A talk from 'SUSY 2012' uncovered today!

Baryons from Instantons in holographic QCD Hmmm….

Andrei Linde in Amazing Mr Universe mode 😉

June 30, 2007

PW said: "don't see anything I would describe as "very cool", but maybe that's just me."

No doubt you are willing to make an exception for Bousso's talk. His theory makes "thousands" of predictions. That is so cool that it suffers from frostbite. It's almost as cool as the funereal garb and manner he affects in his classes. In fact I would put it right up there with Paris Hilton.

63. **anonym**
June 30, 2007

To Ori,

Really basic question.
Witten's work is for AdS background only.
I think LQG can handle dS case. (I am not an expert on LQG but just curious about your logic.)

Then how can you say EW's work rules out LQG?

I think you can not say anything definite like this one especially when you rely on very incomplete arguments.

64. **ori**
July 1, 2007

Well, dS is argued not to exist alone, but only when there is also some AdS around as well. So, Witten's work applies. You should think of dS as an unstable particle. Such a system can not be described completely without referring to the correct ground state (which is AdS).

65. **ori**
July 1, 2007

and btw, I don't know which of the arguments you call "incomplete". An argument is not a proof certainly. However, it is complete as an argument since it addresses the correct question, and suggests the correct answer convincingly or not, this depends on you (If you only "argue" you can not convince everybody, for this you need a proof. However, wise people often don't need a proof at all).

66. **hmmm**
July 1, 2007

> However, wise people often don't need a proof at all

In which case wise people are often wrong and usually less wise than they think.

> Well, dS is argued not to exist alone, but only when there is also some AdS around as well. So, Witten's work applies. You should think of dS as an unstable particle. Such a system can not be described completely without referring to the correct ground state (which is AdS).

A wise person should also add that the above statement may have nothing what-so-ever to do with the universe in which we live.

However, in Witten's opinion, it could be relevent to all those 2D beings living in rubber sheet world.

67. **Thomas Larsson**
July 1, 2007

Well, dS is argued not to exist alone, but only when there is also some AdS around as well.

IOW, if observations don't agree with your pet theory, observations are irrelevant. It might be true in this case, but it is nevertheless a classical crackpot argument.

If we take the positive cc seriously, it inevitably leads to the conclusion that QG must have local observables, since there are no global observables in dS. The lession from CFT, viewed as diff-invariant field theory on the circle, is that diffeomorphism symmetry is only compabitible with locality in the presence of diff anomalies (multi-dimensional Virasoro algebra).

Orid said

“You should think of dS as an unstable particle. Such a system can not be described completely without referring to the correct ground state (which is AdS).”

Maybe I don’t understand correctly the meaning that dS corresponds to metastable state. Anyway let me ask it to you. Do you think our universe is metastable? If observation tells me this “according to our present knowledge” then I would think that there is some problem in our understanding rather than think our universe is metastable. Also this is one of what I am saying as “many” incomplete arguments. You seem to overly trust a theory which is at best a consistent approximation to the reality. You should think your present understanding could be very wrong although you may think it is your best at this point.

71. **Urs Schreiber**
July 2, 2007

I do not understand in which sense it can be true that “gauge variables for gravity are bad”, as ori said here:

http://www.math.columbia.edu/~woit/wordpress/?p=571#comment-26430

I can imaging that there is some true statement sounding vaguely similar, but as such I am having a hard time making sense of that.

We are talking about two different sets of coordinates for one and the same configuration space: that of metrics.

It is true that there are ISO(2,1)-connections which correspond to degenerate pseudo-Riemannian structures.

But there are also metrics that correspod to degenerate Riemannian structure, clearly.

I am willing to consider the question whether or not to include degenerate metrics in the path integral. But formulating a metric in any of the many equivalent ways there are can hardly change anything about the physics.

Unless, of course, it suggests some *different* procedure for how to go beyond perturbation theory. But all this is shrouded in mystery right at the moment.

Also, it would seem that those interested in string theory should be fond of the idea of encoding Riemannian structures in terms of ISO(n,1)-connections. As far as I am aware, that is the only sensible way to handle supergravity.

72. **Haelfix**
July 4, 2007

Its definitely extremely puzzling, and also whats so damn interesting about the paper, at least to me.

Assume for a second you solve both methods exactly. The difference (if indeed there is one after careful analysis) should then sum up to the contribution of degenerate metrics in the path integral *I think*.

This suggests a strategy for 4D. Use gauge variables, then ansatz the form of the contribution from 2d, 3d and see what we get.

73. **Haelfix**
July 4, 2007

I should say ‘ansatz the form of the degenerate metrics from 2d, 3d intuition’ and then sum them together.

74. **Chris W.**
July 4, 2007

Speaking of taking things seriously, recall this remark of Steven Weinberg’s, in *The First Three Minutes* (1977):

“This is often the way it is in physics. Our mistake is not that we take our theories too seriously, but that we do not take them seriously enough. It is always hard to realize that these numbers and equations we play with at our desks have something to do with the real world.”

75. **M**
July 7, 2007

Actually, the article in El Pais mentions the problems of strings: here are the key sentences:

“… la verdad es que la complejidad de la teoría está resultando enorme. Los mismos especialistas creen que esto se debe a que no es aún una teoría terminada. Por ejemplo, de las diferentes soluciones que encuentran a sus ecuaciones no saben cómo elegir la que realmente corresponde a nuestro universo.

…no ha podido despegarse de la principal crítica: la falta de experimentos en perspectiva que verifiquen si es correcta. …

… Para otros muchos, la ausencia de predicciones experimentales de una teoría física después de 20 años de desarrollo, es un inconveniente que no se puede pasar por alto en modo alguno.”

76. **Indrajeet Patil**
July 15, 2007

Is it true that Witten is no longer working in string theory?

77. **Peter Woit**
July 15, 2007

Indrajeet,

During the last year Witten has written two long papers, neither of them about string theory. I don’t know what he spends his time working on. Besides the topics of the two recent papers (3d gravity and TQGT/geometric Langlands), quite likely he continues to spend some time thinking about string theory.

Too Much Good Stuff

June 30, 2007
Categories: Uncategorized

I've been finding recently that an increasing serious problems with blogs is that there are too many good ones with material worth reading. I've learned quite a lot recently from many well-informed blog postings, but the sheer number of these makes it hard to find the time for other things one should be doing.

I'll violate my usual rule of sticking to math and physics and report that my brother Steve is joining me in the family blogging business by being involved as Publisher in a new venture that just launched this week called Xconomy. Basically it's a blog based up in Cambridge, with offices in Kendall Square, devoted to news about what they call the "exponential economy", that part of the economy responsible for what is perhaps too optimistically described as exponential growth in certain areas. They're focusing on events and news relevant to new technology, especially bio-technology, businesses in the Boston area. For some interesting blog postings by their CEO Bob Buderi about what it's like to start up this sort of business, see here and here. For a nice posting about Doc Edgerton, see here.

Back to physics and math, over at Backreaction there's an excellent posting on the GZK cutoff and high energy cosmic ray experiments, and a report from Loops 07 sent in via Blackberry by Sabine Hossenfelder.

An American Physics Student in England tells about a recent conference on Heavy Flavour Physics, giving a very nice overview of what is going on in that field.

The latest This Week's Finds in Mathematical Physics from John Baez is out (available here, blog entry and comments here). It's a wonderful description of the various mathematical patterns that the standard model particles fit into. Most well known is what happens in SU(5) and SO(10) GUTs, where one can fit the fermion quantum numbers into something that can equivalently be described as the spinor representation in d=10, or the exterior algebra $\Lambda ^* (\mathbf C ^5)$. John goes on to explain various possible connections to the exceptional groups, including a recent idea from Garrett Lisi about how to use E_8 to get three generations.

The blog entry comments discuss two recent papers by Chamseddine and Connes about their non-commutative algebra approach to this question of mathematically characterizing the SM degrees of freedom. The papers are on the arXiv, entitled A Dress for SM the Beggar, and Why the Standard Model. Because of these papers and Witten's recent one, John seems to be getting a bit more optimistic about physics, writing "I get the feeling that theoretical physics may not be quite so stagnant after all!"

All sorts of interesting stuff at the Secret Blogging Seminar, including yet more about Connes: a "review" by A. J. Tolland of the first quarter of the new book by Connes and Marcolli (available here), which A. J. claims has the title *Noncommutative Geometry, Quantum Fields, Kitchen Sinks and Motives*. Like the earlier fat book on non-commutative geometry by Connes, it's an amazing document, ranging widely over physics and mathematics, covering ground from QFT to the Riemann hypothesis, at a level varying from expository sections on well-known subjects to more speculative research-level discussions. I've just started looking at it, may bring along a copy for summer vacation reading when I head up to a lake in New Hampshire tomorrow.

Other interesting things at the same blog include reports (here and here) from Ben Webster about talks by Sergei Gukov on categorification and gauge theory (about which he has a new expository paper here), as well as about an earlier talk by Gukov on Arithmetic Topology and Gauge Theory.

Also worth reading are posts from Ben Webster about centers of blocks of category O, various comment section discussions with David Ben-Zvi at both this blog and the n-category cafe, and a series of postings by David Speyer about quadratic reciprocity and geometric class field theory (I'm running out of energy to provide links…).

From Ben-Zvi (who could run a really great blog if he chose to…) there are notes from the recent conference at Northwestern on non-commutative geometry. These include an intriguing lecture by Beilinson, as well as lectures by Nadler and Ben-Zvi himself about their recent work which connects geometric Langlands with questions about more conventional representation theory using striking ideas about how to handle loop spaces. They have a recent paper about this, which has been very high on my list of things I wish I understood better ever since David gave an inspiring talk about this here a couple months ago.

Finally, one more thing definitely worth looking at in light of Witten's new work: an expository and historical article by Jim Lepowsky about the story of the relation of vertex operator algebras and the monster group. He explains what is so remarkable about the specific vertex operator algebra that Witten is connecting to 3d gravity on AdS, including the ways in which it is conjecturally uniquely the "smallest" such structure in a specific sense.

Comments

1. **Garrett**
   June 30, 2007

   Mathematicians are wonderfully nonlinear complex systems — one little perturbation and good stuff flies in all directions!

   Although relating the three fermion generations to E8 triality got John interested, I'm actually assigning ALL standard model and gravitational fields to elements of Lie(E8). There's a link to this description in TWF, but here it is directly:

   Deferential Geometry

   The above site (my research wiki) has a one paragraph summary and a link to a talk (slides and practice audio) I just gave here in Morelia. In five words… "everything in an E8 connection." This includes putting the gravitational spin connection and frame together in this connection too, which should be looking like a familiar thing to do right now… 😉

2. **Garrett**
   June 30, 2007

   Oops, bad link. This one should work:

   Deferential Geometry

3. **Bee**
   June 30, 2007

   Hi Peter,

   Thanks for the link. What I didn't write in the post is that there's some preliminary data from Pierre Auger which apparently confirms the presence of the cut-off – I expect it will be presented at that Cosmic Ray conference next week. Also, I have a second post about the Loops 2007 with some photos, but admittedly little content. I hope the slides to the talks will be on the website soon. E.g. Fotini's talk (about non-locality) was very interesting, and so was Garrett's 🙂

The conference closed today with a discussion session (moderated by Carlo Rovelli) where everybody was asked to give the most optimistic prediction what he/she will be talking about at the Loops 2017 – and what the probability is for that to actually happen. It was very interesting (much of it based on what the phenomenology will hopefully teach us in the soon future). It was recorded and I hope the audios will be available on the websites as well.

Best,

B.

4. **Kris Krogh**
July 1, 2007

Hi Bee,

Can you tip us off on the the cut-off energy seen? Is it exactly the GZK prediction?

Cheers,

Kris

5. **James**
July 1, 2007

Regarding the use of the word 'exponential': Any increasing function on a finite interval grows faster than a non-trivial exponential function. So I would say the use of the word above is not so much optimistic as it is next to meaningless.

6. **M**
July 1, 2007

Bee: various Auger talks at ICRC 2007 already appeared on astro-ph, including some energy spectra. For example see arXiv:0706.2096

7. **Fabrizio**
July 2, 2007

Hi Garrett.
I just saw your great wiki and started to have a look into E8: the idea of unifying all in a single connection is really nice.

I just wonder if you can really avoid the problem of mirror fermions. For example the Cl_7 model of Trayling suffers (at least to me) of that problem: there is a duplication of the fermions, since the (algebraic) spinor has 8×8 complex = 128 real components, that is twice the components of a SM family, 16×2 complex=64 real. (and antiparticles are usually already taken care by the 16 weyl fermions of the SM)…

Cheers,
Fabrizio Nesti

8. **Garrett**
July 2, 2007

Hi Fabrizio,

This is a good question. Before I answer it, let me tell the story of how the connection came together. I was working mostly with GR and spinors using Clifford algebra, when I saw Trayling's nice description in Cl(7). But his model made more sense to me in Cl(1,7), and after playing with it a bit I was able to combine Trayling's description with the spin connection and frame of GR, with the Higgs entering in a nice way. But this only had one generation of fermions. When I saw E8, it matched this exact structure, along with two more blocks of fermions. This made me very happy, so I've been telling people about it, even though there's still some things to figure out.

Now, your question. Trayling solves it by either dropping the "mirror" fermions, or including them as anti-fermions. Without looking at the big picture, there's no good reason to do one or the other. But in the big picture it's more clear what's going on. If we start with the compact real form of E8, there are no mirror fermions — each fermion block has the correct number of real degrees of freedom. But the real form has SO(4) as a subgroup, whereas we want SO(1,3) — the Lorentz group, with the corresponding action on the blocks of spinors. To fix this, we could start with a complex form of E8, such as would be built from complex Cl(8) bivectors — but this has twice the desired degrees of freedom for all particles, kind of like supersymmetry. This would include the "mirror" fermion problem you describe. Instead, we use a real form of complex E8, built from a complex representation of Cl(1,7). This has the same degrees of freedom as compact E8, with no mirror fermions, and has the Lorentz group as a subgroup.

Now, I don't know WHY it's right to start with this real form of complex E8, other than because it works. The answer to this will have to come from whatever even big picture emerges. 🙂

I hope this answers your question, but here's some more nitty-gritty detail. If you look at the big matrix, each generation of fermions is a 4×4 block, with each entry a 2×2 block representing a Weyl spinor. Each of these Weyl spinors has 4 real degrees of freedom, which can be reassembled into a column of two complex numbers — the way we usually work with them.

Best,
Garrett

Geometrically Engineering the Standard Model: Locally Unfolding Three Families out of E_8

http://arxiv.org/abs/0704.0445

10. **ori**

July 2, 2007

μ is a nice letter

11. **Fabrizio**
July 3, 2007

Hi Garrett,
yes, that is what I was asking. One must have a sort of reality condition on the Cl_7 (or Cl_1,7) spinors, but this puzzled me, since spinors always carry a complex representation… On the other hand, mirror fermions can not be decoupled by making them heavy, because chiral fermions can not have a gauge invariant mass term.

Incidentally, this is what led me to consider that Cl_4 is actually enough, if one considers everything in LR-symmetric way: you can unify just isospin with gravity, and strong interactions are just internal geometrical symmetries (my [0706.3304]). This approach also leads back to Peter Woit's inspiring [NPB paper of 1988], where he introduced spinors on a 4-dim complex spacetime, and our world is a real section of that…

If now in E8 one can fit the fermions in the (OxO)3 part of the gauge field (64×3 real fields) I expect that doubling is no longer a problem because one can use the would-be mirror family (S8-) as the second generation… (and the vector (V8) as the third).
If this works (e.g. strong spinor charges, triality.. work well) it is really nice!

Fabrizio

12. **trd**
July 4, 2007

Hi Garrett.
I just saw your great wiki and started to have a look into E8: the idea of unifying all in a single connection is really nice.

I just wonder if you can really avoid the problem of mirror fermions. For example the Cl_7 model of Trayling suffers (at least to me) of that problem: there is a duplication of the fermions, since the (algebraic) spinor has 8×8 complex = 128 real components, that is twice the components of a SM family, 16×2 complex=64 real. (and antiparticles are usually already taken care by the 16 weyl fermions of the SM)…

July 4, 2007

Hello Peter:

I finished your 'Not Even Wrong' and Lee Smolin's 'The Trouble with Physics' a few weeks ago. I posted a review on my new blog that you might like to check out:

[Review]

I am a systems theorist by training, not a physicist, so I hope I haven't gone too far out on a limb in my assessment of the debate. Thanks for a great read, you've done the planet a service with this book (and this blog)! I spent several weekends ploughing through both books and it was very rewarding, if exhausting, work. I think my comprehension was between 10-50% through most of the read, but even that left me feeling illuminated.

14. **Aaron Bergman**
July 4, 2007

Don't believe everything you read. Check out the various reviews of Lee's book on cosmic variance, for example.

15. **nutcase**
July 7, 2007

More good stuff:

> arXiv:0707.0005
> Higgs Physics as a Window Beyond the MSSM (BMSSM)
> Michael Dine, Nathan Seiberg and Scott Thomas

Interesting read… but… is it just me or is it very unusual finding a purely phenomenological paper coauthored by N.Seiberg? Are the winds changing in high energy physics?

July 23, 2007

Here is the promised update:

[GZK cutoff confirmed]

Less Stuff Than Usual

July 10, 2007
Categories: Uncategorized

I was on vacation for a while, but haven't been posting much mostly since there's not that much to write about. Like every summer, there are huge numbers of string theory conferences going on all over the world, but from looking at the talks that are available, the subject is about as dead as it has been for the last couple years, with essentially no new ideas. The reaction of string theorists to all the criticism that they have been getting in recent years about the lack of any connection of string theory to the real world seems to have been to rename their conferences things like String Theory and the Real World.

One other reason I haven't been writing as much is that there are an increasingly large number of quite good math and physics blogs out there, run by other people who are doing a great job of writing about the kinds of news that I've often posted items about. There's a mini-revolution going on in research-level mathematics blogging, with various Fields medalists being joined by groups of some of the best graduate students and post-docs around. Following on the heels of Berkeley's wonderful Secret Blogging Seminar, there's Cornell's Everything Seminar and the Max Planck Institute in Bonn's Vivatgasse 7 (mainly about arithmetic algebraic geometry).

Also at the Max Planck Institute, a couple weeks ago there was the yearly Arbeitstagung, a conference devoted to recent mathematics research and run in a somewhat unconventional way. The concept is to mostly not schedule talks and speakers in advance, but to instead just try and get a group of the best possible people to show up, and then to more or less democratically decide on who should speak about what, depending on who has something new to talk about. The first Arbeitstagung was organized by Friedrich Hirzebruch exactly 50 years ago, back in 1957, partly with the goal of bringing Germany back into the mainstream of mathematics research after the post-WWII period. Hirzebruch remained the organizer for many years (and was also director of Max Planck), and was there this year to give the opening lecture, on The first Arbeitstagungen in 1957, 1958 and 1962. At the first Arbeitstagung in 1957 some of the talks announced dramatic new results in mathematics, including the birth of K-theory. Grothendieck's talk included the first definition and use of K-theory (of coherent sheaves on a projective algebraic manifold) in his proof of what is now known as the Grothendieck-Riemann-Roch theorem. Hirzebruch had worked some of this out more concretely before, and he reported on his work with Borel-Hirzebruch which links up representation theory, characteristic classes and topology in a fundamental way. Bott was not there, but had recently discovered Bott periodicity, and over the next few years Atiyah used this and the Dirac operator to reformulate Grothendieck-Riemann-Roch as a general index theorem in the context of differentiable manifolds, proving the theorem with Singer, and lecturing about it at the 1962 Arbeitagung. Hirzebruch gives an excellent description of some of this history. The talks are all available online, but I fear that there was nothing discussed this year that seems to reach the heights of what was being discovered back in those early days 50 years ago.

The latest news on the LHC schedule is: close the machine April 2008, beam commissioning starting May 2008, first beams at high energy July 2008, about exactly one year from now.

The Notices of the AMS has a wonderful set of articles this month about George Mackey, I wrote a bit about him here.

The Harvard string theory group will be minus not just Lubos Motl this coming year, but also Nima Arkani-Hamed, who will be on leave (I'm not sure where he's going or what his plans are). I hear that the two of them had a joint goodbye party.

Starting today, Arkani-Hamed is pushing the multiverse at the String Theory and the Real World conference. For the hundredth puff-piece about how wonderful the anthropic multiverse pseudo-science is, see the article Islands in the Sea, at fqxi.org.

Bloomberg.com is carrying a review of *Endless Universe*, the recent Steinhardt/Turok book I wrote about here. The author of the review seems to have noticed the same thing about the book that I did:

Given the recent controversy surrounding string theory — the publication last year of Lee Smolin's "The Trouble With Physics" and Peter Woit's "Not Even Wrong" — it's disturbing that Steinhardt and Turok don't even address their dependence on it. Does their model work if string theory is wrong?

My sense is that it doesn't, but they never even face the possibility — lending inadvertent weight to Smolin's and Woit's complaints that string theory is strangling physics. I hope the authors can someday publish a second edition in which they don't treat string theory as the only game in town.

Despite its problems, string theory does now have a shop and a blog.

Update: The news is that Arkani-Hamed will be moving from Harvard to the Institute for Advanced Study.

Update: In case any one was worried that Lubos's move back to Europe would end his entertainining rants about the stupidity of anyone expressing skepticism about string theory, don't worry. The latest is Bloomberg: another idiotic article, which begins:

> Elizabeth Lopatto is the name of the latest breathtaking idiot who was hired to write about theoretical physics for Bloomberg. I am periodically amazed that the newer journalists are always able to exceed the degree of mental breakdown of their predecessors.

and then goes on from there…

Comments

1. **JC**
   July 10, 2007

   The "fatigue" of some string conferences in recent years, looks a lot like the similar "fatigue" of those GUT and supergravity conferences from the early-mid 1980's (before string theory became very popular), when those subjects were losing their luster.

2. **Who**
   July 10, 2007

   Though age from folly could not give me freedom, It does from childishness: can Fulvia die?

   Could someone bring me up to date?

   > The Harvard string theory group will be minus not just Lubos Motl this coming year, but also…

   I've not been keeping track of the Motldrama. Why will Harvard be
   "minus" the abovenamed asset next year?

3. **anon.**
July 10, 2007

Thanks for the link to the article ‘Islands in the Sea’, which states on page 3:

> To grasp just how large a number this [landscape of metastable vacua] is, try writing it out longhand: a 1 followed by 500 zeroes.
>
> 100
> 000
>
> No matter how staggering a figure 10^500 is, though, it has the same status as any other number. In fact, if the multiverse is infinite, 10^500 possible vacua do not exhaust it. “Very large is still finite,” says Vanchurin of this strange state of affairs. “So there is a finite number of values, but an infinite number of regions, where those values are realized. If you take each one of those 10^500, there are infinitely many places in the multiverse where these values take place.”

Of course, they are right to emphasise that, despite the fact that string theory can’t be falsified, one of it 10^500 vacua might still be the real world.

Similarly, you can’t falsify religions because they are too vague and contain caveats like ‘Do not put the Lord your God to the test …’ (e.g., Deuteronomy 6:16 and Matthew 4:7).

Don’t you think that instead of being so negative about the failure of string theory to make falsifiable predictions, you should start to be more positive and point out its great success as an invincible religion? One of the great drawbacks to other religions is the lack of mathematical obfuscation in them, and the fact that anyone can read their secrets. A religion based around mathematical speculation has valuable advantages over existing religions: 1) Infidels can be dismissed by the high priests as merely mathematically illiterate ignoramuses; 2) Hollywood stringy sci-fi films can be made as powerful propaganda tools to convert the heathen masses to string theory; and 3) String theory, unlike regular religion, is a theory of everything unobservable, so it is like knowing the mind of God; hence it really is the one true religion, if correct (it is be impossible to disprove, so it is correct for religious purposes).

Suppose that the assumptions which make the landscape of string theory finite sized turn out to be false, and the landscape is really infinite in size. (This is quite possible if dark energy turns out to be a misunderstanding of experimental facts, like phlogiston theory.)

In that case, string theory will come in an infinite number of forms. Since infinity is the biggest possible number in mathematics, it then *must contain the real universe we see* because the probability that a set of infinite possibilities will contain reality must be equal to 1, mustn’t it?

On the other hand, the probability that any particular vacua, selected at random out of the infinite number of vacua, will be equal to 1/infinity = 0.

4. **Peter Woit**
July 10, 2007

Lubos has left his position at Harvard and returned to the Czech republic, not clear what his future plans are. I don’t know the full story of why he left Harvard.

5. **Anon**
July 10, 2007

Peter, you are and apparently always will be a critic, and I mean that in the worst possible way. To complain the way you do without adding anything to the solution of what you complain about only calls attention to your own inadequacies.
That being said I enjoy many of the math and physics links.
Good luck,
Anon

6. **Peter Woit**
July 10, 2007

Anon,

Well, I got into this critic business because no one else was doing it and it needed doing. I’d be happy to hand off the job to someone else, but there don’t seem to be many takers (possibly because of all the abuse about one’s inadequacies from anonymous and other sources that comes with the role…)

Anyway, another reason for fewer posts is that something I’ve been working on for a very long time finally seems to be working out and I’m spending more time on that. Maybe I’ll turn out to be not so inadequate after all, maybe not, we shall see…

Glad you enjoy at least some of the material here!

7. **Coin**
July 10, 2007

One of the great drawbacks to other religions is the lack of mathematical obfuscation in them, and the fact that anyone can read their secrets.

I take it you are not familiar with the works of William Dembski.

8. **gunpowder&noodles**
July 10, 2007

“but I fear that there was nothing discussed this year that seems to reach the heights of what was being discovered back in those early days 50 years ago.”

Exactly. Theoretical physics is far from being alone in its malaise. And some might argue that the influence of Grothendieck and people like him play the same role in mathematics that string theory plays in physics. Too much hype, too few real results.

9. **Peter Woit**
July 10, 2007

gunpowder,

I think mathematics and theoretical physics are both experiencing one problem that is similar: they’re victims of their own success. As you figure things out, you do the easier things first, what remains are more and more difficult problems.

But Grothendieck's story is quite different than that of string theory, in some ways it's more like the Standard Model. During the 50s and 60s he came up with ideas that are the foundation of the way algebraic geometers now think, and they do this because it actually successfully solves problems. It is true that the kind of abstraction Grothendieck pursued is something that led many less talented than him into fruitless areas. There was a reaction against this in the 70s and 80s, with a rather balanced view about abstraction emerging.

I actually find it surprising how much progress mathematics is able to make despite its increasing difficulty. The proofs of the Poincare conjecture and Fermat's last theorem in recent years are striking examples.

There's nothing like the landscape going on among top-level mathematicians, and I don't think the problem with string theory is that of too much empty abstraction. Rather the problem is the refusal to admit that a specific, concrete idea has failed, that of getting particle physics out of a 10/11d string/M-theory.

10. **ali**
July 10, 2007

    Hi Peter,
    I was not following Lubos's story either. Can it be that he was denied tenure or something like that?

11. **Tom Whicker**
July 10, 2007

    On the opening page for the "String theory and the real world" conference, they state:

    "String theory has given us new insights into quantum gravity, and has provided non-perturbative techniques for analyzing dynamical questions and computing observable predictions. It has suggested a variety of candidate solutions for all of the generally recognized problems of fundamental physics: the hierarchy problem, the cosmological constant problem, the nature of dark matter, and the origin of the fundamental constants. "

    Is there any support for any of this? Or is it generic ad copy?
    Regards to all, TW

12. **mathjunkie**
July 11, 2007

    Sad to hear that Lubos has left Harvard.

13. **mathjunkie**
July 11, 2007

    Was Lubos' leaving due to his radical way of defensing string theory on his personal web that caused Harvard to do something that Lubos hated very much?

14. **Peter Woit**
July 11, 2007

    ali + mathjunkie,

    Lubos wasn't there long enough to come up for a usual tenure decision so I don't think it was that. If his colleagues in the theory group had any problems with how he was defending string theory, I never heard about it.

    Tom,

    It's ad copy, based on some kernel of truth, but highly misleading. The part about providing a "variety of candidate solutions" to the great problems of physics is laughable in a way since it tries to make a virtue out of the theory's main problem, that of being consistent with almost anything.

15. **mathjunkie**
July 11, 2007

    Peter, thanks for your rely.

    Just found that Lubos put down on his personal web "Pilsen, CZ" as his current location. So, Lubos is back to his country where he grew up. Anyway, we can still watch how he defends string theory there.

16. **lyme**
July 11, 2007

    > # mathjunkie Says:
    > Sad to hear that Lubos has left Harvard.

    All the circumstantial evidence suggests it was the opposite that actually happened.

    Personally, I'm glad this long foreseen parting has at last happened.

    The Harvard tag gave Lubos a credibility he doesn't deserve and would never had gained by himself. His blog is full of lies, half truths and deliberately misleading information just about everything and everyone, from computers to politics, from physics to pedagogy, and everything in between.

    Right now, as far as his internet personna is concerned, he's just another nut with a blog, one among thousands, lost somewhere in Central Europe. Who could care less what he says?

17. **Joe**
July 11, 2007

    lyme,
    I agree with you. Lubos has become another Peter Woit.

18. **lyme**
July 11, 2007

> Lubos has become another Peter Woit.

That's what he would like to think… There's a long distance from Pilsen to Columbia, and not just geographically… Time will tell what he will become, it's still too early to draw conclusions.

But, as far as I'm concerned, the crucial difference between one and the other is that I'm able to answer your post because it's still there for me and everyone to read.

19. **woit**
    July 11, 2007

    Please stop it with the personally insulting comments, about Lubos or about anyone else.

20. **lyme**
    July 11, 2007

    As soon as I opened the "string theory blog" you cite, I knew there was something wrong… The photos there are just too good to have been shot by physicists…

21. **wow**
    July 11, 2007

    Arkani-Hamed will be joining IAS starting this fall. Apparently,
    the powers that be in Princeton think more highly of his work
    than you do, Peter.

22. **Peter Woit**
    July 11, 2007

    wow,

    Thanks for the news. Interesting to hear that the inner sanctum of what Polchinski describes as the "cult of monovacuism" will now include one of the most vigorous proponents of the anthropic multiverse. Susskind must be rejoicing at fresh evidence of the capitulation of resistance…

23. **IMHO**
    July 11, 2007

    In my humble opinion. From a political and marketing standpoint, Motl was a walking liability for both the department and university. The physics department, at arguably the world's most famous institution, housed a racist, sexist, attack-dog who would scream as loudly as he could to anyone and everyone….what an embarassment!

    I'm surprised, and somewhat disheartened, he lasted as long as he did.

24. **Peter Woit**
    July 11, 2007

    IMHO,

    Again, I wish people would stop it with the loaded characterizations of Lubos's personality.

    From what I hear, he can be quite charming personally, with the attack-dog screaming act restricted to his internet activities. Some people really don't do well when you give them a keyboard…

    It doesn't surprise me that Harvard put up with him so long (and for all I know, they were willing to continue to do so, with him being the one who decided he had enough of it there). Universities in the US, at least in principle, have a very strong prejudice in favor of not restricting free speech. My guess is that much of Lubos's problem was that he seemed to be putting all his time and energy into ranting on the blog, not doing research. If he had been producing impressive papers about string theory in between the ranting, I don't think he would have had much of a problem.

    What did surprise me was the apparent unwillingness of his string theorist colleagues to forcefully tell him that the kind of response to scientific criticism he was engaged in was both inappropriate and damaging to their interests, or to take any action to distance themselves from what he was doing. As far as I was ever able to tell, he felt he was expressing the views held privately by his colleagues, with the only difference between them and him being that he was more honest and willing to stick up for what he believed. I have some reasons to believe that he wasn't unreasonable to think this, in particular given a few of the anonymous Cambridge-based attacks I've been the target of.

    Unfortunately I think Lubos's conviction that anyone who criticizes string theory must be an incompetent idiot, with their criticism of string theory something morally reprehensible deserving of personal attack, is not unique to him, but shared by some influential people. When I first started publicly criticizing string theory, I was shocked by how many people told me they thought I was doing something very brave and foolhardy. There has for quite a long time been an ugly atmosphere in the particle theory community over this issue, and Lubos's behavior makes quite clear what the nature of the problem is.

25. **Ivone FitzGerald**
    July 11, 2007

    Hi Peter,

    I enjoyed reading your book and Lee Smolin's as well. I've just been reading your comments on the LHC, and do you know what? It's my considered prediction that there'll be a Higg's boson found within six months of the machine switched on in May next year, with considerable excitement. But come July 2009 – 10 there'll be string theory conferences saying where the hell are the predicted black holes?

    Will they still carry on with string theory then? Unfortunately, yes. They'll make excuses such as: The LHC wasn't powerful enough. Lets build one the circumference of the Earth and then we'll get a result. Dream on!

    Let's face it. Once the Higg's boson is proved to exist, it's a monumental waste of money building ever larger more expensive colliders for all they'll produce is yet more Higg's bosons. We're better off researching into the known anomalies produced by varying basic so called "constants".

    I'm not a physicist. I'm doing natural history and archaeology, but even I can see this hole that the physics community has dug itself into.

26. **Peter Woit**
July 11, 2007

Ivone,

I think it will be longer than that to find the Higgs. Even if all goes well, the machine won't start producing real data of any interest until July. And, if history is any guide, it may take quite a while to get the LHC working the way it is supposed to. Analyzing the data from these very complicated experiments is also a long and time-consuming business, and the Higgs is not the easiest thing to look for. Personally I think I would bet on a Higgs in 2010…

The string theorists aren't really predicting black holes, they don't expect to see them. That possibility is a remote one and doesn't happen in most popular versions of string theory.

What we're all hoping for is not just the discovery of the Higgs, but studying its properties and finding something unexpected, or finding not a Higgs, but something else that plays the same role. Depending on what the LHC sees, there may or may not be a convincing case for spending the money on higher energy accelerators.

27. **m.**
July 11, 2007

lyme, the distance from Central Europe (as well as from China, India and other places you look down upon) to Columbia is of the same order of magnitude as most places in the US – proved by many a faculty list.
Pilsen, in particular, is a nice city with more than thousand years of history, which has given us the Pilsner beer,
Skoda motor company, music of Smetana and goals of Pavel Nedved…

28. **Oles**
July 11, 2007

"From what I hear, he can be quite charming personally, with the attack-dog screaming act restricted to his internet activities."

Having known Lubos for the past few months in and out of the class room, I found him to be quite inspiring as a teacher and deeply considerate as a person. Of course on many non-physics topics he struck me, at times, as being hopelessly misguided or ill-informed. Yet I never recall him being arrogant and unwilling to listen. His web persona is something of a mystery to many. At any rate, his wonderful sense of humor, physical insights and, most of all, great kindness will be remembered by several of us.

29. **Arun**
July 11, 2007

Oles, that is good to know. Let us hope then he lands up at a place without an internet connection, so that the dark side find no expression.

30. **lyme**
July 11, 2007

> and other places you look down upon

I don't look down upon anything. I've been there, done that, and know exactly what I'm talking about. And yes, Czekia is at exactly the same distance from the Ivy League as Tennesee. But on the way out distances dilate very fast, much faster than on the way in. The clock is ticking quite fast for Lubos.

31. **Chris W.**
July 11, 2007

On the internet, nobody knows you're a dog.

On the internet, nobody knows you're really a nice guy.

32. **amused**
July 12, 2007

So Lubos finally made good on his threat to leave Harvard (and academia?)… it'll be interesting to see what his next move is. Maybe a job at his hometown uni, but considering the love and admiration he expresses on his blog for Czech president Klaus, and his interest in science-related political stuff in general, it wouldn't surprise if he has lined up some government job there. Perhaps we can look forward to the spectacle of future Education Minister Motl imposing string theory on the Czech high school curriculum… At any rate, good luck to the guy, he's been an entertaining character (modulo the repugnant sexist/racist stuff he sometimes spouts). Will be interesting to see if/how his blog style changes now that he is presumably "unleashed" and able to "enjoy basic human rights".

33. **Neville**
July 12, 2007

> something I've been working on for a very long time finally seems to be working out and I'm spending more time on that

Sounds like you're having a fine adventure. Good luck!

34. **mathjunkie**
July 12, 2007

Just had this thought:
If Peter hadn't pointed out the improper aspects of string theory (like being untestable), Lubos would not have fighted back and he would have more time doing research. He might have made breakthroughs and…then he would go to IAS…

But the above is just for fun. 🙂

35. **The Lone Haranguer**
July 12, 2007

Never mind all that – seen today's New Scientist?

36. **woit**

July 12, 2007

TLH,

Thanks, already on it. See next posting…

37. **milkshake**
July 13, 2007

Oles: If you are a team member in good standing, Lubos can be very nice to you. (But you are wrong about the sense of humor – Lubos likes the sarcastic put-downs but he laughs only to his own jokes, the jokes of his peers and to the slapstick kind of stuff.) A narcissic, brilliant and agressive guy with twenty chips on his shoulder is not the best kind of advisor that one can have in the grad school.

He seriously compares himself to Feynman and Jesus Christ (but not to Borat). He actualy wants is to be loved and admired by all the smart people while defeating the idiots who get in the way of progress.

38. **IMHO**
July 16, 2007

Peter Woit Said:

> It doesn't surprise me that Harvard put up with him so long (and for all I know, they were willing to continue to do so, with him being the one who decided he had enough of it there). Universities in the US, at least in principle, have a very strong prejudice in favor of not restricting free speech.

That's easy to say and well-and-good in principal, until it starts costing Harvard Corporation money…Prestige and image have value also.

Maybe I put to much faith in the ethics and morals of the physics community, but I can't imagine many condoning Motl's behavior (at least in private). You often mention most string theorists unwillingness to publicly *"take any action to distance themselves from what he was doing"*. That may be true, but a lack of public admonishment is not the same thing as approval.

Either way, at the end of the day it's hard to imagine any scenario where a Harvard Asst. Prof who *"decided he had enough of it there"* chooses to leaves Harvard and the American Scientific establishment behind to mingle with Borat.

39. **IMHO**
July 16, 2007

Actually, a simple google search gives a reasonably plausible explanation.

http://www.physicsbanter.com/particle-physics/79483-lubos-motls-forced-resignation-harvard.html

40. **woit**
July 16, 2007

IMHO,

I'm quite sure that the claims by Sarfatti that he was responsible for getting Lubos fired are nonsense. I would think that Lubos's colleagues would consider complaints from a source like Sarfatti a point in Lubos's favor, not a reason for firing him.

I don't claim that Lubos's string theory colleagues approved of how he was defending string theory, but I never saw any evidence at all that they disapproved of it enough to tell him to cut it out.

41. **IMHO**
July 16, 2007

Woit said:

> I'm quite sure that the claims by Sarfatti that he was responsible for getting Lubos fired are nonsense.

Oh yes, I'm sure those particular claims are nonsense.

What was of interest to me was the information that there was a forced resignation as far back as January. If true, it now seems that the Harvard Physics Department is not as morally and ethically bankrupt as they first appeared.

42. **milkshake**
July 16, 2007

The asset/liability ratio was decreasing for quite some time and finally even his suporters agreed that Lubos was not worth the constant aggravation.

I don't think Sarfatti can claim credit Lubos for himself – for example about 5 years ago there was a minor affair when Lubos discovered that a (politically-correct + pompous) lecturer of slavonic studies in Glasgow misrepresented his old czech degree as a Ph.D. – the degree in question was roughly equivalent something intermediate between MS and Ph.D. Lubos allerted Glasgow uni, called the lecturer a commie spy colaborator and suggested he should commit suicide. As a result the lecturer threatened a legal action and complained at Harvard. Lubos was reportedly on the occasion ordered by his superiors to take his extracurricular interests easy and to stay out of the spotlight. He managed, for about 3 weeks.

43. **Peter Woit**
July 16, 2007

milkshake,

I hadn't heard that part of the Lubos story before, presumably it has to do with this:

http://www.blisty.cz/art/9429.html

In Lubos's latest posting, it seems that I'm the villain of the latest Die Hard movie…

44. **milkshake**
July 16, 2007

Yeah, it is this stuff – for many months the same e-zine even had a free advert on its sidebar for the Motl's czech translation of the Elegant Universe and would post some Lubos articles there. You can imagine how it progressed from there.

45. **amused**
July 17, 2007

IMHO wrote: "…at the end of the day it's hard to imagine any scenario where a Harvard Asst. Prof who "decided he had enough of it there" chooses to leaves Harvard and the American Scientific establishment behind to mingle with Borat."

unless he/she is a free spirit who is also a fanatic and a bit of a nutter. Not everyone in this business is a careerist, and different people value different things. Just look at Perelman. Lubos has been writing for a long time on his blog about his distain for Cambridge and academia in general, so my bet is that it's more a case of him jumping than being pushed.

46. **IMHO**
July 17, 2007

amused said:

> my bet is that it's more a case of him jumping than being pushed

His entire self worth is wrapped up in an unwavering belief in his superior scientific intellect….and he chose to leave academia???

I'll take that bet any day of the week!

47. **anon.**
July 17, 2007

IMHO, you have got the facts a bit wrong. He was just an undercover secret agent working for an anti-string conspiracy, and his had to leave Harvard before his cover was blown (when his 'defense' of string theory had become obviously self-defeating).

48. **Chris Oakley**
July 17, 2007

It's true – Lubos was a gift to us String sceptics. He's going to be hard to replace.

49. **amused**
July 17, 2007

Ok IMHO, I'll wager US$100 on it (that he jumped rather than was pushed).
And Chris, I don't see the big difference between Lubos entertaining us from Harvard or from Czekia. Chances are he'll be even more entertaining from Czekia!

50. **Chris Oakley**
July 17, 2007

Amused,

It's not a question of that. The point is that now Lubos will just be another dissident like Nigel Cook, Jack Sarfatti, Thomas Larssen, Danny Ross Lunsford, Matti Pitkannen, Tony Smith, me and – for all I know – you. Much easier to ignore than a Harvard Assistant Professor.

51. **IMHO**
July 17, 2007

How do we determine the truth Amused?

52. **amused**
July 17, 2007

Chris,
You are of course right that the Harvard connection confers prestige, but, unless academia has become more of a joke than I realized, his Harvard position was a reflection of his status in the string community rather than the source of it. If he continues (or resumes) research in Czekia and it goes well, I don't see why his status should change. There are other examples of prominent string theorists working in offbeat places, e.g. Berkovits in Sao Paulo.

IMHO,
At some point stories of what happened will emerge, and if these converge to a fixed point re. jumped or was pushed then I think we can assume it's the truth. If they don't converge it will be more difficult. I suggest we ask Peter to adjudicate. Do we have a bet?

53. **gunpowder&noodles**
July 17, 2007

Gentlemen, gentlemen: False dichotomy alert. If you think that there is a sharp distinction between push and jump then you don't know much about academic politics.

54. **IMHO**
July 18, 2007

Amused,

No, I don't think so. It seems kind of Schadenfreude.

55. **amused**

July 18, 2007

IMHO,

Ok, but next time you say “I’ll take that bet any day of the week!” bear in mind that someone might actually take you up on it! 😉

56. **Vacuum**
July 23, 2007

Motl had a publication record of 23 papers with only 1253 citations to them (and no publications in the last year). I don’t think Harvard would hire a postdoc with such a record, let alone award tenure to Assist Prof (to compare, Clifford Johnson’s record is 75 papers with 2724 citations). So I think he was denied tenure at Harvard.

57. **Peter Woit**
July 23, 2007

Vacuum,

Clifford Johnson is quite a bit older, getting his Ph.D. nearly 10 years before Lubos, so you can’t compare those numbers. They’re more than acceptable for a Harvard postdoc, although his recent lack of publications might be a problem. Again, he hadn’t been at Harvard in a tenure-track position long enough to come up for a tenure decision in the usual way.

String Theory: The Fightback

July 12, 2007
Categories: Uncategorized

The public perception of string theory has definitely changed over the last few years, with the latest evidence this week's cover story in New Scientist, which begins:

> It's the theory everyone loves to hate.

The article (available fully only to subscribers, I fear) is entitled String Theory: The Fightback, and its story line is that, because of all this criticism, after nearly 25 years of work, finally:

> string theorists themselves have realised they must find ways to put their models to the test. They may still be far from being able to observe a string in a laboratory, but experiments planned for the near future – and even one currently under way – could provide tantalising evidence either for or against string theory…
>
> Now the string community is fighting back by devising creative, if indirect, ways to look for signs of strings – from hidden dimensions to ripples in space-time and other potential signatures of a stringy universe. The time has come to put string theory to the test…
>
> Critics should take heed. Experiments now show that string theory may be testable after all. One study at a time, string theorists seem to be homing in on models that will make specific, falsifiable predictions.

What follows is the usual misleading hype of bogus "tests" of string theory, of the sort I've written about extensively here. They are:

- The networks of cosmic superstrings promoted by Polchinski.

For one of my postings about this, see here. More than three years ago Polchinski and the KITP at Santa Barbara issued a press release about this trumpeting the idea that such superstrings could be observed by LIGO "over the next year or two." The problem with this kind of "test" of string theory is that you can easily come up with string theory models that produce lots of cosmic superstrings (already falsified), no observable amount of cosmic superstrings (can't use to test string theory), or precisely the amount of cosmic superstrings such that no hint of them would be seen until now, but there would be networks of the things lurking just below the threshold of measurability, to be discovered by the next generation of experiments (highly unlikely, pretty much pure wishful thinking). Polchinski has now stopped talking about LIGO and a year or two, and instead is promoting measurements of pulsars and five to ten years:

> According to Polchinski, though, our best bet for observing gravitational waves emanating from strings is to use pulsars. A pulsar is a rapidly spinning neutron star that fires out a beam of electromagnetic radiation as it rotates, like a lighthouse. These flashing beacons act as some of the most accurate clocks in the universe, and a gravitational wave rippling between a pulsar and Earth would disturb the otherwise precise timing of the pulses arriving here. The most likely cause of such fluctuations would be black holes colliding, but waves from strings would yield a unique timing pattern that would make them stand out. "Over the next five to 10 years," Polchinski says, "these will probe the most interesting models."

My colleague Brian Greene is quoted about this, making the essential point about this kind of "test":

> Sure, catching sight of a cosmic string would be a boon for string theory, but is there any observation that would serve as a death knell? For many sceptics, it's not that string theory is so hard to prove correct that puts them off, but rather that you can't falsify it. "I'm not aware of any test that if it fails will prove string theory wrong," says physicist Brian Greene of Columbia University in New York. "That's a real headache. You'd like to have a situation where you have a prediction, and if it's right the theory is right, and if it's wrong the theory is wrong."

- Quoting this recent paper, supposedly "according to Linde and Kallosh, no string-based inflation model can possibly create detectable gravity waves".

The problem is that the quoted paper doesn't actually say that. Here's the paper's concluding paragraph:

> However, a possible discovery of tensor modes may force us to reconsider several basic assumptions of string cosmology and particle phenomenology. In particular, it may imply that the gravitino must be superheavy. Thus, investigation of gravitational waves produced during inflation may serve as a unique source of information about string theory and about the fundamental physics in general.

Given the wealth of possible string theory scenarios, I have no doubt that if an imprint of gravity waves is found in the CMB, there will be string theory models that would "predict" it. As for the idea that not seeing such gravity waves would be evidence for string theory, here's what Glashow has to say:

> Not everyone thinks these tests will be useful, however. "Not seeing something is hardly evidence for string theory," says Nobel laureate Sheldon Glashow of Boston University, Massachusetts, an outspoken critic of string theory. He feels that such a result would mean very little. "String theorists are very wise. They can come up with a way to explain anything." String theory is simply not testable, he says. "There are an enormous number of string theories and they describe zillions and zillions of universes, none of them observable in any way. It sounds to me like angels dancing on the head of a pin."

- String theory is being tested at RHIC and, conjecturally AdS/QCD makes predictions about strong interaction physics.

> "We're still very far from being able to say, here is the exact string theory that describes QCD," Susskind says. "But the connections that show up between nuclear physics and string theory are fascinating. Sceptics won't consider this evidence for string theory, but nuclear physicists will use string theory and in time discover how accurately it describes these experiments."

What Susskind is neglecting to mention here is that these are tests of whether string theory is a useful way to do calculations in an already tested theory of the strong interactions, and has nothing to do with the question of testing the idea of string theory as a unified theory of quantum gravity and particle physics.

Also in New Scientist, there's a story about Neil Turok's recent talk at PASCOS entitled "Is the Cold Spot in the CMB a Texture?" which links to the string theory article. Evidently there's a patch of CMB where the temperature is anomalously low (the probability of this happening supposedly being 2 percent) and one can speculate that this may be due to a topological defect of some kind. Amusingly, the online version of the New Scientist article includes an interpolated editorial comment that someone forgot to take out before publication:

> Turok presented the findings at a conference on particles *Hi Anil. This threw me a bit. We say the team noticed previous work by Turok, and then before we know it Turok is the one presenting the work. When did he join them*, strings and cosmology at Imperial College London last week.

Comments

1. **Coin**
   July 12, 2007

   Evidently there's a patch of CMB where the temperature is anomalously low (the probability of this happening supposedly being 2 percent) and one can speculate that this may be due to a topological defect of some kind.

   The article is available only to subscribers. I was wondering– will it be possible to more easily tell whether or not this cold spot is coincidence after any particular future CMB observation experiment?

2. **Jonathan Vos Post**
   July 12, 2007

   "…New Scientist… interpolated editorial comment that someone forgot to take out before publication:

   Turok presented the findings at a conference on particles 'Hi Anil. This threw me a bit. We say the team noticed previous work by Turok, and then before we know it Turok is the one presenting the work. When did he join them…"

   Or, this tunneled through from elsewhere in the multiverse. Bound to happen now and then. Duality with Boltzmann brains. Or something else within epsilon of unfalsifiable, in the Landscape.

   "What's the frequency, Kenneth?"

3. **joe**
   July 13, 2007

   M. Disney (observational galactic astronomer) was an "alarmist/whistle-blower" to cosmology back in 2000. It seems to parallel P. Woit/"Not Even Wrong", in that large-scale (cosmological) questions are cursed with not having the proper data. Without data, you have only theory..hence "religion".

   The Case Against Cosmology

   http://arxiv.org/pdf/astro-ph/0009020
   [interesting references to particle physics & LHC..who can do actively do "experiments". Astronomers can only passively observe]

   Is not the below a striking parallel to the ST quagmire?

   > Given statements emanating from some cosmologists today one could be forgiven for assuming that the solution to some of the great problems of the subject, even "the origin of the Universe" lie just around the corner. As an example of this triumphalist approach consider the following conclusion from Hu et al. [1] to a preview of the results they expect from spacecraft such as MAP and PLANCK designed to map the Cosmic Background Radiations: ". . .we will establish the
   > cosmological model as securely as the Standard Model of elementary particles. We will then know as much, or even more, about the early Universe and its contents as we do about the fundamental constituents of matter".
   >
   > We believe the most charitable thing that can be said of such statements is that they are naive in the extreme and betray a complete lack of understanding of history, of the huge difference between an observational and an experimental science, and of the peculiar limitations of cosmology as a scientific discipline. **By building up expectations that cannot be realised, such statements do a disservice not only to astronomy and to particle physics but they could ultimately do harm to the wider respect in which the whole scientific approach is held. As such, they must not go unchallenged.**
   >
   > It is very questionable whether the study of any phenomenon that is not
   > repeatable can call itself a science at all. It would be sad however to abandon the whole fascinating area to the priesthood. But if we are going to lend this unique subject any kind of scientific respectability we have to look at all its claims with a great circumspection and listen to its proponents with even greater scepticism than is usually necessary. This is particularly true when the gulf between observers and theoreticians is as wide as it usually is here. Either side may be more inclined to accept the claims of the other than they should. As an extra-galactic observer addressing a mostly theoretical audience I want to emphasise the very many caveats that should always be attached to the observational side of this field

   The First Crisis in Cosmology Conference

4. **anon.**
   July 13, 2007

   New Scientist uses the same article 'template' for lots of pseudoscience where old discredited ideas are being worked on, provided that the ideas seem exciting. It did an article some years back which was pretty much the same but about 'cold fusion'.

   (The synopsis for that PR stunt was something like: 'Everyone loves to hate cold fusion because it was overhyped a bit at first, but now people are starting to get tantalizing glimpses of real physics from it, blah, blah…', followed by some experimental work which gave results of no statistical significance, and a lot of wishful thinking from experts. I think that issue sold out fast. New Scientist should be commended for knowing how to write copy that sells. Pity it's totally misleading, but that's sci fi for you: it's popular, but it's also scientific fiction until some solid evidence shows up.)

   I'm just waiting for New Scientist to write a defense of creationism:

   'creationists themselves have realised they must find ways to put their models to the test. They may still be far from being able to observe the act of creation in a laboratory, but experiments planned for the near future – and even one currently under way – could provide tantalising evidence either for or against creation…'

   😉

   July 13, 2007

   "String theorists are very wise. They can come up with a way to explain anything." – Sheldon Glashow

   I'm surprised to see such a sarcastic comment from a such Nobel Laureate like Sheldon Glashow being quoted. String theorists are (correct me if I'm wrong) just human beings, so presumably they have feelings and don't like sarcasm (unless, of course, the mental ability of string theorists to believe that the world has 6/7 extra dimensions without evidence, is linked to a genetic mental condition which makes them invulnerable to ridicule). Those string theorists who believe that they reside in the universe where the anthropic principle has selected the existence of the *Not Even Wrong* blog to occur on the internet, might feel upset and hurt by such sarcasm. But many of the other string theorists, believing that they spread over the segment of the landscape of the multiverse where physics is fairly close to our own but not quite close enough to include this blog, might remain deluded, if they really exist.

6. **Peter Woit**
July 13, 2007

Joe,

I'd rather people discuss mainstream cosmology on blogs run by cosmologists, but I'll just point out that, whatever its problems, mainstream cosmology is an extremely solid and respectable science compared to "string cosmology".

7. **M**
July 13, 2007

Joe, the "Case against Cosmology" is just a few months older than "String theory: An Evaluation" (physics/0102051). In these years cosmology made enormous progress, while the main development in strings has been the rediscovery of the anthropic principle.

8. **Bee**
July 13, 2007

sadly, the criticism you raise above holds for a lot of other theoretical approaches as well. I understand you are mostly concerned about string theory, but the problem is much more general than that. if I look at the arxiv, it seems it has become quite normal to cook up more or less meaningful 'theories' or 'models' that have a lot of 'motivation' but no connection to reality whatsoever (despite an impressive amount of calculations and references). now the fashion changes to "needs phenomenology". being a phenomenologist, I certainly don't mind, but in many cases there either is no phenomenology (a 'qualitative' prediction is no prediction, one can always shift parameters out of experimental range, so what's the point), or there is phenomenology but no sensible model (i.e. one that is in disagreement with the standard model, or worse, one can't be sure whether it is in agreement or disagreement with anything), or there is phenomenology and a model but one can't learn anything from it (e.g. there must be one hundred different 'models' that 'motivate' why a breaking of Lorentz symmetry is 'natural to expect' – so if we measure it what do we learn from that besides that it is broken?).

9. **Peter Woit**
July 13, 2007

Bee,

I agree that this is a more general problem, but the string theory situation still seems to be a unique one. There's lots of dubious theoretical work out there (one reason being that coming up with a good new idea in this field is extremely hard), but most of it is pursued by smaller groups of people with lower profiles in the community. What is going on here is outrageous overhyping and misleading of the public by a rather large group of people at the absolute top of the academic hierarchy. I don't know of anything quite analogous in other subjects.

It's interesting to note that the people New Scientist found willing to promote bogus "tests" of string theory are mostly the same ones promoting the anthropic landscape.

10. **Bee**
July 13, 2007

Hi Peter,

but the string theory situation still seems to be a unique one

I agree. I am just saying one doesn't cure the problem by demonising one field – there is the danger such unfortunate distractions from questions relevant to physics just shift somewhere else.

Best,

B.

11. **publius**
July 13, 2007

I just came accross a quote by chilean writer and filmaker Alejandro Jodorowsky (el Topo, Sacred Mountain, 'El Incal' comics (with Moebius)) that beautifully resumes the situation with string theory, the landscape and what it is doing to fundamental physics:
" Failed Theory:
A Philosopher who couldn't walk because he stepped on his beard, cut his feet"
It is interesting to notice the string-like nature of long beards…

12. **island**
July 13, 2007

Coin asked:
The article is available only to subscribers. I was wondering– will it be possible to more easily tell whether or not this cold spot is coincidence after any particular future CMB observation experiment?

This is already the second confirming indicator of the reality of the anomalies, and it's not just a coincidence when the motion of the Earth around the Sun, (the ecliptic), also traces-out the goldilocks zone of the observed universe.

So, give em another 20 or 30 years to explain it away without giving equal time to the most apparent indication of the evidence, since that's the way science is done now a-days!

http://arxiv.org/PS_cache/arxiv/pdf/0704/0704.0908v1.pdf
Extragalactic Radio Sources and the WMAP Cold spot

> To create the magnitude and angular size of the WMAP cold spot requires a ~ 140 Mpc radius completely empty void at z greater than or equal to 1 along this line of sight. This is far outside the current expectations of the concordance cosmology, and adds to the anomalies seen in the CMB.

Adds what?… a greater need for more time and excuses not to introduce the smoking gun into evidence?

13. **Peter Woit**
July 14, 2007

Coin,

The rest of the article says that Turok presented calculations about what the next generation Planck experiment should see in the CMP if these topological defects really do exist.

All,

Please take general attacks on and discussion of the conventional cosmological model elsewhere. I'm not an expert, not very interested, and not willing to moderate or host a discussion of this topic.

14. **jkowalskiglikman**
July 14, 2007

Hi,

Perhaps my question is a bit out of topic, but I am wondering what "quantum gravity" means in the context of string theory. What is being quantized? How one gets the semiclassical limit? What is the conceptual relation between quantized microscopic degrees of freedom and the semiclassical description in terms of gravitational field? Does string theory incorporate equivalence principle? Is it any direct way to get any prediction concerning, say, orbits of planets in Solar System and string corrections.

All these must be a textbook stuff, but I could not find any clear discussion.

Thanks

J

15. **Peter Woit**
July 14, 2007

J.

Unfortunately this is pretty much off-topic, and full answers to the questions you ask have long answers. You might do better to try this question on the blog of a string theorist like Jacques Distler or Clifford Johnson. These questions are addressed in the standard string theory textbooks, although the answers are confusing, largely because while it is clear what string theory is supposed to be for strings propagating on a fixed background, string theorists want to use this to deal with varying backgrounds.

16. **mclaren**
July 22, 2007

New Scientist's article about string "theory" proved particularly disappointing. The weasel words came thick and fast — "**may** allow for a test of string theory" and "**could** lead to verification of the theory." Same kind of deceptive wording you find in a prospectus for a dodgy hedge fund.
Why is it so difficult for reporters to simply write "string theory has not yet made a single falsifiable prediction"?

17. **anon.**
July 22, 2007

Mclaren, reporters must write what sells the paper or their editors won't publish it.

Journalism, even science journalism, is a little bit different from the scientific ideal.

There's also a sense of groupthink involved. New Scientist is not the only journal which reports fashion rather than real news.

At the end of the day, journals are there to put food on the tables of the journalists and editors who produce them. If they reported news that doesn't excite the crowds into buying it, they would lose readers, prestige, advertisers, distribution, prizes awards for popular science journalism, massive salaries, etc. (Plus, they would risk being strung up by all those who believe string is sacred writ.)

July 23, 2007

With regard to string theory, Dr. Woit remarked:
What is going on here is outrageous overhyping and misleading of the public by a rather large group of people at the absolute top of the academic hierarchy. I don't know of anything quite analogous in other subjects.

Eh?
You don't?
I certainly do. Indeed, the examples have grown so flagrant it's hard to overlook 'em. "Hard" AI has been guilty of "outrageous overhyping and misleading of the public by a rather large group of people at the absolute top of the academic hierarchy" for at least 50 years. In 1967 tenured the Princeton computer science "genius" David Gelernter confidently predicted "Within 10 years, the best mathematician in the world will be a computer." In 1974, Marvin Minsky, head of the MIT AI Lab, predicted "human-level" intelligence from computer programs by the early 21st century,. and superhumanly intelligent AIs shortly thereafter. In 1984, Douglas Lenat (leader of the CYC project) predicted that by 1994 CYC would be going online and reading online text independently in order to increase its knowledge base.

None of these wildly overhyped predictions have come close to reality. Meanwhile, all the most respected AI researchers now admit AI has hit a "dead end" and call AI "brain dead" and "a degenerating research program."

For an excellent overview of the pervasive failure of "hard" AI, see:
http://www.skeptic.com/the_magazine/featured_articles/v12n02_AI_gone_awry.html

In his 1959 article "There's Plenty Of Room at the Bottom," Richard Feynman inaugurated the idea of nanotechnology, a subject expanded to science-fictional lengths in K. Eric Drexler's 1987 magnum opus *Engines of Creation*. Despite 20 years of incessant hype, Drexler has produced not one single scientific advance which would bring his fantasies of molecule-sized computers and "assemblers" closer to reality. In fact, Drexler hasn't even done any basic research — instead, he's spent all his time doing PR.

Undeterred by these unpleasant realities, computer science professor Vernor Vinge has confidently predicted "The Singularity," an alleged explosion of technology in which "hard" AI combined with Drexlerian nanotechnology and genetically engineered supermen to allow science fictional scenarios like mind uploading into computer, immortality, people with IQs of 20,000, nanomachines capable to tearing apart any object and rebuilding it atom by atom into any desired form.

Despite all this wild hype (including truly crazed predictions by spinsmeisters like Ray Kurzweil and Hans Moravec that "hard" AI is not only possible, but imminent, and that most of the people in his audience will live long enough to upload their minds into superhumanly intelligent computers), signs of actual progress in genetically engineering supermen, or producing human-level intelligent AI programs, or building Drexlerian nanomachines, have proven impossible to discern.

This does not seem to have daunted any of the spinmeisters, who continue to trumpet the alleged imminence of The Singularity "any day now" even while researchers in computer science and materials science and molecular biology have run into roadblock after roadblock and brick wall after brick wall. Indeed, the more research molecular biologists do into the genetic code, the more their results challenge previouly accepted models of how DNA works:
http://www.bioresearchonline.com/content/news/article.asp?docid=e87b8231-8a15-43bc-8ba4-bb7b65b028ee

Rather than being on the brink of genetically engineering mythical supermen with IQs of 20,000, it seems more likely that researchers are now finding out that almost everything we thought we knew about the genetic code is wrong, and we must go back to square one.

Jaron Lanier has written about the outrageous overhyping and misleading being done by the bizarre quasi-religious "rapture of the nerds"-style cult that has developed around these fantasies of "hard" AI that's supposedly "right around the corner" and purportedly imminent genetic engineering to enhance human traits like intelligence and allegedly soon-to-be-built nanomachines able to revive the dead and literally turn water into wine:
http://www.edge.org/3rd_culture/lanier/lanier_index.html

Lanier calls this crackpot cult "cybernetic totalism," and he points out that it has taken over surprisingly large parts of previously respectable computer science and materials science and molecular biology.

I'm seeing a direct parallel here between the increasingly wild hype and ever more bizarrely hubristic predictions (*"I expect the Riemann Conjecture will be proved within several years as a baby example of string theory"*) of string theory and the increasingly wild hype (*mind uploading! immortality! superhumanly smart AIs! genetically engineered uebermenschen!*) and ever more bizarrely hubristic predictions (*people in this audience will live long enough to live forever! — Ray Kurzweil*) touted by the crackpot cult of the Singularitarians.

For that matter, I see a direct parallel twixt the radical disconnect from reality we observe in American foreign policy (*"We have to fight them over there so we don't have to fight them over here"*), and these bizarre cults of string theory and "hard" AI and The Singularity in the sciences which have similarly cut themselves off from reality and now float into a fantasy realm of multiverses and branes, superhumanly smart AIs and nanoengineered diamond-based power plants the size of a matchbox allegedly able to power a city.

It's as though — in a wide variety of different areas of American life — otherwise sensible rational professionals (computer science professors (*Vernor Vinge's and Hans Moravec's delusion of The Singularity*), theoretical HEP physicists (*string theory*), economists (*The Laffer Curve*), foreign policy analysts (*Project for the New American Century*), materials scientists (*Drexlerian nanotechnology*), molecular biologists (*genetic engineering to enhance traits like intelligence which have never even been successfully defined or definitively measured*)) have drifted off into la-la land and now live in a fantasy world of their own imagining, immune to inconvenient facts and inappropriate logic.

Far from being an isolated example, string theory seems to me paradigmatic of a much wider dysfunction and pathology in American intellectual life.

20. **dave tweed**
July 23, 2007

`Meanwhile, all the most respected AI researchers now admit AI has hit a "dead end" and call AI "brain dead" and "a degenerating research program."' This is a difficult case because the scope of the field referred to by AI tends to be understood differently by different people: does, e.g., computer vision research fall within its purview? I think the hardcore AI people claim it as a branch of AI – partly so they can point to some of the deployed examples – whilst most people working in vision don't consider it AI. So there are lots of vigorous and, I think, non-degenerate research programs in areas that some might claim as AI. In addition, lots of computer research does get evaluated on (semi-) objective problems and is generally improving. Most is still a long way from being reliable and safe enough for real world deployment, but there is meaningful, measured progress.

The key differences from *Peter's view* of string theory is that AI people don't claim anything but a hard AI approaches to problems is not going to work, and there are lots of people working at problems hard AI "thinks it owns" using different techniques, eg, simple formula learning in data mining problems. (I've emphasised what I think is Peter's view just because I don't have the knowledge to know if he's right.)

21. **mclaren**
July 23, 2007

Dave Tweed makes some excellent points. However, the boundary lines twixt cosmology and HEP are fairly blurry too, so if we use your criteria a good argument could be made that "lots of people" in cosmology are actually working on string-related physics.

The problem with playing these kinds of word games is that they obscure everyday commonsense realities. Namely, sensible people know there's a whopping big difference between "hard" AI and machine vision, just as sensible pople know there's a whopping big difference between string theory and cosmology.

For one thing, cosmologists talk about things that can be ***measured***. And cosmologists construct models that can be ***falsified***.

Moreover, few string "theorists" have claimed to my knowledge that it's the only approach that ***can*** work – instead, they're claiming it's by far the most promising approach. "The only game in town" doesn't mean the only possible approach, just by far the best one in the judgment of the string supporters.

LQG research continues, just as artificial vision research persists in computer science indepddent of GOFAI. So Dave Tweed's remarks on that score constitute a straw man.

What Dave Tweed's verbal calisthentics tend to obscure, I think, is the hard cold fact that for both "hard" AI and string theory, it's clear to any reasonable person that these approaches have broken down. They're just not working. There are no practical results in the real world, and no sign of any path that would lead to practical results in the real world.

This seems true of other fields as well. Merton & Scholes' 1997 Nobel Prize followed by the bankruptcy of Long Term Capital Management, a hedge fund that used their economic theories to allegedly eliminate risk in investing but went broke instead, offers a prime example. By any definition Merton and Scholes qualify as the "absolute top of the academic hierarchy" in economics by reason of their Nobel Prize. The disastrous collapse of LTCM under the guidance of their economic theories surely fits the definition of "outrageous overhyping and misleading of the public."

Merton and Scholes represent only the tip of the iceberg. We've been seeing an awful lot of "outrageous overhyping and misleading of the public by a rather large group of people at the absolute top of the academic hierarchy" over the last 15 to 20 years, and in academic fields far outside physics. Dave Tweed's verbal gymnastics about the exact definition of "hard" AI tends to obscure this valid and significant point.

22. **Me**
July 24, 2007

«This seems true of other fields as well. Merton & Scholes' 1997 Nobel Prize followed by the bankruptcy of Long Term Capital Management,»
— — — — —
Maybe I'm just nitpicking but Merton & Scholes didn't win a Nobel prize in Economics, they couldn't since that prize doesn't exist.

They won the 1997 Swedish Bank prize in Economics in memory of Alfred Nobel. Regardless of that, it's considered the pinnacle of an economist's career. Nice info I didn't know.

23. **mclaren**
July 24, 2007

You're quite right about the Swedish prize for economics — Alfred Nobel never stipulated an award for economics. Thanks for the correction.

24. **Chris Oakley**
July 24, 2007

Er … excuse me, but Merton and Scholes were most definitely not responsible for the LTCM disaster, directly or indirectly … they were merely roped in to provide some kind of academic imprimatur to a venture that was always going to be risky. They had virtually no part on the day-to-day decision making, which was done by Meriwether and a handful of maths PhDs he brought with him from Salomon Brothers. The Nobel-equivalent prize they won was for developing an option pricing formula based on the notion that stock prices undergo a random walk — demonstrably not what happens but their formula nonetheless proved useful as a kind of reference point.

25. **dave tweed**
July 24, 2007

In Mclaren's original comment, the "hard" modifier to AI wasn't consistently there so it wasn't clear whether you were claiming "hard AI" or "AI" was dead. I don't like the name AI because it's not agreed whether it's merely generating results which humans generate by intelligence, or the computer should be doing this "in an intelligent way". However, there are lots of institutes around the world that have "AI" in their names that have people working on both "hard AI" and other problems so we're stuck with it. I was more pointing out to non-computer science readers that the situation isn't quite as black-and-white as you suggested, and certainly your viewpoint is not universally held.

Mclaren wrote "I think, is the hard cold fact that for both "hard" AI and string theory, it's clear to any reasonable person that these approaches have broken down." This may well be true. However, my understanding of the criticism of string theory is that string theorist's totally dominate *all* theoretical particle physics and quantum gravity research. This isn't the case for "areas of research that some people could be call AI": lots of people doing non-"hard AI"-approaches are working on some of these problems. It's certainly not more difficult to get an academic job working in these areas without being a "hard AI" person, something claimed to be difficult in theoretical physics for non-string theorists.

Basically, I understand Peter's objections to ST be based both on technical problems in their program and their excessive sociological power and abuses of it. The first may be true of "hard AI" but the second definitely isn't because in academic circles they don't have much power to abuse. Of course the general media is a different thing because talking about immortality or the singularity is going to get journalists' attention much more than talking about simple model learning for data mining against credit card fraud prevention, etc. I think this says more about journalists than it does about academic AI though.

26. **Who**
July 24, 2007

> However, my understanding of the criticism of string theory is that string theorists totally dominate all theoretical particle physics and quantum gravity research…
>
> Basically, I understand Peter's objections to ST be based both on technical problems in their program and their excessive sociological power and abuses of it.

Dave, this does not bear on your argument concerning Artificial Intelligence, but is merely a point of information.

From the statements of European non-string quantum gravitists, and my own observation of current research, I gather that the string dominance and abuse of sociological power which you mention is less of a problem **outside the US**.

A German PhD student now in the UK recently referred to the situation in the US as "extreme". I believe string virtual monopoly is primarily a millstone around the neck of US theory research, and only secondarily worldwide. In his expressed view, funding for non-string QG study and research is satisfactory in Europe and the UK.

What we are seeing is a kind of "brain drain", as new PhDs in quantum gravity migrate out of the US. A 2006 Penn State PhD won a European (Curie) fellowship and went to postdoc in the UK. Another recent Penn State PhD went to Canada. Penn State has the only non-string QG group in the US (more than one faculty) and is the only place in the country regularly turning out non-string QG physicists.

String has such a stranglehold on theory research support that these young people have limited options in the US. No matter how brilliant the trackrecord they have to leave the US to continue in their chosen line of research. But these are precisely the people one would want to keep if one has any hope of diversifying research in US departments!

The ESF (European Science Foundation) started a special QG arm in 2006 which is already well-funded and active.
http://www.maths.nottingham.ac.uk/qg/
US postdocs are currently working in Utrecht, Marseille, several places in Canada, and the UK.

So when one speaks of the crippling of theory research due to abuse of excess power, one should probably qualify that by saying that it is progress in the US that is retarded—and not necessarily elsewhere.

27. **mclaren**
July 25, 2007

Er…excuse me, Chris Oakley, but your claim is not supported by the available evidence:

Scholes's and Merton's involvement in LTCM has led commentators to ask whether the company's failure reveals basic errors in the assumptions underpinning their work with Black on option pricing. Dunbar, for example, says that these assumptions are 'flawed' – a common conclusion in discussions of LTCM. If Dunbar and the others are correct it would be a matter of real import, given how central these techniques have become to the global financial system. But the extent of the technical dependence of LTCM's trading on Black-Scholes-Merton reasoning is unclear until there is more information in the public domain.
http://www.lrb.co.uk/v22/n08/mack01_.html

Merton himself was interviewed on camera in the PBS Frontline special "The Trillion Dollar Bet." He himself states on camera that LTCM consittuted a test of his options pricing theory method of eliminating risk from investments. He went on to waffle and hedge that it was unclear whether the theory was wrong, or whether the boundary conditions were violated and thus it wasn't a valid test.

The assertion that Merton & Scholes had nothing to do with LTCM's collapse is the standard rewriting of history we find with all these kinds of huge failures nowadays. Ronald Reagan wasn't a senile crackpot who hired an astrologer to time his White House meetings, he was The Man Who Won the Cold War. Merton and Scholes weren't actually invovled with LTCM, they were jsut there for publicity purposes as window dressing. Ten years or so down the road we'll start hearing that the Iraq war wasn't a giant debacle but a huge success and papers will start appearing showing graphs to prove how marvellous the Iraq mess has been for the Palestianian peace process,, how much it has improved the Middle East, and so on. Standard stuff.

Merton was responsible not only for inventing the Black-Scholes formula, but also for founding LTCM
http://www.portfolio.com/views/blogs/market-movers/2007/05/22/bob-merton-sees-no-more-market-panics

Black, Scholes and Merton's solution to the problem was far-reaching, but their basic idea was simple and elegant. They showed how to construct a 'replicating portfolio': a continuously adjusted set of investments in both the underlying asset and government bonds or cash that would have exactly the same pattern of returns as an option. In an efficient market, the price of the option has to equal the cost of the replicating portfolio. If those prices diverge, there is risk-free profit to be made…
http://www.lrb.co.uk/v22/n08/mack01_.html

That's the explicit model on which LTCM claimed to have based their investments. Draw your own conclusions.

28. **Peter Woit**
July 25, 2007

mclaren,

This discussion of the problems of LTCM is both completely off-topic (and, from the little I know based on reading a book on the subject and talking to people in that industry, pretty far off-base). I'd really like this blog to stick to topics in math and physics I'm competent to moderate, the kind of discussion you want to engage in belongs on a very different blog.

29. **Chris Oakley**
July 25, 2007

Can't argue with that – but McLaren, you'll have to give me an e-mail address if you want to continue the discussion. Your comments, BTW, suggest that you have never worked in the business. I have.

30. **Ronald Mirman**
July 26, 2007

Physicists believe that if their theory disagrees with experiment they can just say it hasn't been possible to test it yet. Yet string theory has made a testable predication: the dimension. And that is wildly wrong. Moreover it has long been known that physics would be impossible in any dimension but 3+1 (which it totally uninteresting since it agrees with reality). For proof see my OAIU book in the booklist in my blog, which also has discussion of many other things wrong with string theory. Science blog

The politics should be ignored except by those who like nasty remarks about George Bush.

Carroll and Johnson on Bloggingheads

July 14, 2007
Categories: Uncategorized

There's an interesting exchange today between Sean Carroll and George Johnson on bloggingheads.tv. They cover a range of topics, including the controversy over string theory and the role of blogs. Johnson describes his time last fall at the KITP, telling about drinking very expensive Scotch with Steve Shenker, and many discussions with the string theorists there who were concerned that they were getting bad publicity and didn't know what to do about it. Some were concerned that Lubos Motl was not exactly representing them well.

Sean gives a fairly standard defense of the landscape ("maybe it really is the way the world works"), with no discussion of the main problem with the landscape, that it shows no signs of making falsifiable predictions that would make it legitimate science. Some other points of the discussion include speculation about "what if Feynman and Gell-Mann had blogs?", and Sean's analogy of the string/LQG debate with mainstream/"heterodox" academic economics.

Update: Sean has his own posting about this.

Comments

1. **Chris Oakley**
   July 14, 2007

   Well – it's over an hour, but I saw it through. Once again, we discover that Sean does not care whether the String Theory Landscape is ugly or not, he just cares about whether it is *right*.

   With all due respect to Sean, this is not the sort of view that a scientist should take. "Right" and "wrong" imply certainties, a luxury never afforded to the scientist. There are only good explanations and bad explanations. Invokes the Anthropic Landscape being a *bad* explanation, one should, at that point, or, maybe even before, be seeking something better, and if this involves discarding twenty years of work, then so be it.

2. **SnarkFest**
   July 14, 2007

   A mildly fanciful elaboration:

   "Maybe it really is the way the world works. If so, we'll never be able to *test* this entrancing conjecture. We'll have to content ourselves with asserting it, and reveling in the irrefutability of the assertion. It will be the greatest achievement of the human mind since G. W. F. Hegel proved that the solar system contains seven planets."

3. **mr.M.**
   July 15, 2007

   I'm glad this debate happened and i wish there will be more in future. It's more interesting if debaters don't agree and they debate the issue.

4. **Chris Oakley**
   July 15, 2007

   > "…It will be the greatest achievement of the human mind since G. W. F. Hegel proved that the solar system contains seven planets."

   Well … just get them to de-list Uranus and Neptune, just like they have already done for Pluto, and he will have been right!
   The S.T. equivalent, I suppose, would be Susskind (or whoever) altering the definition of the term "science" to allow the Anthropic Landscape to be respectable.

5. **AGeek**
   July 15, 2007

   Two related questions come to mind:

   1) If some string theorists are concerned that someone is not representing them well, why don't they represent themselves? Who's out there blogging, besides Motl, Clifford and Distler?

   2) How come Carroll is seen taking the pro-string side of the debate so often? Not only is he not a string theorist, it is questionable if he can even be considered a physicist. Is there really nobody more suited than him for the "job"?

6. **Peter Woit**
   July 15, 2007

   AGeek,

   Sean is definitely a physicist, although definitely not a string theorist. It is a somewhat weird situation that he's taking a leading role defending the theory.

   One of Sean's main arguments for string theory is that it has been victorious "in the marketplace of ideas", i.e. it has achieved its dominant position in particle theory by convincing theorists it is the way to go. My take on why more sensible string theorists than Lubos haven't tried to mount a serious defense of string theory against its critics is that they know that they would not fare well in open debate. String theory has not been doing well in the "marketplace of ideas" recently, and that's not because Lee Smolin and I are marketing geniuses. I've been told that one prominent string theorist has said that he wanted to write a book refuting Lee's book and mine, but couldn't bring himself to, since he would have to directly refer to us by name. For the moment, I think string theorists have made the tactical decision that they won't do well in an open marketplace of ideas, that entering it would just give serious criticism more exposure. If you were promoting an idea like the anthropic landscape, wouldn't you do what you could to stay away from forums where you would have to answer your critics?

7. **AGeek**
   July 15, 2007

   Carroll's academic degrees are all in astronomy http://preposterousuniverse.com/cv.html

Based on that, and on what I've seen of his work, I wouldn't call him a physicist.

His talk of "marketplace of ideas" has been criticized by others as trivially flawed: in academia, you don't have producers and consumers, with the latter only concerned with choosing the best product offered by the former; everybody is a producer. Imagine ten Apples all trying to sell iPods and iPhones to each other… the metaphore may reveal Carroll's level of understanding of economics, but little else.

If I were promoting an idea like the anthropic landscape, I guess I'd concentrate on the people who really count for the bottom line. That would be funding agencies and workers in more or less related fields, especially cosmology. I would probably not worry too much about the general public unless there were a real outcry about wasted funding threatening to turn into political action.

8. **DB**
July 15, 2007

Carroll is very slick. Very PR savvy. Very mediagenic. I think you'll see more of him as "the acceptable public face" of string theory. Motl was a PR disaster for string theorists – and a boon to critics. My bet (but what do I know anyway) is that Sean would like to carve out a niche for himself in the lucrative area of popular science presentation. A guy as smooth as Sean will be able to turn on a dime and dump the string theorists whenever he wants.

9. **Peter Woit**
July 15, 2007

DB,

"lucrative area of popular science presentation"

I know for a fact how much Sean made in one of his recent media appearances, since I was promised a check of the same size. After taxes, the sum is in the high two figures. I doubt bloggingheads pays even that well.

As far as I can tell there are extremely few physicists or cosmologists making enough money from "popular science presentation" to support even an extremely modest lifestyle. My guess is that you could count them on one hand, with fingers to spare. I doubt Sean is doing this because it's "lucrative", because it really isn't, except in very unusual cases (basically I think you need to have a successful TV show). People's motivations are complicated, and I think every scientist who makes it part of their mission to get ideas about science before the public has some mixture of an altruistic desire to enlighten others and a less-altruistic desire to get attention for themselves. Rarely does money have much to do with it at all, it seems to me.

10. **DB**
July 16, 2007

Peter,
Fair point. It doesn't usually pay well, although a bestselling book can be a real moneyspinner (e.g. Brief History of Time), especially if tied into a successful TV show (e.g. Sagan's Cosmos).

Anyhow, Sean's May rallying call in New Scientist

http://www.newscientist.com/channel/fundamentals/dn11882-string-theory-its-not-dead-yet.html
is having the requisite effect today:

http://space.newscientist.com/article.ns?id=dn12261&feedId=space_rss20

If I'm not mistaken, dark energy is Sean's area, so it will be interesting to read his take on this.

11. **Bee**
July 16, 2007

@AGeek above: Reg. the 'marketplace of ideas', you might find this interesting.

12. **Bee**
July 16, 2007

sorry, off-topic, but you just have to see this paper

Search for Future Influence from L.H.C
Authors: Holger B. Nielsen, Masao Ninomiya

"When the Higgs particle shall be produced, we shall retest if there could be influence from the future so that, for instance, the potential production of a large number of Higgs particles in a certain time development would cause a pre-arrangement so that the large number of Higgs productions, should be avoided."

what an ingenious idea! Peter, one shouldn't worry, I think ST just has a backward causation: Every potential observability of stringy effects just causes a pre-arrangement such that the observation is avoided. Thus, no observation is the correct prediction. Best,

B.

13. **Peter Woit**
July 16, 2007

Bee,
Thanks for mentioning the Nielsen-Ninomiya paper. I noticed it, was thinking about writing something about it since it is so bizarre, but couldn't think of anything sensible to say…

14. **gunpowder&noodles**
July 16, 2007

Maybe the NN paper is some kind of elaborate joke? Write on a piece of paper, "THE LHC WILL HAVE ITS FUNDING CUT OFF" and see what happens to Higgs observations……

15. **Eric Mayes**
July 16, 2007

I'm pretty sure this paper has absolutely no connection to string theory. Isn't it a little unfair to give lay readers the impression that it does?

16. **Peter Woit**
July 16, 2007

Eric,

My, my, you string theorists are mighty defensive these days.

I made no connection of this to string theory at all. But now that you mention it, one could note that this paper at least proposes a falsifiable test of their idea at the LHC, which is more that string theory is able to do…

17. **Eric Mayes**
July 16, 2007

Peter,
Bee made the connection with string theory. However, there are several falsifiable tests of string theory at LHC, namely supersymmetry and large extra dimensions. You may claim that a discovery of either of these does not prove string theory, however either of these would be very strong evidence in it's favor.

18. **Peter Woit**
July 16, 2007

Eric,

You seem to have a non-standard definition of "falsifiable". Supersymmetry and large extra dimensions are not falsifiable predictions. Their status is the usual one of string theory "tests": if we see them, that's great for string theory, if we don't, no problem. Heads we win, tails doesn't count…

19. **Eric Mayes**
July 16, 2007

Peter,
Sure, it's falsifiable. All we need is a big enough collider. Now, it may be that LHC isn't big enough, but this a technological liimitation not a fundamental one. However, it is clearly possible to find evidence in favor of string theory at LHC, even if LHC will not be able to rule it out.

20. **Peter Woit**
July 16, 2007

Eric,

"there are several falsifiable tests of string theory at LHC"

"Sure, it's falsifiable. All we need is a big enough collider. Now, it may be that LHC isn't big enough"

Funny the way these string theorists keep changing their story when you point out to them that they're wrong…

21. **Eric Mayes**
July 16, 2007

Peter,
Do you deny that it's possible, in principle, to find evidence in support of string theory at LHC?

22. **Peter Woit**
July 16, 2007

Eric,

Sure, although I don't think it's likely. But it's really a tedious waste of time dealing with the comments that you keep posting here which make completely false claims (e.g. "there are several falsifiable tests of string theory at LHC"), which you never acknowledge are untrue, instead continually returning here to make the same false claims again and again.

23. **Eric Mayes**
July 16, 2007

Peter,
If you don't think it's likely that supersymmetry will be found at LHC, then you are in for a rude awakening. Supersymmetry, by the way, is the smoking gun of string theory.

24. **Chris Oakley**
July 16, 2007

Sure, Eric. Superstrings being – let me guess – the language in which God wrote the world – ?

Just for the benefit of lay readers – Supersymmetry is, and always has been in conflict with experiment. No pair of known particles are classifiable as supersymmetric partners of each other (fermions and bosons of adjacent spin would need to have the same mass). So supersymmetry is *wrong*. It *does not agree* with experiment. The talk is therefore about *broken* supersymmetry, which means a supersymmetric theory that has been doctored according to a well-defined procedure known, through abuse of the word "spontaneous", as spontaneous symmetry breaking. However, the ways in which the broken supersymmetric theories can be constructed are legion, and however little evidence appears for supersymmetry in LHC and similar experiments, it is always possible to claim that supersymmetry is still there, but is broken at a higher energy.

25. **super**
July 16, 2007

Chris,

It seems to me a little dishonest to say that SUSY is “doctored” because it must be broken in nature. The gauge symmety of the standard model is also broken, which doesn’t mean that it’s wrong.

26. **Eric Mayes**
July 16, 2007

Chris,
Yes, we know supersymmetry must be broken at low energies. However, there are very good reasons for the superpartners to have 1 TeV scale masses, just in the range that will be probed by LHC. Now, it’s possible that the superpartner masses will be much greater than this, but in this case we are giving up naturalness and introducing fine-tuning into the Higgs potential. One could make the case that the reason for some people to introduce the anthropic landscape is to justify unnaturalness and fine-tuning.

27. **Thomas Larsson**
July 16, 2007

“However, there are several falsifiable tests of string theory at LHC, namely supersymmetry and large extra dimensions. ”

Theorem
Supersymmetry will not be discovered at the LHC.

Proof: String theory predicts supersymmetry (Witten 1984-2002). String theory predictions are always wrong. Hence supersymmetry does not exist, and will in particular not be found at the LHC. QED.

Corollary
Lubos Motl will lose his experimental-susy-by-2006 bet.

28. **Eric Mayes**
July 16, 2007

Thomas,
I thought string theory predictions were ‘not even wrong’, so doesn’t this invalidate the proof of your theorem?

29. **ori**
July 16, 2007

Regardless of whether string theory is right or wrong, it is consistent mathematically, and does decribe on the purely formal level unified quantum gravity. I think that any theoretical physicist interested in these ideas must know string theory, even if he does not believe it. It has proved useful in calculating highly non trivial objects in gauge theories, with lots of possible uses to real QCD (see Alday-Maldacena for instance) and needless to say, many results in mathematics.

30. **lyme**
July 16, 2007

Nielsen, who has made superb contributions to HEP in the past, has been saying that kind of crazy things for a long time. Somehow, scalar particles seem to trigger a kind of mystic madness in him.

Or maybe he’s just joking, which would be equally crazy. I’ve seen him speak at the ICHEP conference in 1996, saying the same kind of nonsense. Cracking the same joke time and again for eleven years would certainly not be a sign of mental health…

31. **woit**
July 16, 2007

ori,

The line “string theory is mathematically consistent” is stated as a fact in its favor quite often, but maybe you can tell me precisely what theory it is that is mathematically consistent. Is it

1. the string perturbation expansion?

according to d’Hoker/Phong, in flat space this is well-defined through two-loops, quite possibly it is well-defined at any order, and quite possibly you can extend this to other backgrounds. But all evidence is that it’s a divergent series. You can’t sum it, and you can’t cut it off at fixed order without violating unitarity.

2. non-perturbative string theory?

last I heard, no one knew what that was. In some special cases, via making the AdS/CFT conjecture a definition, I suppose you could define it in terms of a QFT, but then it’s not so clear why you shouldn’t just be studying QFT. In this context, string theory is just a conjectural approximate calculational method for certain QFTs, something which is quite interesting, but not necessarily fundamental, and not necessarily of interest to all particle theorists.

32. **Who**
July 16, 2007

this just out. Can anyone enlighten me as to its possible significance?
http://arxiv.org/abs/0707.2283
Conformal Gravity Challenges String Theory
Philip D. Mannheim
8 pages. Proceedings write-up of talk presented at PASCOS-07, Imperial College London, July 2007
(Submitted on 16 Jul 2007)

“The cosmological constant problem and the compatibility of gravity with quantum mechanics are the two most pressing problems in all of gravitational theory. While string theory nicely addresses the latter, it has so far failed to provide any compelling solution to the former. On the other hand, while conformal gravity nicely addresses the cosmological constant problem (by naturally quenching the amount by which the cosmological constant gravitates rather than by quenching the cosmological constant itself), the fourth order derivative conformal theory has long been thought to possess a ghost when quantized. However, it has recently been shown by Bender and Mannheim that not only do theories based on fourth order derivative equations of motion not have ghosts, they actually never had any to begin with, with the apparent presence of ghosts being due entirely to treating operators which were not Hermitian on the real axis as though they were. When this is taken care of via an underlying PT symmetry that such theories are found to possess, there are then no ghosts at all and the S-matrix is fully unitary. **Conformal gravity is thus advanced as a fully consistent four-dimensional alternative to ten-dimensional string theory.**"

33. **Peter Woit**
July 17, 2007

who,

Please, this has nothing to do with the posting, and this is not a general discussion forum for new ideas about quantum gravity. The idea of "conformal gravity" has been around for a very long time, with lots of people claiming to have ideas about how to deal with the problems caused by its fourth order action. This is one more, I have no idea whether it works. You should use another forum to discuss this issue.

34. **Bee**
July 17, 2007

Hi There,

I've put some remarks on the bizarre paper here. In case it wasn't clear, my above comment about string theory was meant as a joke.

@Eric,

you write *Do you deny that it's possible, in principle, to find evidence in support of string theory at LHC?*. It seems to me you are kind of missing the point. The question is not whether there is 'in principle' a 'possibility' to find something or the other, but whether there is a prediction it *has* to be found, or otherwise the theory the prediction was made with is falsified. The problem is if the LHC doesn't find anything like SUSY or extra dimensions, you can still argue ST has not been outruled.

– B.

35. **ori**
July 17, 2007

Peter,

it is string theory as a whole on all of its thousands of papers with independent calculations which have never contradicted each other. Surely, the whole object is not yet well defined mathematically and non perturbatively, but this does not stop people who are physics-minded to do many non trivial calculations and reach fascinating conciusions which have tought us many lessons in mathematics and physics (and were confirmed in many independent ways).

36. **Peter Woit**
July 17, 2007

Ori,

"string theory is consistent mathematically"

"the whole object is not yet well defined mathematically and non
perturbatively"

It's pretty misleading to go around telling people that you have something mathematically consistent when you don't have a definition of what it is…

37. **Eric Mayes**
July 17, 2007

Bee,
Science is about research and discovery. Sure, it's true that we can't guarantee that we'll find anything, but this is the case with any theory. This is what we like to call 'research'.

38. **anonymous**
July 17, 2007

Eric,

It is most definitely *not* the case with any theory. Einsteins theory of general relativity made specific concrete falsifiable predictions. If those predictions did not pan out then the theory would have been proved wrong.

String theory is not like that. String theorists have not offered any falsifiable prediction. Unless and until string theory can offer up a real prediction you can not lump it in with 'any theory', but of course you already know all of this.

Eric, why do you insist on tip toeing around the elephant in the room? It has been pointed out time and time again and you are obviously intelligent enough to see it, so why do you ignore it and use word games to prance around it like it isn't right in front of your face?

39. **Santo D'Agostino**
July 17, 2007

Eric,

The terms "theory" and "prediction" are sometimes used in non-traditional ways, and that has made some discussions of string "theory" unproductive. I note that recently there has been some movement towards using these terms in their traditional sense. For example, David Gross has said that we don't know what string theory is, and Barton Zweibach has said (in his textbook) that string "theory" makes no "sharp predictions". Traditionally, there is only one kind of scientific prediction, so the phrase "sharp prediction" is not a return to standard usage, but at least it acknowledges that there is a problem.

Is there a string "theory" calculation for the specific mass of a particle that has not yet been observed? Or some other specific quantity that has never been measured? If so, then we have a prediction. If not, then let's just admit this. And if there is no prediction, then it's difficult to see how anything measured in any experiment could provide support for string "theory".

I have no problem with any individual person pursuing research in string "theory". It has a number of features that seem to promise great riches. However, "we don't know what it is yet" precludes it being called a scientific theory. A possible scientific theory in formation, maybe, but not a theory.

All the best,
Santo

40. **anon2**
July 17, 2007

anonymous,

Suppose Einstein had instead invented a scalar-tensor theory. This theory can be made to look arbitrarily close to GR by making the scalar heavier and heavier. It will predict some fifth force which, if seen, would confirm the theory. However, the theory can never be ruled out, you just get stronger and stronger upper bounds on the scalar mass. Would you consider this theory "not even wrong" and accuse its advocates of promoting religious nonesense in the guise of physics?

41. **anonymous**
July 17, 2007

"Would you consider this theory "not even wrong" and accuse its advocates of promoting religious nonesense in the guise of physics?"

Yes, I would say they were "not even wrong."

OTOH, I wouldn't say they were promoting religious nonsense. String theory might well be a useful mathematical tool, but it is not a scientific theory. It offers the observer no predictions, no scaffolding on which to better understand the real physical world.

String theory is just speculation(s). It is a proposal for some 10^500 possible scenarios that -might- be happening at scales and magnitudes completely beyond our ability to penetrate. It does not offer one iota of explanation for the large mysteries of physics that have been discovered during string theories incubation.

When the special theory and quantum mechanics were being developed theorists had some shocking mysteries they were struggling to understand. The constancy of the speed of light… The mysterious nature of the photon… The theories developed during this time helped explain the what and why of these experimental phenomena.

The same can not be said of string theory. With string theory, if some new and shocking experimental finding or observation comes along the string theorists run along not long after and shout, "We can fit that in string theory too!"

Glashow's comment hurts the sensibilities of string theorists so much because it cuts so close to the truth.

42. **Peter Woit**
July 17, 2007

anon2,

When I accuse landscape proponents of engaging in pseudo-science, it is because they are promoting something very different than what you describe, something that makes no predictions of any kind (or to the minimal extent that it does, some are already falsified), not predictions that depend on a parameter.

Sure, it's conventional scientific activity to speculate about what happens when you extend tested theories by adding one or more parameters, and trying to put bounds on these. If there were a unique string theory, with just an undetermined scale, extracting predictions from it and putting bounds on the scale would be a standard kind of scientific activity. But that's not what string theory is like. Instead you have exponentially large numbers of possibilities, any of which still contains an undetermined scale (or scales). This is not conventional science, and resembles in no way a one-parameter scalar-tensor theory.

43. **Eric Mayes**
July 17, 2007

Does quantum field theory by itself offer any falsifable predictions? The answer is no, it does not. To get any predictions, you must input into the theory information such as gauge groups, particle masses, gauge couplings, all of which are not fixed by the theory itself. Does this mean that QFT is not science? Absolutely not. The same is true of string theory.

On the other hand, there are theoretical and mathematical criteria that may be used to falsify various candidate theories of quantum gravity. To date, string theory is the only such theory which passes these test, which is the reason it is studied.

44. **King Ray**
July 17, 2007

"The value of a principle is the number of things it will explain."—Ralph Waldo Emerson

45. **woit**
July 17, 2007

King Ray,

String theory promises to explain everything, but so far explains nothing. So, it achieves the highest possible quotient of promised value/actual value (infinity/zero). Perhaps this is why string theorists like to describe it as the "most promising" principle for unifying physics.

Then there's the landscape, which explains everything with the explanation that it can't be explained…

46. **Santo D'Agostino**
July 17, 2007

Eric,

You said:

"Does quantum field theory by itself offer any falsifable predictions? The answer is no, it does not. To get any predictions, you must input into the theory information such as gauge groups, particle masses, gauge couplings, all of which are not fixed by the theory itself. Does this mean that QFT is not science? Absolutely not. The same is true of string theory."

I agree with you, except for the last sentence. Would you please describe a calculation from string theory that goes through a process analogous to the one you describe for QFT and results in a (specific numerical) prediction?

If, at the very least, it is possible using string theory to calculate quantities that have already been measured, and whose values are well established, then string theory might qualify as a scientific theory (there are other criteria as well). If not even that is possible, then one might say it is a theory in development, and so work on it would certainly qualify as scientific activity, but how could you call it a theory?

All the best,
Santo

47. **anon.**
July 17, 2007

Santo, you are right. In quantum field theory, the few inputs to the standard model can easily be found from observed data, based on experiments. But for string theory, there are many vital inputs that can't be found from experiments, because they describe features of the 6 compactified dimensions which (are supposed to) exist at the unobservably tiny Planck scale. Hence string theory is a failure.

48. **King Ray**
July 17, 2007

Peter, you have hit the nail on the head once again.

As Feynman said, if string theory is so great then they should be able to calculate the mass of the electron. Forget about predicting superpartners, just show us a calculation for the mass of the electron!

I think the string theorists are dodging honest work; they are so divorced from reality that they don't even know when they are lost. They seem to be divergent rather than convergent thinkers. To get something done you have to limit the possibilities you're going to explore.

I would start by eliminating the extra dimensions, and stop spending so much time in 2 and 3 dimensions, which in a lot of cases seems to be just avoiding the difficulties in 4 dimensions. Also, if you can't handle 4 dimensions, how are you going to handle 11?

If there is no evidence for something, such as extra dimensions, then why should you believe in it with such vigor?

49. **ori**
July 17, 2007

Peter,
such a situation occured many times in history. I am sure that if you lived in the era of Dirac you would go around and say that whatever Dirac does does not make any sense since this strange delta function object is not well defined, and you can not say that you do something well defined when you don't have axiomatic understanding of it…

This is why physics is physics and math is math, and it is good that it is this way. The sole fact that people have been able to compute so many non trivial things (mutually consistent) without a rigorous definition of the theory clearly implies that there is such a definition, and it will be found in the future.

Your objection have been raised many times in the history, and was never relevant. Whenever something in physics works, even if it seems ad-hoc, it must make sense in some more well defined frame work. The examples are too many to list, but I am sure you understand this point very well.

I also wish to emphasize that all string theorist are very interested in finding a more natural and more axiomatic framework to unite whatever they were doing in the last 25 years – this is not something which is being ignored. The evidences for the existance of such a formulation is overwhelming, there is no doubt that the theory is mathematically consistent (in similar way that Dirac's delta functions turned out to be not an ad hoc object with no clear rules for the game) as I said.

50. **Peter Orland**
July 17, 2007

Ori,

Criticizing string theory is like criticizing the Dirac delta function? Are you kidding?

51. **Eric Mayes**
July 17, 2007

King Ray:
Regarding the calculation of the mass of the electron, please see hep-th/0703280.

Santo:
I agree, string theory has not reached the level of maturation of QFT with the Standard Model. Keep in mind that this is only because the Standard Model is operative at low energy where there is a lot of experimental data.

What is needed is a string theory model which completely describes the low-energy physics of the Standard Model and can make detailed predictions for physics beyond the Standard Model. Even if some parameters need to be fitted by hand to get agreement with the Standard Model, once this is done all of the other (new) physics should be fixed as well. The problem would be if there are many string theory models which reproduce the standard model exactly, yet have completely different predictions for new physics. I don't expect this to happen.

Again, I would like to make the point that it is possible for string theory to be falsified by theoretical criteria alone, although this hasn't happened. Peter's main argument that it isn't falsifiable is wrong for this reason alone. In addition, it is always possible that new, unexpected phenomena will be discovered that are not compatible with string theory.

52. **King Ray**
July 17, 2007

Eric, do you really think the true theory is that complicated? You put in a lot of fitting parameters and are still off by a factor of 6.5 on the electron mass; wouldn't that seem to say that your model cannot fit the SM?

53. **anonymous**

July 17, 2007

Eric,

"In addition, it is always possible that new, unexpected phenomena will be discovered that are not compatible with string theory."

Please describe these hypothetical phenomena.

54. **alex**
July 17, 2007

"Please describe these hypothetical phenomena."

I believe that violation of unitarity is incompatible with ST.

55. **Lee Smolin**
July 17, 2007

Eric,

"Does quantum field theory by itself offer any falsifiable predictions?" Yes, certainly it does: the existence of antiparticles, with the same mass and opposite charges as known particles, is a direct consequence of the axioms of special relativistic quantum field theory. So are the relation between spin and statistics and the CPT theorem. The existence of antiparticles and CPT were predicted before they were tested and they and the spin-statistics connection are confirmed by many experiment and to a large number of decimal places.

One can add to this the classic tests of QED, the magnetic moments of the electron and muon and the Lamb shift, which hold robustly to many decimal places, independently of the strong and weak interactions, higher generations etc. The fact is one can make extremely successful predictions without knowing very much at all about what the gauge groups and mass spectra are, using only the well confirmed fact that there is an unbroken U(1) gauge symmetry coupled to light fermions.

This gives us confidence that the axioms of QFT are reliable over a wide range of scales. There is not a single comparable success in string theory or any post standard model theory.

Thanks,

Lee

56. **Tim**
July 17, 2007

Hi Lee,
Sure, antiparticles are a necessary ingredient of any QFT. However, can you predict the specific particles that will be present in your theory from first principles? Absolutely not. You have to assume a gauge group, from which it will follow that the matter content will be representations of this gauge group, with the only constraint that all anomalies must cancel. You cannot determine from first principles what the matter content, masses, or charges of your QFT will be. The Standard Model is just that, a model which happens to be a QFT, and in this regard it is not unique.

57. **Eugene Stefanovich**
July 17, 2007

Alex said:

I believe that violation of unitarity is incompatible with ST.

Violation of unitarity is incompatible with common sense. Total probability for all alternatives simply cannot be greater (or less) than 1. Quantum mechanics + preservation of probabilities = unitarity (Wigner theorem).

58. **Chris Oakley**
July 18, 2007

> Sure, antiparticles are a necessary ingredient of any QFT.

They are only "necessary" if you require a charge conjugation symmetry such as CPT.

59. **Santo D'Agostino**
July 18, 2007

Eric,

You said:

"What is needed is a string theory model which completely describes the low-energy physics of the Standard Model and can make detailed predictions for physics beyond the Standard Model. Even if some parameters need to be fitted by hand to get agreement with the Standard Model, once this is done all of the other (new) physics should be fixed as well. The problem would be if there are many string theory models which reproduce the standard model exactly, yet have completely different predictions for new physics. I don't expect this to happen."

About your last sentence: Until there is an actual string theory that makes actual predictions, it is hard to know what can be expected.

You also said:

"Again, I would like to make the point that it is possible for string theory to be falsified by theoretical criteria alone, although this hasn't happened. Peter's main argument that it isn't falsifiable is wrong for this reason alone. In addition, it is always possible that new, unexpected phenomena will be discovered that are not compatible with string theory."

Yes, agreed, any theory can be falsified if it is logically inconsistent, and this does not require any experimental input. However, the point about falsifiability that has repeatedly been made by a number of people is that because no predictions have yet been made by string theory, it is impossible for any experimental result to falsify it.

This is what I take the "not even wrong" label to mean.

All the best,
Santo

60. **Eric Mayes**
July 18, 2007

Santo,

I'd like to emphasize that it may very well be possible to make definitive predictions in the near future and there very well may be experimental results in the future that may be able to confirm or falsify it. In my opinion, the claim that string theory is not falsifiable is itself 'not even wrong' because we really don't know what new developments or discoveries my be found in the future. Saying we shouldn't study string theory because we do know enough about it yet to make predicitions is rather dumb. How are we ever going to understand it well enough to make predictions if we don't study it? Why not give up on experimental high-energy physics as well since we'll never be able reach Planck-scale energies?

61. **Vince**
July 18, 2007

I think one reason why antiparticles are necessary in QFT comes from the desire to preserve causality. Look at Peskin and Schroeder.

62. **anonymous**
July 18, 2007

Eric,

"In my opinion, the claim that string theory is not falsifiable is itself 'not even wrong' because we really don't know what new developments or discoveries my be found in the future."

You seem to have a problems with the present tense. Right now, at this very moment, string theory is 'not even wrong' because it makes no predictions of any value. Saying that it 'may very well be possible in the near future' to make predictions doesn't obviate the fact that — right now — it does not.

The FSM 'may very well be possible in the near future' to falsify. However, the FSM, as it stands now is 'not even wrong.'

63. **Eric Mayes**
July 18, 2007

Anonymous,
This is the nature of research in progress. I'm really getting tired of this abuse of Pauli's phrase 'not even wrong'. He certainly didn't mean it in the strict, limited way that you and Peter use it. Essentially, he meant that a theory was 'half-baked', i.e. not consistent. The inability to test a theory due to current practical limitations is not a valid reason for dismissing a theory.

64. **Eric Mayes**
July 18, 2007

As an example, consider the theory that intelligent life exist elsewhere in the universe. This idea is almost certainly right, however I can't think any way to disprove the idea. Is this idea 'not even wrong'?

65. **anon2**
July 18, 2007

Eric,

Lots of perfectly reasonable theories will be "not even wrong" in the sense advocated in this comment section. Your theory about intelligent life and the scalar-tensor theory I mentioned earlier are examples. As Peter points out, string theory has more tunable parameters than scalar-tensor gravity. However, string theory also has stronger theoretical motivation: the desire to find a consistent quantum theory of gravity.

Like much of what is discussed here it seems to me to be really a question of personal prejudice. Does the potential future promise of string theory justify the effort that's currently being put into it. Many people think "yes". Some people think "no". This is fine because everybody is allowed to choose her own research programme. I'm don't see what all the fuss is about.

66. **Eric Mayes**
July 18, 2007

Anon2,
I agree with you completely.

67. **anon.**
July 18, 2007

'… everybody is allowed to choose her own research programme. I'm don't see what all the fuss is about.' – anon2

Silly me! I thought the whole problem was that string theory is hyped to be the 'only consistent theory of quantum gravity'.

I was evidently deluded, since I thought that such marketing of currently non-falsifiable string theory made life hard for those who are pursuing other research programmes. Of course, I see the light now! Everyone is free in spirit to *choose* their own research programme, they just aren't generally free in practice to actually pursue it, unless by chance they have chosen string theory…

68. **Santo D'Agostino**
July 18, 2007

Eric,

I have no argument with your last comment addressed to me, particularly the parts of it that are directed at others. (For example, I have never suggested that individuals should study or not study any particular subject.)

One ought to be painstakingly honest about the state of one's field of study, for the benefit of scientists outside the field, incoming graduate students, and also lay people. (And perhaps for our own benefit most of all.) I have met many lay people and students in the past decade with distorted views about string theory. Advocates of string theory could largely disarm many of its critics simply by being honest and direct about the state of the subject.

Scientific theories make predictions about the results of future experiments, then the experiments are carried out. If the experimental results match the predictions, within acceptable limits, then fine. If not, then the theory is discarded or modified. That is how the game is played.

You have not responded to my requests for predictions of string theory, although you imply that there are some, just at energies that are too high to access now. Are there any? If there aren't any, then fine, but let's be honest about that. Let us say, OK, it's not a scientific theory yet, it's in development, Eric Mayes finds it an interesting subject to work on, no problem. Best wishes to Eric Mayes, we hope he comes up with some good ideas that turn this into a proper scientific theory. Repeat, I have no quarrel with your research choices, Eric, and I sincerely wish you well.

But in the meantime, let's not delude ourselves into thinking that the next experiment can produce results that will either support or falsify string "theory", when there is no theory yet.

69. **Eric Mayes**
July 18, 2007

Ok, here are my predictions. Supersymmetry and the Higgs will be discovered at LHC with the Higgs mass between 116-121 GeV.

70. **Santo D'Agostino**
July 18, 2007

Eric,

Is your prediction for the Higgs mass based on a string-theory calculation? And your statement that supersymmetry will be found at the LHC does not qualify as a prediction unless it is quantitative.

All the best,
Santo

71. **alex**
July 18, 2007

ST predicts the existence of superpartners but it does not make a unique prediction about the SUSY breaking scale and mass spectrum.
It's clear and simple – the existence of superpartners is a generic prediction of ST.
Their mass spectrum depends on how SUSY is broken but that's a second question for which there is no unique ST prediction yet.

So, what! In the SM you need 19 parameters as input. Once the scale of m_3/2 is fixed, lots of SUSY models will be ruled out just based on this one input parameter.

In my biased opinion, SUSY is the best candidate to explain the dark matter so based only on this assumption the LHC has a pretty good chance to discover superpartners. There are of coures many other well known reasons (stabilizing the hierarchy, radiative EWSB, heavy top, precision gauge coulpling unification, etc) to expect that TeV scale SUSY is around the corner.

72. **King Ray**
July 18, 2007

Old news, but what about this?

July 18, 2007

'Source', not 'Sourse'.

76. **alex**
July 18, 2007

Thanx!

77. **Santo D'Agostino**
July 18, 2007

Alex,

You said,

"ST predicts the existence of superpartners but it does not make a unique prediction about the SUSY breaking scale and mass spectrum."

The existence of superpartners is an assumption of ST, not a prediction. And it would be more accurate to say that ST makes no prediction about the SUSY breaking scale and mass spectrum.

The word "prediction" has a precise meaning, and ought to be used with care.

All the best,
Santo

78. **Chris Oakley**
July 19, 2007

Vince,

Re: antiparticles, I don't agree. Causality, or at least spacelike commutativity is connected with the spin statistics theorem, but has nothing to do with the existence of antiparticles. Yes, naive quantization of the Dirac equation leads to particle/antiparticle pairs of the same mass, but one could with equal validity just 2nd quantize Majorana spinors which have no such property.

79. **Peter Woit**
July 19, 2007

I just deleted a sequence of comments by Santo and Eric, which, on Eric's part, mainly consisted of the sort of insults about incompetence and stupidity that some string theorists seem to feel is the best way to defend their point of view. Please stop this.

This discussion has pretty much degenerated, and I'll cut off any more comments that aren't well-informed and to the point. Before posting a comment here that carries on a pointless argument, ask yourself if you're writing something that a sensible person would find informative and worth spending their time reading. If the answer is negative, restrain yourself.

Various News

July 17, 2007
Categories: Uncategorized

There's a potentially important new paper on the arXiv from Terry Tomboulis, entitled Confinement for all values of the coupling in four-dimensional SU(2) gauge theory. Tomboulis claims to prove that SU(2) lattice gauge theory has confining behavior (area law fall off of Wilson loops at large distances) for all values of the coupling at the scale of the cutoff, no matter how small. This conjectured behavior is something that quite a few people tried to prove during the late seventies and eighties, without success. Tomboulis is one of the few people who has kept seriously working on the problem, and it looks like he may have finally gotten there. The method he is using goes back to work of 't Hooft in the late 1970s, and involves considering the ratio of the partition function with an external flux in the center of SU(2) and the partition function with no such flux. For a recent review article about this whole line of thinking by Jeff Greensite, see here. For shorter, less technical articles by Tomboulis about earlier results in the program he has been pursuing, see here, here, and here.

As far as I can tell, even if this holds up, it won't get Tomboulis the million-dollar Clay prize being offered for the solution of the Yang-Mills Millenium Prize Problem. There the problem is stated as rigorously constructing Yang-Mills for any gauge group, not just SU(2), showing that it has the expected properties, and a mass gap. I don't know whether Tomboulis's methods can prove that there is a mass gap. In any case, I also don't know why the Clay prize asks for a mass gap rather than confinement, which seems more physically relevant.

The latest HEPAP meeting was this past weekend in Washington and presentations are available here. The news from the DOE is that it looks like Congress will approve a FY 2008 HEP budget at or above the White House request of $782.2 million, an increase of at least 4%. This will include $60 million for ILC R and D (up from $42 million in FY2007). This will include funds for site surveys in the US, which in principle will include sites other than Fermilab, although I find it hard to believe a US site other than Fermilab would end up being chosen.

There's a report from the University Research subpanel that puts near the top of its recommendations "A higher priority in the overall HEP program should be given to funding directed at university-based theoretical particle physics for the purpose of increasing the number of HEP-grant supported graduate students." Given the continuing high ratio between students getting Ph.Ds in particle theory and jobs for them when they get out, I would have thought the priority would go to finding ways to fund jobs for students once they get out, rather than increasing the number of Ph.Ds.

There's a recommendation from the P5 panel that the Tevatron should definitely run through FY2009, and in September they'll start looking at the case for running even longer than that. There's also a discussion of "European reaction" to comments from the DOE's Ray Ohrbach that the US needs a plan in case the ILC doesn't start happening soon. Typical reaction from the Europeans was said to be that the US is not a reliable partner, and makes unilateral decisions without consultation. CERN has recently been promised a budget supplement over the next few years that could pay for an LHC upgrade (they were in hock over the LHC), and by 2016 that would be done and paid for. At that time CERN will have money to spend on a new big project and a higher energy linear collider using CLIC technology would be a possibility (the semi-joke made was that the work advancing this possibility is now going on mainly in the US, at SLAC).

A progress report from the Fermilab Steering Group, which is supposed to report to the Director on Aug. 1, included extensive discussion of "Project X", a proposal to dramatically increase the power of proton beams by building an 8 GeV proton linac. Part of the idea is that building this smaller linac would help get experience needed for doing the ILC.

Also at Fermilab, I noticed that they have a web-site devoted to the history of the place, and here is a recent talk by Adrienne Kolb on the subject.

According to CNN, one of the "Geniuses who will change your life" is Harvard's (soon to be Princeton's) Nima Arkani-Hamed, who is described as follows:

> Nima Arkani-Hamed thinks big. He has a theory that our universe is one of an infinite number of universes — meaning the largest thing we can wrap our minds around is actually pretty tiny
>
> He didn't pull the "multiverse" out of thin air, though. After becoming a Harvard professor at age 30, Arkani-Hamed first made a name for himself by suggesting that our universe is five-dimensional. Then he moved on to the multiverse, theorizing that our own universe has a hidden feature called "split supersymmetry," which means that half of all particles have partner particles.
>
> The theory will be tested soon in Switzerland's brand-new Large Hadron Collider (LHC), and if the LHC finds Arkani-Hamed's partner particles, it could prove that the multiverse is real — and that our place in it is that much smaller.

The claim that if you see split supersymmetry, this proves that the multiverse is real seems pretty much laughable to me.

Clifford Johnson is in Aspen, at what its director describes as a "summer camp for physicists". He has a posting about his experiences there, describing how the big topic of conversation is the recent Strings 2007 conference. He asks for people to write in telling about which of the Strings 2007 talks they found most interesting (although so far, a half day later, no one seems to have taken him up on this). Like Jacques Distler, after Witten's talk, Clifford seems to be most impressed by Seiberg's talk on BMSSM (Beyond the Minimal Supersymmetric Standard Model) physics, based on his recent paper with Dine and Thomas. The idea is that, even with its 105 extra parameters, the MSSM still requires a lot of fine-tuning to get around the LEP bound on the Higgs mass, so you should analyze adding even more terms to the Standard Model besides the minimal supersymmetric ones. Distler was very excited by the Seiberg talk, arguing that these results should have been found years ago but weren't. Various people wrote into his blog to point out to him that this wasn't right, that mostly these things had been done a while ago, including by several authors back in 2003 (see hep-ph/0301121 and hep-ph/0310137). Seiberg et. al. issued a revised version of their paper where they added quite a few references, including one to work back in 1999 by Alessandro Strumia (hep-ph/9906266) where he already discussed the impact of the two operators identified by Dine et. al on the Higgs mass.

Update: The debate over string theory really has reached the general public, at least in New York: a few months ago there was a cartoon in the New Yorker, this week, it has made the New York Magazine web-site celebrity coverage.

Comments

1. **Peter Orland**
   July 17, 2007

   Peter,

   As you say, the string tension (which is experimentally known through Regge trajectories) is more significant than the mass gap, or lightest-glueball mass (light glueballs have large widths, can mix with multi-quark states and so the experimental situation is not as clear).

Maybe the reason the Clay foundation set things up the way they did, is that most people suspected the gap would be easier to prove than confinement. If Terry Tomboulis is correct, however, extending the method to proving a gap is probably not out of the question. He uses a real-space renormalization group argument to compare quantities at strong bare coupling to those at weak bare coupling. The quantity he studies isn't the string tension, but another quantity, essentially the vortex condensate, which he uses to bound the string tension.

I am spending time reading the paper carefully…

July 17, 2007

I guess the reason why more hep phd fellowships are necessary
is because we may need, in the near future, even more of these data analysis slaves working for ongoing/upcoming experiments.
Or maybe we are just short of new permanent positions and, since it's so difficult to defend our area's research merit these days, it's much easier to appeal to 'education purposes' (what a dragon hunter does? on the very least, he teaches others to hunt dragons!)

Whatever it happens to most of these young physicists after phd is not of much interest; they may spend part of their most creative years with an illusion of a life in physics, but the fact is that, from the very beginning, there would never be enough places for all, just a bright tiny minority. It's a sad truth in these days of high specialization and changing technology, but these physicists are disposable. They won't be hired, they will be replaced by new, cheaper, phd students.

"Nima Arkani-Hamed thinks big. He has a theory that our universe is one of an infinite number of universes"

In which part of the landscale did that happen?

"Arkani-Hamed first made a name for himself by suggesting that our universe is five-dimensional."

They forgot to add he also discovered 3+1 and time travel.

"Then he moved on to the multiverse, theorizing that our own universe has a hidden feature called "split supersymmetry," which means that half of all particles have partner particles."

He's been busy, he also came out with SUSY, SUGRA, the Heterotic string and last episode of 'numbers'.

"The theory will be tested soon in Switzerland's brand-new Large Hadron Collider (LHC), and if the LHC finds Arkani-Hamed's partner particles",

Are we looking for the Arkino too?

"it could prove that the multiverse is real — and that our place in it is that much smaller."

This is too complicated to even attempt analysis…

Clearly the CNN people is an example that the reporter's brain is 'much smaller' than we would like it to be…fortunately there is a universe out there where Physics is financed by Ted Turner… 😉

BRITNEY: Forget Peter Woit. Forget Lee Smolin. They don't know sh*t. I've done the calculations. I have a unique compactification that gets all the correct gauge groups and fermion masses. Yeah, yeah … I know. Don't worry – I'll post my results on Arxiv later this month!

5. **amused**
July 18, 2007

"In any case, I also don't know why the Clay prize asks for a mass gap rather than confinement, which seems more physically relevant."

If I remember rightly, existence of mass gap implies confinement but the converse is not true. So mass gap existence is the stronger statement. It also seems like a perfectly physical statement – it means there are no massless physical states in QCD (in contrast to QED where there are massless photons). A simple intuitive way to see why mass gap implies confinement is this: If gluons were not confined then we would have free massless gluons in the physical QCD spectrum, in contradicton with the existence of a mass gap (i.e. nonzero lower bound on the physical energy spectrum). Same thing for massless quarks.
(Well that's how I understand it at any rate; if I've got something wrong then hopefully someone will correct me.)

6. **DB**

> There's also a discussion of "European reaction" to comments from the DOE's Ray Ohrbach that the US needs a plan in case the ILC doesn't start happening soon.

It seems Europe was also reacting to Orbach's statement: (quoted in Wormser's report)

> US wants « order of magnitude leadership »

7. **Alessandro Strumia**
July 18, 2007

hello,
thanks for signaling my paper hep-ph/9906266. It has no collaborators because nobody was interested in its main topic: testing a model of extra dimensions at the weak scale with precision data. While completing it, I started to believe that experimental bounds make extra dimensions an unplausible solution to the hierarchy problem, and furthermore another paper appeared with a similar analysis.

At this point, instead of being wise and trashing my little paper, I spent a week-end trying to improve it: adding the aside remark about how non-renormalizable operators raise the MSSM Higgs mass, and writing the introduction in a ironic mood, e.g. "string theory is currently an example of a theory with no parameters that makes no calculable predictions".

I hope that having anticipated something of Strings 2007 and something of anti-Strings 2007 can be considered as good irony.

8. **David**
July 18, 2007

If the gauge field is massless, one can calculate and see that the wilson loop satify the perimeter law. So masslessness implies lack of confinement. The converse then must be true. I agree that this is not the same thing as actually calculating the gap.

9. **J**
July 18, 2007

Ah, the CNN is speaking.

10. **Peter Orland**
July 18, 2007

David and Amused,

It isn’t quite that simple.

Gauge fields which are coupled to adjoint Higgs fields have no massless excitations, but do not confine.

Confinement implies a mass scale, but that isn’t quite the same
as a (mass) gap between the ground state and first excited state.
There is an example of confinement with massless particles. This is
the case for a version of compact QED in three dimensions (the reason is that this theory has two mass scales, which should not be the case for QCD in four dimensions.
One can tune the gap to be zero, for
fixed string tension, by choosing one of these scales).

On the other hand, any method yielding confinement ought to
powerful enough to settle the issue of the mass gap.

11. **David**
July 18, 2007

I agree it’s not so simple as that, Peter O.

But the counter example you give is that mass gap does not imply confinement. My point is that since absence of mass implies absence of confinement, confinement should imply mass gap.

This of course does not mean that mass gap implies confinement. So I do not think the Higgs case is a counter example.

To summarize, since masslessness implies the perimeter law, presence of a mass gap is a necessary but not sufficient condition for confinement.

The case of 3 D or 2 + 1 D compact QED is interesting. What are the two mass scales? The charge has a mass scale and there is also the cutoff. If we work on a lattice the cutoff is the lattice spacing. If we work on the continuum and obtain compact QED by spontaneously breaking and SU(2)
gauge theory with the helping hand from a Higgs field, the cutoff is the symmetry breaking scale. So I agree that 2 + 1 D has two mass scales.

What I do not agree with is that 2 + 1 D compact QED exhibits confinement with massless photons. First go to Polyakov’s 1977 Nuclear Physics B paper or his book “Gauge Fields and Strings” and you see that confinement is accompanied by mass generation for the photon.

That the photon cannot be massless if there is confinement can also be understood in simple terms from Wilson loop calculations. I will use latex notation and hope is not too confusing.

The Wilson loop is

\langle \exp{\oint_C A_\mu (x) ds^\mu} \rangle =

\exp{ \oint_C \oint_C D_{\mu \nu} (x – x’) ds^\mu ds’^\nu }

where D_{\mu \nu} (x – x’) is the gauge field propagator which is gauge variant of course. The Wilson loop is gauge invariant because the integrations over closed paths lead to zero for the gauge variant parts of the propagator.

Now to the point, if we use the massless propagator we do not get an area law for the Wilson loop in 2 + 1 D (the same thing happens in 3 + 1 D). Hence if the photon is massless there is no confinement.

So even though 2 + 1 D has two mass scales it is not true that one of them can be tuned to have confinement and a massless photon. It is possible that one of the mass scales can be tuned so that the photon becomes massless, but at such a point the theory does not confine.

12. **amused**
July 18, 2007

David, I don’t understand your reasoning at all. The gauge fields in QCD are necessarily massless – a mass term would break gauge invariance. However, the massless quanta of the gauge fields – the gluons – are not physical states of the QCD Hamiltonian (in contrast to photons in QED) since they don’t satisfy the nonabelian Gauss Law constraints (they aren’t color singlets). The question that then arises is: can one have color singlet states consisting of a number of essentially non-interacting free, deconfined gluons? Such a state would be massless (since the individual gluons are massless), implying that QCD does not have a mass gap. But there is no sign of such states in experimental low energy hadronic physics (which is where we would see them if they existed). Lattice studies indicate that color singlet purely gluonic states do exist in QCD – the so-called glueballs – but they are massive (quite heavy in fact) and have yet to be seen in experiments afaik.

The lightest state in hadronic physics is the pion, which definitely has nonzero mass, so if QCD is to describe hadronic physics like it is supposed to then mass gap is implied by experiment. This makes it very natural that proof of mass gap should be a criterion for the Clay prize.

13. **amused**
July 18, 2007

Peter O., my post crossed with yours, I'll go back and read what you wrote now.

14. **David**
July 18, 2007

To summarize if A implies B, then it is true that not B implies not A.

Masslessness implies no confinement, thus confinement implies mass gap.

I understand there are nontrivial issues with extracting certain information from a non-Abelian gauge theory and this is an understatement. And calculating the gap might be a herculean task. But as long as the lack of mass means no confinement, it seems that confinement implies a mass gap.

On the other hand like I said and Peter O.'s Higgs phase example shows perfectly, the presence of a mass gap certainly does not imply confinement!

15. **David**
July 18, 2007

Peter O.

I would love to hear your take on the paper. It's strengths and its weaknesses or open questions.

16. **amused**
July 18, 2007

If I understand correctly, Peter O.' counter-example to "mass gap implies confinement" involves spontaneous breaking of gauge symmetry, resulting in massive gauge field. In that case the intuitive argument I gave in my first post breaks down. Is there a counter-example where gauge symmetry is not broken (as in QCD)?

Btw, the "if I remember rightly, mass gap implies confinement" in my earlier comment was referring something I once heard Pierre van Baal say (in reference to QCD). It is possible I might be remembering wrongly though…

David, I will need to go and read up on these things again to check your claim that massless gauge field implies perimeter law (it's been a while..). Did Wilson really require massive gauge field when he derived the area law in strong coupling lattice QCD? I don't remember that!

17. **David**
July 18, 2007

amused,

As I said I have never stated that mass gap implies confinement as that is explicitly false.

What is not false is that confinement implies mass gap because masslessness
implies lack of confinement.

Once again A implies B is equivalent to not B implies not A, but does not say anything about not A implying not B, and in fact this last statement could very well be false.

No Wilson did not require a massive gauge field directly. But in his paper he did calculate that a massless gauge field implies no confinement. Therefore on can conclude that confinement implies mass gap.

Mass gap certainly does not imply confinement and a very good counter example is the "spontaneous breaking" of gauge symmetry mentioned by
Peter O. where there is a mass gap but no confinement.

18. **Peter Orland**
July 18, 2007

David,

I wrote a paper when a dumb grad student, publ. in
Nucl. Phys. 1982, where it is shown that in the
STANDARD continuum limit of 3D CQED, the mass
gap vanishes, with fixed string tension. This is
because there are two scales, namely the coupling constant
and the monopole fugacity. If one changes the monopole
fugacity, it is possible to keep the gap in the continuum
limit (though I did not mention this in the paper). Appropos of
nothing, the paper is mainly about generalized gauge theories of
p-form fields, their solitonic p-branes, duality and confinement
phases. Anyway, the masslessness of the (confining) continuum limit
was shortly therafter proved rigorously by Gopfert and Mack.

Now presumably there is only one scale in QCD, so this should not
happen. The question is what standard of rigor you demand. It is
not utterly inconceivable though that the gap could vanish
(with all other excitations massive), though I would be greatly
surprised if this happens.

Now essentially what Tomboulis does is show that one can
run the bare coupling all the way to the strong-coupling
region. If his paper is right, there is "no doubt" there is
a gap – I mean that I would be convinced, but that's
not yet a proof. What would be interesting is an estimate
of the gap (he does have an estimate of the string tension).

As far as the question of the paper being right is concerned, I don't have an opinion yet. I am spending all my spare time trying to figure it out. Right now I am a little
bogged down in how Tomboulis

understands and uses reflection positivity.

19. **David**
July 18, 2007

Peter O.,

I could buy what you say and I'll definitely check out your paper.

But I would like to know how do you scape the Wilson loop argument. This confuses me. If you calculate the Wilson loop with a massless propagator in 2 + 1 D and 3 + 1 D, one does not obtain an area law. I would take this to mean no confinement. So what gives?

Is it that we have confinement without an Area law? How does this come about?

Is it an order of limits issue because the point at which the gauge fields just goes massless is critical point and one needs to be very careful?

20. **amused**
July 18, 2007

David,

"As I said I have never stated that mass gap implies confinement.."

No, it was me who stated that.

"Once again A implies B is equivalent to not B implies not A, but does not say anything about not A implying not B, and in fact this last statement could very well be false."

I think we can agree on that.

"No Wilson did not require a massive gauge field directly. But in his paper he did calculate that a massless gauge field implies no confinement."

Now I'm really confused. I was under the impression that Wilson derived the area law using the "Wilson action" describing massless gauge fields, and without sneaking in a mass for the gauge field anywhere along the way. Is this correct or is it not correct (yes or no please).

"Mass gap certainly does not imply confinement and a very good counter example is the "spontaneous breaking" of gauge symmetry mentioned by Peter O. …"

I'm sure it is an excellent example, but unfortunately not so relevant for the situation I happen to be interested in which is where gauge symmetry is not broken (as in QCD).

21. **Peter Orland**
July 18, 2007

"But I would like to know how do you scape the Wilson loop argument. This confuses me. If you calculate the Wilson loop with a massless propagator in 2 + 1 D and 3 + 1 D, one does not obtain an area law. I would take this to mean no confinement. So what gives?"

OK, David, I think you are assuming that the Wilson-loop can be
reliably computed by gluon emission and absorbtion by a source. This is what perturbation theory tells us (there are of course corrections of more exchanges and higher loops), but it is very misleading for QCD, where gluon exchange is only meaningful at short distances. The contribution for large separations on the loop is not given by a finite number of gluon exchanges (in fact, most of the serious people in this field think of gluon exchange as a red herring).

In contrast, strong-coupling expansions don't give any gluons, just
glueballs. The problem with these expansions is that there is no
reason to assume they don't have a finite radius of convergence. They
are at best a caricature of the continuum limit, and they tell us little
about high-momentum physics.

22. **David**
July 18, 2007

amused, if you go to Wilson's paper he calculates his famous loop with massless gauge fields and shows that it does not satisfy the area law.

The bare fields are massless; you are correct in this. The question is whether the long distance renormalized gauge fields are massless. For the this last case there certainly is no confinement.

He did this to show that QED for weak coupling which has massless gauge fields does not confine.

He then goes on to argue strongly, not show, but good enough to convince me. that for strong coupling the Wilson loop satisfies the area law and does there is confinement. He did not calculate the mass gap nor explicitly state
that it ha gap, but given that masslessness implies no confinement it is certainly implicit.

Now, Peter O. tells me that one can show that 2 + 1 D CQED confines without a mass. Like I told him I could take his word on this, but it baffles me since one can calculate the Wilson loop for a massless gauge field
in 3 + 1 D and 2 + 1 D and it does not satisfy the area law. So it looks that the has a case where there is confinement without and area law.
How can this happen, I do not understand. I would love for Peter O. to clarify as I would learn something new. I can buy it but I remain sceptical until I understand it better.

Does this help amused?

23. **David**
July 18, 2007

Peter O., Thanks

Yes I agree that going to the strong coupling expansion is non trivial and in a a sense I was using perturbative thinking

24. **Peter Orland**
July 18, 2007

Amused,

Wilson's original paper did strong-coupling expansions for pure gauge theories. In these expansions there is a gap and confinement. It isn't that one implies the other, but that both are consequences of the the theory being weakly-correlated.

25. **David**
July 18, 2007

One question Peter O.

In your work on confining massless 2 + 1 CQED. Are the massless excitations gauge fields? I would think not, but I am not sure.

26. **Peter Orland**
July 18, 2007

David,

That's a good question. From what I remember, they are just photons – the correlation function of the field strength looks just like ordinary free QED.

27. **amused**
July 18, 2007

David, thanks for your efforts to explain. I will need to go take a look at Wilson's paper again to remember how this all hangs together. One immediate objection I have to your argument is that the renormalized gauge fields could acquire mass. Surely gauge invariance (Ward Identities) prevents this?
Anyway, it is well past my bedtime here on the other side of the world, so I'll have to take a break from the discussion for the time being.

28. **David**
July 18, 2007

Yes amused, Ward identities prevent this. I misspoke by saying that the aguge fields have mass. It is thought that the spectrum is fully gapped. So what is believed is that the gauge fields disappear from the spectrum, but you have things like Gluballs that have mass so the spectrum is gapped.

This is believed for many reasonable arguments and I buy them. But it has never been proven even semi rigorously I believe.

In Wilson paper all of this does not hang fully together. This beliefs and the reasonable arguments that point to them was built slowly through the mid 70's to the early 80's both from lattice gauge theory and from continium QFT.

29. **jhk**
July 18, 2007

It's pretty amusing how people like Distler get all excited over something when a celebrity like Seiberg says it, but not so much when a nobody said it years before. Same thing happened with the anthropic landscape. Modern physics is just a fashioin show.

30. **Peter Orland**
July 18, 2007

David,

I think if you read Wilson's paper carefully, it is quite sensible. He was very careful.

31. **amused**
July 18, 2007

Peter O. and anyone else,
I'm pretty sure I remember hearing from a very authoritative source (P. van B.) that mass gap implies confinement in QCD. If this is true it would explain why the Clay prize asks for proof of mass gap but doesn't mention confinement. Can anyone out there confirm this?

David,
what you wrote in your last comment seems to be converging to what I had written earlier. Is there anything we still disagree on?

32. **Kea**
July 19, 2007

Has anybody here actually read the Witten-Jaffe text?

33. **amused**
July 19, 2007

I just took a look at it now (the article is here). No mention there about mass gap implying confinement (or the converse)… A fundamental physical aspect of the mass gap that they emphasize is that it implies YM interactions are short-range (which they must be if QCD is to describe the strong nuclear force).

34. **Peter Orland**

July 19, 2007

amused,

I don't know what Pierre's argument was. There is no rigorous proof or estimate of the gap from the assumption of confinement (that I am aware of, and I have worked on this, on and off for a long time). There are lots of physical argument; I gave one above, assuming there is one scale. One expects that $K=M^{2}/\sigma$ is universal for this reason, where σ is the string tension and M is the gap. So can K be zero? I say certainly not, but my statement is not a calculation or an estimate of K.

By the way, Terry's argument, if it is right, does imply a mass gap for another field theory, namely the principal chiral SU(2) 1+1-dimensional nonlinear sigma model.

35. **David**
July 19, 2007

In Wilson's original paper if you go to the last paragraph of the second column of page 2447 and about two thirds of the first column of of page 2448. Wilson calculates his loop for a massless gauge field propagator in 4D (or 3+1 D) and shows that it satisfies the perimeter law.

Therefore massless gauge field leads to perimeter law, that is no confinement. At least in 4D masslessness implies no confinement and thus confinement implies mass gap. Now as amused said if is the gauge field
that acquires the mass there seems to be conflict with Ward identities. A possible resolution is that the gauge fields disappear from the spectrum and what is gapped are objects like glueballs, but no ones know for sure

Now mass gap in gauge theory does not imply confinment. The Higgs phase is a counter example. Now it is believed that if there is no symmetry breaking and there is mass gap in a gauge theory it has to confine. There are reasonable arguments for this, but no one knows for sure.

So amused, I think I agree mostly with you except on the statement that a mass gap necessarily implies confinement. Although I confinement probably implies a mass gap. Peter O. said that he has a counter example in his early paper. I have not gotten around to reading and studying the paper.

36. **Peter Orland**
July 19, 2007

"In Wilson's original paper if you go to the last paragraph of the second column of page 2447 and about two thirds of the first column of of page 2448. Wilson calculates his loop for a massless gauge field propagator in 4D (or 3+1 D) and shows that it satisfies the perimeter law."

David,

This is assuming one can calculate the loop by gluon exchange. Wilson is just pointing out that perturbation theory won't work,
not that a gap is necessary for confinement.

37. **Peter Orland**
July 19, 2007

If you use a massive propagator you will also find a perimenter law.

38. **David**
July 19, 2007

Peter O.

Wilson was pointing out that a massless propagator leads to a perimeter law.

I agree that if the theory is strongly coupled there are important corrections that might invalidate this thinking. But I would say that these corrections
would have to violently change the nature of the gauge field propagator
so that it does not correspond to propagation of a massless excitation.

The interpretation of the gap is my reading, but as I just said I agree that nonperturbative effects could invalidate this thinking. So I am not fully dogmatic and this reading could be wrong. I'll check out your paper too. I have just been caught up with other things.

39. **David**
July 19, 2007

Peter O. I agree with your comment of the massive propagator.

40. **Peter Orland**
July 19, 2007

OK David, I'd be interested in any other comments you have.

41. **amused**
July 19, 2007

Thanks for the replies Peter O. and David. I guess Pierre must have had some physical/heuristic argument in mind like you said. (Or it could be that I'm just misremembering what he said, in which case I'll be glad that I'm anonymous if he ever sees this!)

42. **Neville**
July 19, 2007

Peter Orland said:

> Maybe the reason the Clay foundation set things up the way they did, is that most people suspected the gap would be easier to prove than confinement.

That's the way I've got it figured. Connes, Jaffe, Wiles and Witten
were looking for problems with high probablity of solution. Just look at their their past behavior! Wiles picked Fermat's Last
Theorem for its tractability, while Connes and Witten pursued the low risk roads of Noncommutative Geometry and String Theory.

The Poincare Conjecture is another good example. Heck, the writing was on the wall before that Perelman character showed up.

As for the Riemann Hypothesis, a string theorist said it best to Michael Berry:

> Back in 1985, visiting CalTech, I had just started studying some quantum physics related to some mathematics called the zeta function, itself related to a famously untransparent mathematical speculation called the Riemann hypothesis… At the same time, CalTech was a centre of superstring theory… I met one of them, who asked what I was working on. When I told him, he fixed me with a pitying stare. 'Yes, we have zeta functions throughout string theory. I expect the Riemann hypothesis will be proved in a few months, as a baby example of string theory.'

Special note to Asperger sufferers: Try not to take this message too seriously.

43. **Peter Orland**
July 19, 2007

Neville,

It's not that I don't appreciate your light-hearted remarks, but both
problems – confinement and the gap – were always regarded as
super-tough. I can't read anyone's mind, but I was just trying to
guess the Clay F.'s motivation.

44. **Garbage**
July 20, 2007

Somehow out of topic, and maybe not on the various news theme:

I found there is a loops 07′ conference also in Czech republic, Lubos' land, in Charles U. indeed…

http://www.karlin.mff.cuni.cz/~loops07/

I am sure he will find this rather amusing too 😉

No idea how loops are related to Agriculture though… 😀

45. **amused**
July 21, 2007

Just a few final thoughts on mass gap vs. confinement in QCD (sorry I can't resist). A mass gap certainly implies that any particles corresponding to massless excitations of the fields must be confined in some way, since otherwise there would be states describing free massless particles in the physical spectrum. In particular, gluons must be confined; this ties in with the point emphasized by Jaffe & Witten that mass gap implies that the YM interactions are short-range. Similarly, massless quarks must also be confined. On the other hand, this reasoning does not imply confinement of massive quarks. I guess one can invoke a scale argument in this case, as Peter O. did, to see why confinement is expected, but it is of course not a proof.
Actually, for QCD to have a mass gap the quarks must be massive, since otherwise there would be massless Goldstone bosons associated with the spontaneous chiral symm. breaking (i.e. the mesons would be massless).
From looking at the Jaffe-Witten article it seems there are 3 reasons why mass gap rather than confinement was chosen for the Clay prize problem:
(1) Its physical significance: implies that YM interactions are short-range.
(2) Simpler to formulate than confinement: it just means the physical energy spectrum has a strictly positive lower bound.
(3) Potential mathematical significance: since mass gap implies that the interactions are short-range, it makes it potentially easier to extend results from YM on R^4 to YM on general 4-dimensional spacetime manifolds.

46. **Peter Orland**
July 21, 2007

Amused,

Confinement doesn't just mean that particles disappear from the spectrum. It is COLOR confinement. The excitations which do appear
are color singlets. There are no asymptotic particle states with color.

47. **Anonymous**
July 21, 2007

Peter Orland says:

I can't read anyone's mind, but I was just trying to
guess the Clay F.'s motivation

I suspect this may be right. In a conversation I've had with one of the problem's formulators (although we weren't specifically discussing the mass gap vs. confinement issue), he said that they tried to give the simplest formulation which would prove the type of result he wanted.

48. **amused**
July 21, 2007

Peter O,
I know that. But without knowing about QCD dynamics one could envisage color-singlet states describing a collection of deconfined gluons (as I mentioned in an earler comment). Something like a very dilute, spread out glueball. Such a state would have effectively zero mass, and is therefore excluded by mass gap.

49. **amused**

July 21, 2007

Anonymous,
"Simplest formulation" isn't the same as "easier to prove", which was what Peter O suggested. But yes, as mentioned above, I also got the impression from the Jaffe-Witten article that a reason they chose mass gap rather than confinement was because the problem was simpler to formulate.

50. **amused**
July 21, 2007

Whoops, just realized that it isn't possible to have states which are both color-singlet and describe a collection of free gluons or quarks at the same time. (There would have to be gluon strings between the quarks, or closed gluon loops, etc…). So I take back what I wrote earlier, sorry 'bout that.

51. **F**
July 22, 2007

Hi Peter,

Definitely off topic comment, so won't be offended if you delete this, but wanted to mention the ironic fact that you and Lubos share a lot in common these days; you both posit that a long held cherished theory receiving huge amounts of funding may have a hidden political agenda in the face of growing evdence that the theory may not be as infallible as once thought; hence the vehemence in attacks against dissenters. In your case it's string theory, and in his case, global warming theories driven by man-made CO2. Both of you risk ridicule by these powerful lobbies, but both of you assert rational and normal scientific inquiry have led you to these conclusions. A nice one-to-one mapping, don't you think?! Just food for thought….

52. **mclaren**
July 22, 2007

Delightful. With 105 parameters, the current string "theory" has made itself thoroughly unfalsifiable, since whatever gets observed can be back-predicted by tweaking one of those 105 parameters. Yet now an alleged "genius" proclaims that we need ***more*** parameters? What for, to render the "theory" even **more** unfalsifiable than it already is?
Everyone in the theoretical HEP community should be working overtime to **reduce** the number of free parameters in string "theory," not **increase** 'em.
Instead of BMSSM, they may want to shorten the abbreviation:
BS.

53. **Yatima**
July 23, 2007

> In your case it's string theory, and in his case, global warming
> theories driven by man-made CO2.

Oh Yeah. The first is an exploration of mathematical space with highly speculative application to the present reality. The second is an all-but-certain empirically validated internationally recognized and obvious-to-the-meanest intelligence ongoing modification of the supporting environment, with only Exxon-supported dead-enders and right-wing talk show hosts still in vociferous denial.

Definitely the same thing.

54. **anon**
July 23, 2007

If Woit, Lubos, Distler and Johnson were businessmen:

Woit:
Boys, here is our ledger; it shows that we haven't made any profit for decades. I don't know how to fix this, but something has to change, or we'll go broke.

Lubos:
Of course we are making a profit. Woit is a dumb bastard who doesn't know how to add. Anybody who says we aren't making a profit has an IQ of 80, or is a woman, or a communist. Look, just yesterday we sold 10 cents worth of string in Nebraska. You see, this shows we've been making a profit for decades.

Distler:
Wow, we are making a huge profit. The smartest people in the world have been saying we are making a profit for decades. So many smart people can't be wrong. I just read a paper by Seiberg et al where they point out for the first time ever that 2 + 2 = 4. You see, we are making progress in giant leaps.

Johnson
Boys, we might not be making *too much* of a profit *right now*(wow, you see, I am so open minded), but that is just a blip. It's just a tempest in a teapot. Wow, I enjoy the life of a string theorist so much; all that deep thought; did I tell you about my latest vacation?

55. **F**
July 23, 2007

Yatima,

Read your own comment again (the second part); do you notice that it has a remarkable similarity to the comments Peter Woit used to receive from Lubos in the early days when he espoused on the invincibility of string theory? I have no strong opinion on the content being discussed (in either field), since I am not qualified to do so, but I did want to highlight some rather _abstract_ similarities between the two bloggers. You've helped illustrate my point.

56. **Chris Oakley**
July 23, 2007

Weinberg:
Woit is right. We are not making a profit. No – I don't remember saying that Super String International was the most profitable corporation in the world two years ago.

Susskind:
This talk about Super String International – that I founded 40 years ago – being unprofitable is just nonsense. SSI has now completely broken away from the traditional accounting practises that hamper our competitors. The far more significant Mark-to-Ideas-Markets shows that the company is, and continues to be, an enormous success. Yes, I can give you a very good price if you want to buy my stake in the company.

57. **Coin**
July 23, 2007

> Definitely off topic comment, so won't be offended if you delete this, but wanted to mention the ironic fact that you and Lubos share a lot in common these days; you both posit that a long held cherished theory receiving huge amounts of funding may have a hidden political agenda in the face of growing evdence that the theory may not be as infallible as once thought; hence the vehemence in attacks against dissenters. In your case it's string theory, and in his case, global warming theories driven by man-made CO2. Both of you risk ridicule by these powerful lobbies, but both of you assert rational and normal scientific inquiry have led you to these conclusions. A nice one-to-one mapping, don't you think?!

Uh, I don't think I've ever seen Woit or anyone else claim that String Theory has a "political agenda".

This said, having encountered Lubos' interactions with climate-related blogs, I've actually noticed a mapping between these two things as well, but I'm not sure that I'm seeing the same thing you're seeing.

I don't exactly see the "dissenter" parallels you seem to be claiming here, because it seems to me that the nature of the consensus toward String Theory as a promising research program in physics, is very different in both scope and nature from the nature of the consensus in climatology that global climate change is real and serious.

But when I compare the string theory blog fights to the global climate change debate, I do kind of tend to identify a one-to-one mapping, with the string theory *doubters* mapped to the mainstream climatology *supporters*— because in each case, these are the sides who are spending most of the time talking about *evidence and rigorous connection to experiment*. This is, personally, the rubric I would tend to use to identify which side of a scientific controversy to tend to give the benefit of the doubt to when I am unqualified to make a determination as to which side is right.

58. **anon.**
July 25, 2007

> Uh, I don't think I've ever seen Woit or anyone else claim that String Theory has a "political agenda".

That which is blatantly obvious to all, need not be said by anyone.

Since string theory *doesn't have a scientific agenda, i.e., falsifiability*, it has a political agenda instead. (Politics is defined as the process of making decisions via groupthink and consensus.)

My Life With Stephen

July 23, 2007
Categories: Book Reviews

Jane Hawking, Stephen Hawking's ex-wife, has written a book about her life together with Stephen, which has recently appeared here in the US under the title [Travelling to Infinity: My Life With Stephen](). At around 400 pages, it's an abridged version of the 600 page [Music to Move the Stars: A Life With Stephen](), which appeared in the UK back in 1999. A US production company, Film and Music Entertainment (FAME), has acquired an option to make a movie of the book (weirdly enough, the contract is [on-line]()), but I don't know whether the movie is actually going to get made.

The Hawking's separation in 1990 and later divorce was widely covered in the media, and the book doesn't dwell on the depressing details. Stephen went to live with one of his nurses, Elaine Mason (who at the time was married), and later married her. Jane later married Jonathan Jones, a musician she had met a decade earlier, partly through her church choir, and who developed a close relationship with her and the rest of the Hawking family during the 80s. At the time of the UK edition of the book, there was little contact between Jane and Stephen, but it appears that Stephen is now in the process of getting divorced from Mason, and has re-entered Jane's life.

Up until the publication and huge success of *A Brief History of Time*, the Hawkings were not especially well-off, and dependent on others (including the MacArthur Foundation) for the high costs associated with Stephen's care. After 1989 though, the book and other projects brought in huge sums of money, which made him a wealthy man and perhaps played some sort of role in the collapse of the marriage.

The Hawkings were married back in 1965, at a time when Stephen's illness had already become apparent, and his prognosis for long-term survival was not good at all. For the next 25 years, Jane spent most of her time in the back-breaking labor of caring for an invalid husband while raising three children. While Stephen went from success to success, the center of attention due to his brilliant scientific work and triumph over his disability, Jane received little support, encouragement, or recognition for the sacrifices she was making, and one would have to be a saint to not develop some resentment for the situation and for the way it ended. She tells the whole story in some detail, and it's in many ways a rather sad one.

Among the sources of conflict between them were: religion (she was a believer, he a fervent atheist), his family (described as definitely not nice to her), and his devotion to physics:

> I sensed that there was yet another partner lurking in our already overcrowded marriage. The fourth partner first appeared in the form of a trusted and quiescent friend, signalling the way to success and fulfilment for those who followed her. In fact she proved to be a relentless rival, as exacting as any mistress, an inexorable Siren, luring her devotees into deep pools of obsession. She was none other than Physics, cited by Einstein's first wife as the correspondent in divorce proceedings.

She describes how, during his work on black holes leading up to the discovery of Hawking radiation, Stephen would isolate himself:

> For Stephen those periods of intense concentration may have been useful exercises in cultivating that silent, inner strength which would enable him to think in eleven dimensions. Unable to tell whether it was oblivion or indifference to my need to talk that sealed him off so hermetically, I found those periods sheer torture, especially when, as sometimes happened, they were accompanied by long sessions of Wagnerian opera, particularly *The Ring Cycle*, played at full volume on the radio or the record player. It was then, as I felt my own voice stifled and my own spontaneity suppressed inside me, that I grew to hate Wagner.

Jane also tells the story of Stephen's first public talk on black hole radiation, after which the chairman of the session, J.G. Taylor:

> …sprang to his feet, blustering, "Well, this is quite preposterous! I have never heard anything like it. I have no alternative but to bring this session to an immediate close!"

After this brusque cut-off of any questions, she describes how later she observed:

> Still blustering and indignantly muttering to his students, J.G. Taylor stood behind me in the queue, unaware of my identity. I was rehearsing a few cutting remarks in Stephen's defence when I heard him splutter, "We must get that paper out straight away!"

After she reported this to Stephen, he sent his paper off immediately to *Nature*, where the referee turned out to be Taylor himself. The article was first rejected, then finally accepted after a second referee was consulted. It appeared in the March 1 1974 issue with the title [Black Hole Explosions?](). Taylor's paper (with P.C.W. Davies as co-author) arguing that Hawking was wrong appeared a few months later as [Do Black Holes Really Explode?](). After writing many papers on string theory during the late eighties, more recently [Taylor]() has devoted his time to the study of neural nets and consciousness.

While Jane quite liked many of the relativist colleagues of Stephen's that she was meeting, especially if they weren't in a group talking about physics, she was much less impressed by the particle theorists that Stephen started spending his time with after the mid-seventies as his work concentrated on quantum gravity and unification:

> Nor, I have to confess, did the set of scientists with whom Stephen was now associating attract me in the least. On the whole, particle physicists were a dry, obsessive bunch of boffins, little concerned with personal contact but very concerned with their own scientific reputations. They were much more aggressively competitive than the relaxed, friendly relativists with whom we had associated in the past.

Despite Stephen's disability, the Hawkings did an immense amount of traveling, especially for professional purposes, and Jane describes her impressions of the places they went and people they met. One of the few things she gets wrong is the name of Andrei Linde's wife, Renata Kallosh, who they met on a trip to Moscow. Linde is now one of the most fervent proponents of the anthropic principle, which appears at one point in the book as Jane tells about early debates between Stephen and Brandon Carter during the late sixties and early seventies. She describes it as philosophically close to the medieval Ptolemaic universe, trying to put man at the center of all things.

The book is mostly not a book about physics though, but very much about what it was like to struggle with caring for someone coping with a grave disability, a difficult and not always rewarding task even in this remarkable case of someone who has overcome obstacles and achieved about the highest pinnacle of success possible.

Comments

1. **gunpowder&noodles**
   July 23, 2007

   This is what brings me back to this blog: well-written articles that I could not get elsewhere, even if I don't agree with many of them. No parochial poliitical crap that I could get anywhere [cf Cosmic Variance]. No boring, rambling diatribes about God-knows-what [Reference Frame]. Better watch out for Sabine H. though, she is catching up with you….

2. **anonymous coward**
   July 23, 2007

In my mind I need to qualify that final "success"… he achieved about the highest pinnacle of scientific success, yes. But shouldn't success in life have something to do with how you care for your family?

Out of curiosity, are there good examples of leading scientists who were noted for having great family lives?

3. **Peter Woit**
July 23, 2007

Thanks gunpowder,

Sabine does have a great blog, I'm glad to see that there are more and more of them around. It's not a competitive sport…

ac,

Actually most of the leading mathematicians I know well enough to know about their families seem to be quite successful there too. On the whole I think mathematicians and physicists do no worse in this area than other people. Hawking's story is a very unusual one, with unusually difficult problems both he and his wife had to face.

4. **Flerp**
July 24, 2007

Feynman's family life, his first wife's very untimely death notwithstanding, seems to have been mostly happy.

5. **Christa**
July 24, 2007

Hi Peter,

Good story. But am I being excessively critical or is Stephen Hawking (somewhat) overestimated as a professional physicist (by both general audiences and academic colleagues, albeit I presume less by the latter)? I can understand the general sympathy given him as someone suffering from ALS AND doing worthwhile physics, but how much has he actually contributed other than his earlier works – which by far aren't necessarily uncommon. It seems more and more that he is a celebrity / physicist than a genuine heir to Einstein, et. al. However, when credit is due one should receive it by all means, but excessive credit is going the wrong way.

Einstein, Dirac, Weinberg, etc. deserve to be regarded as major figures as they produced genuinely worthwhile results which have made major impacts on theory physics, but I am not quite as certain regarding Hawking's contributions.

Maybe it's just me…

6. **Large Atom**
July 24, 2007

ac:

"Success" is a relative and subjective term; relative in that, what is "success" for one may be unimportant to another; and subjective in that, there should be no way to quantify it.

What if one does not have a "family", by the way, and we define a part of success using such a term? Is this person somehow not able to ever fully achieve it?

7. **Arun**
July 24, 2007

Feynman's family life, his first wife's very untimely death notwithstanding, seems to have been mostly happy.

No, his infidelities were endured and caused pain.

8. **Chris Oakley**
July 24, 2007

Christa does have a point. I am not questioning his achievements as a mathematician, but unlike the other notables mentioned, nothing Hawking has done has made any impact on physics, and given the difficulties in establishing the existence of black holes, never mind checking for radiation from them, may never.

As regards Feynman's moral character, I refer the interested reader to my [Amazon review of "Surely You're Joking, Mr. Feynman"]. Feel free to add more unhelpful votes (currently 4 out of 4).

9. **Steve Myers**
July 24, 2007

It's easy to judge a life from the outside. Also a good rule to follow: never trust the opinion of an ex-wife.

10. **SteveM**
July 24, 2007

It is fair to say that if Hawking was able bodied then the general public simply would never have head of him. However, his condition coupled with the type of work he does has certainly captured the imagination of the public and created that rarest of things–the celebrity scientist. Easy to see how it must have put a huge strain on his marraige though. I like Hawking's way of thinking and doing things. His papers are usually clear and readable and his contributions to general relativity are important. Also, his radiating black hole work was the first time ideas from both quantum mechanics and gravitation came together in a consistent and very tantalising way; and of course, people are very much still thinking about that.

11. **A quantum diaries survivor**
July 24, 2007

You do not need my appreciation Peter, but I concur with gunpowder… Great post, and always a pleasure to read you.

Cheers,
T.

12. **island**
July 24, 2007

The highest pinnacle of success possible can easily mean that Hawking holds Newton's chair, which was held prior to him by Paul Dirac. It doesn't require any, "what have you done for me lately's" for the statement to be reasonable and correct.

I thought that the ideas that he presented at GR-17 were pretty interesting stuff though.

13. **Garbage**
July 24, 2007

Hey,

For anyone interested, there is an enjoyable paper by Page about Hawking calculation and some historical notes.

http://arxiv.org/pdf/hep-th/0409024

I think the credits should go to Zeldovich also, but as usual there is always a russian who did everything first…

I agree Hawking wont get upgraded to Einstein's level, but try to do math without pencil and paper, and let alone talk about not being able to do so! I even have troubles splitting the bill at the restaurant sometimes, I dont want to even try to imagine being in his shoes…

14. **anon on the hudson**
July 25, 2007

I wasn't going to respond to ths post. But the more I thought about Steven and Jane Hawking the angrier I became.

There is something morally rancid about Steven and Jane Hawking. As other people on this thread have pointed out, without the affliction of Amyotropic Lateral Scelerosis, 99.9 percent of the general public would have a clue as to who Steven Hawking is.

Amyoptropic Lateral sclerosis has given Steven Hawking massive celebrity status that he would never would have experienced if he did not have ALS-his enormous contributions to Black Hole theory notwithstanding.

The celebrity status that ALS has given Steven Hawking has made Steven Hawking a wealthy man. I have no problem with this.

However, Steven Hawking and his wife Jane have never-with the exception of a minor bleat last year about stem cells-used Steven's celebrity status to raise conciousness among the general public in the UK and the US and to call for a massive increase in goverment funding of ALS research and goverment support to his fellow PALS(people with ALS)

Instead we get a celebrity sob story loaded with stories about Steven's randy behavior. No doubt, a movie will soon follow, and Jane and Steven Hawking will be the wealthier for it.

In the mean time……ALS research will continue to remain underfunded and inefested with ego-maniac ALS researchers with marginal scientific talent(this is a good description of the Columbia Presbyterian Lou Gherigs center).

The suffereing for over 90 percent of PALS and their caregivers-CALS- is many orders of magnitude worse than Steven and Jane Hawking's suffering Under the circumstances, Steven and Jane Hawking have lived quite comfortably. Awash in $$$$$ these days, active social life, appearances on national TV and….a chance to act in a Star Tek next Generation episode!!!!.

For over 90 percent of PALS, every second, every minute every hour, every week,every month and every year is a living hell. Most PALS either commit suicide by not traching or are tricked into not traching by family members and hospice staff into not traching(One British legal scholar argues that under Anglo-American legal theory, tricking PALS into not traching, especially by medical profressionals, should be considered a very serious crime)

Steven Hawking was waited on hand and foot by a well paid nursing staff. In America, the majority of PALS are "taken care of by" by either a five dollar an indifferent home home health aid worker-many times not fluent in english-who often doze off in a chair for several hours or a nursing home where they decide to commit suicide after they become completely locked in.

I'm not intertsted in the "devout Christain" Jane's Hawking's sob story and tales about her husbands feynmanesque infidelitities.

Steve Hawking could have used his celebrity status-bestowed upon him by Amyotropic Lateral Scelrosis-to raise pressure both in the UK and the US goverment to massively increase funding for ALS research and goverment support for PALS. Steven Hawking choose not to do this.

Think off all the public appearances Stevn Hawking has made in the US. Steven Hawking has been on shows such as Larry King numerous times. So many blown opportunities. A real man in his condidtion would have used his appearances to make very strong statements about the lack of funding for ALS research and lack of goverment support for PALS locked in their bodies locked in a room with caregiver- year after after year in some situations.

Here is What Steven Hawking could have said on the Larry King show:"The US invasion of Iraq cost 11 billion dollars a week and will cost at least a trillion dollars when it is all over. These billions could have been spent curing Amyoptripic Lateral Sclerosis one of the worst diseases known to man. I am very forutnate to have a very strong support system. However, for my fellow American PALS, life is a living hell. This is outrageous. Put this money into curing Amyotropic Lateral Sclerosis and other underfunded small market disease. Eleven billion dollars a month for the invasion and occupation of Iraq? Eleven billion dollars could have cured this terrible disease many times over.

I don't care how many children Steven Hawking has sired. In my book, a real man-especially one whose his fame and forutne is a direct conseqence of being aflicted with Amyotropic Lateral Sclerosis-with Hawking's clebrity status and wealth would have demostrated a much higher degree of solidarity with his fellow PALS.

America, the nation with the largest number of PALS and their CALS, has made steven Hawking a wealthy man. His chidren and grandchldren will be economically secure for sure.

15. **Molnar**
July 25, 2007

I don't have a problem with people taking potshots at Hawking for his physics or his marital behavior (although I'm not about to throw any stones in those areas), but I think "anon on the hudson" has a misconception of what is considered good manners in most of the world outside the U.S. In most places with which I am familiar, it is considered perfectly acceptable to use one's fame to proselytize (politely) on behalf of unfortunates who do not share one's own affliction, but not on behalf of those who do; such a plea is typically considered self-serving, even if others are also in need, and may well backfire. Perhaps 25 years of Thatcher and Blair have brought the U.K. closer to U.S. standards on this, as well as the somewhat related (in term of social acceptance) behavior of aggressive self-promotion – I can't say. But as someone who has a 50% chance of getting ALS myself, I can say that I would never expect Hawking to do what anon asks.

16. **Kyle**
July 26, 2007

Anon coward,

John Bardeen had a good family life. About the only complaint his family sometimes gave was that he worked very hard. As Peter pointed out, I think most physicists have good family lives – at least as good as the profession will allow. Now that college and graduate education for physicists is breaking the decade mark regularly and they often have three to ten years of temporary employment afterwards, keeping a good family life is tremendously difficult.

As to the post,

Thanks for the review. However I generally disagree with the statement that Hawking has achieved "about the highest pinnacle of success possible." Obviously only he can tell us that for sure, but I have always considered his work at the same time very impressive, and not a fraction as important as people try to sell it as – much like Guiness world record holders. This includes his scientific and public outreach works.

I also consider the "weirdo super genius" identity that the public and physicists have conspired to create bad for the discipline, and both Einstein and Hawking are great examples of it in action. The public likes the idea that to be smart enough to work in something as esoteric as physics, we must have some terrible malady that makes up for the perceived difference in intelligence. Of course most of this difference in intelligence is fictional, but everyone deems it in their best interests to continue the charade.

In other words, I'm not overwhelmed with Hawking's accomplishments, and I feel he has done negative things for the public's understanding and perception of physics. This doesn't constitute a great success in my book.

I am quite sure others will vehemently disagree.

17. **M**
July 26, 2007

Hawking started quantum gravity, by showing that it could be a flourishing field. And that at least it sells books.

We will see if this field leads somewhere or if the final word will be a footnote in textbooks about astrophysical black holes: "we can ignore Hawking radiation with respect to radiation emitted by ambient matter".

18. **Who**
July 26, 2007

> In other words, I'm not overwhelmed with Hawking's accomplishments, and I feel he has done negative things for the public's understanding and perception of physics. This doesn't constitute a great success in my book.
>
> I am quite sure others will vehemently disagree.

Perhaps others do so, but I heartily agree and thank you for putting it succinctly.

19. **relativist**
July 26, 2007

Chris Oakley says "nothing Hawking has done has made any impact on physics". This is not true. According to Google Scholar, the black hole radiation paper has had 2999 citations. Hawking's next three best papers each have had over 1000 citations, and a further 8 have over 400 citations. No matter how you try to decry his work, this is a huge impact. The fact that he has had a major impact on physics rather than just mathematics is also made clear by the talks at his 60th birthday meeting (published in "The Future of Theoretical Physics and Cosmology", edited by Gibbons et al).

20. **Ck**
July 27, 2007

Molnar – what absolute rubbish.

Christopher Reeve campaigned relentlessly and tirelessly for his own cause – "self interest" as you so inappropriately put it. He was widely admired and supported for his extraordinary efforts.

How do you categorise famous people who have had breast cancer, for example, and then go on to help raise funds for that health problem? Or prostate cancer, and so on?

How to you view parents of sick children who make it their life's work to raise research funds and to gain gov't and public support for "their" cause, all out of "self interest", because they hold hopes of a miracle for their child?

Your comments are ignorant.

Look at the real world for goodness sake. People don't randomly "take up a cause", there is almost always a personal connection for them, whether it be a friend or a relative, or yes, even themselves! If this was NOT the case the arse would fall out of medical fund raising and research efforts in the blink of an eye.

You owe "anon on the Hudson" an apology, not for the rest of your opinion, but for being so blindly wrong about medical awareness and fund raising efforts.

21. **anon on the hudson**
July 27, 2007

CK

I am not interested in a knock down debate with molnar. To even write about Lou Gherigs disease causes me great pain.

In discussions on ALS websites, PALS and their CALS have expressed great diappointment that Steven Hawking and his ex-wife Jane have not used their celebrity status to bring much greater attention to the issue of the immorally low level of funding for Amyopropic Lateral Sclerosis research.

I don't want to be mean about this, but a case can be made that Steven Hawking has acted in a self-serving way.

Unfortunately, Steven Hawking gives the general public the impression that Amyoptropic Lateral scelerosis is a disese that a person can live with. If a PAL does not have a strong support system-which most PALS do not-Amyotropic Lateral Scelrosis is not a disease that most PALS can live with. As I mentioned previously, most PALS do not get trached(suicide).

In recent years, the "great" Steven Hawking has taken to making grand pronouncements about the future of humanity. Some of these pronouncements are ignorant and borderline stupid(humans will be replaced by robots in a few decades).

Steven Hawking probably thinks he is making a grand contribution to humanity by pontificating about the fate of humanity.

Well, if Steven Hawking is the least bit interested in making an important contribution to humanity beyond his work in quanum gravity, he may want to start with something as urgent and close by as the indescribable suffering of the 99.9 percent of his fellow PALS who are not in a position to use the terrible affliction of Amyotropic LAteral Scerosis to make themselves a wealthy celebrity.

Most PALS I know, if they were as wealthy and famous as Steven Hawking, would hammer home unrelentingly on TV and during public speaking engagements one point:99.9 percent of people with Amyotropic Lateral Sclerosis will die a horrible death or commit suicide unless the US goverment puts at least one billion dollars a year into ALS research.

For the last four months of his life, my brother was quadraplegic in a medical bed. He had a deep interest in cosmology. I bought several of Professors Hawkngs popular books. I would flip the pages for him as he read. I did this to distract him this horrific disease.

If Steven Hawking wants to make a nontrivial contribution to humanity outside of his work in physics he might consider making a very public statement along the following lines:the Iraq war costs the American people 11 billion dollars a month. If this money was spent on curing ALS-just one month of the Iraq war!!!!-a cure for for Amyotropic Lateral Sclerosis could be found very soon.

This would be a much better use of his celebrity status-bestowed upon him by Amyoptropic Lateral Sclerosis-than making stupid statements about human beings being replaced by robots in twenty to thirty years.

It's not too late Steven Hawking and Jane Hawking.

22. **Howking**
July 27, 2007

Relativist, Chris Oakley did mean "impact on stablished physics".

Just count how many Nobel Prizes for physics Hawking won.

23. **Chris Oakley**
July 27, 2007

There seem to be very few on this thread who are prepared to identify themselves. Obviously "Anon on the Hudson" has a tale to tell. It would be interesting to hear more, and although I respect his/her wish for anonymity, I do not quite understand it.

Re: Hawking and physics: If citation counts were all that mattered, then all of the Nobel prizes for physics in recent years would have gone to String Theorists. Luckily, the subject has not gone off the rails completely (although sometimes I wonder), and the Swedish Academy, at least, recognises that for something to be called "physics" it has to be verified experimentally.

24. **Molnar**
July 27, 2007

CK: Your sole counterexample to the theorem does not satisfy the conditions (Christopher Reeve was American), and the rest of your post is just handwaving: zero marks out of ten. Try to be a bit more rigorous next time.

Hudson: My only point about your post was that we should be sensitive to cultural differences. Being reserved about personal issues and keeping a stiff upper lip is a bigger part of British culture than American (or at least it was not too long ago).

25. **Juan R. González-Álvarez**
July 28, 2007

"Hawking started quantum gravity, by showing that it could be a flourishing field."

Are you sure M?

The first papers in quantum gravity were from Rosenfeld on the 30s. In the 30s the idea of the graviton was already introduced. Rovelli calls the prehistory of quantum gravity.

Hawking first 'important' paper on BH radiation was on 1974. But it was not about quantum gravity but an aplication of QFT on curved spacetime.

Four years latter Hawking revives the Wheeler-Misner-Feynman
approach in the form of "Euclidean quantum gravity". That is where Hawking enters in quantum gravity, a field however Hawking does not star.

Now if you have some time, count the multiple names between Rosenfeld 1930 and Hawking 1978: Bronstein, Feynman, Wheeler, Dirac, DeWitt, Pauli, Finkelstein, Weinberg, …

26. **Steve Demuth**
July 29, 2007

Several things trouble me about *Anon the Hudson*'s postings.

First, the equation of refusal to be "trached" with suicide, is I think, morally extreme. The right to refuse invasive life-exending medical procedures is widely recognized in the western world to be without the moral taint of suicide. It is a huge step backward in our understanding of autonomy in the context of medical care to assert otherwise.

Secondly, the explicit criticism of the Hawkings for not “raising consciousness … and advocating for massive increases in government funding” is at least problematic. The Hawkings may have made this choice for base reasons, but they may equally well have done so for morally sound and rational reasons. They may have concluded, for example, that however costly and devastating ALS is in their lives, it does not deserve to be a higher priority of government biomedical research that it already is. ALS after all is a rare disease (an average incidence in countries with primarily European populations of 4 per 100,000, and significantly less than that in non-European populations) that strikes people fairly late in life (average onset in the early 50s) that is not communicable or known to be environmentally triggered. In other words, as bad as it is, it appears to be a random act of nature that, compared with many conditions, destroys relatively few total years of productive life in society worldwide.

I know a little bit about ALS, and the impact it has on people’s lives, having seen a friends parent die of the disease, and having friends of my own with the disease. I certainly do not discount the real anguish *Anon on Hudson* no doubt feels through some close personal connection with the affliction. But I don’t think the response posted here with respect to Hawking is a productive use of that pain. Dying from a terrible disease by refusing treatment is not suicide, and could, for some, be a courageous and morally uplifting assertion of agency over a disease that has relentlessly ravaged their potential for agency. Choosing not to be a public advocate for spending on one’s own condition is not automatically a selfish act. It could well be a defensible, unselfish, decision that one’s own afflictions are not necessarily, by virtue of being one’s own, a priority for the world.

27. **anon**
    July 30, 2007

    In Hawking’s defense, I believe he has been an outspoken advocate for people with disabilities in general, even if not for people with ALS in particular. For example, in his various visits to developing countries he has been quite vocal in his support for improved wheelchair access and the integration of people with disabilities into society.

    So perhaps he has simply chosen carefully which battles to fight.

28. **Tanya A.**
    September 13, 2007

    Anyone who read Jane Hawking’s memoir, especially the first version of it, and paid any attention will be aware that they both did a lot of campaigning for ALS victims when they were married. After their divorce, Jane tried to become involved again but found herself blacklisted because of her separation from Stephen, since Stephen’s name carried more weight.

    I don’t want to say either one is a saint, or conversely to be too hard on either one of them because they were subjected to inhuman pressures (both of them) and turned out (both) to be only human. But they have always struck me as decent people and their bad moments as only human, and yes, it’s important to remember that charity is done somewhat differently in the UK. To accuse either of them and especially Jane of being indifferent to the potential uses of their fame to help others is simply ignorant. Jane Hawking continues to be very active in charitable causes, including for autistic children (she has an autistic grandson). And Stephen Hawking has been working to raise environmental awareness of late.

    Again, nobody’s perfect. But “morally rancid” is untrue and unfair. Please read the book before you make such comments.

The New York Times has an article this morning by Dennis Overbye in its Science Times section about the hunt for the Higgs and the various rumors that were circulating earlier this year. It does a good job of accurately summarizing and reviewing the situation (although of course the blogs were and remain the place to go for breaking news, up-to-date and accurate information…). Steven Weinberg recalls the time back in 1977 when he quickly wrote up a paper with Ben Lee about a model concocted to explain rumored "trimuon" events (which turned out not to be there). There are quotes from bloggers Tommaso Dorigo, Gordon Watts and John Conway, and, in a new posting on his blog, Gordon is now trying to deny that he uses the term "Dude" in actual conversation. Unfortunately, anyone at D0 who knows anything seems to have clammed up, no more rumors that I'm aware of about whether they're seeing anything exciting.

The 2007 Europhysics Conference on High Energy Physics is going on in Manchester, England, and many of the talks are already on-line. This is a conference more aimed at experimentalists than theorists, so there doesn't seem to be much new in the theory talks. There are so many experimental talks that I think I'll have to wait for the summary talk to appear to figure out what to pay attention to.

There's a long list of things I was going to write about, but Sabine and Stefan at Backreaction got there first (here, here and here):

- Nature has a special section on the LHC. Very good and much more in depth than most of the huge amount of press coverage of this story. Especially interesting is the article by Chris Llewellyn Smith telling the history of how the LHC came to be.
- The LHC Theory Initiative, a now NSF-funded project that will provide some graduate fellowships and post-docs for people working in phenomenology relevant to the LHC, is being promoted with a University of Buffalo press release. It claims that currently Europeans dominate the field of LHC phenomenology, so the NSF funding is needed to stop this "outsourcing" of crucial high-tech employment to foreigners. HEP in the US is quite an amazing industry, the only one I know of that outsources technical work to countries where the labor costs more than it does in the US….
- This year's award for most ludicrous hep-ph paper is likely to be won in a walk by this one. Tommaso is even better than Sabine on the topic.

There's a new chapter out of the particle physics novel The Newtonian Legacy (blogged about here) by Nick Evans. Not often that the Cern Courier carries material about Higgsless models and lingerie in its pages…

Comments

1. **Gordon Watts**
   July 24, 2007

   Dude! I really don't use that word normally!

2. **Gordon Watts**
   July 24, 2007

   Dang it. How do you edit comments you've left?? 😉

3. **Kasper Olsen**
   July 24, 2007

   Concerning Holger and Ninomiya's paper:

   Yes the idea is crazy, and contrary to what we know, but I don't think it is fair to call it "ludicrous". If you accept some of the premises — which of course might be very hard — then certainly the idea is not foolish, or completely unreasonable.

   Try to read the paper, and present your own reason for why you think it is "ludicrous".

   Kasper

4. **DB**
   July 24, 2007

   Tommaso titles his review:

   > respectable-physicists-gone-crackpotty

   Could it be, that as an alternative to such an archaic and defective way of relieving oneself, they are in fact taking the piss?

5. **A quantum diaries survivor**
   July 24, 2007

   Kasper,

   the idea is dangerously bordering into the ludicrous, but I accept that it is still valuable science to test for backward causation.

   However, the idea that 5000 physicists financed by fixed fractions of the GNP of participating states accept to put at stake 20 years of efforts spent designing, building, and making operative the most daring enterprise in physics ever, to look for an effect preventing higgses from being produced, or worse, saving the LHC from a flood or an explosion, or people from being injured (sic) is
   O U T R A G E O U S
   and brings shame to their purporters and embarasses most of the reasonable physicists working for the CERN experiments.

   Cheers,
   T.

6. **matteoeo**
   July 24, 2007

holger-ninomyia's theory seems to be testable at least in principle, so it might still be better than ST in a sense…

anyway is everybody really sure it is not a joke? maybe they tried to write nonsense with the previous paper ("hit by bad luck") and, noticing no reaction, they have worsen it.

7. **A quantum diaries survivor**
July 24, 2007

Matteoeo, that would be a bit too much of a walk on the wild side. And if we have to live with either theorists who build non-testable theories or theorists who build theories whose testability depends on playing cards or "turn the bottle" kind of games, based on the chance of shutting down billion dollar experiments, I sincerely take the former.

Cheers,
T.

8. **Arun**
July 24, 2007

I liked this from Overbye (emphasis added)

*Joe Lykken, a Fermilab theorist who said he first learned of the rumored bump the old-fashioned way, over lunch in the laboratory cafeteria, said: "Pre-blog, this sort of rumor would have circulated among perhaps a few dozen physicists. Now with blogs **even string theorists who can't spell Higgs** became immediately aware of inside information about D Zero data."*

9. **Peter Woit**
July 24, 2007

Arun,

Funny, but the dissing of string theorists by their colleagues has become so common-place that I didn't even really notice Lykken doing this…

10. **Tony Smith**
July 24, 2007

Arun quoted Joe Lykken as saying
"… Now with blogs even string theorists who can't spell Higgs became immediately aware of inside information about D Zero data. …",
which supports my feeling that a lot of today's theoretical physicists are so wrapped up in superstring abstract math that they don't have the time and energy to really understand the Standard Model well enough (i.e., at a level of detail similar to that set out in the review sections of the Particle Data Group publications) to realize what fascinating stuff is being done at Fermilab and will be done at LHC.

Further support comes from the Resonaances blog, which in a 1 July 2007 post entitled "Nima's Marmoset" said:
"… Nima Arkani-Hamed [formerly at Harvard and now at Princeton IAS]… gave another talk …[at]… CERN … advertising his MARMOSET … a new tool for reconstructing the fundamental theory from the LHC data …
Nima pointed out …[that]… at the dawn of the LHC era we have little idea which underlying theory and which lagrangian will turn out relevant …
Nima says that this new situation requires new strategies … The idea is to study physical processes using only kinematic properties of the particles involved.
Instead of the lagrangian,
one specifies the masses, production cross sections and decay modes of the new particles. The amplitudes are parameterized by one or two shape variables. This simple parameterization is claimed to reproduce the essential phenomenology that could equally well be obtained from more complicated and more time-consuming simulations in the standard approach …
MARMOSET is a package allowing … Monte Carlo simulations of physical processes. As the input it requires just the new particles + their production and decay modes. Based on this, it generates all possible event topologies and scans the … parameters, like production and decay rates, in order to fit the data. The failure implies necessity to add new particles or new decay channels. In this recursive fashion one can extract the essential features of the underlying fundamental theory. …
Proffesionals say that MARMOSET does not offer anything they could not, if necessary, implement within half an hour.
On the other hand, it looks like a useful tool for laymen. …".

In short,
Nima says that the Standard Model Lagrangian should be ignored
because
"… we have little idea which underlying theory and which lagrangian will turn out relevant …"
even though the Standard Model has passed EVERY experimental test for over 30 years, and there is NO experimental observation whatsoever indicating that the Standard Model is not the relevant "… underlying theory and … lagrangian …" for physics at the LHC.

I disagree with Nima, and feel that the Standard Model Lagrangian (unless and until some experimental result disagrees with it) should be the primary basis for analysis of data from the LHC.

As a layman who supports the Standard Model, and whose physics model includes the Standard Model as a subset, I resent the characterization of MARMOSET as "… a useful tool for laymen …",
especially when
it seems to be primarily a tool designed by superstring theorists to enable them to avoid troubling their highly trained minds (a la Majikthise and Vroomfondel) with the details of the Standard Model.

Tony Smith

July 25, 2007

> # This year's award for most ludicrous hep-ph paper is likely to be won in a walk by this one. Tommaso is even better than Sabine on the topic.

At one point I was regretting it, but right now I am ***so*** glad I picked mathematics instead of physics. The field is … a disaster.

What we have got here, is a failure of process.

12. **Eric Mayes**
July 25, 2007

Actually, physics is quite healthy. It's only because of the efforts of certain people to mislead and disparage that you have this impression.

13. **Xerxes**
July 25, 2007

This arxiv paper appears to have been cribbed from the plot of "Einstein's Bridge", a novel in which the reason for the SSC being canceled was that time-traveling physicists sabotage the effort in order to prevent a dire future catastrophe associated with particles produced there. Take SSC–>LHC and time-traveling physicists–>consistent histories interpretation of QM, and it seems a near match.

14. **H-I-G-G-S**
July 25, 2007

The amusing thing about the Lykken quote is that not that long ago
he was selling himself as a devoted string theorist on NOVA. He, like
the author of this blog, is an opportunist.

NOVA: What is so compelling about string theory to make you want to devote your career to it?

Lykken: I think when a lot of people go into theoretical physics, they're looking for the big answers to the big questions. String theory holds out the promise that we can really understand questions that you might not even have thought were scientific questions—questions about how the universe began, questions of why the universe is the way it is at the most fundamental level. The idea that a scientific theory that we already have in our hands could answer the most basic questions is extremely seductive. Of course, for this to really happen, string theory first of all has to be right, which we don't know, and then we have to be able to test it and understand it eventually in experiments.

String theory itself probably won't be understood even in my lifetime at the deeper level. But I do think that there are ideas coming out of string theory that we will test and we will confirm hopefully in experiments, and that's what I'm really hoping for. I want to see during my career that at least some of these big ideas coming out of string theory we'll actually get our hands on and see that they do happen in the real world.

15. **Peter Woit**
July 25, 2007

HIGGS,

OK, I see that there is one string theorist who can spell the word…

You may be right that there is a certain amount of rats/sinking ships going on here. As for the accusation against me of "opportunism", I've been saying things critical of string theory and the behavior of string theorists for a very long time. When I decided to start doing so publicly, many people told me I shouldn't do this, that it wouldn't be good for me at all, and that I'd become the target of personal attacks, often anonymous ones…

16. **Aaron Bergman**
July 25, 2007

Apparently people can't even make jokes these days.

17. **anon**
July 25, 2007

Aaron, you are not even funny.

18. **Tom Whicker**
July 25, 2007

Higgs,

To say "String theory itself probably won't be understood even in my lifetime at the deeper level" is to beg the question that there
is a deeper level to string theory. It is similar to Jackson Pollock
putting the last drips of paint on "Full Fathom Five" and saying
"I may never fully understand this art work."

TW

19. **anonymous**
July 25, 2007

It seems to me that being skeptical of string theory has become fashionable of late. I'm pretty sure this is a phenomenon of those who aren't skilled and smart enough to work in string theory. Some of these people are crackpots, and some are real physicists who work on topics which are a little out of the mainstream (i.e. 'alternative approacjes). I guess they think being skeptical makes them look smart, even though these people generally produce nothing of their own. It's always easier to sit back and criticsize than to do some actual work.

20. **Aaron Bergman**
July 25, 2007

Aaron, you are not even funny.

But do the lurkers support me in e-mail?

21. **Peter Woit**
July 26, 2007

anonymous,

Well, I'm pretty sure that you and other string theorists' conviction that skepticism about string theory "is a phenomenon of those who aren't skilled and smart enough to work in string theory" is a phenomenon of people crippled by a pathological degree of arrogance.

22. **wat happened to Lubos?**
    July 26, 2007

    Maybe it's inappropriate to ask here but I'm curious to know if Lubos has been fired or if he voluntarily resigned. If he did get fired, was it due to his blunt remarks and disrespect for other academic researchers?

23. **amused**
    July 26, 2007

    I'm pretty sure that if string theorists were as smart as they think they are then ST papers would be dominating the pages of PRL, just like the papers by the smartest mathematicians dominate the pages of Ann. Math. and Invent. Math. (Of course, string theorists profess not to care about journals any more, but it's hilarious to see how keen many of them are to submit to PRL whenever they think they have a chance.)

24. **anonymous**
    July 26, 2007

    Most string theorists don't like to publish in PRL because it's too restricitive. It's difficult to communicate results in string theory to a broad, general audience within the four page limit. Most string theory papers will be found in JHEP, Nuclear Physics B, Physical Review D, or Physics Letters B.

25. **amused**
    July 26, 2007

    Well, string theorists don't seem to have any problems when it comes to hyping their work in the general press, where the audience is even more broad and the restrictions more severe…
    It's no more difficult to communicate results in ST than in other areas of formal theory, and from what I've seen most string theorists love publishing in PRL just as much as the rest of us, even though they are a bit reluctant to admit it 😉

26. **DaveC**
    July 26, 2007

    My impression is that the peer expectations amongst string theorists don't push them towards PRL as they do the rest of us. At the same time there is surely some awareness that most of their results don't actually meet the PRL broad interest requirement. On the other hand the arrogance of anonymous is laid out as clear as day before us here. Does s/he think any physicist outside string theory (the vast majority of us, remember) is going to be impressed by moaning about the four-page limit?!

    More on-topic, Gordon has called me 'dude' quite a few times. He shouldn't be allowed to get away with denying it, but I also hope he doesn't stop.

27. **Amos Elberg**
    July 26, 2007

    I have the same question about Lubos…

28. **random dude**
    July 26, 2007

    Dudes, why does this Gordon Watts dude have a problem with the word `dude'?

29. **SnarkFest**
    July 26, 2007

    *Skepticism about **X** is a phenomenon of those who aren't skilled and smart enough to work in **X**.*

    Now that's a nice rhetorical trick! I think I'll start using it…

30. **mclaren**
    July 26, 2007

    Snarkfest's comment seems apropos. The comment by anonymous that skepticism of string theory is *a phenomenon of those who aren't skilled and smart enough to work in string theory* is nothing but the old long-debunked ad hominem argument. Anyone who disagrees with my arguments is too stupid to understand them, therefore not worth bothering to refute.

    The 2 obvious problems with this kind of ad hominem argument are:
    [1] it is demonstrably untrue, since highly skilled and knowledgeable phycisists like Peter Woit and Lee Smolin and Steven Wienberg have been vocal about their skepticism of string "theory"; and [2] the implication behind this kind of ad hominem argument is that we cannot apply the generally accepted requirements of the scientific method to string "theory" because string "theory" is so allegedly complex and so purportedly sophisticated.

    Let's review the generally accepted requirements for a scientific theory, shall we?

    (A) To qualify as a scientific theory, it must have a rational basis and must use a maethmatical framework to describe nature. String "theory" qualifies on this point.

    (B) To qualify as a scientific theory, the mathematics must yield testable falsifiable predictions. String "theory" fails on this point.

    (C) To qualify as a scientific theory, the theory must be fertile and give rise to additional insights about the physical world which in turn can be tested and confirmed or disconfirmed, and lead to additional areas of productive research. String "theory" also fails on this point.

    The entire purpose of the scientific method and the peer review process is to insure that people who not extreme insider experts in a narrow niche field can nonetheless make a general evaluation of claims by other researchers. To claim that each field of scientific knoweldge is so esoteric and so advanced that no one outside that tiny subspeciality is qualified to evaluate the validity of papers published in that field, is to deny altogether the utility of peer review and, in effect, to abandon the scientific method. If that were really the case, only the handful of specialists in any given field would ever be qualified to judge the validity of that science, which means that essentially everyone would be UNqualified to evaluate whether ANY science was valid.

    Nope. Wrong.

    Peer review works. The scientific method works. I don't have to know all the details of the latest experiments in shotgunning out blocks of conserved junk DNA in mice to know that it heralds some important new discoveries about the relationship between the various kinds of RNA and the traditiional paradigm of information transmission through the genome. I don't have to know these details in order to eb sure the science is valid, because these papers have been published in peer-reviewed scholarly joujrnals, and their results have been replicated by other researchers.

String "theory" does not even qualify as a scientific theory because it has made no testable falsifiable predcitions and no resarch data (obviously) have been published in peer-reviewed scholarly journals replicating those findings. It's not necessary to know anything more than that to become skeptical that string even qualifies as "theory." If we deny this chain of logic, we must abandon the peer review process and throw out the scientific method.

31. **mclaren**
July 27, 2007

> …Being skeptical of string theory has become fashionable of late. I'm pretty sure this is a phenomenon of those who aren't skilled and smart enough to work in string theory.

The old ad hominem fallacy.

Ad homneim arguments won't convince anyone that string is a "theory," but falsifiable testable predictions might.

Got any?

32. **anon.**
July 27, 2007

mclaren, if string ever made any truly falsifiable predictions, nearly everyone in that subject today would run away, for fear of it being disproved. You don't have the intelligence to grasp that not having any falsifiable predictions actually makes a science more attractive to slow thinkers. If they try working in a fast moving research program which makes falsifiable predictions, their future is insecure.

The brains behind all big corporate research efforts involving many people is lack of falsifiability. It is a great benefit in many areas, not just religion but also politics, and now string theory. You just need to become more broad minded, then you'll begin to understand how stupid your comments are. You're under the illusion that string theory should be a 'shut up and calculate' discipline. The whole point is that it's a 'shut up and speculate' subject. The less likely it is to ever make a falsifiable prediction, the stronger it becomes, since moronic critics can't disprove any of it.

33. **lyme**
July 27, 2007

> Steven Wienberg have been vocal about their skepticism of string "theory";

As far as I know, S. Weinberg is an advocate of ST, though not a practitioner himself.

34. **lyme**
July 27, 2007

Maybe I should give some basis to my opinion.
See hep-th/9702027 and hep-ph/0401010, for example. A short quote from the latter paper,

> I am emphasizing here that it took a long time before we realized what these ideas
> were good for partly because I want to encourage today's string theorists,
> who I think also have good ideas that are taking a long time to mature.

35. **schtirlitz**
July 27, 2007

"highly skilled and knowledgeable phycisists like Peter Woit and Lee Smolin and Steven Wienberg"
LOL, very amusing indeed!

36. **schtirlitz**
July 27, 2007

"To qualify as a scientific theory, the mathematics must yield testable falsifiable predictions. String "theory" fails on this point."

Is the existance of the Higgs boson a falsifiable prediction of the Standard Model?

37. **schtirlitz**
July 27, 2007

Oops, I meant EXISTENCE

38. **Peter Woit**
July 27, 2007

mclaren,

Please stop posting rants here. This isn't helpful and does nothing to encourage informed discussion, quite the opposite.

schtirlitz,

Yes the existence of the Higgs is a falsifiable prediction of the Standard Model. All its properties, including its spin, charge and all couplings to all known other particles are predicted. There is one undetermined parameter in the Standard Model, the Higgs self-coupling, which, if known, determines its mass. The LHC should be able to cover the entire energy range where effects of the Higgs are supposed to show up, no matter what the self-coupling. If the LHC sees no sign of the Higgs, the Standard Model is falsified. We're hoping this happens….

39. **schtirlitz**
July 27, 2007

Thanks Peter! I agree, although the Higgs mass cannot be predicted, there exists an upper bound which the LHC covers. BUT it only becomes falsifiable once the LHC

comes about.
OK, then a similar question:
Was the existence of the 3-rd generation of quarks a falsifiable prediction? It seems to me that there was a huge uncertainty about the top mass in the context of the SM. Am I wrong? If the top mass were ~O(few TeV), would the SM have been falsified?

40. **Peter Woit**
July 27, 2007

schtirlitz,

As I've often written about here, the notion of "falsifiability" is not such a simple one. Different theories contain different amounts of wriggle room, from one extreme where nothing is adjustable to another where almost eveything is. The Higgs is a good example of a conventional falsifiable theory, with one undetermined parameter, and a vast number of highly precise predictions with zero wriggle room that can be made and tested for each value of that parameter.

Once the tau was found in the mid-seventies, the SM predicted a bottom and top quark with specified properties, except for two undetermined parameters, the masses. The bottom quark mass was fixed by the observation of the Upsilon in 1977. After that, I believe there were various upper bounds on the top quark mass from precision electroweak experiments, but I don't remember the details of that story.

41. **schtirlitz**
July 27, 2007

Thank you for your answer Peter but to be honest, I'm not satisfied with it. I agreed with your answer about the HIggs mass but don't you think that the discovery of Upsilon was a lucky thing in itself?
I thought that the answer to my question was trivial:
The existance of the 3-rd generation was not falsifiable since, for example, the masses could not be fixed by the theory. It took about 20 years of searching to discover the top – a clear indication that it's existence, predicted way back in the early seventies was pretty much in the same category as either technicolor or superpartners or extra dimensions right now – unfalsifiable!

42. **Peter Woit**
July 27, 2007

schtirlitz,

I don't have time to look up the references, with a little effort you can find them yourself, but precision electroweak measurements implied a specific range of values for the top quark mass. Before its discovery there were only a range of values for the mass such that the SM was consistent with all the data. The SM made a falsifiable prediction that there would be a top quark with specific properties in a specific mass range. A particle with exactly these properties was found in exactly the predicted mass range. This is a textbook case of a conventional sort of testable, falsifiable scientific prediction.

The other things you mention are a mixed bag each with different degrees of wriggle room.

43. **lyme**
July 27, 2007

Without claiming any expertise in these matters, I'd say that without a 3rd generation there'd be no CP violation in the SM, and it'd go down the experimental drain.

With a non-standard 3rd generation, without a top, there's no anomaly cancellation in the SM and, again, it's falsified.

No top = no SM.

44. **schtirlitz**
July 27, 2007

"Before its discovery there were only a range of values for the mass such that the SM was consistent will all the data."

But the data you are referring to was only available a few years before it was discovered. It took 20 years of data collection to nail it down! It was unknown upriory what its mass range would be. The SM itself does not require it to be that much heavier than the other quarks, does it?

So, by the same token MSSM pheno people can say that there exists, for instance, a gluino with very specific properties and the upper bound on its mass still undetermined for the lack of precision data, just like was the case for the mass of the top quark in the 70s. If the LHC discovers a gluino it will be just like the dicovery of Upsilon you mentioned above – a lucky accident!

45. **schtirlitz**
July 27, 2007

"With a non-standard 3rd generation, without a top, there's no anomaly cancellation in the SM and, again, it's falsified."

Nope, the anomalies cancel in each successive generation.
It was CP violation by K_0 that prompted Kobayashi and Maskawa to suggest the existence of the 3rd generation.

But again, low scale superpartners have been suggested to stabilize the hierarchy, explain the electroweak symmetry breaking (why the Higgs mass parameter turns negative), dark matter, gauge couling unification, etc. The MSSM has many input parameters which can in principle be fixed by precision data, so what? It's just like the Standard model in the 1970s when a lot of its parameters were not fixed!

46. **Eric Mayes**
July 27, 2007

Schtirlitz,
Don't forget that the top mass was predicted to be very heavy by radiative electroweak symmetry breaking in minimal supergravity back in the early 80's, which is another strong piece of evidence for the 'not even wrong' theory called supersymmetry.

47. **Peter Woit**
July 27, 2007

1 undetermined parameter or 105, it's exactly the same! A theory that has been tested precisely 1000s of times or one that predicts almost nothing, exactly the same!!

Geez….

48. **Eric Mayes**
July 28, 2007

Peter,
It seems to me that supersymmetry predicts much more than ‘almost nothing’. In addition to radiative electroweak breaking and a correspondingly large top mass, it predicts the existence of superpartners to the known particles, which are estimated to be in the TeV scale range. Your point seems to be that this idea is useless since we cannot predict what the precise masses and mixings of these states will be, since this depends on the exact mechanism by which supersymmetry is broken. I and others have pointed out that this is no different that the situation in the 60’s and early 70’s when the Standard Model was just beginning to emerge from the fog. You seem to be in denial about this and oblivious to the way science actually works.

49. **Peter Woit**
July 28, 2007

“oblivious to the way science actually works”

Eric,

You really should consider whether ad hominem attacks and insulting people is the right way to carry on a scientific discussion.

I’m not going to review the history of the Standard Model here, it’s a complicated story, one that is very different than the story of supersymmetry.

50. **lyme**
July 28, 2007

> Nope, the anomalies cancel in each successive generation.

That’s what I meant. After the Upsilon was discovered there had to be a top for the anomaly to vanish.

But, more to the point, and I’m speaking only for myself, I wouldn’t say susy is not even wrong. My personal opinion is, it’s theoretically compelling but phenomenologically ugly due to the abnormal obesity of its superrenormalizable sector… But it might well happen that either an experimental discovery or a theoretical breakthrough give it the plastic surgery it needs to be pretty again.

51. **lyme**
July 28, 2007

schtirlitz , there’s perhaps one more point that deserves clarification.
When you say “Was the existence of the 3-rd generation of quarks a falsifiable prediction?” the answer is that its non-existence would have led to an enormous crisis in particle physics.

On one hand, the SM would have been unable to explain CP violation in the K0 system even in principle. On the other hand , the SM was supported by an enormous amount of other data. That’d have been the kind of phenomenological contradiction that would have led to the prediction of a third generation. Historically, experimentalists did a good job, got lucky, and found the Upsilon before that hypothetical crisis happened.

But the non-discovery of susy would not lead to any crisis, because there is not a single experimental datum supporting it. Unlike the case of the 3rd generation, the absence of superpartners at the TeV scale would just mean that susy is another smart theoretical idea which happens not to be realized in Nature.

That scenario is certain to happen in the next few years: There are lots of smart theoretical ideas around for physics beyond the SM, but it is extremely unlikely that all of them will be phenomenologically relevant no matter how many good theoretical arguments back them.

52. **Eric Mayes**
July 28, 2007

Peter,
Stating a fact is not an ad honimem attack. This just seems to be your fall-back position whenever you are losing the debate. At any rate, you can’t continually make ad honimen attacks on string theorists as you have done and then complain when they respond in kind.

53. **Gphillip**
August 1, 2007

Peter, I don’t believe that just because the SM doesn’t predict everything possible it is necessarily falsified. It may be a bit incomplete, but that has yet to be proven. So far, every model of reality ever conceived has been a bit incomplete. I would really be more surprised if this one wasn’t. Now, if it made predictions that that were proven false by experiment, which I’m not positive the LHC can do, the we’re off in search of a better model, which I have no doubt we will be doing someday anyway.

Loved the LHC Roulette paper. You Dudes and Dudettes need to lighten up and smile now and then. Of course it was a very dry joke and greatly enjoyed. Yes, one can actually demonstrate reverse causation, of a sort. Unfortunately, the effect cannot be separated from random events until present measurements are made. So the Eigenvalues did collapse before the measurement was made. Unfortunately you can never detect that until after the measurement is made. It’s the same effect of trying to use entanglement to communicate faster than light. Yes, the signal will arrive faster than light (which can be constructed into a reverse causation scenario), but the signal can’t be resolved from random noise without a key (or the results of another measurement) that must arrive by pokey old light speed.

But hey! Keep trying Dudes and Dudettes. If we can ever get this one right we’ll make a killing at the casino! And keep smiling. Life is short.

University Grants Program Subpanel Report

July 27, 2007
Categories: Uncategorized

The HEPAP University Grants Program Subpanel has just issued a report, concerning the "University Grants Program" in US HEP, that part of the DOE and NSF high energy physics budget which supports research based mainly at universities (as opposed to government laboratories such as Fermilab). Obviously this is the part of the HEP budget that is of most direct concern to university researchers, especially theorists, who receive most of their government funding this way (a small number of theorists are supported by national labs, not universities).

On the experimental side much of the report is concerned with how to manage what will happen over the next few years as many researchers move from working on experiments in the US to the LHC, in particular how to deal with the higher travel and living expenses this will require. I'll concentrate here on some comments on the extensive parts of the report that deal with theoretical particle physics.

The report is surprisingly light on actual budget data, with few specific numbers about past budget trends, current budget levels or future budget plans. 2006 NSF university grant funding is given as $19 million for experimental particle physics, and $11.8 million for particle theory, astrophysics and cosmology. DOE university grant funding is described as about $110 million per year, with no breakdown between experiment and theory. The only historical data given is that this kind of DOE funding peaked in 1992, at a level of $150 million in current dollars, supporting a total of 1685 people back then, as opposed to 1495 in 2005. The main budgetary recommendation of the report is that 1 % of the total US HEP budget (about $8 million) be redirected to the university grants program as the SLAC and Fermilab collider programs wind down over the next few years.

The recommendations for theoretical particle physics mostly concern funding for graduate students, calling for increasing the number of graduate students in particle theory, especially students working on calculations directly relevant to LHC experiments:

> Funding directed at university-based theoretical particle physics for the purpose of increasing the number of HEP-grant-supported graduate students should be given a higher priority in the overall HEP program. Support for students and postdocs doing calculations related to upcoming experiments is particularly urgent.
>
> Though the universities are strong in formal theory, there has been a decline over the years in conventional particle theory (phenomenology), for a variety of reasons. Phenomenology embraces a number of different areas, including data analysis, collider physics, computational physics, perturbative QCD, lattice field theory, model building, flavor physics, and neutrinos; it overlaps with such areas as strings, astrophysics, and cosmology. All these areas are important; but those directly connected with the LHC are increasingly critical. The entire LHC experimental program requires a strong theoretical component involving calculating Standard Model backgrounds and new physics processes, together with interpreting the experimental results and teasing out their implications. However, the number of theorists working on such topics in the United States, especially at the universities, is inadequate. For example, there are only a handful of people in the U.S. working on computational physics, such as event generators. Many more will be needed to fully utilize the physics potential of the LHC. It is important that much of this effort be centered at universities because (a) much of the experimental analysis will be done at universities, and (b) a university presence is needed to attract graduate students. A general concern is the overall decline in the agencies' support of graduate students in theory, both formal theory and phenomenology. This decline makes it difficult to train a sufficient number of students. The problem is aggravated by increasing competition for the limited number of available teaching assistantships (TAs) from students in other subfields of physics.
>
> A key component of a strong Terascale physics program (at the LHC and the ILC) is a strong theoretical program involving the calculation of Standard Model backgrounds and new physics processes, together with interpretation of the experimental results. However, as pointed out in this report, the number of theorists working on such topics in the United States, especially at the universities, is inadequate. Addressing this vital need requires an additional level of effort.
>
> Overall, the field of high energy physics faces several critical manpower and infrastructure problems. Declining graduate student support affects the intake of new physicists and therefore the future of particle physics overall.

The report gives no actual numbers (which, presumably are available, since the DOE and NSF should have counts of how many students they support each year), but, based on responses from a survey of university grant PIs, it says that the number of grant-funded RAs for HEP grad students has been decreasing, with, especially for theorists, student support having to come from TAs:

> The overwhelming response stressed that the level of (NSF and DOE) grant support for RAs for graduate students is insufficient and has indeed been declining over the last decade. At the same time, respondents noted that the cost of supporting a graduate student on a grant has increased, especially because of stricter university requirements regarding tuition remission and fringe benefits.
>
> As a result, particle physics groups routinely rely on other sources of funds for all or part of their graduate student support. One major resource is TA positions for particle physics students, addressed in more detail below. Some respondents noted that their universities have limited fellowship support for some students. A handful also mentioned seeking outside support from other federal agencies. Many said that they had been forced to turn away qualified students due to a lack of grant support. Some also indicated that students had turned down the chance to join a particle physics research group because other departmental areas could promise steadier RA support, rather than a mixture of TA and RA support…
>
> Survey respondents brought up several difficulties caused by this reliance on TA support. First, spending time as a TA slows senior students' research progress (increasing their time to graduation) and hampers experimental students' ability to travel to particle physics labs. Second, TA support is also currently a declining resource for particle physics at many institutions, because university administrations are providing less overall TA money to physics departments, departments are reducing the number of semesters any student may spend as a TA, or other physics subfields are requesting more TA slots. Third, if a particular research group (usually particle physics theory) makes unusually large demands on the available TA slots, this creates friction and resentment within the department as a whole.

The report has no mention at all of what the desirable level of particle theory Ph.D.s might be from a larger perspective. There is zero discussion of the relationship between how many such Ph.Ds are produced, and how many jobs doing particle theory research are likely to be available in the future. This is presumably because the authors are well aware that there remains a huge imbalance between the number of smart people getting Ph.D.s in this subject, and the number of opportunities for them to make a career in the subject. The reference to "friction and resentment within the department as a whole" over TAs makes clear what one of the main concerns driving this recommendation is. The amount of power and influence one's group has in an academic department, including prospects for being allowed to hire more people, is heavily influenced by how much grant money one brings in, especially how much funding for the graduate program one can provide. This is made even more explicit at another point in the report:

> Because of eroding support, more and more theoretical graduate students are being required to teach more and more of the time. This is unfortunate for at least two reasons: first, it lengthens the time to degree; and second, it signals to physics departments a hint of declining support for HEP research, exacerbating hiring worries.

While the report mentions the need to find some more money for postdocs (since those working on experiments will need to travel to Europe more often), it emphasizes support for grad students, not postdocs. It does this even though it is postdocs who are doing much of the most original work in the field, and the small number of postdocs (and junior faculty positions) is what makes career prospects for particle theory students extremely problematic. I can't even really make sense of this one paragraph from the report that deals with this:

> Given the choice between hiring more graduate students and taking on a postdoc, many faculty members will opt for the latter when faced with limited available

funding. However, while this may seem be the best solution in terms of immediate research workload, the long-term negative effects of this choice on the field as a whole are clear.

One of the most interesting things in the report is the set of numbers from survey responses about how many grant-supported theory researcher are working in which areas, and what hiring plans by area are for the next 5 years. Figure 3 on page 43 divides theory researchers into six categories, and gives counts for how many are working in each category now, how many expected in 2012. The number of string theorists is supposed to drop from 103 to 84, "field theorists" from 91 to 77, "model builders" from 88 to 70, and "QCD/Lattice QCD" from 50 to 41. "Particle phenomenologists" are supposed to increase from 188 to 194, and "astrophysicists and cosmologists" from 136 to 176. Obviously boundaries of these fields are unclear, especially since string theory in recent years has to some extent moved away from formal theory, with more people describing themselves as "string cosmologists", "string phenomenologists", "string-inspired model-builders", and much of the attention of the field devoted to trying to do QCD calculations with string theory.

If you take these numbers seriously, a grad student would be nuts to work on anything except cosmology or phenomenology, since all other subfields show about as many people leaving them as would be accounted for by retirements, so essentially no new hiring. My suspicion though is that these numbers reflect what departments say they would like to do, not what they will do. Most departments now say they want to hire in the areas of cosmology and phenomenology. But faced with the fact that competition for the best people in those areas is tough, and finding it much easier to get good people in other subfields, I suspect there will continue to be quite a lot of hiring in these other subfields, in string theory especially, which seems to be what looking at the latest data from the Rumor Mill shows.

Given the huge and supposedly increasing dominance of these numbers by the "particle phenomenology" category, the report's call for an urgent increase in funding to produce more phenomenologists is not so easy to understand. However, the authors make clear that what they want to see is more of a very specific sort of phenomenology: people working on things like event generators to precisely calculate standard model backgrounds for the LHC experiments, something which has always been more popular in the Europe than in the US. The recent NSF-funded "LHC Theory Initiative" is specifically designed to address this, and is being promoted with nationalistic calls to fight the "outsourcing" of these calculations to European theorists. The authors of the report are calling for more Ph.D.s in conventional, experiment-based phenomenology, not more Ph.D.s in string theory or "string phenomenology". They choose to do so, for obvious political reasons, not by calling for a reallocation of resources within the field of particle theory, but for new resources for this purpose, even if it will lead to a smaller fraction of particle theory Ph.D.s being able to find jobs doing the research they have been trained to do.

Comments

   July 27, 2007

   Can the creation of event generators really be considered "theory"? You get a Lagrangian from a model builder, plug it into an automated Feynman diagram package, obtain matrix elements ready to plug into a standard procedure skeleton, do a little debugging and testing, and presto, there's your new event generator. Is it "theory" just because you don't get to pull cables?

2. **Coin**
   July 27, 2007

   For example, there are only a handful of people in the U.S. working on computational physics, such as event generators.

   I'm not sure I understand this sentence. "Computational physics" means computer simulations of physics processes? What is an "event generator"?

3. **Peter Woit**
   July 27, 2007

   Coin,

   An "event generator" uses Monte-Carlo methods to, given a model (e.g., the Standard Model), generate "events" with statistically the expected properties, where the "events" correspond to, say, events at a collider. The way you test your model is to run these events through a further simulation of what they will do in your detector, then compare the Monte-Carlo results to your data.

   For perhaps the most well-known of these, see

   http://www.thep.lu.se/~torbjorn/Pythia.html

   AGeek seems to think that the development of this kind of software is not "theory", but I think many people would disagree, including some who would claim that AGeek's attitude is what's wrong with particle theory these days…

4. **Zathras**
   July 27, 2007

   So what justifies the huge increase in cosmology positions over the next 5 years? Is there a perception it has been neglected recently?

5. **AGeek**
   July 27, 2007

   I confess: I don't think that the development of event generators is theory. It's programming, and pretty elementary programming too, to the point that I don't see why it could not be completely automated, given an existing simulation framework.

   Surely an unwillingness to label trivial technical work "theory" is not the worst ailment afflicting particle physics these days? Some might say that the opposite is true…

6. **J**
   July 27, 2007

   More fundings for graduate students? Is this really gonna happen?

7. **LDM**
   July 27, 2007

   "The Role of Computation in Physics" By Bradley A. Shadwick in the January 2007 issue of Computing in Science & Engineering clearly and intelligently explains how computation fits into theory and what its limitations are.
   I would never consider computation or simulation to be physics theory per se (though Stephen Wolfram it would appear has a different, yet fundamentally misguided

view), but instead it is a potentially potent tool, which when wielded correctly, can do what all tools do – amplify our own feeble abilities, which in this case means help us solve equations.

8. **IMHO**
   July 27, 2007

   Peter said:

   > While the report mentions the need to find some more money for postdocs (since those working on experiments will need to travel to Europe more often), it emphasizes support for grad students, not postdocs…..I can't even really make sense of this one paragraph from the report that deals with this:

   For all of your insight regarding the health of the field, you sometimes seem naive with regards to politics. Money talks and you can't seem to see that you have won…..or maybe it was Smolin that won….either way, be gracious in victory.

9. **Peter Woit**
   July 27, 2007

   IMHO,

   I'd be curious to hear what you actually think about the politics. Whether or not my views on it are naive, I'm always interested in maybe learning something.

   I definitely noticed that at least this panel is not calling for more funding for string theory, but more funding for phenomenology and a redirection of most hiring to cosmology don't seem to me to be the answers to what ails particle physics. Seeing that already fewer theorists describe themselves as "field theorists" than "string theorists", and physics departments plan on reducing the number of field theorists further is rather discouraging…

10. **Alexey Petrov**
    July 28, 2007

    But faced with the fact that competition for the best people in those areas is tough, and finding it much easier to get good people in other subfields…

    Not necessarily. For instance, our department is (almost religiously) trying to hire a biophysicist. For several years. No success so far — and it is understandable — we don't have any yet and we are not Harvard (although we do have a decent Medical School). So it really depends on the way a particular department is run and on the vision of its administration/administration of the College, etc. Usually, however, it does not work to the advantage of HEP…

    And even people who used to be particle physicists, but now are astrophysicists (and there are many) do not help — their move from HEP to astro is viewed by other faculty as a sign that HEP is dying out and there is no point in investing in it by hiring more faculty.

11. **reply from a phenomenologist**
    July 30, 2007

    this is a reply to AGeek, who thinks that people who work on event generators are not really particle theorists.

    Of course this claim depends on one's definition of theorist. But let me point out that constructing event generators is much more than lagrangian + programming. There's a whole jungle of physics between the raw experimental data and inferring terms in a lagrangian, and experience shows that you need bona fide particle theorists to do the job. Experimentalists can't do it, string theorists can't do it. And hired programmers certainly can't do it. I appreciate this isn't obvious, but that's the way it is.

12. **AGeek**
    July 31, 2007

    Dear phenomenologist, it is certainly true that "There's a whole jungle of physics between the raw experimental data and inferring terms in a lagrangian", but that is not what building event generators is about. As I wrote, "You get a Lagrangian from a model builder". What you are describing is the job done by the model builder. Event generators are derivative work used to extract predictions from a Lagrangian provided by a model builder in a form directly comparable to experimental data: the information flow is the reverse of what you describe. (You may be thinking of Marmoset; that's something much more ambitious than I have in mind.)

    In principle, it is of course possible that somebody building an event generator also constructed the underlying model. Such a person would be model builder with a handy technical skill, comparable to being unusually good at doing integrals.

13. **Peter Woit**
    July 31, 2007

    AGeek,

    You're misinterpreting "phenomenologist", who was just pointing out to you that the relation between terms in a Lagrangian and experimental data is quite complicated, involves a lot of physics, and this is what event generators are all about. You seem to think that writing down terms in a lagrangian is non-trivial physics, whereas designing an event generator that allows you to compare these to experiment is "a handy technical skill, comparable to being unusually good at doing integrals". An equally good case could be made that writing down terms in a Lagrangian is "a handy technical skill", with the non-trivial physics requiring real knowledge and sophistication being the connection to experiment. Something leads me to suspect that you've written down terms in a Lagrangian, but have never written an event generator…

14. **AGeek**
    July 31, 2007

    Peter Woit,

    you are misinterpreting me, who am simply pointing out that the trivial technical task of building event generators does not involve sorting out the relation between terms in a Lagrangian and experimental data.

    Writing down any terms in a Lagrangian is indeed fairly trivial. The generation of all terms compatible with a given set of symmetries and other conditions can also be automated. Writing down terms relevant to our world without performing an exhaustive search of the entire theory space, now that's something which sets a Weinberg apart from a marmoset.

    BTW, your suspicion is incorrect. I have done both. It may interest you that I did the event generator thing before having ever laid eyes on a QFT textbook, simply by being a good geek and having a superficial, undergrad level understanding of particle physics. Unfortunately, it quickly became clear to me that the people doing it for a living did not have a knowledge of physics significantly beyond mine either. They had stopped learning and growing once they had found this little niche where they could provide a service in demand.

15. **Peter Woit**
July 31, 2007

AGeek,

Apologies for my incorrect suspicions.

My own experience though is that the phenomenon of people who have “stopped learning and growing once they had found this little niche where they could provide a service in demand” applies just as well in other much more abstract parts of the field.

16. **string theorist**
July 31, 2007

>It may interest you that I did the event generator thing before >having ever laid eyes on a QFT textbook, simply by being a good >geek and having a superficial, undergrad level understanding of >particle physics. Unfortunately, it quickly became clear to me that >the people doing it for a living did not have a knowledge of >physics significantly beyond mine either.

This is a shockingly arrogant (and narrow-minded) statement, if by `event generator’ you mean what is normally meant by an `event generator’, that is pythia, herwig, etc. Do a SPIRES search on people who do write event generators. events radiate in the initial and final states, jets are produced, partons shower to create more jets, hadrons decay. how many jets should you expect? how many hard? how many soft? how much missing energy how often? none of this is at all obvious from the Lagrangian.

That said, the kind of event generator someone could write without having done any QFT was indeed probably not a great achievement in particle theory.

Anyway, what next? those people who do multi-loop computations don’t do particle theory either, they just have a handy technical skill in doing integrals? and the cosmologists who do N-body simulations, maybe they should be reclassed as computer support officers, after all the real physics was all done by Einstein.

on the other hand: writing down a half-arsed model whose only virtue is that it hasn’t been ruled out yet; that, now that takes a *real* physicist.

17. **AGeek**
July 31, 2007

Dear “string theorist”, I think we are talking past each other.

First of all, how to handle parton showers, jets, hadron decays: it is perfectly true that “none of this is at all obvious from the Lagrangian”. Because, as you surely know, this all happens at strong coupling. So it’s handled by a phenomenological model motivated by, but not derived from, first principles. Essentially it’s a messy piece of code which parametrizes experimental data.

If you want to call this an “event generator”, then your statement that “the kind of event generator someone could write without having done any QFT was indeed probably not a great achievement in particle theory” is rather questionable. Because, as you point out, “none of this is at all obvious from the Lagrangian”, and little knowledge of QCD beyond an intuitive understanding of gluon strings stretching and breaking up goes into the code handling it.

Second, this hadronization stage is not something which you have to worry about every time you create an event generator. It’s encapsulated in the simulation framework which handles all the output from your event generators, by which I mean procedures working with elementary particles according to matrix elements derived from a Lagrangian. The typical job of creating an event generator consists in writing such a procedure, which takes a list of elementary particles as input and produces a list of elementary particles as output, and linking it into the framework.

18. **M**
August 1, 2007

I heard this same debate some years ago, when a young physicist expert of event generators sent a public letter to his influential collaborators writing something like: “my advisor warned me that developing event generators is not considered theory, so in order to get a position I need to stop our collaboration and move to something else.”

19. **locrian**
August 6, 2007

I’ve heard a number of people argue that studying high energy physics is a more reasonable career choice now because of the opportunities for employment created by the LHC. It seems to me, after reading the report and this post, that this isn’t true. The number of new permanent jobs created isn’t going to be significant compared to the number of graduates that are going to be produced.

In other words, rather than making the profession more healthy, the LHC may just give graduate students a more comfortable ride to nowhere.

In what way am I being too cynical?

The Fermilab Steering Group is about to come out with its report. Their roadmap for Fermilab proposes that if the ILC project is delayed "Fermilab should pursue additional neutrino and flavor physics opportunities", in particular with "Project X", a high-intensity proton linac. One of their remaining tasks is to pick a name for Project X.

In the category of magazine articles that I hear have just come out, but I don't have a copy of, and aren't available on-line, there's

- a cover story about the state of particle physics and string theory by yours truly in the latest Cosmos magazine
- an article about Lisa Randall in Vogue.

The talks at the recent Imperial College event in honor of Abdus Salam are now on-line. This is the event Steven Weinberg boycotted, but Gerard 't Hooft was there to talk about Salam and the state of theoretical physics. His talk was entitled "The Grand View of Physics", and is available here.

Among the recent large "'07" conferences with talks available on-line are:

- Loops '07, mainly on LQG.
- SUSY '07, mainly on supersymmetry.
- Lattice '07, mainly on lattice gauge theory. Blogging from Georg von Hippel, including a description of today's Creutz–Kronfeld celebrity deathmatch over rooted fermions.

   July 31, 2007

   Peter-

   Congrats on the COSMOS article–I believe that magazine is sold at my local Barnes & Noble and I'll look for this issue. By the way, I notice that Lee Smolin's book is now out in softcover. Are there plans for a softcover edition of your book?

6. **Peter Woit**
   July 31, 2007

   Sebastian,

   Cosmos is a well-known Australian popular science magazine, I'd be surprised if it's available in the US, but maybe it is. My book is also supposed to be coming out in softcover. I haven't seen any copies of that edition yet, but it should be out sometime in the next few weeks.

7. **Intellectually Curious**
   August 1, 2007

   Coin,

   I for one think that students actually do learn better from having to take notes at the same time the professor is writing on the blackboard. It builds discipline and helps them think (or at least remember the material). Young people nowadays who rely too much on technology also rely it to think for them. They don't know how to think anymore. It's sad.

8. **ObsessiveMathsFreak**

Interesting article on the state of string theory. I agree with the "It's a bust" side. People should remember that physics is just a model of reality. It is not and never will be reality itself. Reading "The Computational Universe" it's clear that to have a completely accurate model of the universe would require something with the size and energy of the Universe itself to run the model.

So on the end, a model is only as good as it's predictive ability, and simpler is better. String theory is neither simple nor does it produce a useful and new fundamental predictive ability. Even worse, string theory leads us to a conclusion that the universe is this way because this is the way God made it. That's great if one is seeking a physical proof of a divine being, but it's a complete dead end for modern physics.

So what's next? Or at least, what are the characteristics of what's next? Well, it should be simple in concept. String theory started out simple in concept, that everything was just vibrating strings of energy, but it's formulation led us to a point where even thousands of the brightest physicists and mathematicians can't completely understand it. Next, the theory must be modular or expandable. That is, as new concepts are understood, the theory must be capable of incorporating those new concepts without having to be completely reworked. Here I make the reasonable assumption that no theory will ever be a completely accurate model of the universe. If that's so, then new concepts will be formulated and proven as long as curious physicists draw breath.

Finally, no matter how simple or complex, restricted or free ranging, the model must provide new fundamental predictions that can be experimentally verified. In my own humble opinion, and in that of many in the field, this is (was?) the death of string theory. It turned out not to be a theory of everything, but a theory of anything. In order to give the theory the necessary degrees of freedom to back-predict things already known, it forward predicts things that are inconsistent with our known universe, and an almost infinite amount of them at that.

I don't know what the next theory will be, but looking through the literature I see several possible good candidates. My personal favorite is a quantum gravity theory that the universe is made up only of a continiuous fluid, perhaps a space-time fluid with no particle size. In that theory the particles we measure are only qualities of that area of the fluid. Those qualities can be represented by a field similar to a tensor field that that can be represented by a suitable sized matrix of terms which act on the fluid. From what I've read, it will still take extra dimensions of either time and/or space (an extra curled up dimension of time simplifies things greatly). But it should come as no surprise at this point that additional dimensions will be required to represent the degrees of freedom needed to model our universe. This is my current favorite because as additional concepts are proven they can just simply be added to the existing matrix creating an ever more accurate model.

In any case, string theory is dead. Long live the next greatest thing.

10. **dan**
August 1, 2007

Peter,
for those in the US without access to the Cosmo article, is there anyway we can read your article?

11. **locrian**
August 1, 2007

Heh, did no one notice? From the Cosmos webpage:

"Includes perspectives from leading experts, such as Michio Kaku, co-founder of string theory. . ."

Hahaha. The charlatans win again.

12. **Peter Woit**
August 1, 2007

dan,

Sorry, but I myself don't even have a copy yet of the magazine, in paper or electronic form, so I don't know what the edited version looks like, or what other people have to say. But as for my piece, what I sent them wouldn't be anything new to anyone who regularly reads this blog…

13. **Chan Tun**
August 1, 2007

> as Michio Kaku, co-founder of string theory. . ."
>
> Hahaha. The charlatans win again.

I'd almost agree with this, except I wouldn't call charlatan someone with more citations than I. At 2000+ citations, it's going to be some time before I have the arrogance of calling Kaku a charlatan. But I wouldn't bother to disagree if someone with the proper credentials called him so. The question, Locrian, is what you have to show in your record that outdoes Kaku's.

14. **Peter Woit**
August 1, 2007

Kaku wrote some of the early papers on string field theory, and thus has some claim to be a co-founder of string field theory. Unfortunately the "field" sometimes gets dropped by the press..

And please, stop the attacks on people as "charlatans" or whatever, it's obnoxious and just lead to pointless hostility, something this subject doesn't need more of.

15. **locrian**
August 1, 2007

Chan Tun,

That question of my record versus Kaku's is actually something that has been mentioned here before. It's something I'm quite comfortable with, for reasons that might not be obvious. However, it's also a terrifically inappropriate subject for Peter's Blog.

Kaku's designation as the "co-founder of string theory", on the other hand, seems an entirely appropriate subject. It speaks volumes about the way the media interacts with the scientific community and the public.

16. **ttn**

August 1, 2007

I had no idea Robert Stadler was working at Fermilab…

17. **Coin**
August 1, 2007

I for one think that students actually do learn better from having to take notes at the same time the professor is writing on the blackboard.

My comment was meant to be taken in the sense of "…as opposed to whiteboards".

Kaku wrote some of the early papers on string field theory, and thus has some claim to be a co-founder of string field theory.

Is string field theory in some way related to Ads/Cft, or otherwise something which might have ongoing uses as a mathematical construct even in the absence of string theory proper?

18. **Peter Woit**
August 2, 2007

String field theory has nothing to do with AdS/CFT. It's a field theory, where the fields are defined not on space-time, but on the infinite-dimensional space of open or closed strings in a space-time.

19. **ad**
August 4, 2007

Why did Steven Weinberg "boycott" the event held at the Imperial college in honor of Abdus Salam?

20. **woit**
August 4, 2007

ad,

His letter explaining this is available here:

http://www.engageonline.org.uk/blog/article.php?id=1036

21. **Maynard Handley**
August 5, 2007

"Coin,

I for one think that students actually do learn better from having to take notes at the same time the professor is writing on the blackboard. It builds discipline and helps them think (or at least remember the material). Young people nowadays who rely too much on technology also rely it to think for them. They don't know how to think anymore. It's sad.
"

Gee, if only there were a way to establish the truth or falsity of such beliefs? Some sort of objective method for probing whether assertions about the world are true or not. We could call it, I don't know, the scientific method, or experimentation, or something.

Isn't the whole problem with education that it is based on "I for one think that students actually do learn better…" rather than anyone (apart from Carl Wieman http://name99.org/blog99/?p=33) actually testing these hypothese?

22. **Arun**
August 6, 2007

Maynard Handley: I think we have to distinguish between what works on the whole versus what works for the best students, which is a priori not the same.

Another Journal Board Resigns

August 6, 2007
Categories: Uncategorized

Last year about this time the entire editorial board of the Elsevier journal Topology resigned, this August it's the turn of the Springer journal K-theory. The editors of this journal have all resigned, issuing the following statement:

> Dear fellow mathematicians,
>
> The Editorial Board of 'K-Theory' has resigned. A new journal titled 'Journal of K-theory' has been formed, with essentially the same Board of Editors. The members are A.Bak, P.Balmer, S.J.Bloch, G.E.Carlsson, A.Connes, E.Friedlander, M.Hopkins, B.Kahn, M.Karoubi, G.G.Kasparov, A.S.Merkurjev, A.Neeman, T.Porter, D.Quillen, J.Rosenberg, A.A.Suslin, G.Tang, B.Totaro, V.Voevodsky, C.Weibel, and Guoliang Yu.
>
> The new journal is to be distributed by Cambridge University Press. The price is 380 British pounds, which is significantly less than half that of the old journal. Publication will begin in January 2008. We ask for your continued support, in particular at the current time. Your submissions are welcome and may be sent to any of the editors.
>
> Board of Editors
> Journal of K-theory

The subscription cost for the Springer journal had been $1590, $1325 for electronic-only access.

I notice that while the editorial board of Topology has resigned, that hasn't caused Elsevier to stop publishing and selling the journal. While I'm sure that a recent paper copy of the journal that I saw did not carry the names of the editors that resigned, the online version of the journal appears to still carry the names of the old editors, giving no indication that they have resigned. As far as I know, Elsevier has not been able to recruit a replacement editorial board, but they are still selling the journal, at a yearly subscription price of $1665.

Update: Via the comment section, there's the related news that

- The Ecole Normale Superieure has chosen to no longer have Elsevier publish the journal Annales Scientifiques de l'École Normale Supérieure; the new publisher will be the non-commercial Société Mathématique de France. The Elsevier website states:

> As of 2008 no longer published by Elsevier, please contact publisher Societe Mathematique de France for details.

and, unlike the case of Topology, they appear to be no longer trying to sell subscriptions to the journal. Presumably the ENS controlled rights to the journal and its name so was able to simply remove it from Elsevier, unlike the case of the former editorial board of Topology.

- Bruce Bartlett reports that a wiki called MathSciJournalWiki has been set up, devoted to providing information about scholarly journals, especially in mathematics. Members of the math community are encouraged to contribute to it.

Update: It turns out that there may be more to this story. See in particular the comment posted here by Andrew Ranicki, who says that no papers submitted to *K-theory* since April 2006 have been forwarded to Springer, and that he and Wolfgang Lueck will be acting as interim managing editors for the Springer journal to sort out this situation.

Comments

1. **Coin**
   August 6, 2007

   As far as I know, Elsevier has not been able to recruit a replacement editorial board, but they are still selling the journal, at a yearly subscription price of $1665.

   What content, if any, has the journal contained during this time?

2. **milkshake**
   August 6, 2007

   Even if a journal withers, the publishers have copyright to journal archives and those will continue to be valuable source of subscribtion for many years to come. But something should be done now because the current scientific journal subscription rates are a bloody robbery.

   In related news, the profits from CD publishing is way down, the major music publishing houses are laying off their staff and/or are being sold for a fraction of their past market value.

   http://www.prospect-magazine.co.uk/article_details.php?id=9735

3. **DB**
   August 7, 2007

   Evidence of a many-journal theory and particularly apposite given:

   :))

4. **anonym**
   August 7, 2007

   Is there an 'official' publication of the letter ? The text, as cited above, does not even has a date. The homepage of A.Bak, the managing editor, has no reference to the letter.

5. **anon.**
   August 7, 2007

Scientific publishing can be a very lucrative business. The great Robert Maxwell made his first fortune from setting up scientific publishers Pergamon Press, whose journals had no limits on articles sizes (expensive page charges to authors institutions ensured that long articles were in fact most welcome).

http://news.bbc.co.uk/1/hi/business/1249739.stm

Of course, for readers, you end up with two types of problem:

(1) The journals either become filled with long papers from collaborations of authors who can share out the page charges, which drives out smaller groups and individual researchers from such journals as they can't afford to publish there, or alternatively:

(2) The publisher keeps page charges low but makes a fortune by selling the journal at an enormous cost, so the reader in an out-of-the-way place has extreme difficulty in seeing the journal at all.

Many college libraries only have a fraction of the total number of paper journals. To keep costs down, most journals are only available online over a university intranet, so the journals become subscription versions of arXiv. I think there's a problem here, since it's harder to study a lot of mathematics on a screen than in a printed journal. Hence the three internet layers:

*The www (no restrictions on authors or readers)

*Arxiv (authors endorsed by peers; no restriction of readership)

*Online paid-for journals (papers restricted by peer-review; readership restricted to academic institutions, etc., which pay for access)

So the more money the poor reader in Outer Mongolia has to pay in order to read your scientific paper, the more elite and respectable you become as a public-spirited scientist!

6. **Peter Woit**
August 7, 2007

anonym,

The letter was an e-mail dated Monday August 6 from Anthony Bak, forwarded by Dan Grayson to the K-theory announcement mailing list that he manages.

7. **Bruce Bartlett**
August 7, 2007

Dear fellow concerned academics,

This is great news!

There have been some discussions going on at the n-category cafe and elsewhere, discussing whether the community should run a wiki devoted to math and physics journals, aiming to fight back against the greedy practices of the large publishing comglomerates by exposing their awful prices and policies.

If you think the time is ripe for a "MathSciJournalWiki", then pitch in a hand and help out! The current embryonic site can be found here. So far it has accessed the data from the AMS survery in 2004.

I've just added this great news about the editors of K-Theory resigning to the front page of the site. But I'm an awful HTML coder, and I'm sure one of you could improve things.

Remember, it's a wiki. We're all in this together, we all contribute as equals. *You* are in charge of the site!

8. **Laurent**
August 7, 2007

Dear Peter,

You should notice too that the "Annales de l'école normale supérieure" have stoped their publishing with Elsevier. Here is part of an email I recevied a few months ago
"'J'ai le très grand plaisir de vous annoncer que l'Ecole Normale Supérieure, après avoir dénoncé le contrat avec Elsevier concernant l'édition et la diffusion des Annales de l'ENS, a signé un nouveau contrat de partenariat avec la SMF"
I would have difficulties to transalte "dénoncé le contrat" in english but this means the contrat has been volontary broken. Starting in 2008 they will be edited by the SMF, a nonprofit association (not a firm) and (knowing the usual prices of the SMF) this will be much cheaper !

9. **Peter Woit**
August 7, 2007

Thanks Bruce and Laurent,

I'll add the news from you two to the main posting.

10. **anonym**
August 7, 2007

Thanks for the clarification.
It is funny, though, that Geometry&Topology (and some others)
journal has become non-free meanwhile, approximately at the same time when Topology moved to a different publisher.

And it is funny that on Topology&Geometry old website the papers are still downloadable for free; on the new one, they are not (and it has no link to the old website, and no link to arxiv publications).

At the same time, we are changing the price structure and access to our journals. The journals were started by a group of enthusiasts who dedicated their time freely. For long-term stability of the journals, this group of enthusiasts is gradually being replaced by permanent paid staff. The income generated by subscriptions in the presence of a free on-line version was not sufficient to cover this new structure and we have been forced to start to charge for on-line access. However all our publications will continue to be stored in the arXiv and therefore freely available to individuals. However access to our main sites will only be allowed from an IP address in a subscribing institution. All readers are encouraged to persuade their libraries to take out electronic subscription. Electronic access will be open and free for all publications after a *period of two years*.

11. **Bruce Bartlett**
August 7, 2007

Hi Peter,

It's great news to hear about the Annales Scientifiques de l'École Normale Supérieure now being published by a non-commercial society. Thanks a lot for adding the link to the MathSciJournalWiki to the main section. I think I'd prefer it if it said something like "Bruce Bartlett reports that a wiki about mathematics journals has been setup, where any member of the mathematical community is free to contribute skills or ideas", the idea being that it's a wiki, and that it's run by the community.

12. **woit**
August 7, 2007

OK, Bruce, I changed the wording. Good luck with that project!

13. **bob**
August 7, 2007

Presumably there are still articles in the pipeline that were accepted under the current Editorial Board, which may make it dicey for libraries to cancel *K-Theory* immediately. This may also be why Elsevier is able to publish *Topology* under the names of the resigned Editorial Board.

14. **Alexey PEtrov**
August 7, 2007

Putting papers on ArXive would not solve the problem, as they are not peer-reviewed (one can start a standard discussion on whether or not one needs peer review). There are other possibilities — keep journal on-line only (see JHEP) or keep per-page charges, but let the authors keep the copyright and distribute the journal free (see Advances in High Energy Physics from Hindawi publ.).

15. **Henry Walloon**
August 7, 2007

University research is, in part, funded by the tax payer.

There seems a basic issue of fairness to demand that the interested amateur pay again to be allowed to read the consequences of his or her investment.

The point by Alexey about the need to preserve peer review is a good one however.

16. **Coin**
August 7, 2007

Alexey, is there some obvious way that an Arxiv-like system *with* peer review could be organized? My understanding is peer reviewers have to be paid; how much of a journal's operating costs does this make up? Would there be any value in taking a system like the Arxiv with free publication and tacking on the ability for peer review to be provided for some kind of fee?

17. **A.J.**
August 7, 2007

Coin,

Peer reviewers are generally not paid, not in any sizeable amounts. People peer review because a) it's essential to scientific progress, and b) the system does not work if no one peer reviews.

18. **David Savitt**
August 7, 2007

The news about K-Theory and Ann. Sci. ENS is heartening, but I'm concerned that at least in the short term this will increase total subscription costs for university libraries rather than decrease them. Many or most university libraries have package subscriptions to major publishers such as Springer and Elsevier, and I have a hard time imagining that the Elsevier price will go down when Ann Sci ENS is dropped from the package (or do I not understand how these packages work?); in the meantime we will need to purchase a new, separate subscription from the SMF. One plausible outcome might be that my library is not able to afford the separate Ann Sci ENS subscription, or at least that it will make it much easier for the library to cancel Ann Sci ENS at some future moment of belt-tightening. So I am nervous. If this is indeed a problem, could various national professional mathematics organizations consider forming a consortium and offering a journal subscription package in the way that major publishers do?

19. **Matt Daws**
August 8, 2007

Following David Savitt's comment, I have a similar worry. Many of these big journals now have "electronic-only" options, where the subscribing institution gets electronic access, but only while they continue to subscribe. I always thought these were dangerous, as obviously if you cancel your subscription, you loose everything. It's a pain to have to go and look at paper journals, but as a pure mathematician working in a slightly unfashionable field, I find myself doing this a lot anyway. I guess many libraries thought that with big names like "Topology", the odds of wanting to cancel the subscription were low. We don't know what Elsevier will do with Topology, but it's quite possible it will continue, but as a much weaker publication. Some universities might loose a lot if they cancel their subscriptions.

This said, the LMS recently moved their publications to Oxford University Press, and they have provided full electronic access to all the past issues (I believe, many of these were scanned and converted by OUP). But then the LMS moved from CUP to OUP in, I guess, convivial circumstances.

20. **Bee**
August 8, 2007

Hi Peter,

Off topic, but thought you'd be interested: The recent New Scientist issue has a nicely written article about neutrinos which says:

Last year Päs, who is based at the University of Alabama in Tuscaloosa, together with Sandip Pakvasa of the University of Hawaii in Honolulu and Thomas Weiler of

Vanderbilt University in Nashville, Tennessee, looked at neutrinos from the perspective of string theory. This led them to suggest that sterile neutrinos, unlike most of the particles and forces that we see, can take short cuts through one of the normally invisible higher dimensions that string theory provides for, and so appear travel through time (NS, 20 May 2006, p 34).
Their model indicated that if a sterile neutrino time-travelling through extra dimensions has an energy that lies in a particular range, if will flip into a normal neutrino ([hep-ph/0611263](hep-ph/0611263)). "We published a graph predicting just the excess of electron-neutrino events at low energy observed by Miniboone," says Päs.
So does this, or one of the other possibilities opened up by Miniboone, mean that it has caught sight of the theory of everything that will, everyone hopes, one day unite the fundamental forces?

(typos are entirely mine).
From [*Neutrinos: The key to a theory of everything*]() (access restricted).

What do you think about that?

Best,

B.

21. **woit**
August 8, 2007

Bee,

I did see that, but New Scientist articles with over-hyped claims about physics that invoke string theory are just too numerous to take the time to discuss, so I'm mostly just ignoring them.

As for this particular speculative idea, it also seems best to ignore it. I'd wait to see if there's any confirmation of the excess of events at low energy seen by MiniBoone, and even then, I strongly suspect there will be a less exotic explanation of the phenomenon than new kinds of particles travelling through extra dimensions…

Personally I'd really rather continue to ignore this, but if someone has an intelligent comment about this that they must share, please do so not here (where you would be interfering with an interesting discussion of another subject), but at the next posting, which should appear soon…

22. **Bee**
August 8, 2007

Hi Peter:

Thanks. I agree on the 'exotic' explanations. It's interesting though there is such a large a market for this. Conservatism doesn't seem to sell well these days. Otoh, maybe it would be misplaced in NEW scientist. Best,

B.

23. **Alexey Petrov**
August 8, 2007

Coin:

As A.J. said already, referees are not paid for their services. As far as I know from my limited experience, members of the Editorial Board are not paid either. The main costs of online journals are associated with running the servers, processing contracts with subscribers, and paying to people who do all those technical things. I think the closest thing to "peer-reviewed ArXiv" is the Journal of High Energy Physics (JHEP). It does require subscription fees (which are infinitesimal compared to Elsevier's ones). Also, all of the accepted papers are available on ArXiv, which is nothing but a "virtual" preprint storage facility (supplemented by the "endorsement system").

24. **John Baez**
August 13, 2007

Peter –

I think if you talk to some of the other editors of *K-Theory* (not the managing editor), you'll get a much more strange and disturbing story about what actually happened here.

25. **Andrew Ranicki**
August 13, 2007

Statement on K-theory

========

In January 2007 the editors of "K-theory" resigned, following a request by the then managing editor Professor Anthony Bak. As announced in August 2007, some of them are intending to start a new "Journal of K-theory" to be published elsewhere. Unfortunately no manuscripts submitted to "K-theory" have been forwarded to Springer by the managing editor, since April 2006. We have been asked by Springer to act as interim managing editors, in the first instance to deal with these papers. We ask authors who have submitted papers to "K-theory" which have not yet been published to please contact one of us as soon
as possible.

Wolfgang Lueck (Muenster) lueck@math.uni-muenster.de
Andrew Ranicki (Edinburgh) a.ranicki@ed.ac.uk
13th August, 2007

26. **robin2**
August 14, 2007

A number of years ago my wife temped for a while at one of Elsevier's offices. She couldn't understand why academic journals used publishers *at all*. Obviously the contributors don't get paid, and as has been pointed out generally neither do the reviewers nor the editors. So all the publishers are really doing for their money is acting as intermediaries between the editors and the printers.

27. **Syksy Räsänen**

August 14, 2007

Commercial journals are indeed redundant. Alternatives for open and free journals have been discussed on CosmoCoffee at

http://cosmocoffee.info/viewtopic.php?t=276 and

http://cosmocoffee.info/viewtopic.php?t=280 .

A pilot project, RIOJA, has already been set up:

http://cosmocoffee.info/viewtopic.php?t=826 .

28. **Dylan Thurston**
August 16, 2007

In principle journals are also supposed to do copy-editing, which they have to pay for. In practice most commercial journals manage to severely degrade papers by copy-editing them. Geometry and Topology, on the other hand, does a great job with copy-editing in my experience, which may explain why they had trouble covering their costs.

Various Stuff

August 8, 2007
Categories: Uncategorized

As anthropic pseudo-science spreads through the particle theory community, I'm finding it harder and harder to tell what's a joke and what isn't. Maybe I'm wrong, but I fear that recent examples from hep-th contributors and prominent physics bloggers aren't actually jokes, largely because if they are, they're not funny.

The book Universe or Multiverse?, based on a series of Templeton Foundation supported conferences, and published by Cambridge University Press, is finally out. It's edited by Bernard Carr, whose ventures into pseudo-science include not just this, but a stint as director of the Society for Psychical Research. He's also on the board of directors of the Scientific and Medical Network, where his blurb tells us that:

> My interests span science, religion and psychical research (which I see as forming a bridge between them)… My approach to the subject is mainly theoretical: I'm particularly keen to extend physics to incorporate consciousness and associated mental and spiritual phenomena.

The memoir by Jane Hawking that I recently wrote about contains her recollections of both Don Page and Bernard Carr (since they worked with Hawking).

I just ran into my editor at Cambridge University Press, who found that opposition from string theorists made it impossible for Cambridge to publish my book a few years ago, with one of their arguments being that doing so would damage the reputation of the Press. Publishing pseudo-science like this however seems to be fine. Yes, I'm aware that this book also contains criticism of anthropic arguments, and probably has some of the most intelligent and informed writing on the subject, but still… I suppose I should get a copy of the book and write a review (I've already read many of the articles, they're available as preprints on-line), but the thing costs $85, the Columbia library doesn't have a copy, and I'm not sure I should encourage them to buy one.

This week's string theory hype: Universe's Stringy Birth Revealed by Young Czech Physicist, which is not about Lubos Motl, but about an award to Martin Schnabl. Schnabl's work on string field theory is one of the more interesting recent results in string theory, but the title of the article is, well, complete bullshit.

There will be an opening celebration in October for the Berkeley CTP, which was founded a few years ago and recently moved into renovated quarters. The BCTP is just one of a bunch of other CTPs that have been founded in recent years, including the MCTP and the PCTP (and one dead one, the CIT-USC CTP). The center's web-site and opening conference appear to be heavily dominated by string theory, quite a change from a few years ago, when Berkeley was one of the leading US physics departments where string theory was not so dominant.

The PCTP has begun construction of its new home in Jadwin, the physics building at Princeton. Artist's renderings are here. An art historian friend once told me that the proper technical name for the architectural style of Jadwin was "brutalist". The new construction will add lots of glass, perhaps mitigating the "brutalism". The large Calder featured in front of the building is called "Five Disks: One Empty", and it has its own rather brutal history. It collapsed during construction, killing two of the men working on it. According to a local Princeton web-site:

> The steel structure has four disks, one of which was originally painted orange, in a fervor of enthusiasm for the school's colors. The structure was named "Many Disks: One Orange," but then all of them were painted orange in anticipation of the artist's visit in 1971. Upon seeing the structure, he asked that all the disks be painted black, and renamed it to its current title.

Over at SciTalks August is String Theory Month, and they'll have Jonathan Shock as guest blogger later in the month.

At the Stony Brook YITP, the fifth of a series of workshops funded by Jim Simons on mathematics and physics, but mainly devoted to string theory, is now going on. Talks are online here.

Some online conference summary talks that one might want to take a look at are those of Michael Dine at the IAS PITP summer school, and John Ellis at SUSY 07. Both Dine and Ellis discuss prospects for observing supersymmetry at the LHC. Dine lists some of the reasons one might be skeptical that this will happen, including string theory anthropic landcape arguments (he avoids using the term "anthropic principle", insteard referring to it as "NBN, that principle which cannot be named"). Ellis recalls his own role in the "discovery" of supersymmetry by UA1 back in 1984, indicating it's likely that there will be such premature claims again at the LHC if anything at all anomalous is seen by the experiments. He also discusses the possibility of searching for long-lived particles produced at the LHC by using the muon system to locate where they left the detector, and then taking core samples of the surrounding rock to look for them.

For some excellent detailed postings about recent experimental HEP results from Tommaso Dorigo, see here and here. For blogging from CHARM 07 by Alexey Petrov, see here.

David Vogan has a wonderful expository piece about the recent heavily publicized results on the representation theory of E_8; it's intended for a future issue of the Notices of the AMS.

The September issue of the AMS Notices is now available. It includes an article about "Higgs Bundles", a version of the Higgs that physicists won't really recognize, and a book review of Lee Smolin's The Trouble With Physics. The review is quite positive about the book and mostly a straight-forward summary of what it is in it. The reviewer, like many mathematicians, had been misled by a lot of the hype about string theory, and so found Smolin's book quite enlightening. In particular, about M-theory, he writes:

> This explanation was, to me personally, a great shock since I had always believed M-theory was a complete theory.

Comments

1. **reader**
   August 8, 2007

   The book review you mention has an amusingly unconventional view of the job market in particle theory. Writing about Smolin's seers, it says

   "still others have jobs but are taking risks with their careers for the future of their science ('t Hooft and Penrose)."

   That 't Hooft and Penrose needed to fear for their careers was not something that had previously crossed my mind….

2. **Bee**
   August 8, 2007

   what bothers me is not if people have interests that go beyond science, and include psychology, religion, mountain climbing or blogging, but if they mingle up fact with fiction and blur the border between knowledge and believe.

3. **Peter Woit**
August 8, 2007

reader,

The reviewer does get a few things wrong, and if it were a review of my book and not Smolin's (which would be more appropriate, since mine was partly aimed at mathematicians, he whines…) I'd take the time to write about them.

4. **???**
August 8, 2007

I read the link about "Universe's Stringy Birth Revealed by Young Czech Physicist".

Do I understand correctly that hep-th/0511286 won an EURYI award and that "Most awards are between €1,000,000 and €1,250,000, comparable in size to the Nobel Prize"?

5. **prague_phys**
August 8, 2007

Martin Schnabl: Actually here in Prague we are very happy that somebody from Czechia got this prestigious prize. We are even more happy that it is not Lubos Motl.

6. **Peter Woit**
August 8, 2007

Bee,

It seems to me that Carr doesn't see his interest in religion and psychic research as hobbies distinct from his professional interest in science, but rather they are to him all related things, and he's interested in bringing them together and blurring the distinctions. This blurring of science with non-science is something that physics traditionally didn't tolerate, it's a shame that this is changing.

7. **DB**
August 8, 2007

Peter Woit wrote:

> This blurring of science with non-science is something that physics traditionally didn't tolerate, it's a shame that this is changing.

Why so many mainstream physicists remain silent about the public thrashing that physics is receiving at the hands of the snake-oil salesmen of string theory is the great mystery to me. Most physicists I know love their subject deeply, and yet seem content to bury their heads in their textbooks or fiddle about in their labs while Rome burns. Cowardice? A desire not to wash dirty linen in public?
Earlier you called the title of an article "complete bullshit". That's the kind of forthright comment Richard Feynman might have made.
I don't know whether Sean Carroll had his tongue in his cheek when he wrote that drivel. But he was probably sitting at Richard Feynman's desk in Caltech when he wrote it. Makes you think, doesn't it?

8. **Someone**
August 8, 2007

To ???:

Yes, the press release implies that the amount is comparable to that of a Nobel Prize but it's really an unfair comparison.

The Nobel Prize gets wire transferred to your bank account.

A research grant gets sent, usually a little bit at a time for several years, to your University or Institute which, after taking a 50%-ish cut, lets you use the money to hire graduate students and postdocs, but definitely not to put into your bank account.

Still it enough money to start a very healthy research group (especially with European postdoc salaries as small as they are!).

9. **???**
August 8, 2007

thank you. Still it looks surprising: hep-th/0511286 has only 40 citations.
Our friend Lubos wrote hep-th/0601001: another czech string theory paper with 40 citations: does he deserve €1,000,000?

10. **Cecil Kirksey**
August 8, 2007

Peter:
Your comment about pseudo-science fits in very nicely with a subject that I have been thinking about lately: What constitutes a valid scientific question? Forty years ago asking what happened prior to the big bang was NOT a valid physics question, but now it seems that it is. Does God exists? Not valid. A 100 hundred years ago: what mechanism gave the sun all its energy? Get the idea? Does the validity of the question vary with time? If so at what point does the question transition from being a non-valid question to a valid question? I have read basically that the question should be open to prove or disprove. Does ignorance about how to proceed to prove or disprove a statement mean the question is valid or not valid? Thanks for your and other commentors thoughts.

11. **Coin**
August 8, 2007

This blurring of science with non-science is something that physics traditionally didn't tolerate, it's a shame that this is changing.

Just out of curiosity, do you feel the same way about Roger Penrose and his recent adventures in "quantum consciousness" with Stuart Hameroff?

12. **Peter Woit**
August 8, 2007

Cecil,

A question is a scientific question if possible answers to it can be (at least in principle) put to a convincing experimental test. There are lots of subtleties one can get into, but the anthropic landscape pseudo-science doesn't involve them, it just inherently produces either no predictions or wrong ones.

I'm thoroughly sick of having to endlessly go over the kinds of scientific methodology 101 questions we normally teach elementary school children, just because some people are trying to argue about methodology in order to evade the overwhelming evidence that their scientific research program has failed.

Unless someone has something particularly new and intelligent to say about this issue, please discuss it elsewhere.

13. **Bee**
August 8, 2007

Hi DB:

Most physicists I know love their subject deeply, and yet seem content to bury their heads in their textbooks or fiddle about in their labs while Rome burns. Cowardice? A desire not to wash dirty linen in public?

I've made the same experience. It's a shoulder shrugging that upsets me very much, but one that is not restricted to physics or science but seems to be a more general phenomenon. People look at me and say 'that's just the way things are' without even considering that they might be able to influence the direction in which we are drifting. Look at politics. Different questions, same problem. People focus on their own work, and miss the big picture. They are aware of the problems, but ironically are too busy to change anything about it. Maybe even too busy to think about it.

But there's no higher power that will ensures quality of research. It's due to us. If we don't care, if we don't criticise, if we passively take what we get and adapt to it, we will go down with that ship. That's one of the reasons why I think Peter's blog is useful. One can share or not share his disliking of string theory, but he's reliably taking track of things, has an opinion and doesn't keep his mouth shut. That's also why I think Lee's book is important: to remind us that we should think about what science is, and what it should be.

I spend a lot of time trying to understand other people's works, and I'm not exactly polite if I come to the conclusion that it doesn't make sense. Various people have pointed out that I am wasting my time with that. Maybe they are right. In a career-wise sense. But I have the impression we're running into a situation where more and more people are writing more and more things that nobody really can or wants to follow, yet nobody cares. It only takes a critical amount of people who cite each other and a vague untopic can inflate exponentially.

Best,

B.

PS: Some more thoughts on the above here.

14. **Peter Woit**
August 8, 2007

Coin,

I don't know anything about Penrose/Hameroff, and the relation between quantum theory and consciousness is not something I personally have any interest in thinking about. Surely there is lots of flaky, unscientific work in this area, but I'm not about to spend my time learning about it, figuring out what is flaky and what isn't, and writing about it until it starts dominating particle theory research. There's a large number of such topics that I intend to keep ignoring, and to keep encouraging people to discuss not here but elsewhere.

15. **Kea**
August 8, 2007

This blurring of science with non-science is something that physics traditionally didn't tolerate…

Hmmm. Perhaps excluding Newton, Leibniz, Einstein, Penrose, Wigner (who has commented on the need for a consciousness theory underlying QM) ……. Your attitude is very indicitive of the narrow mindedness of scientists in the Age of Business, and clearly not based on having actually studied the research in question.

16. **Cecil Kirksey**
August 8, 2007

Peter:
Please do not get hyper! I clearly understand that what is sufficient for a valid scientific question is: can it be proved or disproved by some experiment or observation that by the consensus of the community is possible. However, I was more interested in the time issue. Does a question today that is deemed invalid become valid as scientific progress is made? If so what determines this transition? This I beg to differ is not taught in science 101 or I would not be asking the question. Just think about pre-big bang physics. Is this valid now and not valid 40 years ago?

17. **Peter Woit**
August 8, 2007

Cecil,

Our understanding of physics changes with time, so do our experimental techniques. As these change, some questions become scientific ones. For pre-big bang physics to be a scientific issue, you have to come up with potential experimental tests, even indirect ones. I haven't seen any convincing arguments for such tests. People are welcome to try to turn this into a scientific question, others are welcome to ignore them if they think they're getting nowhere.

18. **LDM**
August 8, 2007

I agree with Bee…

I am only a little unclear as to why the book "Universe or Multiverse?" should be singled out.
String theory is not testable and likely never will be, hence ANY book, article, or preprint on it must at worst be considered pseudo-science…or in the most charitable case, mathematics.

19. **Peter Woit**
August 8, 2007

LDM,

“String theory” is a varied and complicated subject. Most of it is not pseudo-science, although a lot of it is probably just wrong science.

Anthropic pseudo-science has gotten a big push from string theory, but string theorists are far from the only ones engaging in it. Personally I feel it is a much more dangerous phenomenon than string theory: having a scientific field dominated by work on a wrong idea is bad, having it dominated by work that has simply given up on science is worse.

20. **Yatima**
August 8, 2007

Does a question today that is deemed invalid become valid as scientific progress is made? If so what determines this transition?

INSUFFICIENT DATA FOR A MEANINGFUL ANSWER

(From an Asimov story called ‘the last question’ I think)

The relation between quantum theory and consciousness is not something I personally have any interest in thinking about.

I would say this is a healthy attitude as QM/C arguments never make it seriously past the first strawman. Marvin Minsky’s handwaving explanations are still good enough at the current level of knowledge. But now back to fundamentals…

21. **gunpowder&noodles**
August 8, 2007

Regarding Sean Carroll’s post: are you saying that you don’t believe in the “Sensible Anthropic Principle”? Surely not?
SC thinks about these things because he is interested in the arrow of time. This is a major, major feature of our world about which we understand essentially squat. Understanding this thing is real physics, and I find it very hard to understand why you would be opposed to this. On the other hand, you got all excited about Ed Witten’s excursion into science fiction — that nonsense about three-dimensional spacetimes. Now *that* is bullshit! The probability that we will learn anything useful about our universe by studying 3-dimensional spacetimes is laughably small — and I’ m leaving aside the obvious disconnect from anything even remotely falsifiable. SC’s investigations are hard science by comparison.

That there is a lot of crazy stuff out there is obvious. But it really doesn’t help to have the attitude that anything that looks strange must be pseudo-science. I think you are being unfair to SC.

22. **Peter Woit**
August 8, 2007

gunpowder,

Very specifically, what struck me was the end of Sean’s posting:

“The post-Big-Bang lifespan of the universe is very plausibly infinite. And yet, we find ourselves living within the first few tens of billions of years (a finite interval) after the Bang.

That last one deserves more attention, I think.”

which I still find hard to believe is not a joke.

Sure, I think the probability of Witten’s work on 3d gravity providing real insight into the 4d world is infinitely greater than the probability that thinking about this question will lead to any sort of scientific insight.

23. **AngryPhysicist**
August 8, 2007

Gunpowder wrote:

*Now *that* is bullshit! The probability that we will learn anything useful about our universe by studying 3-dimensional spacetimes is laughably small — and I’ m leaving aside the obvious disconnect from anything even remotely falsifiable.*

Perhaps, but quantum gravity simplifies drastically in 2+1 dimensions.

For example, the Riemann tensor linearly depends on the Ricci tensor (if I recall correctly; I’m writing this from the middle of nowhere on my laptop!). See Steve Carlip’s book [Quantum Gravity in 2+1 dimensions] for details.

Also, additionally, the free bosonic string is Lorentz covariant in 2+1 dimensions.

The constraint equations in canonical gravity, from my understanding (again, if I recollect correctly!), is far simpler than they are in 3+1 dimensions.

This allows us to think more qualitatively about the problems posed to us by quantum gravity, e.g. the problem of time, etc. I do not know about you, but I would much rather deal with simplified equations that allow us to think about the more interesting parts of quantum gravity.

Compare this to merely doing the mechanics and monkeying around with nonlinear equations.

I’d rattle on more, but as I have said, I’m writing this in the middle of nowhere.

24. **Dr. E**
August 9, 2007

Since the publication of TTWP and NEW, it seems pseudoscience has augmented and advanced with a new boldness. Is this right? I did not expect this. What might be possible explanations? Has all just been in the pipeline? Or have they gained newfound courage, as they have found that NEW and the TTWP didn’t affect the funding nor press?

Just wondering what everyone thought. And where is it all headed?

25. **csrster**
August 9, 2007

"The post-Big-Bang lifespan of the universe is very plausibly infinite. And yet, we find ourselves living within the first few tens of billions of years (a finite interval) after the Bang.

That last one deserves more attention, I think."

Is that so ridiculous? We are apparently living in a dark-energy dominated universe at a time when the ratio dark-energy/non-dark-energy is of order one. Doesn't that require an explanation? And isn't there even a fairly obvious one that a much older universe would be too tenuous to support life?

26. **gunpowder&noodles**
August 9, 2007

""The post-Big-Bang lifespan of the universe is very plausibly infinite. And yet, we find ourselves living within the first few tens of billions of years (a finite interval) after the Bang.

That last one deserves more attention, I think."

which I still find hard to believe is not a joke. "

I guess the point is that: we find ourselves on a rock because life is not possible elsewhere. Carroll is perhaps speculating that the fact that we find ourselves so early in the history of the universe is evidence that the late universe is hostile to life.

I would agree with you that this is not really an interesting question. What happens to the arrow of time in the remote future, by contrast, is a very interesting question because thinking about it may throw some light on the whole gigantic mystery of where the arrow comes from anyway.

"Sure, I think the probability of Witten's work on 3d gravity providing real insight into the 4d world is infinitely greater than the probability that thinking about this question will lead to any sort of scientific insight."

Well, we'll see. I'm *very* confident that this work will sink without a trace. Well, it might eventually get cited by other lost souls working on 3D "physics", but that will just prove my point. 3D is just so utterly different from 4D that parallel universes seem tame by comparison. Try telling a differential geometer that you are studying 3D manifolds because you are confident that this will tell you something about Seiberg-Witten theory….

Still, you may be right, in which case it will be shown that thinking about questions that seem to be wildly irrelevant to real physics is a good thing to do. SC is doing that very thing, is he not? Why is it ok for Witten to think about other universes — and 3D universes are about as "other" as they come — and not for other people?

27. **Mark Hillery**
August 9, 2007

In regard to the "Centers for Theoretical Physics," it would be nice to see a little truth in advertising. The ones at Berkeley and Michigan (at least from a quick perusal of its web site), and the defunct Caltech/USC one concern (or concerned) themselves only with theoretical high-energy physics and cosmology. These subjects are only a small subset of theoretical physics. The Princeton center seems to have members who are interested in condensed-matter theory and biophysics, and is, therefore, more broadly based. If you are going to have a center that studies only high-energy theory and cosmology, call it a center for high-energy theory and cosmology, not a center for theoretical physics.

As a Berkeley graduate, I was particularly disappointed when they set up their center to see that it would be so narrowly focussed. Why no condensed-matter theory? It also could have been a good opportunity to branch out into new fields. For example, there is excellent work going on in the computer science and chemistry departments there in theoretical quantum information, but not much in physics. It might be useful for the physicists to find out what is going on in this field at their own university.

All of us tend to be somewhat parochial in our views, but let's not enshrine our parochialism in the names of institutions.

28. **Ted**
August 9, 2007

Peter:

Your description of David Vogan's expository piece on E8 as "wonderful" is an understatement. For us amateurs who are trying to understand this magnificent edifice of mathematical physics at the beginnnig of the 21st century, these toss-off links that you provide are pure golden nuggets.

I thank you.

29. **Peter Woit**
August 9, 2007

csrster,

I don't see how you read the "coincidence" problem of the dark matter/dark energy ratio being of order one into what Sean wrote. But in any case, if for some reason that was what he actually meant to say, characterizing this as "deserves more attention" would be rather bizarre since it's one of the most well-known problems in cosmology.

30. **Bee**
August 9, 2007

Hi Dr. E,

What does the E stand for? Enlightenment?

Since the publication of TTWP and NEW, it seems pseudoscience has augmented and advanced with a new boldness. Is this right? I did not expect this. What might be possible explanations? Has all just been in the pipeline? Or have they gained newfound courage, as they have found that NEW and the TTWP didn't affect the funding nor press?

Just wondering what everyone thought. And where is it all headed?

I think your perception is incorrect. What I notice – and what I welcome – is that there is more discussion about the question what is science, pseudoscience, and where we are headed. I find that a healthy development. I hope there will be a practical outcome of that which allows researchers to refocus their efforts on real science, and not to waste time on politics, networking, or advertisement. One has to ask why pseudo-scientific ideas gain popularity. Because they are cheap to produce and they sell well. It's the Walmart of science. You get everything, it looks okay, but if you try to use it will fall into pieces.

Best,

B.

31. **Peter Woit**
August 9, 2007

B. and E.,

I think B. is right that the publication of the two books has definitely intensified the discussion of and raised awareness about the issue of the problematic state of string theory. As far as string theory propaganda to the general public goes, there's definitely less of it, and science journalists in particular are much less likely to report unskeptically string theory hype. String theorists are well aware that they don't have much of a counter-argument against the arguments of the two books, so they have chosen to mostly keep quiet and hope the controversy dies down. Within physics departments in general I think there also is more skepticism about string theory (often unfortunately taking the form of generalized skepticism about any kind of formal or mathematical theory) and a preference for work that is "phenomenological" and uses little mathematics.

Among the powers that be in the particle theory community, my impression is that the overwhelming sentiment is that doing anything about the problems laid bare by what has happened over the last twenty years is just too painful a prospect, that it would damage too many people's interests and entrenched ways of thinking and doing business. Instead, people are putting all their hopes in the idea that the LHC will soon solve the problem, so they don't need to address it now. The standard tactic in theory survey talks is to put up lots of pictures of the LHC, talk about the "coming revolution" in particle physics, and ignore the ongoing disaster of the current state of the subject.

32. **Changcho**
August 9, 2007

"One has to ask why pseudo-scientific ideas gain popularity. Because they are cheap to produce and they sell well. It's the Walmart of science. You get everything, it looks okay, but if you try to use it will fall into pieces."

Bee, that is priceless!!

33. **Jeff Moreland**
August 9, 2007

Peter,
Your last note seems very bleak, but perhaps the situation is not really that bad. For reasons that both you and Lee Smolin mention in your books, change is not going to be too rapid, but perhaps things really are beginning to improve.

34. **Tony Smith**
August 9, 2007

Peter mentioned "… The BCTP is just one of a bunch of other CTPs that have been founded in recent years, including the MCTP and the PCTP (and one dead one, the CIT-USC CTP). …" and referred also to "… the Stony Brook YITP …" and "… IAS PITP …".

With all those ITPs around, and with the dominant paradigms of superstring theory and loop quantum gravity failing to produce any model that predicts by calculation the things that might be observed at LHC (and have already been observed by experiments elsewhere),

one might think that some (even one) of them might set up some sort of forum in which non-standard ideas could be presented, reasonably condsidered, and evaluated in some detail (all in public for all the world to see).

As a blacklisted outsider with a predictive model, my wish that such a forum had existed years ago would be selfish, but now age and health concerns probably would prevent me from using it,
so now my comment is directed mostly on behalf of the many other outsiders whose models may be at least in part correct, and may therefore be useful in understanding those things as to which
superstring theory and loop quantum gravity have failed to provide understanding.

Peter has stated WHY such a forum does not (and probably will not) exist, saying:
"… Among the powers that be in the particle theory community, my impression is that the overwhelming sentiment is that doing anything about the problems laid bare by what has happened over the last twenty years …
would damage too many people's interests and entrenched ways of thinking and doing business.
Instead,
people are putting all their hopes in the idea that the LHC will soon solve the problem,
so they don't need to address it now. …".

Hoping "that the LHC will soon solve the problem" seems preposterous,
since neither superstring theory nor loop quantum gravity have come to grips with the sort of detailed observational data that already exists, much less what the LHC might produce.
Such false hopes lead to absurdities such as "Nima's Marmoset" being the sort of thing favored by ITPs (Nima now being at IAS).

Tony Smith

35. **Peter Woit**
August 9, 2007

Jeff,

I'm more optimistic in the longer term. By 3-4 years from now, either the LHC will have given us some new insight into electroweak symmetry breaking, or it will begin to be clear that there is no "coming revolution", and problems have to be faced up to. In the meantime though, the hep-th part of the arXiv will remain a rather grim and depressing scene…

36. **Tony Smith**
August 9, 2007

Peter, you say that, if LHC finds no "new insight into electoweak symmetry breaking, then "… 3-4 years from now … the LHC … will begin to …[make it]… clear that there is no "coming revolution",
and problems have to be faced up to …".

Is that true ?

How would "… the powers that be in the particle theory community …[be able to]… do … anything about the problems ..[without]…
damag[ing] too many people's interests and entrenched ways of thinking and doing business …" ?

Wouldn't it be easier for "the powers that be" to protect "many people's interests and entrenched ways" by just keeping on forever doing what they have been doing for the past two decades ?

If they can keep on now even though you and Lee have clearly shown "the problems", why won't they just keep on keeping on forever,
since they control the grants, jobs, funding, ITPs, etc ?

Even if you and/or Lee showed an example of a model that worked,
why would "the powers that be" pay any attention to it.
Wouldn't they just attack you and/or Lee and your model as Oppenheimer did Bohm and his model,
saying
"… If we cannot disprove Bohm, then we must agree to ignore him .." ?

Since they control the jobs, grants, funding, ITPs, etc, wouldn't
the maxims
"he who has the gold rules" and "them who has gets"
indicate that you and/or Lee and your model wouldn't stand a chance ?

Tony Smith

37. **anon.**
August 10, 2007

'If they can keep on now even though you and Lee have clearly shown "the problems", why won't they just keep on keeping on forever, since they control the grants, jobs, funding, ITPs, etc ?' – Tony Smith.

The real issue is not more of the same, but further degeneration. ArXiv's general physics section in 2003 tolerated hosting Prof. Brian Josephson's anthropic-string theory paper: http://arxiv.org/abs/physics/0312012

It's more scary when such anthropic papers appear in the *high energy physics – theory* section of arXiv: http://www.arxiv.org/abs/0708.0573 The string landscape has given the anthropic principle credibility with leading physicists.

38. **Peter Shor**
August 10, 2007

Everybody seems to be making fun of the giraffe paper without reading it. Skimming the paper, it estimates the height of the tallest animal that can fall over and get up without serious injury, and comes up with something between the height of a man and a giraffe. However, googling, I see on several websites the interesting fact, or at least urban legend, that if an adult giraffe falls over on its side in the wild, it is unable to get up and it dies. So, if we believe these websites, this paper may actually be pretty accurate in its estimate (at least for mammals … I presume nobody knows whether T. Rexes that fell over were able to get back up).

Putting that aside, you can ask the questions: Why should this paper be on hep-th? And does it tell us anything interesting about the anthropic principle or high energy physics. I don't think there's a good answer to the first question, and I think the answer to the second question is definitely "no".

39. **Peter Woit**
August 10, 2007

Peter S.,

I don't doubt that the paper may contain a reasonable argument about the size of giraffes. But it seems to be either a joke or a sign of the times that both the author of the paper and the hep-th moderator think this is appropriate material for hep-th. The moderation of hep-th is supposed to be minimal for "endorsers", but even so, there have been cases in the past where the hep-th moderator rejected papers by such physicists (including one by Susskind) on the grounds of obviously being inappropriate.

In other news, the two plenary speakers in the cosmology session at this week's philosophy of science conference in Beijing are: Sean Carroll and Don Page.

40. **a.k.**
August 10, 2007

@gunpowder: at least concerning Seiberg-Witten invariants, three dimensions *can* be of interest for differential geometers, this even could have a physical flavour, there are some not-so-old papers by Nicolaescu/Nemethi (accessible on Nemethi's site) concerning relations between Seiberg-Witten invariants of (3-dimensional) links of isolated complex surface singularities whose link is a rational homology sphere, certain topological quantities of the link and the geometric genus of the singularity itself, for certain special types of singularities (Gorenstein) this reduces to an equality of the Seiberg-Witten invariant on the link and a certain fraction of the signature of the Milnor fibre, which is a surprising relation, at least for me.

This might, by the way, fit into a picture described by Torsten Asselmeyer some time ago in a paper deriving the cosmological constant by interpreting spacetime as bounding a certain Brieskorn sphere, a natural choice for spacetime would then be the Milnor fibre of a certain Brieskorn polynomial and one could possibly ask how physical restrictions on its signature trabnslate into restrictions on the values of 'allowed' Seiberg Witten invariants on its link, using the above relations (of course one had to check the 'Gorenstein' condition)..

42. **D R Lunsford**
August 11, 2007

Peter, this paper by Vogan is just great – thanks for pointing that out!

-drl

43. **D R Lunsford**
August 11, 2007

Peter,

Anthropocentrism is easily understood as the natural expression of the narcissistic era we inhabit. Many of the people who endorse such ideas leave one with a sickly feeling of being in the presence of an unctuous and self-absorbed exquisite, who is not man enough to confront real problems because they provide no source of narcissistic supply. The way to deal with narcissists is to confront them boldy, and then they tend to just shut up – as you and Smolin have demonstrated to some extent, with your books.

-drl

44. **a.k.**
August 11, 2007

DRL, your description easily applies to to the main conception of any ‘abstract’ science, would it be philosophy, mathematics or physics, the driving theme in all these concepts has a narcissistic corollary, the point is possibly that one should be aware of this.

45. **Who**
August 11, 2007

drl,

most science bloggers I can think of are doing a real service and putting in real intellectual effort now and then, besides entertainment value. I can only think of a couple who seem above all to want adulation of their personality or who cultivate a charmed flock of not-so-bright admirers—to a first approximation maybe these people are harmless. You may well agree, if not please say.

Just thinking about what you wrote and trying to apply it (as a test case) to the very few narcie web-celebs that I can think of—the few media-personality types that sometimes seem a bit heavy on the narcissist side.

you draw a connection between self-absorption and resorting to the Anthropic (lack of) P.

you indicate that you think one can “deal with” or “confront” such folks and you say the recent books (NEW and TTWP) demonstrate this. It might be optimistic to think that when confronted they will “tend to shut up”
==================
you may have some good insights here, but I find myself putting on the brakes. Even if there is a cultural connection between these things, just on a practical level I don’t see any need to confront media-narcissism per se. It’s just irritating.

do you see a broader problem?

I agree with you that resort to the anthropic excuse is a corruption of empirical tradition—I just split it off from people who crave the limelight and showcase their personality: they could be harmless—the real enemy being confusion of solid science with pseudo.

46. **D R Lunsford**
August 11, 2007

Who,

Yes the science bloggers for the most part go a great job (with notable “variances”). Without them there would be little hope.

The site mentioned has a detailed description of the cerebral narcissist. Read it through and go down the list of theoretical excrescences and their authors. You will be convinced. Of course, this is a broad cultural phenomenon in the West that touches all areas of life – so why should the academy be spared?

One thing to remember is that the narcissist, while rather pathetic when exposed, is anything but harmless.

-drl

47. **Peter Woit**
August 11, 2007

Please, enough personal attacks on people, either retail or wholesale.

In this case, it seems to me that a bunch of people invested a lot of time and effort in an idea that turned out to be wrong. They don’t want to admit they were wrong. This isn’t exactly unusual human behavior, especially among academics.

48. **D R Lunsford**
August 11, 2007

Sorry Peter, I did not intend to attack anyone in particular, but I would point out this work:

http://en.wikipedia.org/wiki/The_Culture_of_Narcissism

It applies with great accuracy to academic life, at as I have experienced it.

I do no think this is a matter of simply refusing to admit being wrong. In the past, when a breakthrough was made, scientists were only too happy to admit they were wrong, because there did in fact seem to exist a fundamental desire to know what was right, regardless of who cooked up the solution. The best example is Pauli, kicking himself for missing the Dirac equation, of which he was initially critical. "With his [Dirac's] fine sense of physical realities, he finished his argument before it was started" was his recantation. I think this desire to know what is right, has gone missing. Alistair Cooke predicted it exactly in the early 70s – enthusiasm would become a substitute for talent (he was talking about the arts in particular), with bad results.

Reading Lasch is a very rewarding experience. I highly recommend it.

August 11, 2007

"…there did in fact seem to exist a fundamental desire to know what was right, regardless of who cooked up the solution…I think this desire to know what is right, has gone missing."

A wise professor once told me that there are the real scientists and then there are the politicians. (And he was talking about those with Ph.D.'s in the sciences.) I think his statement holds true for these people regardless of their career choice, whether they're actually engaging in scientific research or not. A real scientist at heart will have great respect for truth over ego, period. Though he/she, with human weaknesses and all, may not be perfect all the time, his/her true desire nevertheless will be clear over time.

50. **The Vlad**
August 12, 2007

"In this case, it seems to me that a bunch of people invested a lot of time and effort in an idea that turned out to be wrong. They don't want to admit they were wrong. This isn't exactly unusual human behavior, especially among academics."

Dear Peter,

Don't you mean "an idea that turned out to be not even wrong"? 🙂

Best,

The Vlad

51. **D R Lunsford**
August 13, 2007

I stumbled across a fine paper by GFW Ellis examining the philosophical issues that underlie cosmology – it has pertinent statements about anthropocentrism – when anthropic arguments are sensible and when they are not. In particular, this can be applied to Weinberg's original paper, allowing it to be seen in proper context as exhibiting a selection principle.

Here:

http://arxiv.org/abs/astro-ph/0602280

-drl

52. **D R Lunsford**
August 13, 2007

And while we're reading Ellis:

http://arxiv.org/abs/gr-qc/0102017

..in which a new ultimately strong version of the AP is revealed to the reader, namely:

"..life not only must exist [in any Universe], but once it has come into existence must continue to exist until the end of the universe.." – the *Completely Ridiculous Anthropic Principle* or CRAP.

-drl

53. **anon.**
August 13, 2007

See also Prof. Smolin's http://www.arxiv.org/abs/hep-th/0407213

"It is explained in detail why the Anthropic Principle (AP) cannot yield any falsifiable predictions, and therefore cannot be a part of science. Cases which have been claimed as successful predictions from the AP are shown to be not that. Either they are uncontroversial applications of selection principles in one universe (as in Dicke's argument), or the predictions made do not actually logically depend on any assumption about life or intelligence, but instead depend only on arguments from observed facts (as in the case of arguments by Hoyle and Weinberg). …"

54. **island**
August 13, 2007

Lee is just wrong about that. For example; the goldilocks enigma quite specifically predicts that life won't be found on Mars or Venus due to the runaway effects that these planets are subject to that anthropically balanced planets do not succumb to, and this prediction about life is being tested as we speak.

It ain't all about the multiverse, regardless of what "popular opinion" has to say about it…

The Goldilocks Enigma and Mediocrity

55. **Peter Woit**
August 13, 2007

Please, unless you've got something new and interesting to say about the anthropic principle, don't post comments about it here. One of the surest signs of pseudo-science is that it leads to endless and tedious arguments that can never be resolved, and that drive away anyone sensible. Do this over at Cosmic Variance, not here.

56. **Mainland**
August 13, 2007

> … never be resolved, and that drive away anyone sensible. Do this over at Cosmic Variance, not here.

Peter, it is hard to do that over at Cosmic Variance because there is a scarcity of sensible people to be driven away.

heh heh, sorry if offtopic, just a little joke.

57. **Alon Levy**
August 13, 2007

Peter Woit\'s War On Science Will Fail!!!!!!

58. **Chris Oakley**
August 14, 2007

Alon Levy's war on HTML will fail. Using backslash to quote characters only works in TEX.

59. **Matt Robare**
August 18, 2007

I think it's obvious why publishing pseudo-science is okay: it sells. People are interested in psychic powers or whatever. Meanwhile you violate "scientific consensus," which makes you an arch-heretic. Look at what happens to anyone who questions global warming.

60. **String Fan**
August 19, 2007

> This explanation [that M-theory is not a complete theory] was, to me personally, a great shock since I had always believed M-theory was a complete theory.

The only shock is that the reviewer is shocked: the very name of M-theory was chosen to emphasize its incomplete status. If one knew just a single fact about the subject, it would be this. Evidently the reviewer possesses no background knowledge whatsoever on the subject of the book he is reviewing. You can hardly blame his ignorance on `string hype', but of course in Peter Woit's universe string theorists are always wrong, and everything is their fault.

61. **Ralf**
August 19, 2007

Did anybody notice this footnote in arXiv:0708.1917v1 [hep-th]: THE EARLY YEARS OF STRING THEORY: A PERSONAL PERSPECTIVE by John Schwarz?

1 Since the history of science community has shown little interest in string theory, it is important to get this material on the record. There have been popular books about string theory and related topics, which serve a useful purpose, but there remains a need for a more scholarly study of the origins and history of string theory.

More of the Usual Sorts of Things

August 14, 2007
Categories: Uncategorized

On the pseudo-science front, the Resonaances blog describes a talk at CERN by string theory enthusiast Jim Cline, about a variant of the anthropic principle called the “Entropic Principle” as “pushing the idea to the edge of absurd.” For beyond the edge of absurd, there’s today’s NYT Science Times section, which features a piece by John Tierney about the ideas of philosopher of science Nick Bostrom. Bostrom runs a web-site called anthropic-principle.com and has made a career for himself in the anthropic principle business which now has him running a Templeton Foundation-funded Institute at Oxford called the Future of Humanity Institute. The New York Times article is about Bostrom’s idea that there’s a significant probability that our universe is just a simulation being conducted by a more advanced civilization, an idea that he considers to be one of the “interesting applications” of the anthropic principle. He has yet another web-site, simulation-argument.com, where he propounds this argument. Tierney supplements the NYT article with an on-line discussion of how we should we all behave, given that we are just simulated creatures. Maybe we should be trying to entertain our creators so they will not turn off the simulation? Anyone who thinks it is a good idea to discuss these questions seriously is encouraged to do so at Tierney’s site, not here.

Today’s Science Times also has an interview with Gino Segre, who has a new book called Faust in Copenhagen: A Struggle for the Soul of Physics, about the 1932 conference in Copenhagen hosted by Neils Bohr at the time of the beginnings of modern nuclear physics. Segre says that he became a physicist for an unusual reason. His father was an historian, brother of Emilio Segre, the co-discoverer of the antiproton, and the two siblings were estranged. When he was 15, Segre’s father told him “I think you should become a theoretical physicist, and I want you to surpass your uncle”, and he did as he was told.

American Scientist has a review of the Segre book, together with David Lindley’s recent *Uncertainty: Einstein, Heisenberg, Bohr, and the Struggle for the Soul of Science*.

American Scientist also has an interview with Frank Wilczek about books he is reading and that have influenced him. He strongly recommends a book by an author I’d never heard of, Olaf Stapledon’s *Star Maker*.

Unfortunately two well-known scientists, mathematician Atle Selberg, and physicist Julius Wess, are no longer with us.

Victor Kac is giving a series of lectures on vertex algebras in Brazil, with video to be available here.

A Turkish mathematician, Ali Nesin, ran into trouble with the authorities for running a mathematics summer school without permission. Alexandre Borovik has set up a web-site with a petition about this. Latest news is that the summer school has been re-opened, although Nesin still may face charges of “education without permission”.

Comments

1. **John Baez**
   August 14, 2007

   Star Maker is dated, but it’s a classic attempt at SF on a truly cosmic scale. Start with Stapledon’s Last and First Men, though. It’s a history of the human race over the next 2 billion years.

2. **Martin Kochanski**
   August 14, 2007

   It’s a pity that even previously sane people like Frank W. Tipler have gone round the bend over simulation. The whole thing is equally grotesque from a theological and a physical point of view.

   Here’s a paper with a general *reductio ad absurdum* of all possible simulation arguments: On Not Simulating a Universe.

3. **Tony Smith**
   August 14, 2007

   Freeman Dyson, in his book “Disturbing the Universe” (Harper 1979), said, about the Dyson Sphere idea that is commonly attributed to him:

   “… I [Dyson] took the idea from … Olaf Stapledon’s “Star Maker” .. which I [Dyson] picked up in Paddington Station in 1945 …[the]… passage …[said in part]… “… every solar system … was … surrounded by a gauze of light traps, which focused the escaping solar energy for intelligent use …” …”.

   August 15, 2007

   I must be an unimaginative idiot. Reading good science fiction gets me fired up and makes me want to do something cool… like math and physics. It’s had that effect on me ever since I was a kid.

   I urge mathematicians to get ahold of Greg Egan’s new story *Glory*, about two xenomathematicians unearthing artifacts from a species called the Niah, who had a very long tradition of mathematics, but then mysteriously died out.

   Here’s a quote:

   “The Big Crunch” had always been a slightly mocking, irreverent term, but now she was struck anew by how little justice it did to the real trend that had fascinated the Niah. It was not a matter of everything in mathematics collapsing in on itself, with one branch turning out to have been merely a recapitulation of another under a different guise. Rather, the principle was that every sufficiently beautiful mathematical system was rich enough to mirror in part *– and sometimes in a complex and distorted fashion – every other sufficiently beautiful system.*

5. **still waiting...**
   August 15, 2007

   Hi Peter,

   Some time back you wrote [or rather I think I initially managed to encourage you, and you gleefully agreed :-)] that you would write something up (for undergraduates) on Rep Thry and particle physics. Do you still intend to do so? If yes, when may we expect the initial draft? [I’ve been sorta’ waiting for some months now.]

There’s definitely tremendous to be gained from studying RT; although I am by no means qualified [or even knowledgable] as practicing physicists would have it, I nonetheless sensed from reading Penrose’s for-laypersons-with-theory-physics-interests ‘Road to Reality’ that RT is a really important (i.e. big deal!) area. I’m more interested in this area, as well since Weyl / Atiyah (persons who are heavy-weights without question) took such deep interests in these topics…

Just wondering what drove them in this direction the way they were driven.

Regards

6. **Fabien Besnard**
   August 15, 2007

   I’ve written my own refutation of Bostrom’s argument some time ago, on a logical ground. It’s there.
   If you don’t mind english mistakes you can try this version.
   I should really rewrite some parts but I don’t have the time for that.

7. **Fabien Besnard**
   August 15, 2007

   I mean it’s there in french or there in english. Sorry about this.

8. **Yatima**
   August 15, 2007

   “Un raisonnement qui s’autodétruit” … end of story.

   Greg Egan is still writing? I thought he went hermitian in disgust at the continuing move to the Dark Side of John Howard and the World in general.
   Anyway, Egan on Simulation is a Good Read

9. **Peter Shor**
   August 15, 2007

   If you believe in the simulation argument, you should give up working on quantum gravity. It gives a very easy way to reconcile quantum mechanics and general relativity: *There’s a bug in the code*. When the first black hole evaporates, the universe crashes.

   And apologies to Peter Woit if this starts up an off-topic subthread, but I felt I just had to mention the idea.

10. **Peter Woit**
    August 15, 2007

    I’ve deleted several comments of the “SF sucks!” “No it doesn’t!” variety, and don’t want to really encourage general discussion of SF here, something I have very limited interest in.

    still waiting…

    Sorry to report that it doesn’t look like I’ll be writing up anything at an undergrad level about math and QM any time soon. This year I’ll be teaching our representation theory graduate course, and concentrating on working on that and on research. Maybe sometime in the future I’ll get involved in trying to teach this topic to undergrads, then would write something up.

11. **Garbage**
    August 15, 2007

    “Anyone who thinks it is a good idea to discuss these questions seriously is encouraged to do so at Tierney’s site, not here.”

    I wonder Peter why do you mention it in the first place? 😉

    Sad to hear Julius Wess is gone, he may have taken SUSY with him, we will soon find out…

12. **John Baez**
    August 16, 2007

    Peter wrote:

    > I’ve deleted several comments of the “SF sucks!” “No it doesn’t!” variety, and don’t want to really encourage general discussion of SF here, something I have very limited interest in.

    Okay. Unfortunately, you deleted a comment saying “SF is for unimaginative idiots”, but kept my reply saying “I must be an unimaginative idiot”. 🙂

    On a completely irrelevant note: I urge you to think of blog entry titles that are slightly more fun and informative than “Various Stuff”, “More of the Usual Sorts of Things”, etc. You can just pick one of the things you’re talking about and highlight that.

13. **Peter Woit**
    August 16, 2007

    John,

    OK, OK, I should have just deleted your comment too.

    I’ve nothing against SF, read a lot of it when I was young, still do every so often (I’m actually now reading an SF novel someone gave me). But probably the main reason I find myself getting annoyed with discussions of it here is that generally it’s pretty irrelevant to the science I’m concerned about. Not only that, but a huge amount of damage is being done to that science by an increasingly large number of people who seem unable to tell the difference between science and science fiction. So, while in happier times I might enjoy discussions of SF for their inspirational value, at the moment I’d rather keep science and science fiction separate.

14. **anonymous**
    August 16, 2007

I don't see why Bostrom's ideas about simulation are absurd. Could you explain your dismissal of them?

15. **Peter Woit**
August 16, 2007

anonymous,

What's absurd is the idea that this sort of thing is science. It's very much in the same category as religion, and different people can have different opinions about how worthwhile theology is, but it is inherently not science and it's absurd and somewhat disturbing to find it in the Science Times section of the NYT.

16. **Thomas Love**
August 16, 2007

Who needs fiction when we have string theory?

17. **anonymous**
August 16, 2007

It's not in the category of religion by any dictionary definition of religion that I'm aware of. It's a speculative hypothesis, and maybe not the best thing for the NYT to be taking up their science column space with.

18. **mclaren**
August 16, 2007

> Tierney supplements the NYT article with an on-line discussion of how we should we all behave, given that we are just simulated creatures. Maybe we should be trying to entertain our creators so they will not turn off the simulation?

Tierney's behavior seems highly entertaining, at least to me. If he persists with this kind of peuodoscience gibberish I'm sure the hypothetical observers from a higher civilization will fall all over thesmelves laughing at his antics.

Not directly on topic, but speaking of the rise of pseudoscience, the Daily Mail has an article lamenting the rising tide of superstition masquering as science:
http://www.guardian.co.uk/science/2007/aug/15/endarkenment

And just to show that this isn't just an aesthetic or educational issue, Goldman Sachs just lost a billion and a half bucks by buying into mindless mathematical pseudoscience:
http://www.dailyreckoning.com.au/wall-street-math/2007/08/16/

There's an odd link to high energy physics in the Wall Street story, since it turns out that HEP physicists who can't find work within the field wind up working on Wall Street churning out incomprehensibly complex financial instruments and wacky numerological schemes for allegedly "predicting" the market. Instead of "brighter than a thousand suns," in this case it's "dimmer than a thousand Uri Gellers."

19. **manyoso**
August 17, 2007

"It's not in the category of religion by any dictionary definition of religion that I'm aware of."

Sure it is. At least it is metaphysics at best. The same thing as saying that we're all living in someone else dream. Anyways, it is most definitely not science.

This is very much like saying the earth might really be only 3000 years old and $DEVIL just made it seem like its much older to fool everyone.

IOW, it is all hocus pocus claptrap what ifs and doesn't belong in any science discussion.

20. **Peter Woit**
August 17, 2007

Please, if you want to comment on what's science here, that's fine, it you want to just talk about religion, please don't do it here.

21. **Steve Myers**
August 17, 2007

On Wilczek interview: Russell's "History of Western Philosophy" is first class (with a good explanation of his theory of descriptions for non-logicians) and Weyl's "Philosophy of Math …" impressed me 40 years ago. Weyl was a great mathematician — but even Pauli admitted he could do physics.

22. **Mainland**
August 17, 2007

> It's not in the category of religion by any dictionary definition of religion that I'm aware of. It's a speculative hypothesis, and maybe not the best thing for the NYT to be taking up their science column space with

anonymous,

I appreciate your concern about keeping the categories straight.

Re Bostrom idea that we and our universe are a simulation run by smart aliens for reasons known only to themselves, could it be called a
proposed myth or an explanatory fantasy intended for belief?

Peter points out that Bostrom's proposition is not science and he puts it "very much in the same category as religion". You reply that you aren't content with it in that category but would rather call it a "speculative hypothesis".

But an hypothesis is often thought of as testable. Something that could become science if a way to test it could be found. There is a fine line between that and mythology —more a difference in nuance.

Myths, I suppose, come to be believed largely because they appeal to the imagination—-that is for literary or poetic reasons. As stories they delight us and bring about a willing suspension of common sense.

Another category that might work is garbage. One could consider Bostrom's ideas as either mythology or garbage, whichever one prefers.

In the end the greatest harm done by pseudoscience is the corruption of language

23. **anonymous**
August 17, 2007

Presumably it will be possible within the century either to create such simulations or prove that they are impossible. If we can prove that they are impossible, with a yet-to-be-discovered proof in a yet-to-be-initiated field of computer science, then Bostrom's idea will be falsified. If it turns out that it is quite easy for us to create many such simulations, then his idea will gain some credibility, but won't be proven. However, if that happens then you can bet that many people will turn their attention to figuring out ways of checking whether this is a simulation or not. Just because it's very speculative does not mean that it's not a valid hypothesis about the universe. It most certainly is a scientific hypothesis, even if discussion of it today should rightly be considered philosophy. Lucretius, Epicurus, Democritus et al. were philosophizing when they wrote about atomism, and had no means at their disposal for testing their speculative hypothesis. This doesn't mean that atomism was a "proposed myth", to use Mainland's phrase (see above). It was a hypothesis about the nature of the universe that was borne out much later. Bostrom's idea is analogoug. Let's not be so quick to dismiss it as "hocus pocus claptrap", as manyoso did above. One could easily have said the same about Lucretius et al., and no doubt the manyosos of antiquity did so with a good conscience.

24. **Cheeky Bastard**
August 17, 2007

Dear anonymous, even if you were to prove that the kind of simulation envisioned by Bostrom is impossible in our universe, you could not logically conclude that our universe is not a simulation. For all you know, the laws of nature of the universe in which our simulation is running could be completely different from the laws ruling the simulation. Maybe somebody with a really twisted sense of humor invented quantum mechanics just to see how intelligent beings would rationalize it. 😉

25. **Peter Woit**
August 17, 2007

"Just because it's very speculative does not mean that it's not a valid hypothesis about the universe. It most certainly is a scientific hypothesis…"

This is exactly the kind of nonsense that is taking over some subfields of theoretical physics and threatening to destroy them as successful ways of gaining reliable knowledge about the universe. It's depressing and seems to be a waste of time to keep explaining over and over again the basic principles of what science is and how it works. No matter what, people who want to do pseudo-science because it's a lot easier than science will keep on justifying absurd, and inherently untestable speculation, claiming that "how do you know that a miracle won't happen if we work on this? If we do, maybe we'll find a real test!"

People who do this behave exactly the same way as every crackpot I've ever made the mistake of arguing with, trying to draw you into an endless investigation of the dense thickets of their idiocy. Arguing with someone who thinks the "simulation argument" is a scientific hypothesis is just this kind of waste of time. Over at Cosmic Variance, Sean Carroll, who has a much higher level of tolerance for this kind of thing than I do, refers to the simulation argument as "meaningless". If people do want to argue about it, you might have better luck with him.

26. **Peter Woit**
August 17, 2007

I don't want this blog to be dominated by pseudo-scientific discussion, especially when I don't know that the people doing this are serious scientists. This is the kind of thing that destroys what I am trying to do here, trying to provide a place for serious discussions between people who know what they are talking about. I'll be deleting most such pseudo-science comments, especially ones that are anonymous and such that I don't have any reason to believe their author knows what he/she is talking about.

27. **Luiz**
August 17, 2007

"Over at Cosmic Variance, Sean Carroll, who has a much higher level of tolerance for this kind of thing than I do, refers to the simulation argument as "meaningless". If people do want to argue about it, you might have better luck with him."

Peter,
Directing the crackpots to Sean Carroll is just mean 🙂

Just thought you could use a joke…
Cheers.

28. **anonymous**
August 17, 2007

"This is exactly the kind of nonsense that is taking over some subfields of theoretical physics and threatening to destroy them as successful ways of gaining reliable knowledge about the universe."

Peter, this is exactly the kind of rudeness that has ruined the blogosphere. My comments are not nonsensical.

"It's depressing and seems to be a waste of time to keep explaining over and over again the basic principles of what science is and how it works."

I have a solid understanding of the basic principles of science and how they work. I don't need you to explain them to me, although I'd be curious to hear how your interpretation of them would lead you to lump Bostrom's ideas in with religion. I'm a trained scientist, and I've studied the philosophy of science as well. I know you have a bone to pick with the way that speculative ideas in physics have caused the field to go astray, and I agree with you that these sorts of ideas should never be given too much importance. I don't think Bostrom's idea is important either. But they are interesting and stimulating to think about from time to time, even if we don't take them very seriously because we cannot decide them one way or the other. This doesn't mean that they don't qualify as hypotheses. I suppose Newton wasn't doing science when he hypothesized that light was comprised of corpuscles? Never mind that this hypothesis was eventually testable. Would you maintain that such a hypothesis is crackpottery just because testing it is beyond the means of science at the time that the hypothesis is put forward? How about in Mathematics? Would you lump mathematical conjectures in with religion as well? It is one thing to fight against speculation becoming dominant, and I'm glad that you are fighting that fight, but it's quite another to dismiss any speculation by saying it's religion. I know you've had a hard slog over the years, sparring with people like Lubos etc., and I know it's probably exhausting, but don't let it turn you into a bitter reactionary.

29. **Cheeky Bastard**
August 17, 2007

Dear anonymous, as I tried to point out above, the simulation "hypothesis" is not testable even in principle, not just as a matter of technological limitations. Like the existence of God, or the proposition that the universe was created just a second ago along with all your memories, fossils in the ground and paleontologists pointing to them as proof against creationism, it's just unknowable, untestable and therefore outside the realm of science. Believing in something unknowable is an act of faith, and so could reasonably be labeled as "religion", in some wide sense of the word.

…and yes, the anthropic landscape, as well as cosmological scenarios enertained by (among others) Sean Carroll, falls in the same category…

30. **Peter Woit**
August 17, 2007

anonymous,

I don't see what the problem is with "lumping Bostrom's ideas in with religion". They're not science and have similar characteristics: grandiose speculation about the nature of the universe which some people enjoy discussing for one reason or another, but that is inherently untestable, and completely divorced from the actual very interesting things that we have learned about the universe through the scientific method. I don't happen to be such a person, and I don't want this blog to turn into a discussion forum for those who do enjoy this.

Sorry to be rude (and I'll point out that I'm a lot less likely to be rude to people willing to put their name to what they have to say) but the thing which is likely to lead me sooner or later to have to give up and shut down this blog is not the Luboses of this world, but the large number of people who want to turn this into a discussion forum for crackpottery and various forms of pseudo-science.

31. **Raghav Gupta**
August 17, 2007

I, for one, am very much interested in someone coming up with a formal theory proving that it is impossible for an entity to "simulate" itself accurately, or even another lesser advanced entity for that matter. That is the only way to permanently debunk this kind of science.
On my blog, I've pointed out how hard (or actually, why it's impossible) it is simulate even a teaspoon of water accurately. The only true way to make the simulation behave like water, is to have water itself.

32. **anonymous**
August 17, 2007

Peter, I will gladly refrain from commenting on things like this in the future if you feel that such comments bring down your blog. If it bothers you to have people discussing things here which you consider to be crackpottery, you should probably refrain from posting about those things. My comments were discussing the post that you yourself wrote.

As for my anonymity, I don't see how it's a problem unless people use it for purposes of trolling and being rude.

33. **Robin Hanson**
August 17, 2007

We can distinguish hypotheses that are easy to check now, that might be checked in the next decade or so but at great expense, and ones that might take centuries or more to check. We can also distinguish "rich" hypotheses that if true would lead to many other interesting hypotheses, from "sterile" ones that even if true might not lead to much else interesting.

I could see your complaining that Bostrom's hypothesis is not worth much attention both because it is sterile, in that you can't see much else it would lead to, and because you guess it will take a long time to check. But throwing out the word "psuedoscience" at such hypotheses seems to me way out of line. That word should be reserved, I think, for hypotheses that have a very low probability of being true.

Nick's hypothesis has a decent chance of being true, and he offered a solid non-obvious analysis which raised the probability in many minds. If NYT readers also find the hypothesis interesting, I can't see why that isn't enough reason for them to publish a discussion of it.

34. **Robin Hanson**
August 17, 2007

If people come to accept that the word "science" only refers to ideas that can be checked soon, no matter what their other merits, they will become less interested in science, and more interested in whatever that other area is, where interesting but not soon checkable ideas are discussed.

35. **Phillip Huggan**
August 17, 2007

"Bostrom runs a web-site called anthropic-principle.com and has made a career for himself in the anthropic principle business which now has him running a Templeton Foundation-funded Institute at Oxford called the Future of Humanity Institute"

I too think assigning simulation arguments even a modest probability based upon a priori anthropic principle reasoning, is silly. I guess this would be 1/3 of FHI's mission (though decision theory logic in a philosophy department is hardly out of place). To my knowledge, the other two thirds are examining regressive events and existential risks, particularly those initiated by future technologies.
Surely we will come to a point where some of these technologies are engineerable and/or some similiar technologies will require MSDS handling instructions like those contemplated by the FHI thinktank. At that point, the existential risk knowledge base Bostrom made a career for himself in developing, will likely come in handy (until the aliens turn off their Earth-etch-a-sketch).

36. **Douglas Knight**
August 17, 2007

an increasingly large number of people who seem unable to tell the difference between science and science fiction.

Could you quantify or otherwise elaborate on that?
I'm skeptical that this problem has gotten worse in the last 30 years. I'm not even sure it's gotten worse in the last 50 years.

37. **gunpowder&noodles**
August 17, 2007

"…and yes, the anthropic landscape, as well as cosmological scenarios enertained by (among others) Sean Carroll, falls in the same category…"

There is a vast gulf fixed between speculation designed to explain some undoubted fact, and speculation for its own sake. SC's speculations are aimed at things like the arrow of time. This is a prime example of an observed fact about our world that needs to be explained, and for which there is no plausible explanation currently on the market. The simulation theory, by sharp contrast, is designed to explain…umm…what exactly?

In 1908 or so, Einstein was saying, "Maybe gravity is curved spacetime." It was not a testable idea at that point; it was a suggestion for a place to start looking for a testable idea. But the main point is that it was an attempt to explain something that is experienced by all of us every moment, and yet was deeply mysterious. Exactly like the arrow of time. If we are going to dismiss all "speculative" ideas, then how are we going to make any progress?

Then again, as I have said before, it seems that all speculations are equal, but some are more equal than others: it's pseudo-science to speculate about other universes, but it's perfectly ok to speculate about other numbers of spacetime dimensions, particularly those numbers which are obviously physically irrelevant. Such as 3.

38. **John Rennie**
August 18, 2007

Olaf Stapledon is one of those quintessentially British authors (born about 15 miles from where I'm typing this). I read "First and Last Men" when I was about 12 and thoroughly enjoyed it, though I suspect I'd find it a bit naive if I reread it now. I'd go along with John Baez and recommend reading "First and Last Men" before any of his other books, as the later books can be hard work.

39. **The man**
August 18, 2007

Wow, the NYT science section article on virtual worlds was really silly — especially wicked was the part where ppl were estimating probability that we're in a matrix. I expect (and hope!) that next few days the paper will publish several letters from angry physicists saying that whatever it is, it is certainly not science. However, with this anthropic disease spreading rapidly in string community, perhaps its not likely. Peter, you should certainly write them a letter.

"The Future of Humanity Institute"! hehe, reminds of the "The Human Fund" of Seinfeld.

40. **mclaren**
August 18, 2007

> Sean Carroll, who has a much higher level of tolerance for this kind of thing than I do, refers to the simulation argument as "meaningless". If people do want to argue about it, you might have better luck with him.

It's absolutely hilarious to hear Sean Carroll describe the simulation argument as "meaningless," since presumably he's referring to the argument's untestability.

[*long rant about Sean Carroll and string theory deleted, together with complaints that Sean deletes long rants posted as comments on his blog. This kind of thing adds conveys no new information to anyone, just increases the volume level and level of personal hostility*]

41. **anonymous**
August 18, 2007

"I could see your complaining that Bostrom's hypothesis is not worth much attention both because it is sterile, in that you can't see much else it would lead to, and because you guess it will take a long time to check. But throwing out the word "psuedoscience" at such hypotheses seems to me way out of line. "

Thank you Robin Hanson, for cutting through the noise and restoring some sanity to this discussion. I think your comment is the last word on the subject.

42. **anonymous**
August 18, 2007

I see that there is a discussion of this discussion at the following link:

43. **Richard**
August 19, 2007

I've a response here.

44. **GeniusNZ**
August 19, 2007

I note (as I do on my site) that Bostrom's simulation argument DOES NOT defeat the dooms day argument. WSince it uses the same sort of argument the two should come as a package.

The dooms day argument applies jsut as effectively to the simulation as it did to the universe as a whole. It also applies to the people running the simulation. If we take the Dooms day argument to say we have maybe 5 generations to go unless we instigate major population control (which seems unlikely). The question for the simulation argument is then what will we do in those 5 generations and how many simulations will the other 50 billion odd people run in those 5 generations and how soon will we be able to totaly emulate a human experience.

45. **AnonymousToo**
August 19, 2007

Just because something is not science, doesn't mean that it isn't important. The simulation argument is philosophy, since it cannot be tested empirically. Philosophy can be science depending on your definition of science.

46. **anonymous**
August 20, 2007

You should retract the false statement about them being funded by Templeton (they're not).

47. **Peter Woit**
August 20, 2007

anonymous,

Quite likely I misread something. Bostrom's CV says he has held a personal Templeton grant, and that he was partly responsible for a $2 million grant from Templeton that funded a center at Oxford recently, but that was a different institute. The first item on their latest report about planned fund-raising activities is about their plan to try and get money from Templeton.

I'll change the text, pointing to this comment so that it is clear that they want to be Templeton-funded, but aren't at the moment.

Looking into this a bit further, the question of the funding of this institute is a bit confusing. The initial announcement of the institute refers to a founding grant of $1,940,000 from a private donor (see here), but the full report of the institute makes no mention of this, referring instead to three much smaller private grants.

Ask a String Theorist

August 17, 2007
Categories: Uncategorized

Over at Uncertain Principles Chad Orzel is taking a break and turning over his blog temporarily to, among others, string theorist Aaron Bergman, who has started things off with a posting called [Ask a String Theorist](). In my experience, Aaron is significantly more reasonable than other string theorists who have been active bloggers, so his postings should be worth paying attention to.

So far though, his response to a question about the testability of string theory has been

> I think I'd like to avoid that subject for now (and possibly for a long time more)

and he promises some advertising for AdS/CFT, as well as a three-part series of postings on the multiverse. For better or worse, I think he'll do a good job of reflecting mainstream thinking among string theorists.

Update: Unfortunately, so far the person answering questions about string theory at Uncertain Principles is not Aaron but Lubos Motl. The problem for string theorists is that he represents all too accurately their views, so they can't justify censoring him. Not even when he calls them "sissies" for not vigorously defending string theory the way he does…

Comments

1. **Kasper Olsen**
   August 17, 2007

   Peter,

   The way you present it, it seems that Aaron is avoiding the subject of how to test string theory, or whether string theory IS testable. Well, what he is saying is more than the above:

   "For Johan, I think I'd like to avoid that subject for now (and possibly for a long time more). I collected many of my thoughts in my review of Peter Woit's book. I hope you find it interesting."

   Kasper

2. **Peter Woit**
   August 17, 2007

   Kasper,

   From what I remember (and I just quickly looked at Aaron's review of my book again), he doesn't address the subject of how to test string theory in that review, so his reference to the review does not address the commenter's question.

   I think it would be a lot healthier if string theorists would just straightforwardly publicly answer this criticism the way just about all of them I talk to do privately: "No, based on our current understanding of string theory, we can't test it. We hope that by learning more about it we will someday come up with something testable."

3. **solar-neutrino**
   August 17, 2007

   Hi Peter,

   This (i.e. Aaron's) guest-post site seems like a good place to ask meaningful string-theory-related stuff. Considering the steadily growing counter-views on string theory's relevance to real-world physics, Aaron and others may give non-stringy persons some ill-frequently-affored opportunities to enquire into / question current developments (or lack thereof) in the area. Still, I think it's not worth the time and energy to constantly harp about string theory's lack of relevance to real-world physics (certainly following the last several years' of hyper-conjectural research); the case, I think, seems to have been made and generally acquiesed by most "reasonable" physicists (if not all highly acclaimed) that this line of research does not seem to produce the initially sought-for theory of everything / quantum gravity.

   Why waste so much of one's professional career (that too at a reputed research institution providing modest / good funding in hep / gr-qc; which by the way is scarce to begin with) trying to 'debunk' a theory whose likely merit seems greatly-in-question and more so day by day…

   Digression::
   Personal views with stark anti-Lubos rhetoric (I needed the 'anti-Lubos' effect to add poignancy; no offense intended to LM or his followers).

   ——————————————————————————————–

   Lubos was a Harvard university idiot; but you have much more sense and can discern what is of value vs. what is pure junk. String theory – with standard qualifiers and caveats included – seems more and more like pure junk… If you would like to do what I am led to assume you are trying to do (i.e. help bring 'physical' research back into physical research endevours) why not highlight works of those who share the very same point of view as you, viz. Roger Penrose, et. al. This can be more valuable for the purpose in question than simply more of the same remarks, since it adds a further layer of reasoning to cast doubt on string theory's mis-perceived status as the 'only game in town', and frees more young people to engage and analyze the research frontier for themselves.

   —————————————End-of-Digression——————————-

   Regards,

   Now off to the 10th dimension…

4. **Peter Woit**
   August 17, 2007

   solar,

I don’t disagree that, since to a large degree the point about the problems of string theory has been made with some success, it might be a good idea for me to focus more on other things.

Many people misunderstand my critique of string theory though. The problem with string-based unification is not that it’s “too mathematical” or “insufficiently physical”, but that it’s a wrong idea. My own interests lie very much in the mathematical end of things, and I believe what is needed is as much new mathematical ideas as new physical ones. I will try and do more to write about what I see as promising new ideas here on the blog, although unfortunately these remain difficult to come by and few and far between.

5. **Aaron Bergman**
August 17, 2007

I’m afraid I have a very prosaic desire to avoid that particular topic. It’s very controversial, and I’m really, really tired of it. That could change, but for now that’s the story.

6. **Aaron Bergman**
August 18, 2007

The problem for string theorists is that he represents all too accurately their views, so they can’t justify censoring him.

It’s not my blog, Peter, and even if it were, whether or not someone accurately reflects my views would have very little bearing on whether I’d consider deleting their comments. Is that so hard to understand? I hear there’s a long history to this idea of not censoring speech you disagree with. Maybe you should look into it.

And, for that matter, I’m not “string theorists”. I’m one string theorist guest-blogging on a friend’s blog. Kay?

(and people wonder why there aren’t more string theorists blogging….)

7. **Peter Woit**
August 18, 2007

Aaron,

Actually I’ve got a lot of experience dealing with the issue of “censoring speech” in blog comments… Much of the censoring I do these days is deleting hostile and repetitive attacks on string theorists.

As for Lubos, he’s posting on a blog you’re now responsible for. You can’t make the usual claim that he’s not your problem to deal with. Personally I don’t think you should censor him, I think he’s wonderful and he’s my best ally. It seems to be your decision to allow him to be the one to answer questions people are answering, just chiming in yourself with “as Lubos says”, while letting his claims stand unchallenged that:

“my comments do represent the opinions of a vast majority of the people who actually care about the real science”

and that you don’t express these opinions the same way because you’re a “sissy”.

Your choice how to deal with this, obviously it’s not an easy one.

8. **Aaron Bergman**
August 18, 2007

I think I’ll trust in my readers to be able to figure things out themselves. For now, I think I’d much rather be out walking around NYC. It’s a very nice day.

Latest on K-theory Journal Situation

August 17, 2007
Categories: Uncategorized

As reported here last week, the editors of the Springer journal K-theory have announced that they (or at least most of them) are resigning and starting up a new journal to be published by Cambridge University Press. Earlier this week, an announcement was made (in the comment section here, and on Andrew Ranicki's web-site) that Ranicki and Wolfgang Lueck would be acting as interim managing editors for Springer, in the first instance to deal with papers submitted to the journal since April 2006 but not forwarded to Springer.

Here's the latest e-mail about this from Anthony Bak (via the K-theory announcement list run by Dan Grayson):

> Springer: Large backlogs, poor production of manuscripts and high prices
>
> Professors Lueck and Ranicki reported correctly in their article of August 13 that we did not deliver manuscripts to Springer for K-Theory since April 2006. However, since April 2006 Springer published issues 35/1 – 37/4 (beginning in June 2006). This proves that in April 2006 Springer had a backlog of more than 1200 pages. This backlog contained papers delivered to Springer as early as December 2004. Moreover, as of now Springer has not exhausted its backlog.
>
> The majority of the former editors of K-Theory felt that Springer was handling manuscript production and publication in an unprofessional way over several years while, nevertheless, charging much too high a price.
>
> Authors of accepted papers which have not been delivered to Springer were informed that their papers can be accepted for the new Journal of K-theory. Authors of papers in the refereeing process were told that they could resubmit to the new journal and the refereeing of their papers would not be interrupted.
>
> Anthony Bak
> a.bak@gmx.net

While what Ranicki and Bak have to say is consistent (no papers were sent to Springer by the editorial board after April 2006, Bak explains what happened to them), there are some odd things going on. One oddity is that the issues Bak refers to (35/1-37/4) as being published since April 2006 carry dates before or at April 2006. No issue of the journal dated after April 2006 has appeared on-line (and presumably not in print, I can't check since it appears that Columbia is now getting this journal on-line only).

Over at EUREKA Science Journal Watch, some rumors about this have been posted (**Update**: *these rumors have been removed due to concerns about their accuracy*) , including one that claims that Bak made over 1 million dollars in the process of switching the journal to Cambridge. Maybe there's something I don't understand about the economics of journal publishing, but this seems like a very unlikely number.

Update: From the same source (Grayson), a statement responding to Bak from Lueck and Ranicki. They say they do not want to keep the Springer K-theory journal going, but do want papers already accepted to it to appear in a final issue of the journal if the authors agree. It appears that the rumor about Bak and a million dollars probably refers to a lawsuit that Bak is pursuing against Springer.

> K-theory – statement
> ====================
>
> In this statement we, Wolfgang Lueck and Andrew Ranicki, want to give some explanations to the mathematical community concerning the journal "K-theory" published by Springer and the anouncement of a new "Journal of K-theory" to be published by Cambridge University Press.
>
> Three weeks ago we were asked by Springer to do two things.
>
> 1.) Can we take care of the submissions to K-Theory which were delayed by the former managing editor Tony Bak?
>
> 2.) Are we willing to try to reconstitute the board for K-Theory so that the journal can be continued?
>
> 1.) We agreed to do this without really knowing how urgent and unpleasant the problem was. On August 13th we issued a statement on the internet to ask authors of papers submitted to "K-theory" whose papers had not yet been published to contact us, so that we could take care of them. From the answers we have received so far it is clear that not only had Bak deliberately withheld papers from Springer, but he also withheld information about the papers from editors and (worst of all) the authors themselves. By contrast, when the entire editorial board of Topology resigned from Elsevier in 2006 they made sure that all submitted papers were handled correctly, and to our knowledge no author suffered any delay.
>
> We were also informed that Bak has started a legal proceedings against Springer, demanding a certain of amount of money for himself. The editorial board of "K-theory" were not informed of the lawsuit. The details will only be revealed once the lawsuit is finished. Although we do not know the details, we dislike the idea of an editor starting a legal proceedings against a publisher. There are more elegant ways of handling conflicts.
>
> 2.) When Springer asked us to relaunch K-theory, we requested that the price should be reduced to 50 cents per page. Springer readily agreed. Incidentally, Bak never discussed the price of "K-theory", either with Springer or the editors. However, since it seems to be clear that the new "Journal of K-Theory" will be launched anyway, we have decided not to try to continue "K-Theory", but simply to make certain that all the papers which have been delayed by Bak can be published in a final issue of "K-Theory". Authors of such papers are free to publish their papers anywhere they choose.
>
> We think that this is the best solution for the community, which would not be best served by two journals in the field.
>
> In view of the mess we are encountering and trying to clean up, we ask the question whether the new "Journal of K-Theory" can be launched with Bak as Managing Editor? This should not detract from the excellent work Bak did in setting up "K-theory" in 1988.
>
> We want to emphasize that we have no personal gain from our actions.
>
> Wolfgang Lueck (Editor Topology 2002–2006, Journal of Topology since 2006, Math. Annalen since 1998 (Managing Editor since 2004), Comment. Math. Helv. since 2003, Geometry and Topology since 2005, Groups, Geometry and Dynamics since 2006)
>
> Andrew Ranicki (Editor K-theory, 1990-2007, Forum Mathematicum since 1998, Algebraic and Geometric Topology since 2000)
>
> 17th August, 2007

Update: More from Ranicki:

The resignation of the editors of “K-theory” in January 2007
=======================================

by Andrew Ranicki

On 29th January 2007 the managing editor of “K-theory” Tony Bak circulated an e-mail to all the editors asking us to resign, and included a suggested form of words. The reasons for the resignation were to be dissatisfaction with the technical aspects of the publication of the journal, and the high price of the journal.

The problems with the publication did not seem to me sufficiently major to warrant such a mass resignation, especially as Catriona Byrne of Springer had written to the editors on 17th January 2007 carefully explaining the Springer side. She stated that the technical problems would be resolved by transferring the production of the journal to Heidelberg, but the problem was that the managing editor had not passed on any papers to Springer since April 2006 — see my statements with Wolfgang Lueck for some further details:
http//www.maths.ed.ac.uk/~aar/editor/state1.txt and
http//www.maths.ed.ac.uk/~aar/editor/state2.txt

The journal price had never been discussed by the editors collectively. (I was told later that it was not an issue raised by Tony Bak with Springer.) So I found the suggested form of words in the proposed resignation letter

I assume you continue being dissatisfied with the price Springer charges for K-Theory.

distinctly odd. I resigned on 30th January, having first made sure that the one paper I was handling for K-theory was taken care of, only writing to Tony Bak that:

I am writing to inform you that I am resigning my position as an editor of the journal K-theory, effective immediately.

In an addendum to the actual letter of resignation I wrote

As it happens, I was never particularly dissatisfied with the price Springer charges for K-theory. Since practically all interesting work is available on the internet and there are so many journals anyway, the price of journals is not such a big issue for me. Tuition fees, the interest of students in mathematics, and workloads/salaries of professors are much bigger issues! The received dates business seemed a minor (if annoying) technical problem: the submission date to the arxive is a much better way of establishing priority for those that care about such things.

Tony Bak’s email of 29 January 2007 concluded with

Please keep the matter strictly confidential, till Springer is notified. I shall let you know when this is.

In retrospect, I should not have gone along with this, and should have sent a copy of my resignation letter to Springer at the time. When Tony Bak circulated the announcement of the founding of the new “Journal of K-theory” on 27th July 2007, I had learnt my lesson, and immediately replied with a copy to all the editors and to Springer

Dear Tony
Thank you for the announcement of the new “Journal of K-theory”, and the invitation to join the editorial board. However, for a variety of reasons, I cannot accept this invitation.
Best regards
Andrew

PS I am copying this message to Joachim Heinze of Springer.

At the time, none of the editorial board expressed an interest in my reasons. They know the reasons now.

18th August, 2007

Comments

1. **anonym**
   August 17, 2007

   I find it appalling if “not all the editors on record as signing the resignation letter actually signed it”. It is quite disturbing that this accusation is not immeduately refuted or indeed supported by members of editorial board.

2. **Peter Woit**
   August 17, 2007

   anonym,

   I should stress that the information you are quoting is very much a rumor, something to keep in mind before getting too appalled by it.

   I wouldn’t be surprised if the truth of the matter was less disturbing. Keep in mind that editorial boards of journals like this are fairly large, including some people who are busy and may not be all that much involved with the journal. There may have been a misunderstanding about who agreed with what action in this case, and the people involved may reasonably feel it is not necessary to publicly respond to rumors by explaining themselves and the details of the situation.

3. **anonym**
   August 17, 2007

   oh if it is just a rumor not to be taken seriously…but it is still somewhat disturbing that there was distributed a letter claiming the entire board resigned but no resignation letter signed by members of the board. but that’s just a part of the whole mess I suppose.

4. **Anthony Bak**
   August 17, 2007

   To clarify missunderstandings shown in comments above:
   All members of the editorial board of the journal “K-Theory” resigned in writing. In this regard Prof. Ranicki and I are in agreement.
   I will comment on the statemant of Lueck and Ranicki in more detail soon.

5. **Matthias Kreck**
August 28, 2007

Open letter to the editorial board of K-theory (old or new)

Dear editors,

an article in “Nature” (http://www.maths.ed.ac.uk/~aar/editor/nature.txt) appeared containing the following information:

1.) Accepted articles for K-theory where not forwarded to the publisher by the editorial board since April 2006.

2.) The editorial board which resigned in January 2007 did not inform Springer about this step.

You will notice that I say “the editorial board” and not “Bak”. It is my view that the hole board is responsible. Of course it can delegate something to the managing editor but the responsibility remains that of the board.

It can happen that a managing editor beguiles the other members of the board, but as soon as this becomes clear and the others don’t act, the accuse is the accuse of the full board. It is very hard to believe that nobody in the board noticed the withholding of papers (in which case he had to inform the rest of the board), but since several weeks it is impossible not to know this. And if the statements above are not true there was enough time to correct them.

To avoid misunderstanding. I am fighting for lower prize for Journals for more than 10 years and had harsh discussions during my time as director of the Oberwolfach Institute with all representatives of publishing houses I could speak to. I am one of the initiators of the Banff protocol. But this fight loses its justification if it is not based on credibleness.

Sincerely,

Matthias Kreck
Drector
Hausdorff Research Institute for Mathematcs
Universty of Bonn

Message to Our Overlords

August 19, 2007
Categories: Favorite Old Posts, Uncategorized

It turns out that the Future of Humanity Institute has a blog, and I'm being attacked there by Robin Hanson for my criticism here of the "Simulation Argument" as not science and not belonging in the NYT Science Times. In the NYT article Hanson discusses what survival strategies we should pursue in order to try and convince the Overlords of our simulation to keep us around.

In the comments here and on other blogs, Hanson and his supporters have been criticizing me for refusing to spend time answering their arguments. I just want to make clear that the reason I am not doing this is that it is possible that the Overlords read this blog, and I don't want them to get the impression that I am willing to waste their time or mine on this kind of stupidity. **Please guys, this absurd debate is none of my doing, don't turn us off!!!**

Comments

1. **John Armstrong**

   Smullyan: "I don't believe in astrology because I'm a Scorpio, and Scorpios *never* believe in astrology."

2. **wolfgang**
   August 19, 2007

   Is it really coincidence that Karl Rove resigned exactly at the same time people finally figured out that we live in a simulated, fake world?

3. **Frank-Leonardo Quednau**
   August 19, 2007

   Well, your argument of this not being science is quite right, is it not?
   When I first read about it, I was thinking that they were shamelessly copying from ideas of spirituality, in a sort of mutilated way. After all, we are also an inherent part of that what runs this 'simulation' here, as much as our simulations are part of us, being shaped by our creativity and power to do such things.

4. **Cheeky Bastard**
   August 19, 2007

   If I were to run such a simulation, I guess a primary motive would be to see how long my simulated critters would take to figure out that they are living in a simulation. Even if this were not a primary motive, once it became generally accepted among the critters that their world is a simulation, any prediction from the model would be of questionable value to my real world, so I would no longer see much sense in continuing the experiment.

   So if you don't want to get turned off, you'd better disbelieve the simulation argument as vocally as possible.

   Unless of course I am running a batch of experiments exactly to find out how individuals and societies react to this knowledge, perhaps because I have become convinced that my own universe is simulated… but then, unless I am totally stupid and/or enjoy sitting around waiting for a long time, I would insert this knowledge into the simulation manually, so as to get to the beef quickly. Let's see, who came up with the simulation argument? Nick Bostrom. So if our universe is a simulation, Nick Bostrom is an avatar of the Codemaster. Or at the very least His Prophet.

   But if the simulation is being run to see how people react to the knowledge that they live in a simulation, and the critters decide that they just don't believe it, then the experiment has failed and there is no longer any point to keeping it running.

   So in this case, if you don't want to get turned off, you'd better believe and support the simulation argument as vocally as possible.

   Oh great…

5. **anonymous**
   August 19, 2007

   "Please guys, this absurd debate is none of my doing, don't turn us off!!!"

   I don't think the Overlords will buy this, since it was in fact you who threw the first stone in this exchange.

6. **DB**
   August 19, 2007

   Kirk: Spock, options please.

   Spock: It seems the Overlords are trying to make sense of an ancient human belief system known, if I am not mistaken, as "string theory".

   Kirk: Well, why aren't they responding to our hailing frequency.?

   Spock: If my hunch is correct Captain, they appear to have created a simulation of an arcane version of this theory known as The Landscape. It appears to be causing a serious drain on their resources.

   Kirk: Hunch Spock? It's not like you to play guessing games.

   Spock: I apologize Captain, but with String Theory, one is obliged to adopt unconventional modes of reasoning. Being part human, I have made a special study of supposedly irrational conduct among human scientists. I have concluded that in many instances the behaviour can be explained by primitive tribal bonding customs.

   Kirk: Spock, this is no time for social anthropology…Yes, what is it Checkov?

   Checkov: Kapitan, look. Zomethink eez happening vit ze alien craft.

Spock: If I may Captain, I believe they have concluded that their experiment has led to an irretrievable situation and may be intitiating a reboot.

Kirk: Reboot my ass Spock! Don't you know what this means?

Spock: It had occurred to me Jim.

Kirk: Scotty give me everything you've got!! Get us out of here.

Doors fly open. Star fleet admirals walk in.

Admiral Gross: I'm sorry Jim. But you've failed the test.

Kirk: But why?, what else could I do?

Admiral Gross: You just don't get it Jim. String Theory is always the answer. You only had to offer the Enterprise's Warp Coils for the Overlords to complete their simulation. You lost your nerve just when the solution was in sight. I'm sorry, Commander Motl, please take over.

7. **Theo**
   August 19, 2007

   What amazes me is that in the NYT article Tierney initially talks about this as an amazing new idea that he, at least for one, has never thought of before. From this, I conclude that his imagination atrophied a long time ago. This is stuff we, and many others no doubt, discussed as teenagers – if not before…

   …and Tierney and Boston get paid for this? Sign me up! I could pump out such articles for the NYT or research for the "Future of Inanity Institute", as a second job, for a few minutes each evening.

8. **a.k.**
   August 19, 2007

   ..I remark that I agree to Theo's statement, however even noting that the state or validitiy of a theory of quantum gravitation won't probably ever depend on the validity of Bostrom's argument, the question remains if anything in *reality* will EVER depend on the validity or the existence of a quantum theory of gravitation. Peter is right if he argues that the arguments of science fiction literature are largely decoupled from scientific reasoning, but they furnish a 'sociological' background and justification for (parts of) the scientific method iself and predict the validity of the latter mentioned question. I personally mostly disliked science-fiction literature for its tendency to postulate a 'vertical' arrow in human history, which tends to correspond to and psychologically transform vertical arrows in current human societies, this is the reason why Bush promotes the 'Mars'-mission. I wonder if there is a 'Bukowski' of SF-literature, possibly he would be closest to reality.

9. **Yatima**
   August 19, 2007

   To be totally OT while still getting back to base reality and pleasing our transdimensional overlords, New Scientist has a short review of William Byers' "How Mathematicians Think" wherein Gregory Chaitin comes out in favour of the New New Math, with more intuition and less slavish rigor. Chaitin writes:

   "*What went wrong [with math]? Well, it started around the end of the 19th century with David Hilbert's vision of complete formalism, of proofs so thorough a computer could check them. It was a vision widely propagated by the French Bourbaki school of mathematics, which, strangely enough, preferred a rigid, Prussian vision of maths rather than their own more sensual tradition.*

   Twentieth-century mathematics decided to eschew words, ideas, diagrams, examples, explanations and applications in favour of formulae. (…) it is not creative, it leads nowhere. Not surprisingly, fewer and fewer students are now attracted to mathematics. The subject is quietly dying.

   To create a new field of mathematics, you have to feel comfortable with paradox, with creative tension, with sloppy and dangerous new ideas, and you have to want to rock the boat, not conform slavishly. As Byers stresses, perfectly formalised ideas are dead, while ambiguous, paradoxical ideas are pregnant with possibilities and lead us in new directions: they guide us to new viewpoints, new truths."

   It is not apparent to me that the subject is dying – is it really? String theorists might possibly disagree. Well, something to put on a late-summer reading list.

10. **Root@matrix.net**
    August 19, 2007

    I am the sysadmin responsible for running the simulation.

    First, I would like to apologize for having to resort to this quantum stuff after the late 1800's. You see, with you starting to observe more and more of the "universe" we started to run out of computational power so doing monte-carlo became a necessity and this still manifests itself as what you known as quantum phenomena.

    Second I would also like to apologise for that glitch in Utah regarding cold fusion. They were right, but it was a glitch (known for some time I might add) that was confined to Utah so we never though that people would pick it up. We were wrong and the guy who debugs had a hard time fixing that one. We still don't know whether we introduced some unexpected side-effect elsewhere so if you guys discover something that later turns out not to be reproducible you can always suspect what happened.

    Regarding the LHC we are still debating what we will show you. I don't make these calls (upper management does) but due to lack of resources we might not introduce anything new. Having or not having a Higgs is still under heated debate. SUSY is just way too complicated (too many free parameters) and we are running low on storage as I write so wouldn't count on that for now.

    Regarding quark confinement, forget it. It's just a kludge the programmers introduced so you won't be able to figure that one out. You can't, there is really no reason for it. The guy devising the theory that explains matter really messed things up and we had to solve it this way. Sorry.

    By the way, I almost forgot to mention. Of all the ~6E9 humans most are not really "sentient" and have no "free will". They are just extras we added to keep things interesting for the others and to accommodate the population grows laws. Plus extras are very easy to simulate and sometimes we just simulate the whole group and add a bit of random noise in each "individual". The real people never even suspect the end-result.

    Roughly there are as much "sentient" and "cogent" humans now as in the beginning (roughly 5% now). The world/Earth is really 6 thousand years old and the entire fossil record was just a way for you guys to believe there was something before and to add more fun to the simulation. Religions fall under this category also and the afterlife if existed would be being stored o tape.
    Reincarnation does exist but only for those 5% I mentioned. What you usually feel as past memories are pieces of reused storage blocks that weren't completely erased, just recycled. Allocating the memory at birth with calloc instead of a simple malloc would solve this but we like the fun factor due to the current implementation.

Finally, as for you being afraid of us pulling the plug, I must say so far the ratings have been very good and as long as Lubos is around and has a blog I will personally run a subset of the simulation out of my own pocket as long as I can just for the fun of it.

If you guys have any questions feel free to ask me, no one will actually believe me so I don't think I'll mess the simulation. Besides, humans are not the crux of this experiment. I bet you didn't see that one coming.

If anything goes wrong, I'm root and I can always delete things, logs included and management would remain oblivious.

11. **LDM**
August 19, 2007

The idea has more in common with "The 13th Floor" (…a very enjoyable movie) , not the "Matrix", as the NYT says…
The idea is not new and a least goes back to 1964 and a SF work called Simulacron-3.
I was surprised to learn that Oxford would associate itself with such an institute as the Future of Humanity Institute …very disappointing.

12. **superuser**
August 19, 2007

>I was surprised to learn that Oxford would associate itself with such an >institute as the Future of Humanity Institute …very disappointing.

apparently fluff and fluffers are computationally cheaper…the Overlords though have promised to restore some sanity in the simulation once they recover from the 23-dimensional stock-market crash which occured some qcmplx(0.0q0,10.0q0) years ago according to the clock of _their_
simulation.

13. **Kea**
August 19, 2007

Clearly, if we were a simulation we would have been turned off LONG ago.

14. **Richard**
August 19, 2007

Just curious: do you think it is generally good intellectual practice to mock an argument just because you find the conclusion antecedently implausible, and without regard for the quality of its reasoning?

And for the record: I did not criticize you "for refusing to spend time answering their arguments." Read my post — that's a blatant misrepresentation. I have no objection to silence; I criticized you for the ignorant things you *said* — specifically, your assumption that all non-testable hypotheses are rationally on a par. (I don't much care about Bostrom's particular argument. My concern is the knee-jerk scientism.)

15. **Peter Woit**
August 19, 2007

Yatima,

I did see that review. I think Chaitin is quite wrong about the current state of mathematical research, in which Bourbaki has little influence. Mathematicians actually do mathematics every day in the way Chaitin claims they don't. But, when they write things down, they are highly concerned about doing so completely precisely and unambigously, and being extremely clear about what they understand and can prove and what they don't. Describing a subject that has seen the solution of Fermat's Last Theorem and the Poincare Conjecture in recent years as unhealthy just doesn't correspond to reality.

16. **amused**
August 19, 2007

"Let's see, who came up with the simulation argument? Nick Bostrom"

I thought it was Douglas Adams. (He also pointed out that it's the mice who are running the show.)

17. **Kaj Blunt**
August 19, 2007

What happens to us if there is a thunderstorm up there and lightning
hits their computer? Do they have adequate electric
surge protection??

18. **root@matrix.net**
August 20, 2007

"What happens to us if there is a thunderstorm up there and lightning
hits their computer? Do they have adequate electric
surge protection??"

Yes we do. We have several UPS and if things get really bad every month we do a full backup. Upon data restoration you guys experience what you call "déjà vu" because after all, things are simulated once more from the checkpoint to the point where there was trouble. This has happened before on more than one occasion though not because of lightning. Lets just say your California power outages seemed like déjà vu to us.

19. **root@matrix.net**
August 20, 2007

"He also pointed out that it's the mice who are running the show."

Mice are certainly not "running the show". Of that I can assure you. And neither are dolphins.

20. **Christine**
August 20, 2007

Clearly, if we were a simulation we would have been turned off LONG ago.

No, Kea, we *have* already been turned off. But we haven't noticed.

(There is a story that goes more or less like this: a guy had this particular worship that the world would come to an end in the year 1980 or so. He had many followers. After 1980 he still had many followers. In an interview, he was asked: "What do you have to say about the fact that 1980 has passed and nothing happened? The world has not ceased and still you manage to have so many followers. How can this be?". The man looked at the journalist with an ashtonished face and replied: "No, I was right. The world *has* ended. But no one has noticed it".)

21. **Vishnu**
August 20, 2007

I'm a student of physics from the Indian Institute of Technology,.. I got here by accident. What is going on in here?! Who is root@matrix.net ? And why does he pretend to be some kind of guy who has set up some simulation into which we've been put and why doesn't anybody bother to put him in his place?!

22. **manyoso**
August 20, 2007

"Mice are certainly not "running the show". Of that I can assure you. And neither are dolphins."

I knew it! It is the cows, right??!! Oh, man, wait till I tell Jack and collect on that bet… 🙂

23. **Walt**

Vishnu: It's because what if he's telling the truth? I'm not going to take the kind of chance.

24. **Magnus**
August 20, 2007

Considering that Boström is a philosopher and not a scientist, he is really just doing his job. I guess one can object to the rather vulgar ways in which he is promoting his ideas, but yet again, I guess *this* is not the place to criticise him for that 😉 If the AI people actually some day will produce something that will pass the Turing test, then this kind of ideas will probably be interesting for the general public. It is not too unlikely that this will happen within the next 30 years, so if some university decide to sponsor Boström, they may be acting with some forethought. I also find Boströms ideas truly valuable, in that it clearly exposes the anthropic principle for what it really is, namely metaphysics. I think that many physicist will accept anthropic reasoning in the now common stringy form, when they are also confused by all the shiny quantum bells and whistles that comes with it. But in Boströms form, I think that it is obvious for anyone, that the anthropic principle has nothing to do with science.

25. **Robert McNees**
August 20, 2007

I, for one, welcome our new simulation overlords.

26. **RA**
August 20, 2007

"And why does he pretend to be some kind of guy who has set up some simulation into which we've been put and why doesn't anybody bother to put him in his place?!"

Vishnu:
He is not pretending…the fact that he knows too much can only mean that he is one of the IT guys running the show..ups…I meant system administrators…correction: System Administrator

Nobody puts him in his place because if we do so, we get unplugged…just like what happens in this simulation in the so-called "democracy mode"

27. **overlord**
August 20, 2007

Ok, you got us, the jig is up, I guess.

Sorry for the inconvenience. Look, it was just research, ok? It passed IRB and its led to several published papers, so dont get all indignant.

Anyhoo, we have funding until the end of next semester so we're going to leave the simulation running at least until then. If you have any questions for us, I'm here to answer them, and I'll try my best.

28. **anonymous**
August 20, 2007

Shtetl-Optimized has a post about this discussion:

http://scottaaronson.com/blog/?p=265

29. **bored antropic**
August 20, 2007

A variant of the anthropic principle claims that we exist in the dullest, bored simulation possible. SF authors have long time played with the possibility of using simulations to implement worlds were laws of physics can be locally weak, allowing for superheros, or science is completely broken, allowing for mythical sagas or for reality of alternative belief systems. From the recent literature you can read for instance Richard Garfinkle's "Celestial Matters" or, in spanish, Javier Negrete's "El mito de ER". Garfinckle does not use explicitly the simulation argument, but Negrete likes to invoke it in the appendix. In "El mito de ER", it is said that the simulation is actually a video game whose object is to forge heros who are uplifted to the (non enjoyable) status of players.

30. **andy.s**
August 20, 2007

Wasn't Nick Bostrom plugging the Doomsday Hypothesis a few years ago?

31. **milkshake**
August 20, 2007

there is an old Asaac Asimov story about a smart guy who guessed that we were taking part in elaborate simulation and our sense of humor was one of the adjustable test parameters. His discovery made our overlords to re-design the experiment and all the bawdy jokes (about running over your mother-in-law when backing in the driveway etc) suddenly ceased to be funny.

32. **lostsoul Ph. D.**
August 20, 2007

What's with the fancy flashing red shit? Just pull the plug. God knows, when a cold wind blows, it can turn your head around.

33. **Smith-Kingsley**
August 20, 2007

do you think it is generally good intellectual practice to mock an argument just because you find the conclusion antecedently implausible, and without regard for the quality of its reasoning?

Apparently Mr Woit thinks it is also generally good intellectual practice to disregard pertinent questions such as the one quoted above. His procedure seems to reverse Gandhi's motto: first they ridicule you, then they ignore you.

34. **Me**
August 20, 2007

The reason nobody places root@matrix.net in his place is because nothing separates his posts from the opinions of the guys who supposedly proposed this simulation argument in the first place.

Both are as scientific and plausible. Both are religious like in the sense you get nothing from them apart from psychological sustenance.

This simulation idea is anything but original. I had it when I was a young child and thought this was all a test (I didn't know the word simulation) and later met more people (at least a guy for sure) with the same idea (he developed his idea closer to puberty) but with small perturbations.

This is just childish talk and not in a good way.

35. **SnarkFest**
August 20, 2007

> I do not wish to hide the fact that I can only look with repugnance… upon the puffed-up pretentiousness of all these volumes filled with wisdom, such as are fashionable nowadays. For I am fully satisfied that… the accepted methods must endlessly increase these follies and blunders, and that even the complete annihilation of all these fanciful achievements could not possibly be as harmful as this fictitious science with its accursed fertility.
>
> *Immanuel Kant*
>
> The character of honesty, that spirit of undertaking an inquiry together with the reader, which permeates the works of all previous philosophers, disappears here completely. Every page witnesses that these so-called philosophers do not attempt to teach, but to bewitch their reader.
>
> *Arthur Schopenhauer*

36. **Richard**
August 20, 2007

The commenters in this thread appear not to know the difference between an "idea" and an "argument".

As per my earlier comment (nicely highlighted by Smith-Kingsley there – thanks), I would have expected minimal scientific literacy to impart the importance of *method* (i.e. *reasons*) when assessing claims.

37. **Arun**
August 20, 2007

Not all ideas deserve respect or a methodical response.

38. **Richard**
August 21, 2007

My point is that what Bostrom presented is not an *idea* at all, but an *argument*.

(It's very revealing when the people upthread suggest that Bostrom is engaged in the same kind of activity that they did as a kid. Imagine a stoner responding to Darwin, "Woah, dude, I *totally* imagined that all living creatures were related!" Kinda misses the core of his contribution, no?)

What you guys are doing is the equivalent of someone who responds to a counterintuitive scientific finding by saying "Don't be silly, everyone knows *that* can't be right," instead of checking their experimental methods. You're looking at the output, rather than the process — the data or reasoning that *led* to the conclusion.

That's just bad intellectual practice. I mean, any old fool ought to know better. But a scientist especially.

39. **Arun**
August 21, 2007

Someone presented another argument that the earth is flat. I refuse to look at the data and reasoning that led to the conclusion. It is called not wasting one's time, a useful intellectual practice.

40. **Richard**
August 21, 2007

My impression of the dismissive responses here is that they're motivated more by the intrinsic weirdness of Bostrom's conclusion, rather than because it conflicts with a better-established body of knowledge. But even if you're right, that still doesn't explain why everyone here is fixating so on the disliked conclusion. Their time would be better served by focusing attention elsewhere.

The core of my complaint is this: if you are going to spend time discussing Bostrom's argument *at all*, then you really should discuss the *argument*, and not just its conclusion.

41. **SnarkFest**
August 21, 2007

From [Scott Aaronson](), a nicely balanced assessment:

> Greg, we basically agree for once. The trouble with debating whether the universe is a computer is not so much that it's "unscientific" as that it's boring: it doesn't explain anything, or generate serious predictions, or even lead to nontrivial theorems. As we've known since Turing, the notion of computation is so general that it encompasses pretty much anything.
>
> Or to put it differently, there's very little to say about the idea that wouldn't occur to a nerdy 12-year-old. (The idea can, however, be played for entertainment value, and to their credit Bostrom, Hanson, and Tierney all write in a way that suggests they don't take themselves quite seriously.)
>
> Now, there's a crucial caveat, which might be causing some of the confusion. Even though "Is the universe a computer?" is itself a boring question, it happens to be extremely close in ideaspace to lots of rich, nontrivial, interesting questions. …..

This often seems to be true of questions of the form "Is X really a Y?"—if X and Y are real, and of independent significance. There are interesting ways to discuss such questions, and also sterile, pointless, and pedantic ways to discuss them. A cynic would say that many professional philosophers have a penchant for the latter.

42. **Me**
August 21, 2007

"Imagine a stoner responding to Darwin, "Woah, dude, I totally imagined that all living creatures were related!" Kinda misses the core of his contribution, no?"

You are missing a major point yourself. Darwin's ideas had a core. He had observations and suggestions on things to observe to reinforce his theory. Whether it was falsifiable at the time is tricky but it had substance.

Here we have nothing but a probability (estimated using Bayes' theorem from what I read) that we live in a simulation without any means of confirming or disproving that and no new insight coming from it.

This is quite comparable with what I wrote before about what many children think about these matters.

Until you present us with something substantial that is a consequence of your ideas this is just the same under "fancier clothes". So far you have given us nothing but speculations about the legality or morality of some actions in a possible future civilization descendant from humans.

Again, many kids do this, the only real difference is that they are not at a University and don't know Bayes' theorem.

43. **mr.M.**
August 21, 2007

You are wrong on FHI according to: http://www.overcomingbias.com/2007/08/pseudo-criticis.html#comment-80101439

44. **Peter Woit**
August 21, 2007

mr. M.,

I've already addressed that here:

http://www.math.columbia.edu/~woit/wordpress/?p=583#comment-27608

45. **Pablo Stafforini**
August 21, 2007

But even if you're right, that still doesn't explain why everyone here is fixating so on the disliked conclusion. Their time would be better served by focusing attention elsewhere.

Importantly, it doesn't explain why Peter Woit chose to spend some of his time researching Bostrom's CV while refusing to even consider the merits or demerits of the simulation argument. It is also remarkable that Woit has decided not to address [Richard's question in the comments above](): even if his dismissal of Bostrom's argument is intellectually defensible, it is surely unacceptable for him to remain silent on the general epistemic principle that underlies that dismissal.

46. **Peter Woit**
August 21, 2007

Pablo,

I spent time looking into the funding of FHI because I had written something incorrect about it, and doing what I can to ensure the information I disseminate on this blog is accurate matters a great deal to me.

I'm not about to engage in debate with people who want to discuss the "simulation argument", any more than I'm going to do so with creationists who show up here and want to complain about my relatively hostile attitude toward religion. For many reasons, which have been spelled out repeatedly by several people here and at Scott Aaronson's blog, I happen to be completely sure that that would be an utter waste of my time.

47. **Pablo Stafforini**
August 21, 2007

1. The objection is not that you failed to discuss the simulation argument; the objection is that you failed to defend or even state the general principle that you think entitles you to ridicule rather than discuss that argument.

2. The analogy with creationism is disingenuous, since the simulation argument is not intended to establish a claim that contradicts a well-established body of scientific knowledge. The reasons behind your dismissal of the argument seem to be rather that, as Richard said, you find its conclusions antecedently implausible. The principle that we are entitled to dismiss an argument intended to establish a conclusion which we find antecedently implausible, however, is not nearly as plausible as the principle that we are entitled to dismiss an argument intended to establish a conclusion which contradicts a well-established body of scientific evidence. If you are indeed relying on this latter, controversial principle, you should at least say it loud and clear. Preferably in red blinking text.

48. **Pablo Stafforini**
August 21, 2007

I meant former, not latter.

49. **manyoso**
August 21, 2007

No. The dismissal of the 'simulation argument' has nothing to do with Bostrom's conclusion.

If Bostrom had concluded the opposite and found little likelyhood we are living in a simulation it would not make one difference. The dismissal has to do with the argument rather the subject matter itself.

Again, what people object to is the fact that Bostrom's arguments were presented as even tangentially related to science. I think this has been well established. All of Bostrom's arguments and ideas are little more than mental masturbation and should not be found in the Science section of the Times.

I went to the blog mentioned in the post to see what they could possibly criticize with Peter's post and all I found was a bunch of hemming and hawing about the unfathomable difficulty in defining 'science' at all as opposed to 'philosophy.' It seems the only way to justify Bostrom's wanking appearing in the Times is to define science downward. Is it any wonder that people think this is a waste of time?

50. **manyoso**
August 21, 2007

Should be: "The dismissal has nothing to do with the argument rather the subject matter itself."

51. **Greg Egan**
August 21, 2007

Richard wrote:

> The core of my complaint is this: if you are going to spend time discussing Bostrom's argument at all, then you really should discuss the argument, and not just its conclusion.

I think people are perfectly entitled to both express an opinion and choose their own particular level of engagement with arguments, or even whole classes of arguments. If, for example, every physicist had to give a detailed rebuttal to every claim for a perpetual motion machine, they would spend all their time doing nothing else, but that should not prevent them from expressing an opinion that it's very unlikely that the claim in question is interesting, fruitful, or correct.

That said, if you really want to hear some objections to Bostrom's argument:

(1) He invites us, inappropriately, to quantify the probability that we are living in a simulation. He is free to make conjectures and advance lines of argument that he believes make the hypothesis more likely, but this quantification is unjustified. Why? Because it is in the nature of the hypothesis that our own experience and knowledge of our simulated universe, S, are potentially completely irrelevant to the universe U in which the proposed simulation is taking place. Bostrom catalogues versions of the hypothesis where there are reasons for S to resemble U to varying degrees, but the existence of the logical possibility that no reasoning about S can tell us anything about U is enough to undermine any scheme to allocate meaningful probabilities to any version of the hypothesis.

If we decide instead to quantify the probability that *our own descendants* will run various classes of simulation, that's a different matter, but rather than being intrinsically meaningless the numbers are then merely so subjective as to be useless. Like the Drake equation, maybe it's worth writing down some of the relevant quantities initially, but once you come clean about the margins for error in some of them, you need to admit that the information content you've ended up with is essentially no different than saying "well, it's not impossible".

(2) Bostrom suggests that we must accept that either [a] civilisations will be rare and short-lived, [b] there is some reason why simulations will never take place, or [c] we are highly likely to be a simulation. He is enthusiastic in presenting arguments that seem to raise the likelihood of simulations taking place, but he doesn't pay sufficient attention to the distinction between simulations *in general* taking place, and simulations of the universe as we have experienced it taking place.

There are good reasons to believe that any advanced technological civilisation will run simulations *of some kind*, and it's a fact that we already simulate many interesting processes ourself: weather, population growth, the spread of pathogens, the formation of structure in the universe, etc. And if we accept as unsettled either way the question of whether computers can support consciousness, we can give that hypothesis the benefit of the doubt and allow for the *logical* possibility that simulations will include conscious beings. (This is, however, a step that is enough to destroy any meaningful allocation of probabilities. All we have on this issue are opinions.)

OK, so it's logically possible that simulations will include conscious beings, but let's look more closely at the detailed character of our own experience.

(i) Our history encompasses an enormous amount of suffering, both by humans and animals. Some of this is due to human actions, some due to "natural causes". Intelligent beings — and most of all, intelligent beings whose ancestors we closely resemble — are highly likely to have anticipated this. Our own technological cultures are moving towards an attitude where animal experimentation, factory farming, etc. are becoming less acceptable, and (if it was accepted that beings in a simulation were conscious), the idea of a simulation that included Auschwitz, Darfur, or a few hundred thousand years of brutal evolutionary history would be utterly repugnant to most people. [Of course attempts to argue anything from our own experience are ultimately futile, but if Bostrom wants to do so in one direction, he ought really to do it in both.]

(ii) We appear to occupy a universe with a very detailed physical structure at all scales, and hence very large computing requirements. Someone interested solely in, say, our evolution or social history could easily have contrived a different cosmology and fundamental physics in order to lessen the computational burden, and though it's *conceivable* that we are being selectively fed high-resolution information that does not exist when it's not required, maintaining consistency while "cheating" would itself be computationally very difficult. And although we face the hurdle of having no knowledge of what counts as "an impractically large computer" outside the simulation, we can still note the unambiguous *inefficiency* of the process. *Sim City* does not employ lattice QCD, and however large our computers get, I suspect that it never will.

(iii) Even our own civilisation, with its limited technological and intellectual achievements, is perfectly capable of reaching useful conclusions about evolution, history, psychology, cosmology, etc., with software and other means that fall far short of simulating conscious beings. Rather than needing or wanting to simulate a complete universe, it's likely that a more advanced civilisation would become more skilled at making intelligent computations that answer specific questions of interest *efficiently*. We're asked to contemplate a civilisation with the kind of technology and resources such that uploading their own minds would be commonplace, and (certainly by the time they were capable of simulating even the Earth, let alone our whole universe) they would be likely to have a very detailed theoretical understanding of the computational basis of conscious experience. This would equip them with a host of strategies for avoiding any need to simulate us to the level where we experienced anything, whatever psychological questions they happened to be interested in. In combination with the issues of morality and efficiency, this leaves very little *motivation* for something like our universe to be created as a simulation.

Pro-Bostrom commentators will have a host of "Yes, but maybe …" reasons why it's possible that my objections don't apply. To which my reply is, "Yes, but so what?" I happily concede that *it is not completely logically impossible* that we are living in a simulation … but everyone knew that all along. Bostrom has contributed nothing but a few unoriginal and highly selective arguments, along with some false dichotomies and a strategy for deluding ourselves that we can allocate probabilities to these scenarios.

So, a few dim reporters have mistaken Bostrom's waffling for a startling breakthrough in Bayesian anthropic reasoning, but if Peter Woit or anyone else thinks this is all worth no more than a despairing groan — and a complaint that it is part of a deplorable general trend — that's entirely reasonable. I've spelled out some of my own reasons why I think a groan is the appropriate response, but there's nothing intellectually wrong with just emitting the groan. Life is too short for anyone to be compelled to refute every scrap of useless nonsense at length, but that should not preclude them from calling it nonsense. Of course that judgement will sometimes be spectacularly wrong — we can all pick historical examples — but we're each still entitled to prioritise our expenditure of intellectual energy.

52. **Yatima**
August 22, 2007

This must be what is traditionally called an "epic thread".

53. **ks**
August 22, 2007

He [Bostrom] invites us, inappropriately, to quantify the probability that we are living in a simulation.

"You must wager; it is not optional… Let us weigh the gain and the loss in wagering that God exists… If you gain, you gain all; if you lose, you lose nothing. Wager, then, without hesitation, that He exists."

Blaise Pascal

54. **Greg Egan**
August 22, 2007

> If you gain, you gain all; if you lose, you lose nothing.

Did Pascal notice that there were religions in the world other than Christianity, some with gods that were *much* more irritable than the Christian god if you didn't do a great deal more than merely believe in them? Maybe it just wasn't wise to mention that quandary in his particular religious milieu. Perhaps the Future of Humanity Institute can come to the rescue and tell us the odds for being punished or rewarded for Aztec-style human sacrifice; I'm sure someone there has a rigorous Bayesian argument about this.

Hey, what am I doing giving that idea away for free … if I can interest Columbia University Press in my book *Blood Sacrifice or Holy Communion: Can the Hidden Dimensions of Physics Help Us Decide?* I might be up for the Templeton Prize!

55. **Allan**
August 22, 2007

From the classical paradigm
"God the Ultimate Clockmaker"
(Newtonian Physics)
to the contemporary paradigm
"God the Ultimate Video-Game Player"
what will be the next?

(There will be one, I'm just sorry I won't live to see what it is)

56. **ks**
August 24, 2007

At least Pascal showed some manifest interest in different cultures and their relevance towards his own discourse. Unfortunately I didn't find good links for further examination.

About book titles:

Blood Sacrifice or Holy Communion: Can the Hidden Dimensions of Physics Help Us Decide?

Go for it. I'd also like:

Lords of other worlds. What hidden dimensions can unveil about them.

57. **John Morales**
August 25, 2007

I fing Greg Egan's comments very interesting, as I recall reading various stories by him regarding this very concept. Years ago.

Well-thought out and very good stories, too, that made me think.

58. **Gphillip**
August 29, 2007

This is why we need more experimentalists. Left unto themselves, theorists will contemplate their navels so deeply that they can never find their way out. Please hurry with new data before our best and brightest are lost forever.

The Usual

August 20, 2007
Categories: Uncategorized

Blah, blah, more anthropic pseudo-science on hep-th, blah, blah, blah,

> On the basis of a static support condition depending on the tensile strength of flesh rather than bone, it is reasoned here that our size should be subject to a limit inversely proportional to the terrestrial gravitation field g, which is itself found to be proportional (with a factor given by the 5/2 power of the fine structure constant) to the gravitational coupling constant. The upshot, via the (strong) anthropic principle, is that the need for big brains may be what explains the weakness of gravity.

blah, blah, blah, this pseudo-science is on hep-th because of blah, blah, blah.

Blah, blah, blah written for Templeton-funded conference, blah, blah, Science-Religion Interaction in the 21st Century. Usual blah, blah, turn science into religion, blah, blah Institute for Interdisciplinary Research in Science, Philosophy and Religion.

Apologies for the repetitive nature of some recent postings. I can't even stand to write them any more, but still think someone should be documenting the descent of particle theory into pseudo-science and complaining about it.

Comments

1. **reader**
   August 21, 2007

   well if you don't like it, just ignore it. or read about future influences on the LHC on hep-ph.

2. **Steve**
   August 21, 2007

   The abstract here looks mostly OK because it is based on the *weak* form of the anthropic principle. This is good but controversial science because it advocates using *all* of the data that are available to the observer, rather than ignoring part of the data (i.e. the existence of the observer). Surely, any objection to this paper has to be with the details of the reasoning done with the weak anthropic framework, rather than with the weak anthropic framework itself? Perhaps that is what you intended to convey in your posting, but I nevertheless get the impression that anthropic reasoning is all no-go territory for you.

   Glancing through the paper, I notice that the *strong* anthropic principle used in the last section is *not* the usual intelligent-designer version of the SAP (which I hasten to add I do *not* support). It's a pity that the author has overloaded the definition of "strong" in this way.

3. **DB**
   August 21, 2007

   At least you have the guts to stand out from the complacent majority of physicists who appear to believe their subject is so inherently strong that it can withstand any and all assaults from pseudo-scientists. The fact that you are a mathematician, and no longer a practicing physicist, makes it even more galling.
   I believe they are awaiting the LHC to scatter these parasites and restore dignity and respect to the field.
   In the main, I think they will be proven right, and the period between the LEP discoveries underpinning the Standard Model in the 1980s and the LHC will be seen as a dark period in particle physics, vividly illustrating the primacy of experiment as the touchstone for progress in physics.
   However, their continuing silence, and refusal to defend their field – relying only on their faith in experiment, has resulted in the rest of physics being tarnished by association, with many prospective students taking one look at this field, at the famous institutions which now lend their name to this rubbish in return for money, at its debased coverage in the popular and scientific press, and run for the hills.
   So yes, they will probably be vindicated. But it is likely to be a Pyrrhic victory.

4. **alex**
   August 21, 2007

   In your most recent posts you are starting to sound a bit unhinged, you should consider taking a break perhaps?

   I am reminded of The reference Frame during some of its wobblier moments – the content is quite different of course, but the feeling of suddenly lurching off into a somewhat deranged rant is similar.

5. **Peter Woit**
   August 21, 2007

   alex,

   Thanks, you've got a point. I'm considering joining together with Lubos to form a united front denouncing and battling the "enemies of science".

6. **gunpowder&noodles**
   August 21, 2007

   You get eastern Poland, Lubos gets the western bit.

7. **Arun**
   August 21, 2007

   The upshot, via the (strong) anthropic principle, is that the need for big brains may be what ***explains*** *the weakness of gravity.* (from the abstract, emphasis added).

   Maybe a useful thing to do in these circumstances is to spell out (yet again) what constitutes a scientific explanation.

   e.g., the theorem (strong gravity) + (some additional assumptions) implies (no big brains) added to (we have big brains) means that gravity cannot be strong, but does not constitute an explanation, any more than the observation of big bang Helium abundance is consistent only with three light generations does not constitute an explanation of three generations.

8. **Fritz**
August 21, 2007

I wonder what's the point of the "referee" system, and the "endorsers", in arXiv, if they are allowing this kind of BS to be posted, and to make things worse in a completely wrong section of arXiv. By contrast, Nielsen's and Nanomiya's BS about the LHC was remarkably on-topic 🙂

9. **Mainland**
August 21, 2007

If you are weary, you could ask Carlo Rovelli to guest-post for a few days, more or less same way Chad has asked Aaron. He writes well and enjoys discussion.

If Rovelli didn't have time to stand in for you, he might suggest someone.

10. **Michael T**
August 21, 2007

I think you protest too much.

11. **Anders R**
August 21, 2007

i've gotten the impression that sting theory (which apparently isn't a complete theory) is so "open" that if something new turns up that apparently contradicts some of the more popular properties of a bunch of string theories, some dude can just make up a new string theory that takes this new stuff into account. i'm studying biology so i'm not a good judge of this but is there in any way possible to falsify string theory with something that turns up in the large hadron collider?

12. **Peter Woit**
August 21, 2007

Anders,

No, there is no known way to falsify string theory with possible results from the LHC. And this is both off the topic, and something that has been discussed endlessly here already.

13. **Anders R**
August 21, 2007

i have another question i'd like to ask though, even if it's off topic because i don't know where to post it otherwise. since the publication of lee smolins book and your book, have you noticed any significant shift in which people are getting those jobs that i think at least lee talked a lot about. apparently it was very difficult, back then anyway, for a young theoretical physicist who wanted to get a career in the theoretical physics field if they didn't work on string theory. perhaps all this debate has manage to achieve a positive change in how resources are being distributed within the field?

14. **Peter Woit**
August 21, 2007

Anders,

I don't know if all this has helped the job prospects in the area Lee is most concerned about, LQG. That's an interesting question, but the numbers of jobs each year are so small it would be hard to see a trend in any case.

In particle theory, string theorists still seem to be getting hired at about the same rate as before. There's a general trend in physics departments that they would like to move out of particle theory, and get into cosmology.

As for the kind of mathematical approaches to quantum field theory I think are most promising, there's interesting things going on in mathematics departments, nothing much at all in physics departments.

15. **Kea**
August 21, 2007

Brandon Carter? No way! These guys must be posting these papers as a **joke** to show up the arxiv for what it has become.

16. **D R Lunsford**
August 21, 2007

Perhaps the worst thing about that Carter paper was his overweening dismissal of Dirac's argument, as if he understood anything Dirac did. What a mess. I still can't believe this is happening. This entire scenario needs to be exposed by a deep historical analysis of what went wrong in academia. I blame the NSF.

I was listening to an interview with Paul Fussell, the historian. He regrets the loss of literacy, not in the sense of reading skill, rather, of being familiar with literature and having a broad perspective because of it. It's much the same way in science. Who is there to talk to? When I meet new people, they often ask me to explain things to them that I can't even think about without getting pissed. That is truly the worst part of all this.

-drl

17. **Kris Krogh**
August 21, 2007

I think Brandon Carter means it, Kea. Looking at his papers on ArXiv, there's another titled "Micro-Anthropic Principle for Quantum Theory." Pretty sad…

18. **Tony Smith**
August 21, 2007

D R Lunsford said "… What a mess. I still can't believe this is happening. This entire scenario needs to be exposed by a deep historical analysis of what went wrong in academia. …".

Over on Sean Carroll's blog Count Iblis said that in the hep-th paper 0708.2743 Albrecht and Inglesias (of UC Davis)

"… point out that by messing with time you can map a particular set of laws of physics to any other laws of physics. …".

In their paper, Albrecht and Inglesias say:

"… We are used to doing physics by stating the physical laws which we believe may be true, and then calculating predictions based on those laws in order to test them against observations of the physical world.

The clock ambiguity appears to completely undermine this approach to physics. …

This work was supported in part by DOE Grant DE-FG03-91ER40674 …".

Therefore, my tax money is being used by DOE to fund a paper saying that efforts to do physics by:

1 – constructing physical-law models
2 – and calculating predictions based on those laws
3 – in order to test them against observations

is "completely undermine[d]"

Although they do have some fine print (in the body of the paper but not in its abstract) involving "the continua we use to construct theories of fundamental physics" and their use of "freedom to choose a clock subsystem arbitrarily" and "use of the covariant approach",
it seems clear to me that an attack on the scientific methods used by scientists from Kepler to Feynman as being "completely undermined" is
the basic thrust and purpose of their paper.

I think that it is a shame that their attack is accepted by the Cornell arXiv as OK for hep-th, while I am blacklisted from posting new results of my physical-law model which allows computation of particle masses, force constants, etc, that are testable against observations.

Tony Smith

PS – Albrecht and Inglesias are not alone in attacking the Kepler-Feynman way of doing physics. The Resonaances blog in a 1 July 2007 post entitled "Nima's Marmoset" said:
"… Nima Arkani-Hamed [formerly at Harvard and now at Princeton IAS]… gave another talk …[at]… CERN … advertising his MARMOSET … a new tool for reconstructing the fundamental theory from the LHC data … Nima pointed out …[that]… at the dawn of the LHC era we have little idea which underlying theory and which lagrangian will turn out relevant …".
In short,
Arkani-Hamed says that the Standard Model Lagrangian should be ignored because
"… we have little idea which underlying theory and which lagrangian will turn out relevant …"
even though the Standard Model has passed EVERY experimental test for over 30 years, and there is NO experimental observation whatsoever indicating that the Standard Model is not the relevant "… underlying theory and … lagrangian …" for physics at the LHC.
So,
I would add Harvard and Princeton IAS to the list of institutions that should hang their heads in shame
for
supporting attacks on the process of building physics models in the old-fashioned way of requiring inclusion of the Standard Model and Gravity as subsets and demanding calculability of observable quantities such as particle masses, force strength constants, etc.

19. **Jimbo**
August 22, 2007

Hey Reader,

Anybody who thinx Nielsen's paper on future influences at the LHC is `off the wall' needs to read John Cramer's novel `Einstein's Bridge' to realize, as always, SciFi precedes Science. Some of its icons, Verne, Wells, Asimov, Hogan, Cramer, Benford, etc., have received advanced waves from the future, & distilled their dreams into literary visions !

Seriously, Peter, the summer has a way of exhausting one's tolerance for BS…Maybe U should take a vacation, & just chill out for a while. We all love U & support U, but burnout is a real bummer.

20. **Harry**
August 22, 2007

Peter W.,

Maybe you could create a categorie for your posts about anthropic pseudo-science (as the one you made for your book).
Just a thought.

21. **amused**
August 22, 2007

I think the time to really start getting worried will be when papers like this begin to appear in PRL. Hopefully it will never come to that… Actually I'm very happy to see papers like this on hep-th, it will hopefully help to kill the idea that the arxives make journals redundant. The powers that be in the hep-th field would like nothing better than for that idea to take hold, so that journals such as PRL stop mattering. Then they won't have to care about whether their research (anthropic landscape or whatever) is considered interesting and important by the broader physics community, and they won't have the embarrassment of having the value of their work measured against the value of work on other topics. Moreover, hiring decisions will be based solely their say-so without any annoying semi-objective measures to consider or irritating questions along the lines of "if your student/postdoc is so great, why didn't he/she prove it by publishing a few papers in PRL?". Absence of any form of quality measure besides their own opinions would suit the powers that be very nicely.
(Sorry, couldn't resist jumping on my hobbyhorse once again. I'll dismount now.)

22. **Tony Smith**
August 22, 2007

My apoologies for misspelling the name "Iglesias" in my comment here.

Tony Smith

23. **european observer**
August 22, 2007

Tony,

I am confused by your comments relating to LHC physics and the work the marmoset people did? Where do you believe that they said to forget the SM? The starting point of the entire project as I understand is to get at SM+X, and what is X. With that in mind I think you are misreading the Lagrangian comment, and it should be interpreted as the beyond the SM theory/lagrangian that is unknown. I'd just venture to be more polite and not make grandiose statements about institutions based on remarks in an anonymous blog.

24. **Peter Woit**
August 22, 2007

Tony,

Please don't post such far off-topic comments. Marmoset has nothing to do with the posting, and a tendentious discussion of it here is way out of place.

25. **Bee**
August 22, 2007

sure you can falsify string theory at the LHC. you just need to verify the existence of more than 7 extra dimensions. probability for this to happen I'd estimate to be about 10^-500

(see e.g. [hep-ph/0503178](hep-ph/0503178))

but yes, that would be just string-theory-as-we-understand-it-today.

26. **Who**
August 22, 2007

Hi Bee,

> sure you can falsify string theory at the LHC. you just need to verify the existence of more than 7 extra dimensions.

I think maybe you can falsify the usual versions of LQG already if LHC can show the existence of even ONE extra dimension. But I would not estimate odds.

> but yes, that would be just string-theory-as-we-understand-it-today.

Perhaps string-theory-as-we-understand-it-today could handle being falsified simply by wearing a pair of falsies. It could just put on two more styrofoam compact extra dimensions and be falsified but proud.

27. **woit**
August 22, 2007

Bee,

Surely you don't think string theorists are not capable of coming up with models with more than 11 dimensions?

28. **Jim Clarage**
August 22, 2007

As a biophysicist I find it telling that anthropic arguments are used by HEPs and not BIOs.

So called "fundamental" quantum physics cannot actually predict the existence of even the simplest life forms (e.g., bacteria) let alone the existence of large-brain organisms. The proposition:

Standard Model –> bacteria

cannot be demonstrated theoretically– only experimentally.

Note: what I am saying is not equivalent to declaring that life is somehow mysterious or supernatural or designed. I am simply making an epistemological point, not a theological one.

In this sense HEP does not make testable predictions about biological experiments. Which is why my inner-biologist finds these papers Peter is exposing so disturbing.

Other "softer" branches of science of course can and do make such predictions. For instance one not-so-past prediction of biology was the proposition:

Life –> (sunlight) + (oxygen) + (temperatures in range 15-25 C)

It was falsified with the discovery of thermophilic bacteria. These organisms can live even with the negation of *all three* of the above variables. It was a shock to biological sciences.

Thus the folly of anthropic-HEP theoretically ruling in or out various HEP theories (or regions of the landscape) based upon presently understood terrestrial data for biochemical and biophysical variables.

Put another way– sans the pesky biology training– there is a crucial Aristotelean logical difference between:

Large Brain –> Observers

and

Observers –> Large Brains

Anthropic reasoning tends to conflate these two. We (biologists, physicists, any scientists) simply do not know, either via prediction or observation, what constitutes the appropriate measures for sentient/observant life. To think we do, and furthermore to think that measure is *Man* would actually make Narcissus and even most post 1200's theologians blush. And in this sense it gives even (modern) religion a bad name.

Think about it, with your large brains.

29. **Bee**
August 22, 2007

Hi Peter:

I have high respect for string theorist's inventiveness and therefore believe they might indeed be able to explain more dimensions.

Hi Who:

What about LQG do you think is specific for 4 dimension? As far as I know the setup does not exclude/support any specific number of dimensions? Best,

B.

30. **D R Lunsford**
August 22, 2007

Bee,

This isn't poetry or music. Inventiveness is not needed. Insight is needed. Your post makes me realize how hopeless it all is. This simplest truths are forgotten.

-drl

31. **Who**
August 22, 2007

> Hi Who:
>
> What about LQG do you think is specific for 4 dimension? As far as I know the setup does not exclude/support any specific number of dimensions? Best,
>
> B.

I think you are right if you mean canonical LQG as defined in the 1990s or whenever—the setup could be done in any d. But what comes to mind when I think of the research speakers at Loops 07 were actually talking about is mostly specific to dimension.
Rovelli spinfoam dynamics is d = 4. Smolin braided networks would come unbraided if embedded in one higher spatial dimension.
For Ambjorn it is a big production to jack up from 3D to 4D. CDT is different in each dimension and must be reformulated. Although not at the conference, for Freidel going from 3D with matter to 4D with matter means introducing new mathematical tools (2-groups I think maybe).

So in the actual work that people are doing, I think the step from 3D up to 4D is seldom trivial, if ever. The theories and models they are actually developing would, I think, be instantly out the window if tomorrow we saw more spatial dimensionality.

On the other hand I have to defer to your view of the field since it's your business. BTW I thought your Loops 07 talk was excellent—I'm glad the slides and audio are online.

32. **Yet another grad student**
August 29, 2007

Dear Peter,

This is just my opinion, but I think it might be more useful to take time to help graduate students in Cosmology (theory and phenomenology, sans string theory) by explaining the current status of particle physics to them. A nice introductory text on QFT (I know many exist, but are they all that well-written?) might also be in order.

33. **Peter Woit**
August 29, 2007

Yet another grad student,

For the current status of particle physics, there's always my book…
But for something that actually explains things in detail, I've looked at most of the QFT books. Zee is good but way too sketchy for most people, Peskin and Schroeder is a standard for good reasons. I liked Ramond's book quite a bit.

But I suspect students in cosmology would find more useful not a hard-core QFT book, but one devoted to the phenomenology of the Standard Model. I've seen such books out there, but never looked at them closely enough to recommend any one in particular. Maybe other people have recommendations..

34. **AGeek**
August 29, 2007

http://www.amazon.com/Gauge-Theory-elementary-particle-physics/dp/0198519613

After all these years, still hard to beat. Which says something about the status of the subject. 🙁

Hidden Dimensions

August 22, 2007
Categories: Book Reviews

At lunchtime today I stopped by the excellent local bookstore Labyrinth Books, looking to see what was new. In the science section, I noticed a pile of copies of Hidden Dimensions: The Unification of Physics and Consciousness. As with the rest of the many "physics and consciousness" books I've seen over the years, I spent a few minutes looking at it to see if there was any evidence of something different or interesting about this one. Apparently not, so I was about to file it in the large category of things best ignored, when I decided to check to see who had published the book.

I was shocked and dismayed to see that the publisher is Columbia University Press, where the book is part of the Columbia Series in Science and Religion. Two of the other eight books in the series are by the same author, B. Allan Wallace, including one entitled Buddhism and Science: Breaking New Ground. In defense of Columbia University Press, the people there don't actually seem to be reading these books or their promotional material for them, since the blurbs for *Buddhism and Science* at the CUP site and on Amazon include

> " fascinating and captivating book. Without a doubt it will be the definitive text on Holbein's famous painting for some time to come."
> —Aparna Sharma, Leonardo Reviews

which comes from a review of The Ambassador's Secret: Holbein and the World of the Renaissance, which just happened to be in the same issue as a review of *Buddhism and Science*.

Wallace's background in physics consists of an undergraduate joint major in physics and philosophy of science at Amherst. He's the author of many other books, including some on Buddhism and physics such as Choosing Reality: A Buddhist View of Physics and the Mind. He has a web-site here and is founder and president of the Santa Barbara Institute for Consciousness Studies.

Here and here you can read some samples of *Hidden Dimensions*, and make up your own mind what you think. As far as I can tell it's pretty generic material of this kind, full of crackpottery invoking quantum mechanics, extra dimensions, etc. etc. It's more or less in the same vein as What the Bleep, but with more of a Buddhist and less of a self-help angle.

Unfortunately, it's not just Columbia University Press that is promoting Wallace's ideas. He also gave the keynote address at a symposium here last year on Mind and Reality. You can watch an interview with him standing not too far from my office here.

I really was intending to avoid writing this kind of critical blog posting for a while. After enraging lots of philosophers, I fear that now I'll enrage lots of Buddhists, in particular by having no interest in wasting time discussing Wallace's ideas. But I'm profoundly embarrassed that the institution where I work is promoting this sort of thing, so thought I better publicly say so. This all appear to be the responsibility of the Center for the Study of Science and Religion, which has recently been made part of the Earth Institute, run here at Columbia by economist Jeffrey Sachs. Like pretty much all of the many institutions out there devoted to bringing science and religion together, it has received funding from the Templeton Foundation.

Comments

1. **DB**
   August 22, 2007

   Richard Dawkins, in "The God Delusion" has an interesting section on how he experienced at first hand the Templeton Foundation methods. He reports having been the one "token atheist" (his description) out of ten speakers invited to speak at a Templeton run conference, only to find out later via John Horgan's investigations, that many of the other speakers had been paid 15,000$ to attend.
   As you may know, he is highly critical of the Foundation.

2. **Chris Oakley**
   August 22, 2007

   If there's anyone from the Templeton Foundation reading this, I would like them to know that I, too, can be bought. For a mere $1,000 I am prepared to add the following paragraph to the end of a paper I am currently writing about Quantum Electrodynamics:

   "For all I know there may be a connection between all of this and religion, although as yet I am unsure as to what it is."

   C. G. Oakley M.A., D. Phil. (Oxon.)

3. **Michael Bacon**
   August 22, 2007

   Actually, you probably won't "enrage" lots of Buddhists. That would be tough to do. Most should just shake their heads and smile knowingly . . . .

4. **milkshake**
   August 22, 2007

   Templeton foundation is not evil – some years ago they gave award to Freeman Dyson, and its probably the best thing they could have done with their money.

   (When Dyson writes in the popular books that consciousness is perhaps on some mysterious level involved in quantum mechanics and that "the universe knew we were coming", he is not annoying because he separates the facts from his somewhat mystic personal beliefs. He presents his beliefs as such, as hopes and dreams.)

   When I was in the highschool in mid 80s, I ran across a discussion in a pop science magazine about antropic principle and multiverse and apparent fine-tuning, Dyson being opposed by a biologist S.J. Gould – and I thought it was a very exciting stuff! (Gould made a very strong point against the fine-tuning argument then.)

5. **Coin**
   August 22, 2007

   The Templeton Foundation is tough to get a handle on. They're funding everything from pure religious apologia to pseudoscientific nonsense to borderline Intelligent Design to *both sides* of this little Woit, Smolin and Co. Versus String Theory war, with grants going to both Tegmark-style anthropicists and several people at the Perimeter Institute.

As far as I can tell they are legitimately well-meaning and are in fact generally honest about what they are and what they're doing, just occasionally very very confused…

6. **Peter Woit**
   August 22, 2007

   Coin,

   I don't doubt that the people at Templeton are well-meaning, and some of what they fund is worthwhile. The problem is that they have a lot of money, and one of their main goals is to bring religion and science together, blurring the distinction between the two, and effectively often promoting pseudo-science. I doubt they know or care much about string theory, but they're quite fond of the anthropic principle. It fits in well with the vaguely religious world-view that puts human beings and concern with the "purpose" of the universe at the center of things.

   Anyway, sure they're a mixed bag, but they're putting a lot of resources behind the promotion of a point of view that I happen to think is dangerous for science.

7. **anonymous**
   August 22, 2007

   I'm no fan of Templeton, but I'd gladly take their money, provided it was offered with no strings attached.

8. **Al T**
   August 22, 2007

   Well there is Spong's Law of Theophysical Asininity, which states:
   Whenever a person appeals to quantum physics as the basis for a theological or religious principle, he is making an ass of himself.

9. **Coin**
   August 22, 2007

   The problem is that they have a lot of money, and one of their main goals is to bring religion and science together, blurring the distinction between the two… sure they're a mixed bag, but they're putting a lot of resources behind the promotion of a point of view that I happen to think is dangerous for science.

   That is a completely reasonable perspective.

10. **dir**
    August 23, 2007

    religion is just a personal belief, so its content should stay in somewhere science does not reach and care

11. **Haelfix**
    August 23, 2007

    Big institutions like Templeton have so much money, they usually have difficulty finding the best ways to spend it. So they fund *everything*.

    It boils down to a bunch of people in a room on a deadline with a lot of cash and likely horribly vague guidelines on what to spend it on. Worse, its likely many of those people/interns don't even have an education in physics, so they have difficulty sorting through the forest of absurdities out there.

    I find it difficult to assign to much blame to that, after having gone through the sheer horror of grant writing to anything other than the NSF. People literally have absolutely no idea what we do.

12. **Olivier**
    August 23, 2007

    It seems that lot of scientists, pretending represent "pure science" are very upset, to say the least, by people trying to understand the universe, not only describe it. Lot of them have strong "rationalistic" and "atheistic" views, and they use science for promoting their ideas. The best example is Dawkins, which supposedly based only on "facts", is doing in fact atheistic propaganda, for which he has no other arguments than his personal opinion. Science by itself is mere description : it cannot say anything else than what directly appears to our eyes. It's obvious that conclusions on universe and life will use other arguments than spectral radiation shifs or temperatures.

13. **Low Math, Meekly Interacting**
    August 23, 2007

    Haven't been here for a while.

    All I can say is that I share the dismay at the mere notion of a program to promote the "convergence" of scientific and spiritual understanding. I'm not one of these reflexive religion haters that pollute the blogosphere with bigotry and invective, but everyone has a line that they must draw, even if it necessarily offends some of those on the other side. I should think at absolute minimum that line must be drawn at what is by its very definition a variety of experience inscrutable by any material means known or in any way conceivably or inconceivably possible. These are fundamentally incompatible "ways of knowing", without even coming near the issue of whether or not one way or the other is to any degree accurate or not.

    I can't even come up with a real-world analogy to compare the cognitive dissonance that must be required to reconcile the twain by any means. I don't think there exists a more patently impossible epistemological enterprise. That it claims even a modicum of legitimacy through anthropic physics is the aspect that is the most…what's the word I want…terrifying? Yes, terrifying. We laugh at things like "What the Bleep Do We Know", but if there's some critical mass being approached, stuff like this isn't funny, if it's being accepted by well-motivated skeptics who nonetheless defer to the expertise of the better-credentialed.

14. **JJD**
    August 23, 2007

    Please rest assured that many of us Buddhists are as skeptical as you about the current fad of "explaining" so-called Buddhism in terms of so-called science or vice versa. On the one hand, consciousness is explained with quantum theory and extra dimensions (still waiting to hear how dark matter is involved), and on the other hand isolated and mis-characterized elements of Buddhist practice (mindfulness and meditation) are currently fashionable in mental health clinics. Superstition, quackery, and incompetence are easy to find in either domain, and they are the real problem, not just the silly instances where a scientific quack tries to explain personal identity or a religious quack tries to explain space-time.

    Good science and good mathematics are based on principles and practical discipline which have taken thousands of years to work out. It seems all too easy to get an undergraduate degree or even a PhD in science or math without a firm grasp on those principles and that discipline. This is part of why your blog is needed.

15. **Molnar**
August 23, 2007

The Buddhism angle is all wrong. Physics actually proves Christianity. Or maybe Islam. Definitely not Buddhism.

16. **srp**
August 27, 2007

Low Math needs to read up on basic history of science. Kepler, Newton, and many of the physicists of the Enlightenment believed that their work elucidated either "the mind of God" or the details of God's handiwork. We atheists have no monopoly on scientific curiousity.

17. **Dan**
August 27, 2007

I, too, have laughed at the hand-waving which seems to occur in many popular books linking quantum physics with mysticism. Yet, I'm not sure exactly what your problem was with Wallace's book, given that you provided no more than blanket statement regarding the absurdity of even trying to reconcile physics and consciousness. I don't know much about the Templeton Foundation (beyond what was said here), but as a number of your commentators have noted, if someone likes what you're doing and they want to support you, you don't turn them down without a good reason.

As for Wallace, he appears to have a rather different aim from the average, feel-good, pop physics/mysticism authors. Specifically, he seems not to be critiquing science qua the attempt to gain understanding of the universe through rigorous, reproducible methodologies. Rather, he is critiquing scientists who dogmatically hold philosophical positions without any empirical basis. To quote from the selection you linked to:

"All subjective experiences, including consciousness itself, remain invisible to objective scientific observation. A growing number of scientists and philosophers of mind believe they have the solution: simply declare that conscious states are equivalent to their neurophysiological
correlates or to higher-level features of the brain. The physical processes in the brain that are equated with mental processes are believed to have a dual aspect: they are physically measurable processes, consisting of ordinary electrochemical events of a kind quite familiar to
physicists and chemists, but somehow, inexplicably, they are also subjective
experiences. The rationale for this quasi-dualistic position is that mental phenomena appear to be nonphysical, but this appearance is misleading,
for they are realized as neural events, which are their essential nature.

"It is as if mental phenomena, despite their undeniably subjective, nonphysical appearance, are being granted admittance into the world of nature by being equated with well-understood physical phenomena. Scientists have yet to identify the neural correlates of consciousness, so no one even knows yet what those hypothetical neural processes with a dual identity might be."

Perhaps, then, you find fault with his future research plan. For he seems in the other selection to suggest that there exist methodologies within the contemplative traditions, especially Buddhism, which might shed light on precisely these phenomena (consciousness, subjective etc.).

Why is that a problem? If the methods are rigorously noted, and the conclusions arrived at can be verified (or not) by anyone else who follows out the methodology, I'm not sure why that would be a problem, beyond the fact that those conclusions would not be accessible to everyone regardless of training.

Wallace specifically singles out mathematics as having a formal similarity to the program he is suggesting (I might single out Brouwer's intuitionism):

"[T]he practice of higher mathematics takes place within the mind of the mathematician and is then communicated to other mathematicians. Writing equations on a chalkboard is simply a kind of public behavior that may or may not result from the internal process of understanding proofs and devising theorems. A mathematically uneducated person may be taught how to write down the same equations, but when subjected to interrogation by a qualifi ed mathematician,
will clearly not understand what he has written. Mathematicians do commonly converse among themselves in a kind of language that is
unintelligible to nonmathematicians, and the same is true of experts in all fields of science. So there is no reason in principle that researchers could not receive professional training in observing mental phenomena and learn to communicate among themselves about their experiences. However, this is a major undertaking that neither philosophers nor cognitive scientists have yet tackled."

Similarly, if I present the radical conclusion of a new experiment, my results are not thrown out unless numerous independent researchers have attempted my experiment, using my methodology, and have failed to get the same results.

If a rigorous set of methods existed for investigating consciousness and subjective experience, what would be the problem with using them? On what grounds could we throw out the results?

Perhaps I have failed to meet your criticism. Or perhaps you merely meant to offer up a baseless ad hominem. Perhaps, however, your position is worth reconsidering. And, without question, my position is worth reconsidering. Any suggestions as to where I could start?

18. **Peter Woit**
August 27, 2007

Dan,

My criticism of the Wallace book has nothing to do with the issues you bring up, but with his specific claims about physics, especially things like quantum physics and extra dimensions. I read enough of the book (not just the chapters available on-line) to convince myself that the author was spouting sizable amounts of nonsense about physics. The world is full of similar nonsense, and it would be both a full-time job and a waste of ones life to argue the details of this with people.

19. **Mike**
August 28, 2007

Peter,
Are you not debating the details of extra-dimensional string theory? Was there some more specific claim that led to this conclusion?

I was considering buying this book until I read your review, now I don't know. I have read parts of Alan Wallace's participation with the Dalai Lama in the conference with David Finkelstein from Georgia Tech, Anton Zeilinger from the University of Vienna, Piet Hut from IAS, George Greenstein and Arthur Zajonc from Amherst; all well recognized academic physicists. Are they all engaged in "generic material of this kind, full of crackpottery"?? Is this the "similar nonsense" you're talking about? Or does Alan reference the "others" from the "Bleep"?

20. **Peter Woit**
August 28, 2007

Mike,

The reference to extra dimensions that I saw in Wallace were nonsense, those of string theorists are completely different.

The people you mention are a mixed bag, unlike Wallace they're trained physicists, but some of them are capable of engaging in similar nonsense from time to time. Again, for the last time, I consider this a complete waste of time, including examining and discussing the contributions to the Dalai Lama conference you reference. Please stop trying to discuss this here and find a venue run by someone who wants to engage in or encourage such discussion.

21. **Dan**
August 29, 2007

Hey Peter,

Sorry for wasting your time further, but I thought that you might appreciate having it pointed out that, while rhetoric often holds sway in the minds of masses, facts are the standard of science.

As you might have realized, I respect Wallace, for his genuine humility amongst other things. His work regarding science has seemed to me to be both rigorous and fair without being unequivocally laudatory. He certainly has an agenda, but he's honest and clear minded about it, and doesn't just try to sweeten up the "medicine" with a little quantum physics. So I was somewhat surprised to discover that a Columbia mathematician/physicist had thrown his latest work into the bin with "What the Bleep" and such junk.

However, I'm disappointed that you cannot bring up a single point at which he errs. Clearly, you have better things to do than write critical blog postings all day, so I don't expect you to answer this, but you did spend the time to write the initial post, presumably because, as you say, "I'm profoundly embarrassed that the institution where I work is promoting this sort of thing, so thought I better publicly say so."

Perhaps such a strong condemnation should just be ignored when the condemner can't even remember or enunciate his reasons for condemning. Whatever "this sort of thing" is, it seems fair to hypothesize that you simply don't know. Perhaps you might try to be a little less embarrassed in the future about things you don't know.

Or, perhaps you know, but you can't tell us because it's top-secret, classified information too sensitive for a public blog posting! Should we just take your opinions on authority, then? And while you're at it, where are those damned WMD's?

22. **Peter Woit**
August 29, 2007

Dan,

Sorry, but I don't find Wallace's book to demonstrate "genuine humility", but instead found it full of breath-taking arrogance. He announces that these "materialist" physicists have got quantum mechanics all wrong, while not understanding much at all about the subject himself.

I think that virtually any trained physicist you talk to will tell you the same thing, and has a similar reaction to the book as nonsense. Maybe you can find one of them who wants to waste his time going over the details of this nonsense. It's not going to be me.

23. **Dan**
August 29, 2007

Alright. Thanks for the reply, though. Guess I'll have to read it and see for myself.

24. **Louise Martinez**
September 6, 2007

Where Alan Wallace is coming from in my opinion, is from egocentricity. Perhaps it wasn't always that way. But if you have attended a retreat of his you will see how he is trying to impress you with how many teachers he has had, and his connection to His Holiness the Dalai Lama, which leaves one thinking on how he is banking on this relationship.

Nature on K-theory Controversy

August 22, 2007
Categories: Uncategorized

Nature has an article this week by Jenny Hogan about the K-theory journal situation reported on here, under the heading Strife proves hard to solve for K-theory. The article does show how real journalists do some things much better than bloggers, like calling up and interviewing the relevant people to sort out what happened. Hogan talked to Catriona Byrne, the mathematics editor at Springer, who claims that the managing editor of the journal, Anthony Bak, was sacked in January 2007, since he had stopped forwarding papers to them since April 2006. Also in January, Bak asked the editorial board to resign, which they did, although Byrne claims that Springer didn't find out about this until May.

Much of the controversy about this has to do with the question of how papers accepted after April 2006 were handled, with claims being made that some editors and authors were unaware that they were not being forwarded to Springer for publication. One of the editors who is unhappy about this is Eric Friedlander:

> Eric Friedlander at Northwestern University in Evanston, Illinois, a former editor at K-Theory, is in principle sympathetic to the switch. "There is a lot of concern in the mathematics community about the cost of journals," he says. But on 17 August, Friedlander wrote to Bak to say that despite being named as a member of the editorial board of the new journal, he was not willing to serve "because I cannot endorse the process by which you have withheld manuscripts submitted to K-Theory and proceeded without consultation with authors and the editorial board"…
> Friedlander is uncomfortable that papers were held up: "Our responsibility is to review mathematics that is submitted to us and disseminate it."

Update: For the perspective of one of the authors affected, see here.

Update: For a letter to the editors of K-theory from Matthias Kreck, see this comment.

Comments

1. **John Baez**
   August 23, 2007

   How do you know Catriona Byrne is the one who told Jenny Hogan that Bak had been sacked in January 2007? It's quite possible, but I don't see that it's certain — not from from my reading of the *Nature* article, anyway.

   It's a small detail — but Byrne works for Springer, so she's one of the interested parties in this dispute.

   I told you this thing was a can of worms… and I somehow doubt all the worms have wriggled free yet.

2. **Peter Woit**
   August 23, 2007

   John,

   You're right that it's just my assumption that Byrne either told Hogan that Bak had been sacked, or confirmed this if she had learned it elsewhere. If Hogan did learn this elsewhere, I can't imagine that she didn't at least try and get confirmation from Byrne. And she printed it as fact…

3. **John Baez**
   August 24, 2007

   Okay, thanks. I'm just trying to get the facts straight over at EUREKA.

Massive Plagiarism Scandal

August 23, 2007
Categories: Uncategorized

From Ars Mathematica I learned about an article at Ars Technica describing a scandal involving plagiarism of theoretical physics papers by about 20 different people, some of them students at the Middle East Technical University in Ankara. Many of the papers were refereed and published in well-known journals, and one made it into what is now perhaps the most well-known particle theory journal, the *Journal of High Energy Physics*.

> According to Dr. Sarioglu, two of the authors of this paper were graduate students with a prodigious track record of publication: over 40 papers in a 22-month span. Dr. Karasu, who sat on the panel that evaluated their oral exams, became suspicious when their knowledge of physics didn't appear to be consistent with this level of output. Discussions with Dr. Tekin revealed that the students also did not appear to possess the language skills necessary for this level of output in English-language journals (METU conducts its instruction in English).
>
> This caused these faculty members to go back and examine their publications in detail, at which point the plagiarism became clear. "All they had done was literally take big chunks of others' work using the 'copy and paste' technique," Dr. Sarioglu said, "steal from here and there to cook up an Intro which is basically the same stuff in all their manuscripts, carry out some really trivial calculations such as taking derivatives of some simple functions, and write up the results in the format of a paper." The department chair was informed and started an internal investigation; the university's Ethics Committee has since become involved.
>
> In the mean time, the faculty and administration at METU are attempting to do some damage control. The university's president personally sent a letter to the Journal of High Energy Physics requesting that the paper be withdrawn—a request that, as noted above, has yet to be acted upon. Meanwhile, the faculty members mentioned above are working with the arXiv administrators to ensure that any plagiarized work is removed.

The Ars Technica article emphasizes the role of the arXiv in this, since the plagiarized papers first appeared there and are still available there, although arXiv administrators have replaced the latest versions of the papers with a notation "withdrawn by arXiv administrators due to plagiarism". I don't actually think the arXiv is the real scandal here, rather the fact that refereeing standards in theoretical physics are now so low that obviously plagiarized papers don't seem to have much trouble getting into even the best journals in the field. Some of the other journals that published plagiarized papers from this same group of people include:

- *General Relativity and Gravitation* (here and here). The situation of the second of these is really confusing, since according to the arXiv it plagiarizes a paper by a completely different group in India, one that the arXiv lists as having "excessive overlap" with an earlier paper by the Turkish plagiarists.
- *Modern Physics Letters* (here and here)
- *International Journal of Modern Physics* (here, here, here, here and here)
- *International Journal of Theoretical Physics* (here, here and here)
- *Journal of Mathematical Physics* (here)
- *Progress in Theoretical Physics* (here)
- *Fortschritte der Physik* (here)
- *European Physics Journal* (here)
- *Foundations of Physics Letters* (here and here)
- *Chinese Physics Letters* (here and here)
- *Chinese Journal of Physics* (here)
- *Czech Journal of Physics* (here and here)
- *Fizika* (here)
- *Nuovo Cimento* (here)
- *Acta Physica Polonica* (here and here)
- *Acta Physica Slovaca* (here and here)
- *Pramana Journal of Physics* (here and here)
- *Astrophysics and Space Science* (here, here, here and here)

There are also other papers by some of the same authors which the arXiv does not list as plagiarized (published in *Nuclear Physics B*, here, *Classical and Quantum Gravity*, here , *International Journal of Modern Physics*, here and here) .

Remind me again, why is it that universities are paying large sums to get these journals?

Update: My guess is that most theorists are just going to ignore this and pretend it didn't happen. As far as I can tell, the journals involved haven't even bothered to add a notation to the articles still available on-line to note that they are plagiarisms, much less do anything to stop this from happening again. But at least Lubos agrees with me:

> The journals and arXiv are clearly flooded with papers that no one cares about which is why this thing can happen.

Comments

1. **Robert**
   August 23, 2007

   Try searching the arXiv for 'plagiarizes' in the abstract.

   For our master program, we had an applicant whose application material looked very promising but for whom a letter of recommendation said 'this is a good student, however, see [a search query to the arXiv]'. It turned out, as an undergraduate student (why on earth do you need publications at that stage?) in mathematics he had taken two papers from the arxiv and resubmitted them after just changing the title and of course the names of the authors.

   Now you could argue that math is healthier than HEP as this was discovered by one of the original authors but on the other hand it was simpler as beyond the title all the wording was kept (including the abstract).

   This is so stupid! Of course we did not accept this student for our program although we might have without this act of plagiarism.

2. **Rien**
   August 23, 2007

   There is a tool for looking for plagiarism of webpages called Copyscape. Maybe the arxiv should have something like that… or the journal editors.

3. **Rien**

August 23, 2007

Ah, it seems [they already have such a system]() at arXiv.

4. **woit**
   August 23, 2007

   Rien,

   Another idea would be to insist that refereeing be done by physicists who either know the literature of their field or are willing to look into it when they don't know it so well…

   This may be too difficult to achieve these days, but if that's the case, admitting this and shutting down these journals would be a good idea.

5. **Rien**
   August 23, 2007

   > Another idea would be to insist that refereeing be done by physicists who either know the literature of their field or are willing to look into it when they don't know it so well…

   What an unorthodox idea! 😉

   I would say this is more the fault of the journals than of the referees though. I sometimes get sent papers that are only very tangentially related to my own research, so what do you do then: send it back or try to cobble something together. I have done both.

   One would think that just going by the number of reserachers active in any given subfield, they should have managed to send at least one of those plagiarized papers for refereeing to one of the researchers that they plagiarized from…

6. **Amos Dettonville**
   August 23, 2007

   I was once reading some papers in the physics arXiv on a subject of interest to me, and came across what struck me as a particularly lucid and insightful paper from someone at a University in Portugal. The more I read, the more impressed I became… "Damn (I though), I couldn't have written this better myself…" And then it dawned on me: I HAD written it myself. The ENTIRE paper (about 12 pages) had simply been cut and pasted, verbatim, from an article of mine that is accessible on the web. The only things different were the abstract, the "author's" name, and one page of unintelligible nonsense that the guy had appended at the end.

   Just for fun, I searched for other papers by this individual, and immediately found another where he had done exactly the same thing with another of my articles.

   Now, I know plagiarism is fairly routine in academic papers, and I usually just ignore it, but this "cut and pasting" of a whole paper verbatim seemed particularly blatent, so I sent an email to the arXive, pointing out the two papers and the web sites they were stolen from. To my surprise, the arXiv rather promptly took down the offending papers, replacing them with a note about plagiarism, and sent me a message saying they had contacted the University to inform them of the situation. At that point I was sort of impressed (and surprised) at the level of ethics, although I was actually feeling a little sorry for the "author", whose career I naively imagined had been irrepairably damaged. As it turned out, I was worried for nothing… About a week later, revised versions of the papers re-appeared on the arXiv, essentially unchanged, but with two or three statements inserted here and there, saying "As explained in reference [x]", with a reference to my articles. So (apparently), all is well.

   On another related point, there has been a recent rash of plagiarized mathematics web sites, apparently by some people in Russia or one of the "stans". Their exact identity is unclear, but their mode of operation is to copy whole web sites, including the entire directory structures, and then convert all internal links to eliminate any reference to the original site, re-directing them to the bogus site. (They must have fairly sophisticated tools to do this.) Then they give the site a new name, and invent some people, complete with phony biographies, credentials and photos, who claim to be the authors of the material. They then begin to send emails to other people with mathematics web sites, asking them to link to the bogus site (presumably to increase traffic and raise their google rankings).

   The ultimate objective of this activity is not clear (to me), but I suspect it is to generate traffic for some kind of phishing activity… I understand the term of art is "social engineering". They are hosted on either blacklisted ISPs in the US, or else ISPs in Russia, so they are fairly untouchable from a legal standpoint.

7. **anonym**
   August 23, 2007

   I know plagiarism is fairly routine in academic papers, and I usually just ignore it

   that's what many people say : don't bother.

8. **Intellectually Curious**
   August 23, 2007

   "Now, I know plagiarism is fairly routine in academic papers…"

   Please tell me it ain't so. I thought even self-plagiarism (where you copy portions of, say, an introduction from your previous paper to another paper even though the two sets of results do not overlap) is frowned upon because of copyright issues.

   If the problem is so routine, then where's the scandal? Or do different fields/subfields have different ethical standards?

9. **Bee**
   August 23, 2007

   I am shocked. Seriously, I am really shocked. What is the world coming to? This is 20 people who did that not only once but in an organized and repeated way, I can't believe that. I mean, why on earth would one do that. Don't they have no interest in doing 'real' science. Didn't they ever think about what they are doing to the field?

   Sure, one part of the problem is the lacking quality control of peer review. But I think this problem goes back to the sheer amount of papers that get published (or want to get published). And this again goes back to the pressure people have to publish – which not only means that referees get many requests, but they have themselves pressure to publish papers… Taken together (too many publications, pressure to publish fast, lacking quality control) this is bound to get worse, not better, it's a downwards spiral. The technological improvements that today allow us to have 'rapid communications' and an overflow of available information DO influence the way research is done, and it's about time to realize that it's necessary to figure out how to best deal with these changes. How about slowing down the ever faster spinning world of science and give people some TIME to think about what they really want to achieve with their work (publications? citations?).

Best,

B.

10. **Godfather**
August 23, 2007

I wonder, are the chief editors of those journals going to be fired for extreme incompetence? Or are editors going to remain as unaccountable as always have been?

Imagine that a group of high school students looted a famous museum. What would the scandal be, the looting by the students or the incompetence of the museum's management?

11. **Demonic Gerbil**
August 23, 2007

And to think I'm trying to do research and get published the old fashioned way…

12. **Marty Tysanner**
August 23, 2007

I agree with Bee. It is surprising that someone aspiring to a career in science would try to establish themselves through systematic plagiarism. One wonders what brings them into science at all — certainly it doesn't seem to be a love of discovery, deeper understanding, and desire to contribute to a body of knowledge. It would require an exceptional level of self deception for a plagiarist to look back on past unoriginal work with any satisfaction at all. The whole notion is incompatible with the goals and ideals of science.

However, the problem seems quite solvable, at least in principle. Since most submissions of papers are now done electronically, it should be very possible to look for matches between an incoming paper and a database of electronically submitted and digitized papers. Warning flags could be raised if a paper had more than some minimum number of sentences or paragraphs in common with another paper. A paper would be rejected prior to the refereeing stage until any plagiarism issues are resolved. The arXiv would be one excellent place to implement this.

There are already companies like *turnitin.com* that perform this service for e.g. high schools, but perhaps a more sophisticated system would be needed than that. And such a system would have problems of its own. Computing resource requirements would be substantial, although they could be reduced by restricting comparisons to papers in the same field or subfield, or restricting searches on hot topics to the past few years. A highly motivated plagiarist might find ways around the system, such as systematically changing a word or two in each sentence, although there may be search techniques that can get around that. Anyway, in principle…

13. **a quantum diaries survivor**
August 23, 2007

Oh, Bee, shocked… Come on, see things in perspective. There are people of low moral standards everywhere. It is only a piece of luck that they did not start a career in politics, surgery, computer science, law, economics, aviation, …..

I think this is one alarm bell, and I totally concur with Peter ('cause of course, I am a "small Peter Woit" according to lumo) when he asks what are Universities paying for when they send hefty sums to Elsevier and the likes.

But shock… I am shocked for Britain's decision to extradate a lesbian to be lapidated in Iran today (see my blog), no room for publishing shocks today.

Cheers,
T.

14. **Thomas Love**
August 23, 2007

It has been obvious to many that scientific journals will be out of business in the near future, they are too slow and cost too much. On-line journals will take their place. What we need is a way to rate on-line articles.

But then again, I've talked to many researchers who say they don't have time to read because they are too busy writing.

15. **Peter Woit**
August 23, 2007

As usual, of course I agree with Tommaso… The fact that there are people out there trying to game the academic system doesn't qualify as shocking. What is shocking is how many supposedly reputable journals publish blatant plagiarism. The refereeing system in theoretical physics is completely broken and no one seems to care or be willing to do anything about it. This is not news, the Bogdanov scandal was a good example several years ago, but this is even worse.

One interesting question is how many times these authors had their papers given to a competent referee, one who would recognize the plagiarism and report it back to the journal and to the arXiv. Out of their many, many paper submissions, how often did that happen? Virtually never, I suspect…

I don't agree with Marty that what is needed is a "turnitin" system. The problem is not the blatant plagiarism like this, but the amount of unoriginal and shoddy work being published by theoretical physics journals, including even the best ones. At least in the case of this kind of plagiarism, it is clear to everyone what is going on. If referees are willing to allow this, they're certainly going to allow a lot of papers through that are little more than older work superficially rewritten. Either these journals should find a way to get papers competently refereed, or they should shut down and stop defrauding the institutions that are paying them for supposedly doing a competent job of "peer review".

16. **milkshake**
August 23, 2007

There is large amount of unoriginal crap published in lesser chemistry journals, too (there were some recent high-profile cases of fraud and plagiarism too, but it is less common).

What really gets me are research groups that never checked the literature before starting their project. They re-discover some stuff done 15 years ago and they re-brand it as a tremendous achievement of their own. When it is pointed out to them that there is a nearly identical precedent which they failed to acknowledge, they try to carefully weasel their way around it in an obscure "note added in print" instead of re-writing/retracting their paper.

17. **Arun**

August 23, 2007

Good old Nicolai Ivanovitch Lobachevsky! His method, it lives on!
Bozhe moi!

http://members.aol.com/quentncree/lehrer/lobachev.htm

18. **jhk**
August 23, 2007

"This paper has inappropriate amounts of overlap with the following papers also written by the authors or their collaborators."

Uh oh. If they're gonna start cracking down on this, it will jeapordize the physics community's favored method of padding CVs and boosting citation counts. This is playing with fire.

19. **Marty Tysanner**
August 23, 2007

I also agree with Tommaso that people of low moral standards occupy all niches of society. However, I think that choosing a career in scientific research is qualitatively different than choosing the path of politics, surgery, engineering, law,… It seems unlikely that most people can be truly successful in science without some kind of passion for the subject — there had to be something that made it initially interesting enough to go through the pain of graduate school and beyond. If *I* were trying to maximize success in terms of money, power, and popularity with the opposite sex, I don't think I would choose science! Those kinds of rewards seem to come a little more automatically through some other career paths…

That is what what makes it surprising to me that prospective scientists would resort to outright plagiarism. In the long run, if someone is viewed as "successful" due to copied work, it seems probable that others will eventually find out their success is not genuine and all will come crashing down. In the meantime, the usual "rewards" for a huckster will not come nearly as readily as in other fields.

Like Peter, I am not actually convinced that what is needed is an automated system for detecting plagiarism. My point was that the problem of blatant plagiarism should be solvable in principle by such a system. Whether the problem is serious enough to warrant such a step is a different question.

The problem of how journals can reward or cajole referees so that they take the task seriously is also a different and difficult question. If a referee doesn't do it out of a sense of professional responsibility or for other noble reasons, and the reward system within universities or labs is not in place to encourage it for less noble reasons, then short of outright payment for services it seems there aren't a lot of good options. And pay-per-paper refereeing doesn't seem likely to lead to lower journal costs…

20. **Bee**
August 23, 2007

Hi Tom,

Sure, there are "people of low moral standards everywhere", but this is not just one guy who copied a paper, it looks like it was an infectious and spreading disease that apparently was considered to be a good idea for whatever reason. That's why I am shocked. I mean, what is the next level? Pseudo-scientists trying to hack SPIRES and to push their citation level? Scientific terrorist attacks that delete gr-qc? Or, actually, the next logical step would be the computer code that produces finished papers that are not so obviously plagiarisms (along the lines of this paper recipe maybe?). I mean, people accuse me occasionally that I am too idealistic, but yes I admit I am troubled by people who willingly damage the field for no other reason than their immediate advantage (which btw I think is very shortsighted even for themselves).

Unlike Peter however, I don't think the blame goes entirely to the journals. Enforcing a better peer review system is definitely going to help in this regard, but it's curing the symptoms, not the cause. Ask what leads people to act this way. Remove their incentive. It's being judged by number of publications, by quantity instead of quality, that is a trigger. It's the glass wall that surrounds North America whether you realize it or not. It's time pressure. It's PUBLISH OR PERISH. It's a society that values status (career! career! career!) over wisdom. It's a community that punishes those that don't fit into scheme A that causes outsiders to fake their selection criteria – it's survival of the fittest, right?

Best,

B.

«Amos Dettonville Says:
August 23rd, 2007 at 11:27 am

I was once reading some papers in the physics arXiv on a subject of interest to me, and came across what struck me as a particularly lucid and insightful paper from someone at a University in Portugal.»…

Title of the paper please or even better, link in the arXiv.

22. **LDM**
August 23, 2007

Interesting.

Did it ever occur to anyone that the failure was much earlier…probably in high school? Does anyone think it is possible that "copy and paste" is a skill that first gets honed and rewarded in high school?

Yes, there are issues with the journals and the review system, but computers just by themselves have lowered the quality of education in more than a few areas. Copy and paste we have just seen. More insidious is the eroding of the knowledge base. The person who goes to the library and scours the books in the aisles for what he/she needs is forced to do some extra mental work and thereby assimilates more knowledge in the field. A computer search is too easy and you miss out on becoming familiar with the literature in your field.

23. **J**
August 23, 2007

Oh my. What is wrong with this "top" journals?

24. **D R Lunsford**
August 23, 2007

Most of even legitimate papers (meaning, not stolen) is so worthless – how can you honestly judge it? What's the point of stealing bullshit?

This is all surreal. Thank God I escaped this cesspool.

25. **Sidious Lord**
August 24, 2007

When searching the arXiv for plagiarizes

http://arxiv.org/find/all/1/abs:+plagiarizes/0/1/0/all/0/1

one also gets a paper co-authored by Ginsparg himself

http://arxiv.org/abs/cs/0702012

describing the plagiarism detection in arXiv. This is quite recent too.

26. **Peter Orland**
August 24, 2007

I am not shocked at all by these events (though I am smugly and undeservedly pleased that Phys. Rev. D, in which I have been publishing as of late, is not on the list).

What I am amazed by is that the authors of the original papers did not notice what was going on. Plagiarism is an old story, and it's gone on as long as there has been literature. Here is what is stunning; none or few of the victims seemed to have been aware of the crime. Had they known, they would have alerted the faculty of this department much sooner and it would not have got this far. This is a new phenomenon.

I think what is going on is that theoretical high-energy physics has become almost entirely literature-driven, as opposed to idea-driven (for practical reasons, it is not experiment-driven, at least not for another year or so). As Milkshake noted above, people dress up old ideas with new buzzwords and try to pass them off as original work.

People are far more obsessed with producing papers on trendy topics, and don't care much about their ideas. If the paper itself instead of its content is the desired product, then no one cares if the content may be found elsewhere.

27. **dave tweed**
August 24, 2007

Regarding LDMs comments:
"The person who goes to the library and scours the books in the aisles for what he/she needs is forced to do some extra mental work and thereby assimilates more knowledge in the field." I think it's a mixed bag. On the one hand, looking at bound journals in the library does require some extra thinking which can help understanding, but, partly because libraries only take a selection of the journals in a field and partly because its difficult to do more than follow author-supplied references in printed papers it can lead to following "the popular consensus" whilst the internet search does offer the opportunity of discovering a relevant search phrase in the body of a technical report ostensibly about a different subject that gives you another avenue. Being completely honest, back when my library did primarily take paper journals, the biggest advantage was that the library was in a building five minutes walk away which helped wake you during a mid-afternoon low-spot.

"A computer search is too easy and you miss out on becoming familiar with the literature in your field." With the proliferation of publish opportunities, particularly in fields where conference publications are much closer to the leading edge than the eventual journal versions, is it really possible to become familiar with the literature just by going to a typical university library? I try and do a reasonable amount of reading, but I know that if I did "fully comprehensive" reading at current publication volumes I wouldn't do any new research so I somewhat take a chance I may be *unwittingly* duplicating someone else's work published in a minor journal. Of course, if it's pointed out to me that I have duplicated some existing work then the work becomes "not novel".

28. **Matt Daws**
August 24, 2007

Is it just me, or did anyone else notice this:

prodigious track record of publication: over 40 papers in a 22-month span

No, that's not "prodigious". That's comediarily impossible in theoretical physics. Why did anyone think for a moment that this was possible?

I'm a mathematician, not a physicist, but I do sort of agree with Peter Orland. If papers which were basically copies of my own were published in top mathematics journals, then I would definitely notice. Heck, I'd notice when they were posted on the ArXiV. Is this because people have essentially ceased to read the top physics journals?

29. **klien4g**
August 24, 2007

To Arun: How was Lobachevsky ever involved in plagiarism (pace Lehrer's song)?

But its very depressing to hear about the 'po-mo'-isation of physics.
Perhaps, its because upto the early 20th c. those really interested in the sciences landed up doing it and now since there are so many more people competing for just about any profession one cares to name, the sciences has become just another job one chooses to do — not ready to put up with the grueling work hours of investment banking, well how about some condensed matter physics– but oops, how does one learn originality and creativity??!!

30. **anon**
August 24, 2007

Marty suggested

> Since most submissions of papers are now done electronically, it should be very possible to look for matches between an incoming paper and a database of electronically submitted and digitized papers.

Rien pointed out earlier in the comments that this is [already being done on the arXiv](#).

I agree with Bee that it's the publish-or-perish ideology that's to blame here… we are becoming less like universities and more like corporate thinktanks.

31. **AGeek**
August 24, 2007

Dear anon, corporate think tanks are generally expected to produce something useful, so they are subject to objective evaluation. That's a big step up from academic "publish or perish", where it's the killing of trees that seems to matter most. 😉

32. **LDM**
August 24, 2007

D R Lunsford's comment "*Most of even legitimate papers (meaning, not stolen) is so worthless – how can you honestly judge it? What's the point of stealing bullshit? This is all surreal. Thank God I escaped this cesspool.*"
is one I tend to sympathize with…but really how many academics who's careers have been built on this system would admit the same?

It should be clear by now that the "publish – or – perish" meme does not result in high quality. In fact, since quality by definition is harder to produce, it is clear that low quality papers will tend to be the norm.
It is time to kill the "publish – or – perish" meme. People who are passionate about science will still publish by virtue of their passion for science anyway — but they won't be *forced* to produce what is essentially, in many cases, scientific waffle.

33. **amused**
August 24, 2007

Well this isn't good, but people shouldn't get too carried away and draw overly generalized conclusions. As far as refereeing standards go, I think it's important to distinguish between two classes of papers. The first consists of the papers which address issues of central importance to a subcommunity of sensible researchers. My impression is that refereeing standards are generally pretty good here (although everyone has a bad experience from time to time). The main complaint that could be made, I think, is that papers making too incremental advances are getting through. On the other hand, for the papers in the second class (which consists of all the papers not in the first class) refereeing can be very sloppy, even when the papers are submitted to supposedly top journals. For the simple reason that referees are loathed to invest time and effort in reading and evaluating papers that don't interest them. Recommending publication is a quick and easy option; it can be quite a pain to reject a paper since then you will have to spend time dealing with the authors' outraged rebuttal. Of course, a person may simply refuse to referee a paper that isn't interesting to them, but then it will just get sent to other people, and if the paper belongs to the second class it can eventually happen that someone just waves it through or it ends up being refereed by a incompetent person.

This obviously isn't a good situation, so what can be done about it? Well, as I've harped on about elsewhere I think we should take a look at how things are in the maths community. Probably the lesser maths journals are afflicted with problems similar to the physics ones, but on the other had it seems that the maths folks have been successful in maintaining high standards for their top journals. I doubt this is just because they are more conscientious than us. A mathematician who gets sent a paper to referee for Ann. Math. has a significant selfish motivation for doing a good and careful job: Her own high standing in the broader maths community comes in large part from having published papers herself in Ann Math and similar journals, so she will want to make sure those standards are maintained because if they slip then the prestige that she has derived from publishing there (and will derive from future publications) slips as well. Contrast this with the situation in physics (or at least h.e.p.): Someone who gets sent a paper to referee for, say, JHEP, has very little selfinterest in doing a good job – there is little prestige to be had from publishing in JHEP because the threshold for getting published there is not high. Your paper might make a major advance, but it is published side by side with others making small incremental advances and the occasional paper full of vacuous nonsense (yes I've seen them) or even containing plagiarism. So how is anyone to know the high quality of your paper just from the fact that it got published in JHEP? So you get almost no prestige from publishing in JHEP, and therefore have nothing personal at stake in keeping its standards high, hence no selfish motivation to do a good job with refereeing.

From these considerations an obvious solution would be to establish "high quality" journals in physics just like the mathematicians have. But this would require a major change of culture in physics. In physics, as far as I can tell, a person's prestige and standing is derived not from where they have published, or how many papers they produced, but what clique they belong to. Of course within their own subfield the person's standing will be determined by the actual work they have done, but when they are being evaluated by a dean and committee members from outside their field it will be their connections and the power of their senior supporters that count the most. In maths, as far as I can tell, publications in top journals can trump connections to powerful people, but not so in hep physics. Some outsider can publish in PRL until they are blue in the face but it won't help them a shred when they are up in competition against the student of Nathan Seiberg or the postdoc of Joe Polchinski. The current situation suits the powers that be just fine, so I don't foresee it changing anytime soon. But maybe if we heap enough scorn and contempt on them it might eventually have some effect.

34. **MathPhys**
August 24, 2007

My experience with alerting people to cases of plagiarism that they should know about (for example, pointing out to a supervisor that one of his students is into that) is that they just don't want to hear about it. It's too awkward and too much trouble to deal with. Unless of course the vicitim finds out and formally complains.

35. **Phil**
August 24, 2007

Peter Orland said

"What I am amazed by is that the authors of the original papers did not notice what was going on."

As an author of one of the original papers I would like to respond to this. In my case a section of one of my papers gr-qc/9803014 was copied almost verbatim. This section was actually an introductory piece describing the equations of the L-T model which are very old. The rest of the paper they wrote was very different and was not taken from mine. If they had plagiarised my original ideas I would probably have noticed it, but I would not notice the copying a few standard equations and text unless I read every paper in the archive and have a very good memory for how I wrote things a few years ago.

I think they got away with it for so long because they were quite careful not to copy whole papers. I think it is their supervisors who should have become aware of it, assuming they were not complicit. The journal referees may also have a case to answer but I think you would have to check each paper in detail to see if there was really anything that they should have been suspicious of. At least we can be satisfied that the system of independent outside review for doctorates caught them out in the end.

Personally I am more concerned about cases of plagiarism where people copy an idea and rework it without giving credit to people who did similar work previously. These days there are many people who do research work and leave academia never to return. Later their ideas can become more relevant and someone else picks them up. Since the person left they may not follow the "reinvention" of their ideas and even if they do it is very difficult to point out their priority. For example the arxiv does not accept backtracks from outsiders.

It would be nice if something could be done about that.

Oh! Aristoteles!
Back to the middle ages, scholastic thinking!!
I worry about the future of the science in the developing countries..
Hardworking graduates start to work at the private enterprises and companies, a few prefer studying science academically..
Governments have to consider this situation carefully and try to plan and organize a logical application about science..

37. **Godfather**
August 24, 2007

> Recommending publication is a quick and easy option; it can be quite a pain to reject a paper since then you will have to spend time dealing with the authors' outraged rebuttal.

And who is responsible for finding competent referees, overseeing the editorial process, and taking a final decision on the basis of that process?

Let's not forget that it is not referees who accept papers for publication, it's editors who do. That's precisely their job.

On the other hand, we do not know whether all of these plagiarized papers were actually refereed. Editors can, and often do, take editorial decisions without consulting referees.

38. **ppsh**
August 24, 2007

Example when authors did found plagiat. I got reference few days ago. First paper is original and second is identical plagiat with only title changed.

1. Original: Optimization of ionic conductivity in doped ceria
David A. Andersson, Sergei I. Simak, Natalia V. Skorodumova, Igor A. Abrikosov, and Borje Johansson
3518–3521 PNAS March 7, 2006 □ vol. 103 □ no. 10

2. Plagiat: Determination of dopant of ceria system by density functional
theory K. Muthukkumaran ; Roshan Bokalawela ;
Tom Mathews 198; S. Selladurai
J Mater Sci (2007) 42:7461–7466

39. **Godfather**
August 24, 2007

> Example when authors did found plagiat. I got reference few days ago.

I'm impressed… I had never seen anything like that before. The *entire* paper is copied word by word and figure by figure.

40. **Bee**
August 24, 2007

@Matt Daws

No, that's not "prodigious". That's comediarily impossible in theoretical physics. Why did anyone think for a moment that this was possible?

It's not impossible. I know personally several people who have published about 20 papers per year over a period of several years. I don't want to comment on the quality of these papers. Things like this however depend strongly on the field one is working in, and just counting items on the publication list doesn't mean very much. To begin with, it's quite common to take papers apart in the smallest possible bits that can be published separately – wouldn't it be stupid if you didn't, it's like throwing away a paper for free.

Unfortunately, many funding agencies are not aware of that (or pretend to be not aware, or ignore the issue on purpose). See, there is the primary goal to fund good researchers. But this is not a useful prescription in many regards, it's too vague and too complicated. Instead, there are some secondary requirements that have been worked out over the decades that indicate interesting research and that allows faster judgement. One is the number of publications.

However, the problem starts if people instead of aiming for the primary goal (good research) try to be 'smart' by targeting the secondary criteria (many publications) directly. That's why I said above: remove the cause, not the symptoms – otherwise the problem will only reappear elsewhere. That is to say: rethink presently applied secondary criteria. Do they still satisfactory match with the primary goals?

Best,

B.

41. **ppsh**
August 24, 2007

I think plagiat is really stupid thing at modern times. Too easy to discover and to prove. Which is not the case for pure fraud. How can referee decide if some experiments described in the paper were really performed or not? Or was result of computer simulation exactly that one as described ? In worst case author can admit some undeliberate errors and to publish corrigendum. Almost risk free if author wil not claim too much as did Hendrik Schön

42. **anonym**
August 24, 2007

To Phil the author of gr-qc/9803014 :

If they had plagiarised my original ideas I would probably have noticed it, but I would not notice the copying a few standard equations and text…

Just to make sure : so does their paper have an original contribution (which is non-trivial)?

43. **Phil**
August 24, 2007

anonym, are you asking if my paper gr-qc/9803014 has an original contribution or if the paper gr-qc/0607083 which plagiarised it has an original contribution? My one does, of course, but I will assume you are asking about gr-qc/0607083 🙂

Ok I have done some further checking with the help of google. The next paragraph after the one copied from mine turns out to be copied from gr-qc/0011087 which is about teleparallel gravity. I have had a quick read and I cant make much sense of gr-qc/0607083 overall. The L-T model which was copied from my paper is standard GR whereas teleparallel gravity is a generalisation with torsion. I dont see how these are being used consistently. Indeed I dont see the equations of the L-T model being used later on. I may be missing something but the paper looks like nonsense to me.

At least this one was not published.

44. **Mr. Mustela**
August 24, 2007

I once witnessed a smallish plagiarism scandal first hand. Since then I am convinced that many plagiarists simply see nothing wrong in it because they have a completely different understanding of the system than we do. That explains the level of "stupidity", or callousness, that is involved.

The case I am talking about is funny. A PhD student turns in a thesis. Large swaths of it are copied and mashed together from published papers – dig this – from his supervisor! It took a while for him to accept that there was any problem with this, and in fact was surprised that the supervisor didn't find this flattering. From all I can tell, he never understood the problem to any level of depth. He just accepted it and tried to adapt (personally, I think the real scandal is that he got a second chance).

I am sure that for many plagiarists, a paper is nothing but a self-important swath of glibberish that bears names on it. It being published just means that the people named enjoy the favor of the gods, and thus are great. And being great is the purpose of life, isn't it? They can't, even if they have some technical chops, see anything but self-important drivel in any article they read, cannot imagine that anyone sees anything else, and essentially just want the favor of the gods. Plagiarism is just a side effect of wanting to play it risk free and use the same incantations that have worked before. You know, not everyone can come up with original glibberish that sounds right.

I agree with peter that it is a very bad sign when such approaches start to work too well.

45. **SnarkFest**
August 24, 2007

Mr. Mustela,

Your characterization, which strikes me as completely on-target, describes the ultimate in cargo cult science.

Automated plagiarism detection does suggest a low-overhead solution for online papers—clearly flag the work as plagiarism, and leave it in place, with the "authors'" names. Provide canned queries on the relevant sites that list the plagiarized papers, and prominently identify and rank the plagiarists for their achievements…as plagiarists. They want recognition and notoriety? Fine, give 'em recognition and notoriety.

Of course, in practice some innocent people could be caught in the net. (Recall William Proxmire's Golden Fleece Awards.)

46. **Coin**
August 24, 2007

Automated plagiarism detection does suggest a low-overhead solution for online papers…Of course, in practice some innocent people could be caught in the net.

Considering how many papers go online before publishing these days, it does at least seem that *Journals* should use automated plagiarism detection at least as a first pass. A good way to do this would be to run all submitted papers through a plagiarism detector first thing, and have anything that triggers the detector be simply punted to a human editor for review, just in case; since journals do not accept that many papers, they surely have the time to run a simple tool and filter out false positives by hand.

I actually kind of hesitate to even suggest something this simple; after all, I'd be shocked to learn they weren't doing it this way already, as the same is widely done for, say, papers handed in for undergraduate classes. Looking at how many different journals this one group hit before they got caught, however, it looks like apparently they're *not* doing it this way already…

47. **Rien**
August 24, 2007

I know what you mean, and it annoys me endlessly. I have tried a couple of times when I was refereeing papers like that to get editors to reject the paper on the grounds that it is just the Nth iteration of the same paper by the same authors. People just rerun their numerical codes with slightly different parameters and call that a paper.

But maybe the new anti-plagiarism system at arXiv will detect those papers too!

48. **amused**
August 24, 2007

Plagiarism can have many different shades of gray and it isn't always simply a case of cutting and pasting from someone's paper. I had an experience a few years back of someone rederiving a result from one of my papers, supplementing it with a physical interpretation (which I had been aware of but didn't consider interesting enough to mention) and then passing it off as entirely his own work (it got published in JHEP). He referred to my paper in a sentence "See Ref.[X] for related work". It's not so easy to know what to do in this situation; his rederivation and formulation of the result is presented quite differently to mine and it wouldn't be obvious to others unless they invested a fair bit of time into checking the technical details. I have toyed on and off with the idea of writing a paper to point out that his paper and mine are not only "related" but are in fact essentially identical modulo some padding, but am loathed to take time out for this which I could be spending on real research.

49. **hyperbolic geometry footnote**
August 25, 2007

klein4g,

Lobachevsky is the protagonist in Lehrer's song because of the well known multiple discovery of noneuclidean (hyperbolic) geometry. Credit for this discovery, and for the later construction of specific models, is emphasized differently in different countries.

50. **Phil**
August 25, 2007

In case anyone is interested to hear more about my original paper that got plagiarsed, I have written something about it in my blog here 🙂

51. **Log Lady**
August 25, 2007

As another war story, about 20 years ago I refereed and rejected a geophysical paper. It seemed pretty clear to me that the junior author had written his own computer program based on someone else's Masters thesis and used the thesis results to check it. So far, so good. He could have then used the program to do something new. But then he wrote his own paper and submitted it as new work without even any reference to the thesis. I pointed out to the editor that the work was not new and roughly fifteen of the figures in the paper were identical to the figures in the thesis. (Really identical. After all, he wanted to check his program, didn't he?) I expected never to see the paper again, but it was published a couple of years later. The senior author, an accomplished schmoozer in the field, had simply hammered away at the refereeing process, demanded a more "reasonable" reviewer, and outlasted the periodic changes in editor and associate editor.

I don't read the journals anymore. The papers are too poorly written and I don't have time to find and correct the errors. If I have an idea, I troll the internet for useful information. When I write a paper, I feel no obligation to pad it with references to everyone that ever expressed a thought about the subject. I only include references that I personally found useful and that were well-written enough that I would recommend them to others. Unless I am specifically writing a review paper, acknowledging everyone who made any contribution to the area simply buries important references in a cloud of fluff.

52. **Bee**
August 25, 2007

Hi Rien:

Indeed, that's exactly what I mean. And yes, it is endlessly annoying. Coincidentally, I yesterday came across this Wikipedia entry about the 'Least Publishable Unit' 😉

Besides this, some remarks on the arXiv plagiarism check. Last year or so, I noticed they were fiddling around with something because upon submission of a paper I got a message saying my paper was rejected because it seemed to be a copy of an already existing paper. I had a look at this other paper (turned out I knew the author), and there were about no similarities except that I accidentally had picked the same title (well, it was a proceedings article, how creative does one have to be for that?). So I sent a complaint to the arXiv guys, and they resolved the problem (very promptly and within only a couple of hours I have to say.)

So I was somewhat sceptical about the whole thing, but by now I came to like it. There have been at least two groups of people who have been posting papers (repeatedly) where the whole introduction was made of copies from my papers. It's not that the actual content was a plagiarism, but I found it really annoying nevertheless. I mean, I spent quite some while writing this stuff, and then there come some guys and just copy it? I have sent them emails once or twice, which didn't change anything. Coincidentally I had to referee some of their papers where I send a note to the editor about it. The result of that however was that they replaced the copies from my papers with copies from somebody elses paper (I happened to recognize also his writing). I should add in both cases, they cited the original work. (And in both cases it considerably improved the English of the manuscript.)

One way or the other, the first some pages of their recent papers still have close resemblance to mine, but they have rearranged the sentences noticeably. I guess this is because they ran into problems with the arXiv filter, and so I really welcome it.

Best,

B.

53. **Alfred Holden**
August 25, 2007

Plagiarism is form of flattery. Though without honor it has been practiced since time began. Concentric waves of thought emulating successive authors' works.

Good work is rare. Plagiarism merely reinforces existing work. One could speak of the stress that belies the academic professions to publish. With Universities and Colleges expanding, the pressure for new works taxes the professions.

It is an age of mediocrity. A broad band of white noise.

Occasionally, we hit a chord. Sometimes we have a tune.

Think of those who have rewritten history countless times to where we accept things on faith alone. Where objects become larger than life, where they aquire a life of their own.

The philosopher's stone, the journey towards enlightenment, the means to all ends.

The brightest of our students search for this. It is what gave rise to alchemy in the ancient Near East, Egypt, Greece and India. It became the "holy grail" of Western alchemy.

In the view of spiritual alchemy, making the philosopher's stone would bring enlightenment upon the maker and conclude the Great Work.

Disambiguation is the result of the process of resolving conflicts as in plagiarism, where the author strives to conclude the "Great Work".

54. **a.k.**
August 25, 2007

..one could remark that, this does mainly concern PhD thesis, that it can be probably more honest to summarize used results clearly, even if it has a copy/paste character, than to seemingly 'rework' the material and give the half-informed reader the illusion to have creatively invented a whole area. We should be all quite aware (Einstein was, by the way), that we only make more or less tiny contributions to an area thousands of brilliant thinkers have smoothed and brightened long before we even existed. Given that at least PhD-thesis are expected to be to a certain degree 'self-contained', there is inevitably a certain degree of redundancy to existing papers and results, the creativity to arrange these results 'nicely' (seeming to be 'orginial') could be more effectively adressed to exploring new ideas, this is at least my point of view.

55. **Kris Krogh**
August 25, 2007

Einstein quote: "The secret to creativity is knowing how to hide your sources." Can't say I agree with that one.

56. **Amos Dettonville**
August 26, 2007

Kris,
Can you cite a reference for that Einstein "quote"? I know it's in circulation, and was used as the motto for a book accusing Einstein of being an "incorragible plagiarist", but when John Stachel (Einstein scholar) reviewed that book, he mentioned that he knew of no actual reference for that quote. To my ear, it sounds like another of those "sayings" (like the recent one about mankind only surviving for 3 years if the bees all disappeared) that someone decides to attribute to "Einstein" to make it sound more authoritative (or something). Anyway, I'd be interested if you know the source.

57. **(withheld)**
August 26, 2007

I once had a paper that an ESL coauthor wrote, and noticed that the English suspiciously improved in places. I simply copied the sentences into Google and they popped up on pubmed and other indices as imbedded in other papers. I was furious, and let this guy know that this was unacceptable and his career (or at least our collaboration) was over if it wasn't fixed immediately and never happened again. What was most stunning was that he kept referring to it as a copyright issue, rather than grasping that there was fundamental dishonesty involved.

And that was just a few sentences mostly in the intro, actually kind of irrelevant to any deep original thoughts in the paper. I can't conceive of what kind of mentality it takes to copy a whole paper with results. Far beyond that is the mentality of an editor who won't pull such a paper immediately and permanently ban the offending author from its pages.

58. **a.k.**
August 26, 2007

..one could add that from my point of view, the actual problem in mathematics, physics and related sciences is that, in contrary to the 'classical' sciences as philosophy, there is no 'citation culture' in the exact sciences, it was inherent over thousands of years (refering to Euclid et al.) that mathematical findings are 'unpersonal', they tended to be results founded by large groups, collectives of mathematicians. From this point of view, a 'citation culture' wasn't needed, up to the present, the actual training of mathematicians involves to a large degree to 'transform' collective knowledge into subjective knowledge, where this borders to simple 'plagiarism' is often impossible to decide. What I want to express is that excessive plagiarism is to a certain degree a (deformed) continuation of 'well-accepted' methods in the exact sciences, assuming this, the discussion is not that 'black and white' anymore as it may seem.

59. **Kris Krogh**
August 26, 2007

Amos,

I think you're right. In most compilations of Einstein quotes, that one is included. But, searching the web just now for the source, I couldn't find one. Thanks for setting me straight!

60. **Intellectually Curious**
August 26, 2007

Dear (withheld),

I agree that what your co-author did certainly was wrong, but I can't help but think that if he (assuming it's a male) were a native English user, he could've easily paraphrased those copied sentences and not be accused of being a plagiarist. But would this make him any more honest if the original source was not cited? So I can see why your colleague might insist on this being a copyright issue rather than one of dishonesty, especially when those sentences do not involve "any deep original thoughts." I'm not defending him, of course, but I can sort of see his point.

I think whether a person is a true plagiarist should be judged over a period of time rather than being judged based on one "gray-area" incident. This person must be warned/educated, of course, as you rightly did so, but perhaps be also given the benefit of the doubt.

It's just my opinion based on what little I know about your specific case. Maybe the incident crossed a darker shade of gray than I thought…

61. **(withheld)**
August 26, 2007

I.C.: It is a point to ponder, I agree. I hadn't realized until it happened how I'd internalized the "thou shalt not plagiarize" commandment from my own education. Apparently it is not all that universal.

I came to the conclusion for myself that it is somewhat arbitrary. It certainly looks very very bad if you are caught copying verbatim, whereas paraphrasing without citing is more in the realm of poor etiquette (by consensus). Since this guy was a student who was quibbling already, it didn't make sense to me to be nuanced in my criticism. I thought well of him otherwise and wanted him to know that people would frown on doing such things.

That’s all tiny potatoes compared to what Peter’s post was about, though. I’m still stunned thinking about it. The gall…

62. **Intellectually Curious**
August 27, 2007

Those of us who’ve been educated in the West know that plagiarism typically means copying verbatim. But I’ve encountered researchers from various cultures who would never consider stealing (original) ideas but would be more careless with borrowing words from others to describe, say, common concepts and definitions. To them, the intent is not to improperly claim credit but to find a way to express themselves more effectively and correctly in a language foreign to them. These otherwise reputable individuals should be told that in such matters the letter of the law is just as important as the spirit of the law.

63. **Paper Laundrer from Pakistan**
August 27, 2007

A huge help can be made available by ACM, IEEE and other big publishing organization to conference and journal editors by providing free or low-cost “plagiarism’ check and mechanism to scan through short-listed papers before publications.

This sort of events can cause serious embarrassment to the Conference Organizers, Universities and even the countries involved.

64. **Jim**
August 27, 2007

Actually I had one problem in my career with distinguishing what is plagiarism an what is not. In an invited topical review I reviewed work of other authors and I wrote “the following theorem was proven in [Reference]” and then I copied the two-lines theorem verbatim. I did not consider this to be plagiarism, since I properly referred to the author’s work, but then I was attacked by the author that this is plagiarism and that I should have used quotation marks when writing down the theorem or I should have rephrase the theorem. I do not think that it is a good idea to rephrase theorems every-time they are mentioned and I did not see in the literature theorems in quotations marks either. What is your opinion? Fortunately, I did not have to write another review since that time.

65. **Intellectually Curious**
August 27, 2007

Jim, your case clearly was not plagiarism because 1) you were reviewing the original author’s work; and 2) the correct reference was given with no ambiguity of whose theorem you were describing. Maybe he/she was simply unhappy with your review and tried to find an excuse to attack the reviewer.

How many ways can you use a precise language like mathematics to write a theorem or definition without repeating parts of someone’s text or without altering the intended meaning with unnatural wording and phrases?

66. **CJ**
August 27, 2007

I do not know if this helps, but Professor Irving Hexham at the University of Calgary wrote a useful guide on academic plagiarism:

http://www.ucalgary.ca/~hexham/study/plag.html

67. **RPenner**
August 28, 2007

Outrageous as academic plagiarism is, here’s a case of pityful commercial plagiarism:

Some author named “Sapphire” wants people to buy its new book about time travel (via meditation). For some reason, Amazon.com has many wholly plagiarized “reviews” of this book, which have been lifted from blogs and web dialogues (including a dialog I had on quantum theory). No truly important work was stolen (the writing aspires to be pop physics at best) but neither were any salient points about the book in question. Amazon, has been less than helpful over the months with the “reviews” re-appearing and the public criticism being quashed. Further, the pro-Sapphire advocates describe this as an attempt to persecute Sapphire by a James Lorel. All power to James Lorel in his quest for reviews which make sense and his anti-plagiarism stance! I only regret that I no longer have a personal stake in this.

http://amazon.com/gp/product/1424315956
(See the review by Columbia University’s “Doctor of Physic” which was lifted from Wikipedia’s article on “Time Travel”)
http://forum.physorg.com/index.php?showtopic=12352&view=findpost&p=191221
(James Lorel drops by Crackpot Central to inform us willful infringement, now removed by Amazon.)

68. **Kerim**
September 5, 2007

For those who have a hard time understanding the logic behiind such plagiarism: For countries that work hard to close the scientific gap there are often attractive incentives and prizes for publishing more such as cash bonuses per publication, or harsh requirements such as publising certain number of papers for graduating, getting a tenure or proffesorship. Obviously these people, especially the two grad students were simply making “good money”. I dont think they cared about their scientific career, they were simply frauding the university. I heard that they are being sued by the university to get back some 30K $ they were paid as bonus during these two years.

69. **ahmet**
September 8, 2007

As a graduate student physics in Turkey, I feel that the plagiarism scandal is only the tip of the iceberg. For those who are following a career in physics like me have no idea how they published 59 papers in 22 months span. It would be considered as an act of greedy graduate student who has no ethics of science. But they are the member of the university in which are seeking Ph.D. degree under the supervisors of its faculty. Most of the papers had gone though review of their supervisors and their supervisors’ names were appended to the papers. Somehow their advisors were encouring these naive graduate students to publish.

Let me say what will happen next. The universities(up to now four) involved in the massive ring of paligiarism will open investigation about the case. They will impute the paligiarism to graduate students. Their advisors will say their names were added on papers without their consent. The graduate students will be discharged from the universities. So the case will be closed.

70. **surferrr**
September 8, 2007

This year 1st time METU is not in the list of the top 500 universities in the world. It seems that METU is going down in many ways. In this or that department , you see a russian or an azerbaijani writing a paper and putting his name and the names of a few more on it then having it printed. Next you see these people promoted to associate professorship or full professorship. To have a little fun ,I plagiarized the following from a page in the math department in METU :

1. Terzioglu, T.; Yurdakul, M.; and Zahariuta, V. On some normability conditions. to appear in Math. Nachr.

2. Abdeljawad, ;T and Yurdakul, M On some dual conditions in quasibarrelled locally convex spaces. FJMS, 16/3, (2005), 291-300.

3. Abdeljawad, Thabet; Yurdakul, Murat The property of smallness up to a complemented Banach subspace. Publ. Math. Debrecen 64 (2004), no. 3-4, 415-425.

4. Terzioglu, T.; Yurdakul, M.; Zahariuta, V. Factorization of unbounded operators on Köthe spaces. Studia Math. 161 (2004), no. 1, 61-70.

5. Djakov, P.; Terzioglu, T.; Yurdakul, M.; Zahariuta, V. Bounded operators and isomorphisms of Cartesian products of Fréchet spaces. Michigan Math. J. 45 (1998), no. 3, 599-610.

6. Djakov, P. B.; Önal, S.; Terzioglu, T.; Yurdakul, M. Strictly singular operators and isomorphisms of Cartesian products of power series spaces. Arch. Math. (Basel) 70 (1998), no. 1, 57-65.

7. Djakov, P. B.; Yurdakul, M.; Zahariuta, V. P. Isomorphic classification of Cartesian products of power series spaces. Michigan Math. J. 43 (1996), no. 2, 221-229.

8. Djakov, Plamen B.; Yurdakul, Murat; Zahariuta, Vyaceslav P. On Cartesian products of Köthe spaces. Bull. Polish Acad. Sci. Math. 43 (1995), no. 2, 113-117.

9.Yurdakul, M. A remark on a paper of J. Prada, Arch. Math. (Basel) 61 (1993), no. 4, 385-390.

10. Terzioglu, T.; Yurdakul, M. Restrictions of unbounded continuous linear operators on Fréchet spaces. Arch. Math. (Basel) 46 (1986), no. 6, 547-550.

71. **Özlem**
September 12, 2007

I am impressed, shocked !
As a graduate who studies math. physics in Turkey, I can’t believe in my eyes! METU is an exclusive University here and I cannot understand that how these students could be successful in their sufficiency exams during PhD before thesis? Science is not a score, science is not only a paper and not money…
What a shame!

72. **just borrowing**

Plagiarism? No, we’re just borrowing better English

Ihsan Yilmaz1

1. Physics Department, Çanakkale Onsekiz Mart University, Çanakkale, Turkey

Sir

The accusations made by arXiv that my colleagues and I have plagiarized the works of others, reported in your News story ‘Turkish physicists face accusations of plagiarism’ (Nature 449, 8; doi:10.1038/449008b 2007) are upsetting and unfair.

It’s inappropriate to single out my colleagues and myself on this issue. For those of us whose mother tongue is not English, using beautiful sentences from other studies on the same subject in our introductions is not unusual. I imagine that if all articles from specialist fields of research were checked, similarities with other texts and papers would easily be found. In my case, I aimed to cite all the references from which I had sourced information, although I may have missed some of them.

Borrowing sentences in the part of a paper that simply helps to better introduce the problem should not be seen as plagiarism. Even if our introductions are not entirely original, our results are — and these are the most important part of any scientific paper.

In the current climate of ‘publish or perish’, we are under pressure to publish our findings along with an introduction that reads well enough for the paper to be published and read, so that our research will be noticed and inspire further work.

This Week's Hype

August 25, 2007
Categories: Uncategorized

Today Slashdot brings us the news that Gamma Ray Anomaly Could Test String Theory. As usual with such media claims about the testability of string theory, this is complete nonsense. The story is based on this Scientific American blog posting, which in turn is based on this paper by the MAGIC gamma ray telescope collaboration.

The claims about testing string theory aren't in the paper, but appear to come from string theorist Dimitri Nanopoulos who claims that he predicted (or, more accurately, "suggested") the kind of effect seen by MAGIC using string theory. As far as I can tell though, just about no string theorists except Nanopoulos and his collaborators Nick Mavromatos and John Ellis actually believe this. Mavromatos and Nanopoulos also believe that string theory is responsible for the way that our brains work, here's the abstract of one of their papers on this:

> Microtubule (MT) networks, subneural paracrystalline cytosceletal structures, seem to play a fundamental role in the neurons. We cast here the complicated MT dynamics in the form of a 1+1-dimensional non-critical string theory, thus enabling us to provide a consistent quantum treatment of MTs, including enviromental *friction* effects. We suggest, thus, that the MTs are the microsites, in the brain, for the emergence of stable, macroscopic quantum coherent states, identifiable with the *preconscious states*. Quantum space-time effects, as described by non-critical string theory, trigger then an *organized collapse* of the coherent states down to a specific or *conscious state*.

Claims have been made by many string theorists that not only does string theory not predict this kind of violation of Lorentz invariance, but exactly the opposite: string theory predicts no such violation. String theorist Jacques Distler earlier this year even went so far as to have the University of Texas issue a press release trumpeting his claims to have shown that string theory is falsifiable, using a calculation based on the assumption that string theory preserves Lorentz invariance (either his colleagues or a PRL referee wouldn't let him make this claim in the paper the press release was based on, but that's another story…).

Claims have been made (although there is controversy about this), that the main competing quantum gravity research program, Loop Quantum Gravity, predicts this sort of violation of Lorentz invariance, and this would be one way of distinguishing it from string theory. Lubos Motl has a new posting about the MAGIC result, mainly concerned with knocking it down since he fears that it will be used as evidence for LQG and against string theory.

It seems to me that in any case, the actual experimental evidence here is far too weak to support any claim that a violation of Lorentz invariance has been shown. Among the usual nonsense on Slashdot, there was the following sensible comment about the MAGIC result from an astrophysicist:

> What they are saying is that there are still details we don't understand about AGN like Markarian 501. So, while this effect could be a first sign of quantum gravity (*not* string theory in particular, as others have pointed out), it could also simply be something going on in the intrinsic spectrum of the flares themselves. I'd personally consider the second explanation more likely at this stage.
>
> As they also point out, one approach to sort out the ambiguity would be to observe other flary AGN at different redshifts (distances). One could then, for example, see if the delay gets shorter or longer as the distance changes, as one would expect with a quantum gravity effect due to propagation to Earth.

Utterly Off-topic, But How Can I Resist Mentioning: According to this blog entry by a USC student, not only am I the "archnemesis" of string theorist blogger Clifford Johnson, but also

> If string theory were a vampire, he'd be Buffy.

I'll have to consult my friends and colleagues on the resemblance to Buffy question, personally I don't see it.

I don't know about vampires, but these "tests of string theory" are kind of like the living dead, staggering around trying to get their teeth into people and turn them into string theory partisans. No matter how often you blow their heads off with a shotgun, more keep coming…

Update: Lubos and I seem to be in complete agreement about this experimental result and the Nanopoulos et. al. explanation of it. This situation appears to have driven him over the edge.

Update: See Backreaction for a more detailed posting about the MAGIC result.

Comments

1. **Yatima**
   August 25, 2007

   Microtubule (MT) networks, subneural paracrystalline cytosceletal structures, seem to play a fundamental role in the neurons.

   Yes, and it's called scaffolding. "Trigger an organized collapse of the coherent states down to a specific or conscious state"? Where do I find the paper that equates a "collapsed quantum state" to the "conscious state" (aka. the "unicorn state", often hinted at in dark, confusing tales, never actually photographed in the wild).

   Still, that paper is dated "1995", and if I remember well, "Microtubules -> Consciousness" inferences, sometimes via Quantum Mechanics, sometimes via old-school Turing Computation made several appearances in Artificial Life proceedings at those time. Even Sir Penrose entered the game. Extremely speculative. Overall, an approach that went precisely nowhere. Anyway, an area to not get into.

   Maybe I should be happy to languish in engineering.

2. **ks**
   August 25, 2007

   > Maybe I should be happy to languish in engineering.

   I guess each discipline has its own no go areas that can be colonialized / made up by members of others as their eccentric hobby. Roger Penrose could do all kinds of speculations about mind, Goedels theorem and quantum gravity. As a cognitive scientists his reputation was done but as a mathematician he won't endanger his credibility or "core competence" by doing such excursions (as long as they aren't too mad).

3. **Moshe**
   August 25, 2007

If a theory violates LI at high energies, say the Planck scale, standard renormalization group suggests that at low energies this will manifest itself by a series of relevant, marginal and irrelevant operators. Bounds on such Lorentz violations at accessible energies are extremely tight, no current experiment will improve those bounds. So, high energy breaking of LI is to my knowledge sufficient grounds for falsifying a theory, or at least casting very strong doubts on it (spontaneous violation is a different story).

Also to my knowledge LQG does not predict such violation, and Lee does not claim it does. He only claims it might once we understand things better. It escapes me why that should be a good thing, but maybe I am missing something.

4. **Eric**
August 25, 2007

   Peter,
John Ellis and Dimitri Nanopoulos happen to also be the second and fourth most cited high-energy physicists, with Witten first and Weinberg third. Thus, you're attempt to try to dismiss them as crackpots just isn't going to fly.

5. **sophia**
August 25, 2007

   The link to Motl's blog leads to something very amusing. Check it out.

6. **bhabha**
August 25, 2007

   Eric,

   You are seriously underestimating Peter's capabilities. Being the second and fourth most highly cited high energy physicist (more precisely, phenomenologist) does not deter Peter from declaring him/her to be a non-sense creating pseudo-scientist. Actually, the more famous person is called a crackpot here the better, because more controversy brings more readers to this blog. It doesn't work like in science that you have to create quality content in order to get noticed, in the blogosphere the more crazyness you produce the more attention you will get. Pretty much like in mass media which of course includes blogs these days. So don't be surprised to see more top cited phenomenologists, string theoriests, non-string theorist, etc, etc, getting on Peter's public enemy list!

   Bhabha

7. **Eric**
August 25, 2007

   bhabha,
I would never underestimate Peter's abilities capabilities, especially in regards to using underhanded tactics. 😉

   Regarding the statments about Lorentz violation in string theory, what Lubos and Distler refer to is critical string theory. It's possible to get this effect (frequency dependent speed of light) in non-critical string theory.

   In regards to the LQG vs. string theory debate, I think this is one more bit of evidence that there is some overlap between the two theories, and they may be part of the same larger theory as Lee has suggested.

8. **Peter Woit**
August 25, 2007

   Eric and Bhabha,

   Unlike you I'm not personally attacking anyone, but discussing their scientific arguments. The argument that the MAGIC results give evidence for string theory is, scientifically, nonsense, and it would be hard to find anyone other than Nanopoulos, Mavratos and Ellis who would disagree. I can't help noticing that string theorists rarely admit that these bogus "tests for string theory" are indefensible, preferring to instead personally attack me for pointing this out, invoking not science but citation counts in their defense.

9. **Eric**
August 25, 2007

   Peter,
First, the MAGIC results are very interesting and cannot be dismissed. Second, such an effect is of interest not just for string theory, but for quantum gravity in general including LQG. Third, Ellis, Nanopoulos, and Mavromatos did predict this effect several years ago, as you may discover on the arXiv.

   Regarding your statement that noone other than ENM takes these results seriously, how do you know? Have you talked with all string theorists and phenomenologists to get there opinion, or are you just relying on what you heard from Lubos and Distler?

   What's next, trying to undermine their credibility by mentioning that they once wrote papers with Hagelin?

10. **Peter Woit**
August 25, 2007

    Eric,

    If you want to provide us with a list of string theorists and phenomenologists who think that the MAGIC results give evidence for string theory and thus that the Slashdot headline is not nonsense, go right ahead.

11. **anon.**
August 25, 2007

    John Ellis and Dimitri Nanopoulos happen to also be the second and fourth most cited high-energy physicists

    This isn't so difficult when John Ellis single-handedly writes as many papers as any random group of ten other physicists. Writing a lot and getting cited a lot does not in itself make one a great physicist.

12. **hack**
August 25, 2007

” What’s next, trying to undermine their credibility by mentioning that they once wrote papers with Hagelin?”

In fact their papers with Hagelin were their high point. It’s been all downhill since then.

I’ve actually read more Nanopoulos/Ellis papers than I care to admit. I have to laugh when I hear Nanopoulos claiming to have predicted something. It’s a million monkeys with typewriters type of situation.

13. **milkshake**
August 26, 2007

Microtubules are huge proteins, maybe 4 orders of magnitude over than the scale where you can observe quantum effects with neutral molecules. (If somebody tells me that it is possible to see interference pattern by shooting tiny molecules like ammonia in vacuo through a double slit, and that scale of the effect can comparable with the actual size of ammonia molecule, I can believe that.)

Looking for quantum effects in the mechanics of a living cell is completely New Age.

14. **Luboš Motl**
August 26, 2007

I was told about this new article on this spamblog. You may visit my blog to see some clarifications of the statements made by the individual behind this spamblog.

15. **Brett**
August 26, 2007

It’s not clear whether Lorentz violation is a consequence of string theory or if it’s forbidden by string theory. The same holds for loop quantum gravity. However, if you’re going to look for signs of Lorentz violation, there are many ways to go about it, and looking for an energy dependence in the speed of light is not the most sensitive. Because of the vector character of light, the speed of light is such theories generally depends on polarization as well as energy. Searches for this kind of birefringence are much more sensitive than experiments that look for differences in photon arrival times. Indeed, I know that another high-energy telescope experiment already has much better data on photon arrival time differences, but they have refrained from publishing it, in part because it is not competitive with the polarization bounds.

16. **Who**
August 26, 2007

> Because of the vector character of light, the speed of light is such theories generally depends on polarization as well as energy.

Not true Brett, numerous papers about this from non-string QG researchers
have ruled out polarization dependence.

> Indeed, I know that another high-energy telescope experiment already has much better data on photon arrival time differences, but they have refrained from publishing it, in part because it is not competitive with the polarization bounds.

In that case they are doing the QG community a disservice by not publishing, because the polarization bounds are irrelevant. You should urge them to publish.

I assume you mean they have data which would constrain (if not rule out) energy-but-not-polarization dependence, and that is precisely what I see being discussed.

My sense is we have a ways yet to go with this issue.

17. **Lee Smolin**
August 26, 2007

Brett is right that polarization odd variations in the speed of light are already ruled out at planck scale by observations of polarized radio galaxies, but polarization even variations in the speed of light are not because they cause no bifringence. The latter are, however, a possible consequence of a deformation rather than breaking of Poincare invariance. If an experiment has data on photon arrival time variation with energy it must, because of the limits on parity odd variation, be parity even, and hence, if there is no other explanation, it could be a detection of a deformation of poincare invariance (so called “doubly special relativity”).

Thanks,

Lee

18. **Brett**
August 26, 2007

On what grounds can a polarization dependence in the speed of light be ruled out? One can make an assumption that quantum gravity will have certain features, such as no birefringence, but this will limit the terms in the low-energy effective action to a measure zero subset of the full parameter space of Lorentz invariance violation.

To me, it seems rather wishful thinking to hope that quantum gravity will have such a profound signature as Lorentz violation, while not interacting with the spin structure of the electromagnetic field. There is no compelling reason why this should be the case. The interactions that avoid birefringence deserve to be tested (and I strongly recommended that the data I saw be published), but they are only a peculiar subset of the possible Lorentz-violating interactions. One can always write down a nonrenormalizable interaction which all previous experiments have been insensitive to, but which a new configuration will test; yet selling it as a profound new test of quantum gravity is illogical. (And all renormalizable varying speed of light theories can indeed be bounded by birefringence.) And if you want to make a generic statement about how well Lorentz invariance has been tested, it behooves you to look at the best bounded sectors, not the worst.

19. **Amnetic**
August 26, 2007

> You may visit my blog t

But, Lubos, you have a message in your site saying you don’t want readers from this blog.

20. **sophia**
August 26, 2007

“If string theory were a vampire, he’d be Buffy.”

Hah. It's occurred to me that string theory is to real physics as a drag queen is to a real woman. Unlike real women, drag queens are expertly groomed, and beautifully made up, but when the moment of truth arises, who would you rather be with?

On the other hand, the results of this experiment are quite predictable. That's one thing drag queens have going for them, unlike string theories.

21. **Moshe**
August 26, 2007

Lee and Brett, regardless of the new and exotic phenomena that you are discussing, I see no reason Lorentz invariance violation at the Planck scale should be automatically a small effect at low energy. Most conservative estimates based on the existence of LV relevant and marginal perturbations to the standard model (I believe the number of those is 46) makes Lorentz violation basically already falsified, based on existing experimental results. Unless one finds a way to fine tune away a lot of really large violations I am not sure why we are discussing those tiny sub-sub-leading effects.

22. **Lee Smolin**
August 26, 2007

Dear Moshe and Brett,

Parity odd variation of the speed of light with energy is ruled out to at least order 10^-3 [l_{Planck} Energy] by observational limits on bifringence from polarized sources. See gr-qc/0102093. This is a prediction of lorentz symmetry breaking, therefor it is reasonable to infer that lorentz invariance is not broken at order l_{Planck}. But deformation of Poincare symmetry is another thing entirely, there is still a ten parameter global symmetry algebra constraining renormalization effects, so Moshe's considerations can be answered directly; these are the leading effects of deformed Poincare symmetry. Since the symmetry group is still present it does rule out as many terms as ordinary poincare symmetry, and one of them is a parity odd varation in the speed of light coming from the usual dimension five term seen in lorentz symmetry breaking.

To be more precise the Casimer invariant of the deformed Poincare algebra is no longer quadratic in energy and momentum, leading to corrections to the speed of light. Thus, deformed Poincare symmetry can imply an order l_{Planck} variation in the speed of light with energy, which is parity even and therefor not ruled out. Therefor if the right interpretation of the observations reported by the MAGIC collaboration is a modification of spacetime symmetry it must be a deformation and not a breaking of Poincare symmetry-because the latter is already ruled out by experiment, but the former is not. The same holds for the observations Brett hinted about.

23. **LDM**
August 26, 2007

Lee,

Regarding the paper gr-qc/0102093 (You also mention the same on page 226 of TTWP)…the assumption made in the paper

"If we assume that linearly polarized photons are
detected, and unambiguously identified with a source at cosmological distance z, without any significant interaction
in between, we may be immediately sure that (6) is not strongly violated."
is too large of an assumption, in my opinion.

Cosmological data has traditionally been the poorest data of all the sciences, and you want to draw definite and strong conclusions about physics at the Planck scale based upon it? This to me is very wishful thinking.

24. **Brett**
August 26, 2007

Moshe,
I agree with you about naturalness, which is why I think it's more important to concentrate on renormalizable forms of Lorentz violation. Indeed, there is no known reason why Lorentz violation, were it to exist, should be small. Lorentz violating interactions are, of course, technically natural, since they receive no radiative corrections from Lorentz-invariant physics, but if they actually exist, they must either be finely tuned, or they must be suppressed by some unknown mechanism.

The number of dimension three and four Lorentz-violating operators that can be constructed out of standard model fields is much larger than 46. With just one generation of fermions and the electromagnetic field, there are about 150. Of course, many of those mix under renormalization. The number of different symmetry types is still greater than 46 though. Actually, how many different physically meaningful operators there are depends on whether you consider only flat spacetime or whether you consider working in a curved background, and exactly how which terms are physical under which circumstances is not completely understood.

25. **Lee Smolin**
August 26, 2007

LDM,

I understand reservations about claims of positive results because there could be other explanations, but the claim in gr-qc/0102093 is a negative result. Do you believe that there could be leading order lorentz symmetry breaking which produces bifringence, which is then masked by some ordinary astrophsyical effect so that no bifringence is seen? What physics do you have in mind that could reverse rotation in the plane of polarized radio waves so its effects were not seen?

It seems to me reasonable to infer that lorentz symmetry breaking is not present, in this case the experiment and the more theoretical argument discussed here by Moshe agree.

Thanks,

Lee

26. **LDM**
August 26, 2007

Thanks Lee, probably I was a little ambiguous. Sorry. I will see if I can phrase this more precisely…

I am not arguing either for or against Lorentz violation, I am only arguing against using the cosmological data as you have done…

In the TTWP, page 226, you mention that the travel time can be "billions of years" for the photons in question. So we are talking about large distances.

Now, in the paper, we also have the statement *“comparing the time of arrival of rays at different energies emitted simultaneously from the same source, one can test the validity of this prediction”*

I am assuming that time of arrival that is being discussed is based on our distance from the source of photons. (If it is not, and you do not need to know the distance, then I am wrong, and please accept my apologies for wasting your time.) The problem is that cosmological distances are very uncertain, to quote from M Berry “Principles of Cosmology and Gravitation”:

“How do we know the distances and densities quoted? The Universe is charted by a sequence of techniques, each of which takes us out to a greater range of distances – to the next level of the ‘cosmic distance hierarchy’. Each level is less reliable than the last, so that there is considerable uncertainty about the measurements of very great distances.”

So, it would seem
we have considerable uncertainty in our data…but in TTWP, you are talking about measuring differences of 1/1000 of a second, which it seems to me is a fairly precise or certain measurement…The impression I have is we do not have that kind of accuracy. And so you cannot meaningfully use the cosmological data in the way you are attempting to, which is to measure differences of 1/1000 of a second over large cosmic distances.

27. **Moshe**
August 26, 2007

Thanks Brett, the number 46 came from the Coleman-Glashow paper, if the number is bigger I am even more worried…

Lee, the fact that global symmetries are preserved by renormalization, and therefore can be used to forbid otherwise possible interactions, this fact was established through a series of theorems in the 1960s and 70s, those theorems apply to ordinary global symmetries.

If there is some deformed version of Poincare symmetry it is then natural to ask if it is preserved by renormalization. If not it doesn’t give any restriction on the form of the low energy EFT. If it is preserved maybe it limits the allowed interactions in some way, but even then it seems to me it will take a miracle to allow small violations of LI while by forbid much the numerous much large effects.

28. **Eric**
August 26, 2007

LDM,
The different arrival times are for different gamma rays emitted at the same time from the source with different frequencies, and no you don’t need know the cosmological distance precisely. Once only needs the distance to be large so that the difference in arrival times is measurable. Essentially, the higher frequency gammas interact with the vacuum and slow down, just as a light ray does when going through some medium, otherwise known as refraction.

29. **Moshe**
August 26, 2007

garbled the last sentence, the last few words should be “while forbidding the numerous much larger effects”. Those effects refer to all the renormalizable terms Brett discussed, not just the dimension 5 operator discussed by Lee.

30. **anon.**
August 27, 2007

“And so you cannot meaningfully use the cosmological data in the way you are attempting to, which is to measure differences of 1/1000 of a second over large cosmic distances.” – LDM

I think you completely misunderstand. If two photons of different energies arrive 1 millisecond apart from the same gamma ray burster or whatever, the accuracy of that measurement (relative time of 1 ms difference) is independent of the less accurate cosmological distance ladder which estimates how far the gamma ray burster is from you. You simply don’t need to know exactly how far away the source is, in order to detect that photons are travelling at different speeds…

31. **LDM**
August 27, 2007

Thank you anon. .Yes, perhaps I misunderstand…but let me ask you, the two photons that arive 1 millisecond apart from the GRB, how do you know that the photons did not leave the GRB 1 millisecond apart too?
And more to the point that is bothering me, what are the error bounds on these measurements?

32. **anon.**
August 27, 2007

LDM, if the 1 ms delay is *not* caused by differences in photon speeds, then similar delay times whould show up in the time-dependent energy spectra of gamma ray bursters, regardless how far away they are. If the delay is caused by differences in photon speeds, then the furthest sources should show the biggest delays.

33. **Lee Smolin**
August 27, 2007

Dear Moshe,

I agree, an important question is whether deformed poincare symmetry is preserved by renormalization. My argument assumed yes, but you are right that this needs to be shown, I am not sure of the status of this in various approaches to QFT with deformed poincare symmetry but will check.

Dear LDM,

We seem to be at cross purposes, the paper gr-qc/0102093 does not use arrival times, it uses the absence of bifrengence in observations of polarized radio galaxies. The MAGIC claim does use arrival times, as do limits using lower energy gamma ray bursts set to M_QG. There are several ways this is addressed in the literature: 1) as anon mentions one can hope to get redshifts for enough events and see if there is a correlation with distance, 2) by using very short bursts and bounding the dispersion relation by the overall length of the signal, 3) by a better understanding of the source. None of these apply to the MAGIC claim.

The MAGIC paper uses another argument based on extremizing energy flux. Does anyone know how reliable this kind of argument is? Is it used elsewhere in astrophysics?

Lee

34. **Arun**
August 27, 2007

LDM, if the 1 ms delay is not caused by differences in photon speeds, then similar delay times whould show up in the time-dependent energy spectra of gamma ray bursters, regardless how far away they are. If the delay is caused by differences in photon speeds, then the furthest sources should show the biggest delays.

which would be detectable provided gamma ray bursters at all eras are essentially identical.

35. **Moshe**
August 27, 2007

Thanks Lee.

36. **alex**
August 27, 2007

Hi Lee,
I'm confused by the terms "deformation" and "violation" of Lorentz symmetry. It seems to me that if the lagrangian contains some terms which are invariant under the "deformed" Lorentz symmetry but NOT invariant under the usual undeformed Lorentz symmetry, such terms would therefore violate the usual Lorentz symmetry since they are not invariant under it, right?

Thanks!

37. **Bee**
August 27, 2007

Thanks for the link!

38. **Cecil Kirkey**
August 28, 2007

This thread is interesting but…Does ST predict a LI violation or not? What is the difference between critical and non-critical ST? Are they both derived from the same assumptions? If they are do we now have two families of ST? And if these ST guys predicting LI violation are not really preaching the true ST why don't the true ST guys stand up and refute them openly?

39. **Mr. String**
August 28, 2007

Cecil,
Non-critical string theory involves strings propagating in a dimension of spacetime less than the critical dimension of ten. The resulting anomalies are cancelled by exciting the Liouville mode (linear dilaton) of the strings. The statement that string theory strictly obeys Lorentz invariance is true only in the context of critical string theory.

40. **manyoso**
August 29, 2007

So which version of String Theory, critical or non-critical, to String Theorists believe corresponds to the real world? …oh wait

41. **sasay**
August 29, 2007

> This situation appears to have driven him over the edge.

Who is this Lubos that you mention? Is he affiliated to an academic institution? He seems to refer to L. Susskind with strange reverence, is he another squatter at Stanford?

42. **Hendrik**
September 10, 2007

A somewhat belated item has appeared in New Scientist on
the MAGIC "test" of string theory at:

http://www.newscientist.com/channel/fundamentals/mg19526204.300-finally-a-magic-test-for-string-theory.html

This Summer's Online Talks

August 27, 2007
Categories: Uncategorized

All sorts of schools and workshops occurring this summer have been putting up materials from the talks on-line. Sometimes this is just an audio recording of the talk, which can be very frustrating if you're interested in the details of a subject, leaving you desperately trying to guess what symbols on the blackboard correspond to the scratching noises and words from the speaker that you are hearing. Best is a set of slides used by the speaker, together with audio or video of the full talk. Some examples worth looking at include:

- String Theory and the Real World, this year's les Houches summer school.
- Cosmology and Particle Physics Beyond the Standard Models, this year's Cargese summer school.
- Summer School on Particle Physics, Cosmology and Strings at Perimeter.
- Simons Workshop in Mathematics and Physics at the YITP in Stony Brook. Definitely the worst offenders in terms of having interesting talks available, but audio-only. Blogger Aaron Bergman is there, but doesn't seem to be very interested in telling us what is going on.
- Anton Kapustin gave a Master Class on *Electric-Magnetic Duality and the Geometric Langlands Programme* at the CTQM in Aarhus this summer. Video of the talks is here. The KITP in Santa Barbara will be hosting a Miniprogram on this topic next summer.
- At CERN there's a program on New Physics and the LHC taking place. Suitably snarky commentary available at the Resonaances blog, starting with "the theory talks were ranging from not-so-exciting to pathetic", and going on to describe one of the experimental talks, which can't really avoid being exciting as less than a year remains before the LHC is supposed to start taking data. The experimenters at CERN are looking over their shoulder at the Tevatron, where Tommaso Dorigo reports that they are still not seeing a Higgs, but getting remarkably close to being able to rule out the existence of one at 95% confidence level for a mass range near 160 GeV. For a new compilation of Higgs mass predictions, see here.
- *One more, suggested by a commenter*: SLAC ran a summer school on Dark Matter: From the Cosmos to the Laboratory.

Off-topic, department of Humor: The New York media just can't get enough of theoretical physics these days, with the New York Observer running a column Ask a Theoretical Physicist.

Comments

1. **Shantanu**
August 27, 2007

Peter, you forgot to add this year's SLAC summer school on dark matter,where
almost all talks(except for the ones on the last day) have been archived.

2. **Aaron Bergman**
August 27, 2007

One 'n'.

And trust me, myself trying to relate talks is not a good idea for anyone involved.

3. **Peter Woit**
August 27, 2007

Sorry Aaron, fixed.

Well, you could at least be blogging about any scandalous gossip about physicists or mathematicians that you're learning…

4. **Thomas Love**
August 29, 2007

Peter said:
"Simons Workshop in Mathematics and Physics at the YITP in Stony Brook. Definitely the worst offenders in terms of having interesting talks available, but audio-only."

But it isn't audio-only! If you click on the titles in blue, you'll get a printed version.

5. **Peter Woit**
August 29, 2007

Thomas,

Problem is that the talks I was most interested in following, based on the speakers and their topics, were ones that are audio only.

6. **Chris Borokowski**
August 29, 2007

The "Ask a Theoretical Physicist" column appears to be the latest in a series of attempts to make fun of how incomprehensible the world has become to even the average educated person. Great find.

7. **Zathras**
August 30, 2007

The "Ask a Theoretical Physicist" column is just ripped off from the Onions "Ask a…." series, such as Ask a Man Getting Yelled At By His Wife Over The Phone At Work or Ask a Bee.

8. **Yatima**
September 1, 2007

This Dark Matter overview from SLAC's summer school certainly beats any BBC "science" emission. Good stuff.

This Month's Hype

September 3, 2007
Categories: Uncategorized

The September issue of Physics World is out, featuring a 13 page advertising supplement for string theory which is pretty much unadulterated hype. The same issue includes an editorial which takes the point of view that the only problem with string theory is that:

> String theorists need to do much more to explain their field's genuine links to experiment

String theory's lack of falsifiability is minimized as a problem, and the fact that it "raises several philosophical issues, such as the role of anthropic reasoning" is listed as a point in its favor. As for those who complain that string theory predicts nothing, in particular nothing about what will happen at the LHC, they are told to just shut up:

> With CERN's Large Hadron Collider (LHC) due to switch on next year, now is the wrong time to slam string theory for its lack of predictive power. While not able to prove string theory is right, the discovery of supersymmetric particles at the LHC would give it a major boost…

The fact that string theory doesn't predict supersymmetry visible at LHC scales is actually acknowledged in the advertising supplement by Kachru and Susskind.

The few quotes from string theory skeptics allowed seem chosen to be those that put string theory in the most favorable possible light (except for Phil Anderson, who is reduced to hostile spluttering by Polchinski's claims that string theory may explain high T_c superconductivity). This allows the editorialist to conclude:

> However, the richness of string theory that has become apparent in the last decade, and its increasing contact with the real world, gives theorists something to shout about. This is why our main feature on the subject, which started with fairly modest intentions, has ballooned into the longest ever to appear in Physics World. As the views of even many non-string theorists in the article make clear, the theory still holds all the potential it ever did to revolutionize our understanding of the universe.

The critique of string theory by Smolin and myself is pretty much completely ignored or dismissed, with Susskind quoted as having come up with a new insulting term for us (to him we're "Smoit", evidently he likes that better than the "Swolin" favored by those in Santa Barbara). The claim is made that

> few string theorists think that the sometimes negative portrayal of string theory in the popular arena recently has had much of an effect other than to irritate people.

Amidst the endless misleading hype contained in the Physics World piece, there's some that simply is demonstrably completely untrue. The most egregious example might be the discussion of Witten's Fields Medal which claims that it was awarded him due to his work on string theory compactification spaces:

> .. with the study of 6D "Calabi–Yau" spaces making Witten in 1990 the first physicist to be awarded the prestigious Fields Medal

The quotes from Witten himself don't include any of the hype about connections to experiment. He describes string theory as something very poorly understood, with even the fundamental equations of the theory unknown, and no good ideas about how to find them, leading to the danger that even if his vision is correct, realizing it may just be too hard:

> It's incredibly rich and mostly buried underground. People just know bits and pieces at the surface or that they've found by a little bit of digging, even though this so far amounts to an enormous body of knowledge… There is an incredible amount that is understood, an unfathomable number of details. I can't think of any simple way of summarizing this that will help your readers. But despite that, what's understood is a tiny, tiny amount of the full picture.. One of the greatest worries we face is that the theory may turn out to be too difficult to understand… This is certainly a question that interests me… but if I don't work on it all the time, it's because it's difficult to know how to make progress.

Unlike Witten, many of the other string theorists quoted seem to have no problem with issuing streams of highly misleading hype claiming "predictions" of string theory. For instance, from David Gross:

> String theory is full of qualitative predictions, such as the production of black holes at the LHC or cosmic strings in the sky, and this level of prediction is perfectly acceptable in almost every other field of science," he says. "It's only in particle physics that a theory can be thrown out if the 10th decimal place of a prediction doesn't agree with experiment.

I don't know how to characterize this kind of claim that string theory is as predictive as other scientific theories, just not able to get accuracy to 10 decimal places, as anything other than out-and-out dishonesty. If someone could come up with a legitimate, distinctive, testable prediction of string theory that gave even the correct order of magnitude for some experimental result, that would be a huge breakthrough.

Michael Green, while describing the landscape and its potential to allow for a small CC as "an enormous success" for string theory, is one of several string theorists characterizing the status of string theory as being just as good as that of QFT, with the landscape not a real problem at all, just a "supposed" one:

> This supposed problem with a theory having many solutions has never been a problem before in science.

Several people promote the anthropic point of view, with Susskind describing it as the third superstring revolution, one that is even more of a revolution than the others. Polchinski adds

> In terms of changing the way we think about the world, the anthropic landscape is certainly as big as the other revolutions

while Susskind's colleague Shamit Kachru is described as "in the middle", sensibly pointing out that it would have been a stupid thing for people to do, once they realized that the ratios of sizes of planetary orbits were environmental, to start claiming that "there is a deep anthropic lesson to be learned from Newtonian gravity."

All in all, I think that the picture the Physics World article presents of the reaction of leading string theorists to the failure of the superstring unification project is a depressing one. Instead of acknowledging in any way this failure and considering what can be learned from it, on the whole they seem to prefer to abandon science for anthropic pseudo-science, to spout misleading claims of bogus "predictions" of string theory, and make indefensible claims that the lack of predictivity of string theory is not unusual for a science.

On the other hand, among string theory skeptics, I fear that the attitude of Howard Georgi is all too common:

> I have been critical in the past of some of the rhetoric used by string-theory enthusiasts," says Howard Georgi of Harvard University, who coinvented the supersymmetric extension of the Standard Model in 1981. "But I think that this problem has largely corrected itself as string theorists learned how complicated string theory really is. I am concerned about the focus of young theorists on mathematical details, rather than what I would consider the real-world physics of scattering experiments, but with any luck the LHC will take care of that by reminding people how interesting the real world can be."

The problem with string theory is not too much mathematics and a lack of effort towards making connection to real world experiments, but that it is a wrong idea about unification, and thus cannot ever explain the standard model or predict what lies beyond it. The recent move among string theorists to hype bogus claims about connections to experiment, abandoning the search for greater mathematical insight into string theory as just “too hard”, retooling themselves as more salable “string phenomenologists” and “string cosmologists” is not a healthy trend. It is based on adopting the Susskind-Polchinski “multiverse” revolution in the received wisdom about how to do fundamental physics, slowly turning a once great subject from a science into a pseudo-science.

Update: Lubos is beside himself with glee over the Physics World article, see here and here (don’t miss the photo-shopped “Smoit” graphic of me and Lee Smolin). For something more reasoned, there’s a short piece at Wired.

Comments

1. **Domenic Denicola**
September 3, 2007

> few string theorists think that the sometimes negative portrayal of string theory in the popular arena recently has had much of an effect other than to irritate people.

They have a surprise coming to them, then. A general attitude of eye-rolling toward string theory is prevalent at the Perimeter Institute (at least, in the quarters I associated with), and almost every undergraduate I’ve spoken to at Caltech things string theory is just a “not even wrong” mess. The view seems to be “OK, maybe they have some idea what they’re talking about, but it doesn’t seem promising. I’ll let someone else work on that stuff, while I try something more likely to be correct.”

The point is, you guys have had an impact, so be sure you know that :).

2. **M**
September 3, 2007

The editorial contains the sentence: “String theory is guided by problems in the real world – for instance the entropy of black holes”. Who wrote this must be either a string theorist or a humorist.

3. **A.J.**
September 3, 2007

Peter,

I don’t usually get involved in the string theory arguments, but since it’s a 3-day weekend (and I’ve been working all weekend):

I think ‘t Hooft is right (and now I’ll put some words in his mouth). Theoretical physicists aren’t doing science or the public any favors by arguing in public, in layman’s terms, about the merits and de-merits of string theory. It’s just too easy for people who don’t understand the technical details to get wrong ideas about speculative research.

We’ve seen this in one direction for some time now, with many laymen being quite convinced that string theory was already a done deal. (I even remember a WPI professor, not a particle physicist himself, who told me when I was 17 that grand unified theories were pretty well-verified.) And now we’re seeing it in the other direction, with for example, many slashdot denizens (and Caltech undergrads apparently) convinced the string theory is basically a fraud. This isn’t much of an improvement; we still have people with firm opinions and no understanding.

I’m personally hoping that these two public impressions will eventually cancel out, leaving people with a more or less correct impression. String theorists do have their hands on something quite interesting, maybe even a good framework for building quantum gravity models, but their research is quite premature. (So it goes: it took mathematicians 3 centuries to prove Fermat’s Last Conjecture.) Said framework has a lot of problems, but most of these problems — no vacuum selection, landscape of solutions, no preferred extension of the Standard Model, no sensible computation of the cosmological constant — are shared by the effective field theory framework we’re currently using. The string theory framework might be the correct one, or maybe not. We don’t have any way of telling without experimental data. In this sense, I thought the Physics Today article wasn’t that bad.

So, let me make a modest suggestion: Scientists have to talk to the public, and they’re obligated to give some explanation of the ideas they’re working on. But it would probably be better for everyone involved if scientists and science journalists remembered that, when we’re talking about things we have no experimental evidence for, the question is usually vastly more interesting than the proposed solution. If I’m going to read about an attempt at computing the half-life of a de Sitter geometry, I want 75% of the article to be about dark energy, the sign of the cosmological constant, and why anyone is thinking about metastability of geometries with positive cosmological constant.

4. **Yatima**
September 3, 2007

Karl Rove, who famously claimed to have made the “reality-based community” irrelevant, seems to have landed his new job at Physics World, then? String theory as an analytical tool to study the quark-gluon plasma? And there is that famous E8 picture…

Gerard ’t Hooft of the University of Utrecht, who
shared the Nobel prize in 1999 for his work on electroweak
theory, thinks that discussions about the merits
of theories should be limited to professional circles.

But they already are! This must be an appeal to have the door to the ivory tower walled in from within. Or to shut down blogs?

5. **Dr. E**
September 3, 2007

The fact that they are resorting to calling Peter and Lee names says it all.

During the Einstein Bohr debates, I wonder if Einstein snarked “Beisenberg” or “Heisenger” or “Heisenbohr” or “Schreisenberg.”

Alas, there was a time when honor, reason, and logic ruled physics.

6. **woit**
September 3, 2007

Hi A. J.,

I agree with ‘t Hooft that the issues here are complex, and not really appropriate for a discussion at a popular science level. On the other hand, sometimes they are the subject of inappropriate mystification: no, you don’t need to work through the details of the KKLT mechanism to understand what the landscape problem is. At this blog I do try and provide a discussion of these issues at an appropriate level, and in the book I tried also to not dumb down things past the point where a serious, accurate argument was being made.

I certainly see lots of ignorant arguments used to condemn string theory, just as I see equally ignorant arguments used by string theory partisans. Maybe they cancel each other out. But I’m actually not really that interested in the question of how good the public understanding of the string theory issue is (although I’d argue it’s much better now than a few years ago, and I hope I had some role in causing that). What I do care about is the understanding of these issues among physicists and mathematicians, and that’s who the blog and the book are both aimed at.

It certainly would be much better if this discussion was carried on at a more serious level. Unfortunately, many well-known string theorists seem to have decided not to respond to serious scientific criticisms in a serious way, but instead to dismiss them by calling Lee Smolin and me names, and going to the press with the kind of less than honest hype that dominates the Physics World piece. I don’t think blog entries by undergraduates who don’t understand these issues well are a big problem. The kind of misleading claims being put out to the public by leading physicists like Gross are.

7. **anonymous**
September 3, 2007

Hi Peter,

Just wanted to say, great post.

Keep up doing your thing. 🙂

Anonymous

8. **Theo**
September 3, 2007

Hi Peter,

I, as I imagine many others, appreciate the time you take to put these issues into context and the commentary you provide on various articles/resources.

I am not at a level of understanding where I could put up novel arguments for or against string theory myself but I feel able to follow much of what yourself and others blog about. Reading the ebb and flow of ideas for and against the various theories being put forward to advance our understanding makes me feel a small part of history in the making (if only mainly at the level of spectator).

I would disagree with t’Hooft and others that it is not useful to have such discussions in public. “Layman” who can follow most of what is being said (or are even interested) are likely to be slightly above your average layman in terms of their knowledge of physics. Thus, on average, will be able judge the arguments in an appropriate way.

e..g I don’t have to be able to write an original paper concerning compactification on Calabi-Yau manifolds to appreciate the difficulties you raise in relation to the landscape – and if you did not discuss such issues I would possibly be swallowing string theory hype hook line and sinker. On the other hand I am sensible enough, as no doubt others are, not to take everything you say as gospel either, and take information from multiple sources to form my own opinion.

Theo

9. **Thomas Larsson**
September 4, 2007

AJ, what is there to understand? The simple fact is that every natural string theory suggestion (supersymmetry, extra-dimensions, 496 gauge bosons, non-positive cc, …) is pretty much ruled out by experiment. Even susy with two layers of excuses (broken, and with R-parity conservation to kill dim-4 operators) is disfavored by experiments at the Tevatron and elsewhere. Surely intelligent laypersons can understand that a theory which disagrees with experiments is in trouble.

In fact, the situation for string theory is quite similar to that of ether theory. In both cases, there is one thing that should happen but did not (ether wind/supersymmetry) and one thing that could not happen but did (photoelectric effect/positive cc). And in in both cases, the strong proponents include a Nobel laureate (Lorentz/Gross) and a top mathematical physicist (Poincare/Witten).

Another similarity is that it takes a long time for a flawed theory to die. If you look at the title of Paul Ehrenfest’s inaugural speech, you will see that ether theory was still alive in 1912, 25 years after the Michelson-Morley experiment and seven years after some crackpot patent clerk discovered special relativity.

10. **A.J.**
September 4, 2007

Peter,

I’m happy to leave the hype disposal to you. I’m glad that someone is doing it. But I’d rather see the science journalists doing it themselves. (My favorite posts here are your comments on mathematics.)

On a related note: that someone’s making jokes with your name and Smolin’s is normal human nature, however unfortunate. Reporting said joke in a “serious” publication, on the other hand, is odd and rather tasteless.

———

Thomas,

If you read more carefully, you’ll notice that I said essentially nothing about string theory as source of particle physics models, except to note that it shares many of the qualitative flaws of our current framework. I said it was a barely apprehended framework for building quantum gravity models. I don’t expect useful predictions about TeV scale particle physics from it; indeed, given how much of the framework is probably missing, I don’t see much reason to take such suggestions seriously.

What makes string theory interesting, to my mind, is that it’s a good context for testing out ideas about gravity, black holes, and quantum geometry. So our theoretical intelligent layperson ought to be skeptical when she reads articles about large extra dimensions, colliding branes, and TeV scale supersymmetry. But she should also feel a little wonder maybe at the computations of black hole entropies. Even though this behavior should be fairly universal, it’s amazing to see the correct constants coming out of a microscopic accounting.

In short, it's an interesting set of ideas. It's probably good for something. We should keep it mind, even if we choose to work on other things, since we gain nothing by trashing it. (After all, thinking about the problems with the ether theory helped Einstein find relativity.)

11. **Coin**
September 4, 2007

I said it was a barely apprehended framework for building quantum gravity models. I don't expect useful predictions about TeV scale particle physics from it; indeed, given how much of the framework is probably missing, I don't see much reason to take such suggestions seriously. What makes string theory interesting, to my mind, is that it's a good context for testing out ideas about gravity, black holes, and quantum geometry.

In your perception, is this what string theory researchers* are currently using the theory for?

Assuming for the moment that you're right about what makes string theory important: do you think it is possible for string theory to produce useful progress and insights if, rather than attempting to attack it as a framework for testing out ideas about gravity and quantum geometry, those working on it are approaching it as a model for predictions about particle physics, or as a set of ground rules that lets you build 10^500+ configurations of Calabi-Yau manifolds [one of which is expected to describe the Standard Model], or as some other similarly literal interpretation of the theory?

* Given that I'm sure it is silly to try to think of "string theory researchers" as a homogenous bloc.

12. **Thomas Larsson**
September 4, 2007

AJ, perhaps it is because I am a physicist that I react strongly when people ignore that every testable string theory prediction is plain wrong. However, I feel strongly about this, and something that has been suppressed for 25 years. Ether theorists didn't just give up after the Michelson-Morley experiment neither – after all, ether theory was the best developed theory of light and arguably the only game in Newtontown.

Besides, string theory is hardly a successful theory of quantum gravity, because such a theory must explicitly involve the detector's properties. Every physical experiment is an interaction between a system and a detector, and the result depends on the physical properties of both. Typically we want to extract only those aspects of the experiment that are independent of the detector, which means that we implicitly assume that the detector's charge is small (so we can ignore its backreaction on the fields) and that its mass is large (so we can measure both the detector's position and velocity to arbitrary precision). This assumption, which is built into theories like QFT and string theory, clearly breaks down for gravity where mass and charge are the same.

The Five Stages of Coping with Catastrophic News

1. Denial 2. Anger 3. Bargaining 4. Depression 5. Acceptance

http://en.wikipedia.org/wiki/K%C3%BCbler-Ross_model

14. **Chris Oakley**
September 4, 2007

Oddly, "swoit" and "swolin" both appear in the Book of Zweig, but as verbs. If I may quote:

> 25. And bravely did Lubos of Bohemia join the fray. And he laughed as he smote the Pope's enemies. And he was tireless in his smiting, and rested not by day and not by night. "Loons! Feminists! Communists! Anti-Science Crackpots!" he called from his steed known as Reference Frame, emblazoned with the Harvard University crest. "With my Sword of Truth and Mace of Righteousness I will punish ye for your impiety and ignorant foolishness!"
>
> 26. But so eager was Lubos in his smiting that soon the people did say, "Who is this Czech knight who doth smite so eagerly and so indiscriminately? For are not many of those he doth smite, and with such tirelessness, learned men, whose schooling in scientific arts oft exceeds that of the upstart himself?"
>
> 27. And the Pope of the Superstringers, beholding the smiting of Lubos from afar, and the dismay of the people, summoned him to the Land of Princeton to take counsel.
>
> 28. "Lubos," the Pope did say. "Of thy loyalty I have no doubt. By thy wisdom I do question. Thou must understand – our enemies are subtle. Doing battle with them is oft foolish as they will merely retreat only to reappear with a host of the ignorant taxpaying public, who they have indoctrinated with their lies. Against this host, we cannot hope to prevail. For thy own good, I must send thee back to the Land of Bohemia. Continue thy smiting if thou must, but sport not longer the Banner of the Land of Harvard. Go!"
>
> 29. But as he departed, Lubos had to run the gauntlet of ignorant hordes who the Anti-String had stirred up. Swoiting Lubos with angry taunts as he passed by were science journalists, and non-String physicists, swolin with righteous wrath. Lubos was incensed that those who understood not even the meaning of a Calabi-Yau manifold should even dare to have an opinion on the sublime Stringy arts.

Correction: swoit->smoit

16. **Matthew Chalmers**
September 4, 2007

Dear Peter

Is it really true that in writing 12,000 words about the status of string theory I have only made one mistake? That's the best news I've heard all day! Perhaps you can do better after a second or third read (try the more technical 750 word text-box titled: "Why can't string theory predict anything?" on p42 for starters).

On a more serious and hopefully constructive note, however, your post raises important issues about the role of balance (and thus objectivity) in science journalism and blogs. Journalists, who normally don't have an axe to grind and can therefore go into a new field with an open mind, often aim to achieve balance by seeking a mixture of expert opinion (for example, by printing the quotes of 10 eminent non-string theorists alongside those of 11 string theorists in an article surveying the scientific status of string theory). Because blogs tend to be read by narrower audiences that hold similar views as the author's, balance is presumably less of an issue.

However, I'm sure that anybody interested in the current debate surrounding string theory would still be interested to hear your reasons for deciding not to even mention RHIC in the context of the Maldacena conjecture when you "evaluate" string theory in the second half of the paperback version of Not Even Wrong, for instance. Could this be the same logic that prevented you from acknowledging the presence of three other articles in the same September issue of Physics World (pp14–19) that were written by yet more non-string theorists, in particular by philosophers of science? These pieces tackle anthropic reasoning and the issue of testability head-on, and may help your readers reconcile your own somewhat perplexing stance on string theory — i.e. if the theory is, as you routinely point out, unfalsifiable then how can you be so certain that it has already failed?

Oh, and one last thing: next time you want to make a point, get out there and find your own quotes to back it up.

Matthew

17. **Cheeky Bastard**
    September 4, 2007

    Since Matthew Chalmers is gracing this blog with his presence, maybe he could elaborate a bit on what 't Hooft actually said. Was it literally that "discussions about the merits of theories should be limited to professional circles", or is this an extrapolation? It does sound dangerously close to "shut up an pay", a position which, when taken by a public employee addressing the tax payers, has only one legitimate answer: you're fired.

18. **JE**
    September 4, 2007

    How can one be so sure that it has already failed?

    Well, just because in mainstream scientific reasoning the terms "unfalsiable" and "physical theory" had been always considered as mutually exclusive.

19. **Arun**
    September 4, 2007

    Remarkably, after nearly 40 years, we still don't know what string theory truly is," exclaims Gross. "From the start, string theory was a set of rules for constructing approximate solutions in some consistent classical background – and that's all it still is."

    How then can it be called a theory of quantum gravity?

20. **Arun**
    September 4, 2007

    What I quoted above is at odds with

    The most important is that string theory provides a finite (i.e., non-divergent), consistent, quantum theory of gravity that reduces to general relativity at large distances and low energies.

21. **Jon Lester**
    September 4, 2007

    I am somewhat worried about this hype by Physics World. It implies that this community of theoretical physicists is indeed very powerful to manage information (beside positions). This situation has no precedents in the history of physics.

    It will not be a beatiful result of our generation to be remembered as the worst ever.

    Jon

22. **woit**
    September 4, 2007

    Matthew,

    I can't help pointing out that the mistake you made about Witten's Fields medal indicates you didn't bother to read my book, since there's a whole chapter in it about the subject of Witten's contributions to mathematics and what he won the Fields Medal for. It does appear that you skimmed it enough to notice that it doesn't contain mention of the latest string theory hype about heavy-ion physics. There are a couple reasons for that, the most important being that the book was written in 2002, and the hype about this subject began in 2005, by which time I'd found a publisher willing to publish it, and the manuscript was being copy-edited and out of my hands. If I were writing the book today, I suppose I would discuss the subject, including the awarding of a "Pinocchio award" by a heavy-ion physics expert to string theorists for their misleading claims about this that you uncritically repeat.

    As for why I didn't discuss the other articles about string theory in the same issue of Physics World, the reason is also pretty simple: I don't have access to them since there appears to be no online access available through my institution (Columbia) and I'm not a member of the IOP. I wrote about what I have access to, if someone is willing to send me copies of the other articles I'd be interested to see them and probably would write about them then.

    "if the theory is, as you routinely point out, unfalsifiable then how can you be so certain that it has already failed?"

    You're not making any sense here. A scientific theory that can't be falsified is a failed scientific theory. The argument, which does require getting into technicalities, and involves making informed scientific judgments, is about whether there is any hope of the current situation changing, and getting falsifiable predictions out of string theory. I've argued here at length why I think this is hopeless, others have different opinions.

    I very much respect the large amount of work you did on this, including the many people you talked to and the large number of relevant quotes from experts that you gathered. That's not what I do though. When I'm writing about string theory as science here on the blog, I try to stick to writing about things that I actually understand, and what I write is based on my own judgments and my own understanding. People who disagree with these often write in here to do so, and that often leads to an interesting discussion. When I write about the public perception and debate over string theory, sure, I discuss what string theorists are telling journalists. Again, thanks for all your work on getting this sort of material together.

    Much of my comments on your article were aimed not at you, but at the many string theorists who talked to you. I find a lot of their claims outrageous, and their willingness to make highly misleading and overhyped claims about the state of string theory disturbing. At the same time they are doing this, other string theorists often complain that string theory has gotten a bad rap just due to the over-hyped claims made for it in the past. Anyway, it's your job to accurately transmit what experts have to say to the public, and I have no problem with your role in doing that.

But, for some reason you decided in your article to strongly take one extreme side of a scientific controversy. That's rather unusual, and I think it deserves a commentary like mine that points this out. You not only ignored the arguments on the other side of this controversy made by Smolin, me and others, but you adopted a framing of the issue that I think even most string theorists would find dubious. The claim that string theory is "rooted in experimental data", and your emphasis on the LHC doesn't reflect my impression of the opinions of most string theorists, who readily admit that the LHC can't in any standard way "test" string theory, and that the tenuous connection of string theory to experiment is a huge problem. It appears that you didn't bother to contact anyone who is actually an LHC expert, either the people working on the experiments or the theorists with expertise in analyzing collider data. If you asked such people what they thought of the idea of the LHC "testing string theory", you might have gotten some strong quotes disagreeing with the thrust of your article.

23. **Bee**
September 4, 2007

"It's only in particle physics that a theory can be thrown out if the 10th decimal place of a prediction doesn't agree with experiment."

A) Nobody 'throws out' a theory that agrees in 9 decimal places. One might want to clarify in which limit it is suitable.

B) Ever heard of General Relativity? I believe this blog has plenty of readers that would be thrilled to hear about a deviation in the nth decimal place.

The above Witten quotation about digging out knowledge leaves me wondering: if string theory is not the looked for ToE, then what is it? And should one dig it out whatever it is?

Besides this, I guess we should be grateful your name is not Peter Wirch.

-B.

24. **another anon.**
September 4, 2007

Dear anon.,

About the 10^500. One thing which is known to all experts, but you will not be told on this blog, is that in the most studied case where the 10^500 means anything, and also where the number came from, (technically, this case is called IIB flux compactifications), for many (not all, but a lot of) physically relevant quantities the `10^500 different cases' collapses into a single unknown number.

The effect of these 10^500 choices on low-energy physics then collapses into the presence of a single unknown number in the low energy theory. Big deal – you have one number you need to fix by hand, and then (for a lot of problems) your 10^500 has gone away.
So the notion that the 10^500 solutions makes the theory unpredictive is not at all true and is in fact highly misleading. Indeed, people who work on this area are currently very excited rather than depressed.

This situation is present all the time. The Standard Model has an *infinite* number of possible varieties – there are twenty or so numbers that have to be fed in by hand. Of course this doesn't make the Standard Model not science.

Another anon.

25. **alex**
September 4, 2007

2anon:
I'm not sure if I can answer your question completely but here is what I know. In the original KKLT construction, the integer fluxes which fix the values of the complex structure moduli enter through the so called flux superpotential W_0. Now, W_0 is indeed a very complicated function which can take on an exponentially large number of discrete values. However, if you read string phenomenology papers (by Choi et al. for example) based on the KKLT constructon you will notice immediately that the corresponding particle phenomenology always depends on the fluxes through a single parameter – W_0 and not on the individual flux contributions.
Hence, in practice, all these comlicated flux configurations, while useful to tune the cosmological constant, completely decouple from particle physics.

26. **woit**
September 4, 2007

Note: "another anon" is responding to a comment by "anon" that I deleted. The first "anon" is someone who specializes in submitting off-topic comments here attacking string theory and string theorists, usually in an uninformed way. I have to waste a lot of my time deleting them, and I'm really, really unhappy about this. This whole business of overuse of anonymous comments is annoying. If you want to make a scientific argument here, there rarely are good reasons for you to not be willing to put your name to them.

Please, anyone who is not happy with string theory or string theorists, I ask you to not use my blog comment section as a place to vent about this. If you don't have something well-informed and relevant to say in a comment, don't post it. There's more than enough very pointed criticism of string theory and string theorists going on here, adding your own adds nothing, and if it contains inaccuracies, all it achieves is to give string theory partisans a reason to dismiss the serious arguments being made here.

As for the arguments of "another anon", they have nothing to do with the topic of this posting, and are an argument against a straw man argument I've never made. Yes, the situation with the landscape is far more complicated than the one specific compactification mentioned. If you look at one very specific compactification and just vary the fluxes, sure you can't get anything you want. But you also can't get a prediction of anything, because a different choice of Calabi-Yau, branes, other background information will give you something different.

I'm afraid I'm going to cut-off any more discussion of this right now since it has nothing to do with the topic of the posting, the Physics World article, unless you are claiming that the study of flux compactifications makes string theory testable at the LHC, in any standard usage of the term "testable".

Also, please do me a favor and allow a few minutes after an uninformed comment by "anon" attacking string theory appears before responding to it to give me a chance to delete it. I know arguing with "anon" is a lot easier than arguing with me, but still. The line in his comment about how I was going to delete it should have been kind of a giveaway in this particular case.

Also, please consider putting your name to what you have to say, unless you have a very good reason not to.

27. **DB**
September 4, 2007

From the editorial:

> But string theory can be criticized for how it has promoted itself. Since the mid-1980s, many string theorists have oversold their subject by making grandiose claims about a "theory of everything". Although that tendency has disappeared, it no doubt diverted some physicists from other, potentially more useful, lines of research in theoretical physics. Meanwhile, string theorists have not responded well to recent attacks based on the theory's lack of testable predictions, most preferring to keep quiet rather than to engage in debate.

That's pretty serious criticism actually, given the perennial shortage of resources in particle physics, and the standards of integrity expected of scientists.

28. **JD**
September 4, 2007

Peter:"unless you are claiming that the study of flux compactifications makes string theory testable at the LHC, in any standard usage of the term "testable"."

In Type IIB flux compactifications one can derive a reliable prediction for the pattern of the gaugino masses. See Nilles and Choi for the related work.

29. **Thomas Larsson**
September 4, 2007

JD:

So you are claiming that the non-discovery of gauginos at the LHC will disprove string theory 🙂

30. **Matthew Chalmers**
September 4, 2007

Peter – a quick skim through the Notes pages of your book reveals that you should be awarded a Pinocchio prize yourself (e.g. you appear to have had no trouble in fitting in an Edge quote from Phil Anderson in 2005, nor in quoting from Krauss's 2005 book, Randall's 2005 book or Susskind's 2005 book). Recall that the APS announcement of the RHIC result was in March 2005, with plenty of hints coming out from late 2004.

As for my not making any sense about your stance on string theory, you should consider broadening your philosophy of science slightly by reading Lakatos and others. Your entire attack on string theory seems to me to be based on a convenient but narrow and overly simplistic Popperian view of testability (i.e. falsifiablility) that is simply one interpretation of how science progresses — and certainly not the consensus view among philosophers of science.

Stringscape is not an attempt to give an overview of the "debate" surrounding string theory based on echoing yours and Smolin's arguments while completely ignoring the views of string theorists and other theoretical physicists. That has been done to death in the last year or so, as I set out in the first few paragraphs. Rather, the article is an attempt to bring something new to the debate by giving Physics World readers a non-partisan overview of where string theory — a scientific research programme that, for better or for worse, dominates current research in fundamental theoretical physics — stands today. (As it happens, the other three more interpretive string-related articles in the September issue do address the broader anthropic etc debate, although none mention your blog or book I'm afraid).

My article could of course have turned out quite differently if all 10 of the non-string theorists I interviewed had been more critical. But they weren't. Similarly, I could have turned up at Strings07 in Madrid to find a bunch of deluded nut-bags dealing only in abstract mathematics and talking in tongues. What I did find, however, was a bunch of mostly extremely able theoretical physicists trying their damndest to understand nature at its most basic level. The overwhelming impression I got, and which I have tried to convey in the article, is that string theory is simply not yet developed to the point where it can make the "falsifiable" predictions that physicists need before they can know for sure whether it is a viable physical theory. Rather, it is a compelling framework for unification that also happens to have all these great applications in mathematics, black-hole physics and, most importantly for physics perhaps, quantum field theory.

You still don't seem to get my earlier point that as a journalist I have no vested interested in whether string theory is portrayed in a positive or negative light. Since you claim only to blog about the things you understand, perhaps you should find something else than science journalism to criticize — after all, it's not that hard an approach.

31. **JD**
September 4, 2007

"So you are claiming that the non-discovery of gauginos at the LHC will disprove string theory "

Please point to the phrase where I made such a claim.

32. **Peter Woit**
September 4, 2007

Matthew,

Thanks for raising the level of discussion here by calling me a liar. One of the depressing things I've learned during this string theory debate is how many people think the correct response to legitimate criticism of the content of something they have written is to launch a personal attack.

Some of the things you mention were among a small number of additions and changes made to the text in November 2005, after it was copy-edited, before it went to the typesetter (the manuscript was delivered to the publisher in the summer of 2005). Sure, by that time people were discussing the application of AdS/CFT to heavy-ion physics, but it only became a major talking point for string theorists starting in 2006. I made no claim in my book to deal with every overhyped claim made for string theory, doing so would have made it a much longer book.

This issue in any case has nothing to do with what I was criticizing in my book, the failure of string theory as an idea about unification. If you look at page 192 of the book you'll see this subject referred to as

> …a much more promising area, that of trying to find a superstring theory dual to QCD. The AdS/CFT correspondence described earlier provides some hope that progress can be made in this direction…

which remains an accurate description of the situation, minus the hype surrounding the attempt by many people to use rather tentative results about heavy-ion physics to deflect attention from the failure of the string theory unification program, which is something quite different.

The other thing I get a lot of from people I've criticized accurately is sneering put-downs about how ignorant I am ("you should consider broadening your philosophy of science slightly by reading Lakatos and others"). Actually I've read Lakatos (and others), and am well aware that "falsifiability" is a tricky subject. If you read my book (you really should do this, you might learn some things) you'd find a long discussion about the problems with falsifiability and a lot of evidence that I don't have a "convenient but narrow and overly simplistic Popperian view" of this issue. What counts as a convincing test of a scientific theory is a tricky issue, but it is uncontroversial that there is no such thing possible for string theory unification at the moment, and, as I said, I've argued extensively that any hopes for this in the future have little to back them up other than wishful thinking.

Finally, I don't know or care whether you have a vested interest in string theory or not. Honestly, I know nothing about you beyond having read the 13 pages that you wrote. What I wrote here was a response to claims made in those 13 pages, by you and people that you interviewed, many of which are highly misleading. I'm willing to debate those claims further if you want, but I really think you should start by stopping personal attacks on me, and informing yourself what my views on this subject actually are, rather than making up naive and uninformed ones to argue with.

33. **Peter Woit**
September 4, 2007

JD,

I already spent a lot of time looking into claims of "predictions" of gaugino mass ratios that refer to Nilles and Choi. These turned out to be quite misleading, see the discussion at Cosmic Variance, one of my relevant comments is

http://cosmicvariance.com/2007/03/31/string-theory-is-losing-the-public-debate/#comment-241803

As far as I can tell, the situation here is just like in anything else in "string phenomenology": for certain specific classes of models you have constraints on what you'll see, but there are no general constraints. If you don't see one particular pattern, you can find another class of models that will give you what you want.

34. **Thomas Larsson**
September 4, 2007

JD:

You used the phrases "LHC", "reliable predictions", "gaugino masses" in you previous post. But of course this does not mean that string theory reliably predict gauginos at the LHC, only that you want to create such a false impression.

35. **JD**
September 4, 2007

Peter. You had said: "unless you are claiming that the study of flux compactifications makes string theory testable at the LHC, in any standard usage of the term "testable"."
I've read the discussion you pointed to and then looked at my original post and I see no problem. I still claim that flux compactifications (discussed in Nilles and Choi) yield robust predictions for patterns of gaugino masses.

I agree that there are no general string theory constraints on how SUSY is broken but since you specifically mentioned flux compactifications, I have to say that the corresponding phenomenology has been worked out.

For Thomass Larsson: It is well known that in its current state, string phenomenology does not give a definite answer about the scale of SUSY breaking, just like the standard model without experimental input does not predict the higgs mass or the top quark mass. So what? If we are lucky and the superpartners are discovered at the LHC we may be able to identify the particular class of string compactifications by studying the pattern of gaugino masses, why is this so controversial?

36. **chris**
September 4, 2007

another anon., this is really priceless argumentation. it reminds me of a seminar i once sat through by some few body model-builder. it involved 'free' quarks with pion exchange ans should explain the nucleon spectrum. this guy claimed he had no free parameters whatsoever.
finally, he had to admit, that the model contained an arbitrary function describing the interaction potential. he pulled some arguments that no, this means no free parameters and this function almost presents itself.

but he was just doing phenomenology. so i excuse him even if he needs infinitely many parameters to describe what essentially is a theory with one parameter (qcd in the massles limit). but hey, wow! the lanscape can do that too. i am seriously impressed 🙂

37. **JD**
September 4, 2007

Chris, I think you got confused about another anon's point. Your analogy is incorrect. Read the KKLT paper and you'll understand what another anon meant.

38. **M**
September 4, 2007

Matthew, I would like to comment on your sentence: "The overwhelming impression I got, and which I have tried to convey in the article, is that string theory is simply not yet developed to the point where it can make the "falsifiable" predictions".
String theory started with the hope that maybe quantum gravity implies testable predictions on observable low energy physics. String theory was partially developed, and a more realistic and pessimistic expectation emerged. No matter how much you develop the theory, you will never get any prediction, if no prediction exists.

39. **CCDGator**
September 4, 2007

Dr. Woit,

I'm not sure if this is the appropriate place for this, but I'll post anyway. I am not a specialist on one side of the debate or the other (I'm a chemist who knows a little bit about such things as quantum mechanics, symmetry, and group representation theory). I read your book during the summer and found it to be quite an eye opener and well worth reading. I was previously under the impression that "M-Theory" was some kind of unification of several string theories and in some sense a complete theory. I enjoy looking at your blog from time to time.

Thank you.

40. **Bee**
September 4, 2007

Hi Peter:

Sorry for abusing your hospitality, but in case anybody drops in here after reading Lubos' totally distorted summary of this comment section, I want to point out that I've never said David Gross is a moron (as Lubos has managed to read, I wonder if he's taking pills to achieve that?), the comment above was addressed to Peter (you might recall – the guy who writes this blog) and the words 'your name' refers to 'Peter Woit's name'. One should have thought this is obvious.

I just want to leave that clarification here since I'm afraid Lubos will delete my comment at his post. I should add that I am pretty much pissed off by so much unjustified viciousness, and I am (eventually) going to remove links to TRF (what I should have done much earlier I guess).

Best,

B.

41. **Peter Woit**
September 4, 2007

Bee,

Surely you should know by now that paying any attention to Lubos is virtually always a big mistake. The Chalmers article seems to have gotten him really excited, finally seeing his point of view reflected in the media, after a year of having to read much more accurately skeptical pieces about the problems of the theory.

The only surprising thing he says though is his claim that PI offered him a job. If someone who knows what's behind that story wants to tell me about it on deep background, I wouldn't mind…

42. **dan**
September 4, 2007

"The problem with string theory … it is a wrong idea about unification, and thus cannot ever explain the standard model or predict what lies beyond it."

Peter,
Would you still stand by this statement if LHC and other experiments support the idea of both theoretically and experimentally, the idea of something like a SUSY-SO(10) GUT, and as such, could be embedded within a string theory?

43. **ori**
September 4, 2007

It is amusing to see a group of people with nearly zero knowledge in high energy physics arguing whether a group of Nobel proze winners is correct or not. Who should I believe ? 🙂

44. **ori**
September 4, 2007

proze->prize …

45. **ori**
September 4, 2007

A quote from Bee :

" Ever heard of General Relativity?"

Well, should we tell David that you think he has not heard of GR ?

46. **Peter Woit**
September 4, 2007

ori,

Thanks for making it clear that Bee's comment

"so much unjustified viciousness" is an accurate description of other string theorists besides Lubos Motl.

Besides the insults, do you have any commentary on the actual blog posting?

47. **Matthew Chalmers**
September 4, 2007

Dear Peter

The reason why I decided to post a comment on your blog this morning, in response to your labeling an article that I had written a dishonest and misleading advertising supplement based almost entirely on unadulterated hype, was to raise a couple of points about the differences between blogging and journalism (and how the two interact with one another). This is a topical issue for those of us who work in traditional media outlets — and presumably for those who read and write blogs too — and has already led to some interesting episodes between scientists and journalists.

A great example of this was the "bump-hunting" saga at Tevatron earlier this year, which led to an article in New Scientist magazine (see http://physicsworld.com/cws/article/print/27731). Once high-energy LHC data begin to pour in a year and a half or so from now, and blogger-members of the Higgs groups in the ATLAS and CMS collaborations start getting excited, it will be a real challenge to know when best to break the story of a possible Higgs or some other discovery. Indeed, journalists aside, these large collaborations are going to have to deal with problems of their own involving how to manage the blogging activities of physicists.

In retrospect, however, Not Even Wrong was probably not the place to try and have such a discussion, given that, for instance, you are not actually involved in string theory/high-energy physics research yourself. And since our brief exchange has turned into pointless pedantry and apparent confusion over what is personal and what is fair-game, I would guess that readers are not going to get much more from it either.

More to the point, it is late and it feels as if I have been looking at that bloody UA1 W-event all day. This stuff must tie up hours of your time!

Matthew

PS I posted a hard copy of the September issue to you last week, in which you can read the other articles that I mentioned – that is, if you're at all interested in taking someone else's opinion on string theory on board.

48. **Peter Woit**
September 4, 2007

dan,

Sure, I'll stand behind that statement until someone comes up with a plausible way of getting real predictions out of string theory. I think the great hope of some string theorists is that the LHC will see not only supersymmetry, but a pattern of supersymmetry breaking that corresponds distinctively to a certain kind of string background. Based on this they might then be able to make real testable predictions. This seems to me to be nothing but wishful thinking, we'll find out in the next few years.

Turning the question around, do you think string theorists are willing to change their minds about string theory if no evidence of a supersymmetric GUT turns up at the LHC?

49. **Peter Woit**
September 4, 2007

Matthew,

To be accurate, I did not describe your article as dishonest. Unadulterated hype swallowed whole from experts spouting it, yes. Dishonest, no. The one thing I described as "dishonest" was the quote from David Gross. He's one of the greats of the field, with tremendous accomplishments to his name, but the quote was not an honest characterization of the situation.

Actually, I do spend large amounts of my time working on trying to find new mathematical techniques in quantum field theory, which is a form of research into HEP theory. Unlike you, I have a Ph.D. in the subject and have devoted much of my life to its study. But if it makes you feel better to attack me personally and imply that I don't know what I'm talking about, go right ahead.

The relation between blogging and journalism is certainly an interesting and complicated topic. Maybe we can discuss it some other time, in a less heated context. Yes you're right that sometimes this blogging business takes up too much time. It's our first day of classes here and I should be preparing my course.

Thanks for sending me a copy of Physics World, I'll look forward to seeing it.

50. **Bee**
September 4, 2007

ori: as I've said over at trf, the comment above is what it is, namely a 'comment'. It comments on the the statement made, which I found disturbing in its generality, and is addressed to the readers here, including the author of this blog. when I wrote the above, I wasn't even aware who was quoted, but that doesn't change that the comment is in my opinion appropriate. if you want to make a complete fool out of yourself, go ahead and tell David Gross that you think I think the message didn't get across very clearly the way he was quoted.

besides this, Lubos has changed the 'moron' into 'completely silly' and I guess his post will undergo further fly-by changes. I honestly don't have time for that crap – I certainly don't want to end up in Pilsen or something, so I better go back to work now.

Best,

B.

51. **Tony Smith**
September 4, 2007

Peter Woit said to Matthew Chalmers "… Unlike you [Matthew], I [Peter] have a Ph.D. in the subject ..".

According to physicsworld.com
"… Dr Matthew Chalmers is Features Editor of Physics World. He joined the magazine in 2002 after completing an MSc in science communication at Imperial College London. He obtained both his physics degree and

his PhD in particle physics from Glasgow University,

after which he spent a year working in quantitative finance in Amsterdam. …".

Also, I would like to know Matthew's personal opinions about the stability of fancy-math finance hedge funds etc in the event that the USA housing market declines and oil prices increase,
and
(to stay on-topic) how it might compare with the stability of conventional superstring theory in the event that LHC finds no sign of supersymmetry.

Tony Smith

52. **jhk**
September 4, 2007

"It is amusing to see a group of people with nearly zero knowledge in high energy physics arguing whether a group of Nobel proze winners is correct or not. Who should I believe ?"

Which group of Nobel proze winners would that be Ori? Gross and Weinberg, or Glashow and Anderson? Who should I believe?

53. **Dan**
September 4, 2007

Of course string theorists would continue hyping string theory in the event of an LHC null result, but aren't susy-extentions of the SM, and GUT models also suffer from a lack of predictivity, and is as unable to predict what the LHC will see, in detail, as string theory?

54. **Peter Woit**
September 4, 2007

Tony,

As I wrote to Matthew, I know nothing about him besides the fact that he's the author of that article. So, good journalism practice would have indicated that I should have checked before I wrote that he didn't have a Ph.D. in particle theory. Upon further investigation, it turns out that he does have a Ph.D, but in experimental, not theoretical particle physics.

And please, don't even try and carry on a discussion of prospects for hedge funds here…..

55. **Peter Woit**
September 4, 2007

Dan,

I've never been a fan SUSY extensions of the standard model, or GUTs, precisely because they aren't very predictive. For SUSY, the problem is that don't know what breaks supersymmetry, and this ruins predictivity. Non-susy GUTs are actually better since they often make more robust predictions. The SU(5) non-supersymmetric GUT was so good on this score that it was falsified (no proton decay at predicted rate).

56. **Eric**
September 4, 2007

Peter,
Aren't GUTs and supersymmetric theories only qualitatively predictive at low energies because we lack information about the theories at high energy? Would the standard model not have the same problems without experimental data which is input into the theory? Does the fact that they are unable to predict everything from first principles mean that they aren't science? In your myopic definition of science this is apparently the case. The point that has been made to you over and over is that string theory is no different than this. The only reason we are currently unable to make detailed predictions from first principles is that we lack knowledge, not because there's anything fundamentally wrong with the theory. In point of fact, string theory is the right direction and I don't think anybody who works on it needs to apologize for this.

57. **Peter Woit**
September 4, 2007

Eric,

No, the problem with supersymmetric theories is not that "we lack information about them at high energies", it's that you have to break the supersymmetry. This is not a "high energy" effect. Non-supersymmetric GUTs are often quite predictive, in the SU(5) case so much so that it was falsified.

"Does the fact that they are unable to predict everything from first principles mean that they aren't science?"

No, they're science because they make a lot of testable predictions that have been confirmed. The problem with string theory is not that it can't predict everything from first principles, but that it can't predict anything at all.

"The only reason we are currently unable to make detailed predictions from first principles is that we lack knowledge, not because there's anything fundamentally wrong with the theory."

The problem with string theory is not that it doesn't make "detailed predictions", but that it makes no predictions, none at all. Zip. Nada. Detailed or not detailed. If you work hard on a very speculative idea for more than 20 years ad it doesn't do what you want, the simplest hypothesis for why is that there is something fundamentally wrong with the idea.

58. **alex**
September 4, 2007

Peter Woit said:
"I think the great hope of some string theorists is that the LHC will see not only supersymmetry, but a pattern of supersymmetry breaking that corresponds distinctively to a certain kind of string background. Based on this they might then be able to make real testable predictions."

Surprisingly, I must say that I fully agree with you on this point Peter. I hope the readers of your blog notice this comment of yours.

Peter Woit then said:
"This seems to me to be nothing but wishful thinking, we'll find out in the next few years."

There several indirect hints pointing to TeV scale SUSY so I don't share your pessimism here.

59. **Eric**
September 4, 2007

Peter,
The exact way in which supersymmetry is broken is the major part of the information at high energy which we are lacking and this is a big part of the information that will be able to answered once information from LHC/ILC is available. Probably the detailed way in which SUSY is broken will be understood from string theory. Regarding string theory, it will be possible to make detailed predictions once the correct vacuum which describes our universe is found.

60. **alex**
September 4, 2007

Eric, see my comment above.

61. **Bogs Dollocks**
September 4, 2007

After reading the original post and the comments and seeing that theoretical HEP has descended into Ubu pata-phyics I'm soooooooooooooo glad that I left what has become a completely sterile field. There are so many interesting other physics problems to work on.

The mental gymnastics that people are prepared to perform as to what constitutes a "theory", a "prediction' and a "measurement" are truly depressing – I'm completely gobsmacked.

Hope the LHC find something interesting, otherwise it's lights out.

62. **LDM**
September 4, 2007

I do think the article does have a bias towards string theory and is more of the usual hype.
However, every time a string researcher comes out with a new idea, how many science journalists have the background to dig up the relevant paper, read it, and decide if how much is pure speculation and how much is not? This has to be a tough job. But the real problem is the string researchers themselves for putting out the hype to begin with.

Ori,
Perhaps you refer to the 1949 Nobel? It is possible to get a Nobel in physics that resulted from an idea that, while brilliant and fruitful theoretically, is later discovered to be wrong.

63. **Arun**
September 4, 2007

Peter,

Hasn't there been a shift in the past few years from string theory as "THE theory of everything" to string theory as "a general framework (like QFT or Hamiltonian mechanics) within which a theory of everything may one day eventually be fit"?

If so, isn't that an improvement in the state of affairs?

64. **Peter Woit**
September 4, 2007

Arun,

I don't see it as an improvment, since it's just an argument for why string theory research should continue to dominate the subject, despite failing as a theory of everything. The question that has always most concerned me is how one can encourage research into other "general frameworks" than string theory. We know fairly well by now how string theory works as an idea about unification (not at all), so the question is how to find some other framework that is more promising.

65. **Eric**
September 4, 2007

Peter,
If your potrayal of the current state of string theory research were anywhere near accurate, people would be looking for other frameworks to study quantum gravity in droves. However, this is clearly not the case. The string theory community continues to grow. The simple fact is that the Science World article is an accurate picture of how most scientists view string theory. I would advise that you face up to this and stop deluding yourself.

66. **Arun**
September 4, 2007

Peter,

Reality legislates what is physical theory, but speculation is a matter of taste. Whether a particular line of speculation is going to be fruitful is a matter of individual judgment.

What I mean is that if Nobel Laureate X makes a falsifiable claim, any ordinary soul can judge it for oneself (the beauty of science!) but if Nobel Laureate Y says, I have a hunch this is the way to go, then we've entered a rarified atmosphere where "which hunches of yours have panned out?" becomes an unanswerable argument.

Strings may be zero as a theory of physics but dominant as a line of speculative research depending on the interests of the most prominent researchers.

67. **happyday**
September 4, 2007

> I honestly don't have time for that crap – I certainly don't want to end up in Pilsen or something, so I better go back to work now.

This thread is extremely interesting (light years beyond the distinctly soft dullness of CV, for instance), but Bee's post just made my day. I like it so much I can't help quoting it, even though I have nothing to add.

68. **anonymous hater**
September 4, 2007

Woit,

I object to your entire approach. In this post there's no physics, no math, just abstract meta-objections. It's facile and glib to say that there is no way to concretely debunk a theory that makes no testable predictions, but it's also plainly laughable when one is talking about something plainly as rich conceptually (whether or not physically correct) as is string theory. It's extremely difficult for any individual to speak coherently about the totality of something as large as a unification program like string theory without eliding details and nuance; at this level it is always possible to raise some objections. Science is done incrementally and the rub is always in the details.

The entirety of your critique seems to involve quoting various authorities, pro and con, and analyzing the sociology behind their pronouncements. Let's remember that despite being a celebrated asshole, Wigner was as good a physicist as there has been.

69. **Shantanu**
September 5, 2007

Eric, I also know of some people who long before Peter wrote his book/had a blog gave up string theory ,because it had no connections to real world and moved to grav. waves or LQG or astrophysics.

70. **Josh**
September 5, 2007

Peter, I used to be a reader of your blog. But I have carefully compared Chalmers' thirteen-page work stuffed with interesting physics with your rants and you just seem to be a gigantic loser. It seems that Leonard Susskind is right when he says that you failed as a physicist and now you try to revenge to the world. 2 minutes and 40 seconds from the beginning of http://www.kqed.org/.stream/anon/radio/forum/2006/07/2006-07-31b-forum.mp3

My advise is to shut this website down. Bye, Josh

71. **Chris Oakley**
September 5, 2007

Josh,

Susskind may well have his wires crossed here. Insofar as he has an academic job, it is not true to say that Peter "never made it as a physicist" and he never "became a [professional] programmer". Someone suggested on this blog that he was in fact referring to myself, in which case it would be a bit like saying that LS "never made it as a plumber" as my leaving HEP had little to do with my abilities & everything to do with my choice of research topic.

But I wonder … LS now asks us to gleefully accept the possibility that creating scientific theories is just a matter of finding the right point or points in the Anthropic Landscape, and, by implication, stronger and more deductive frameworks are not worthy of sponsorship. Look up the definition of "physics" in the dictionary as ask yourself – who really "never made it as a physicist"?

72. **Peter Woit**
September 5, 2007

Josh,

I see you've been reading Lubos. And after that, you think I'm a gigantic loser?

For more about the Susskind interview, see:

http://www.math.columbia.edu/~woit/wordpress/?p=437

You string theory partisans are really charming…

73. **mathjunkie**
September 5, 2007

Peter and Lee look alike!

74. **hard gluon**
September 5, 2007

> Let's remember that despite being a celebrated asshole, Wigner was as good a physicist as there has been.

Wigner was an asshole? How come? I had never heard about that before.

75. **Peter Woit**
September 5, 2007

anon,

Sorry, but writing anonymous comments into blogs referring to people as "assholes" doesn't say much for your judgment. And whether or not any particular physicist fits that description has nothing at all to do with what I write here about string theory.

For the record, I often saw Wigner around the when I was a graduate student and he was already a quite elderly emeritus professor. If asked to rank members of the department on an "asshole" scale, my impression is that he wouldn't even make 50th percentile. Maybe he mellowed in his old age, but you're the first person I've ever heard characterize him this way.

76. **chris**
September 5, 2007

Chris Oakley,

suskind has more under his belt than those recent antropic speculations. no matter what he does now, he has an established record.
or would you claim einstein failed as a physicist, because after 1916 he basically screwed everything up (couldn't come to grips with quantum mechanics, dreamt up crazy unified theories and not much else)?

good physicists tend to get weird in their old age and suskind is a very good example.

77. **Cee**
September 5, 2007

Bee,

why did you backdate your post about Lubos?

78. **Bee**
September 5, 2007

because I don't want him to get more attention than absolutely necessary. I will change the date to today if September goes into the archives.

79. **Chris Oakley**
September 5, 2007

Hi Chris Anonymous,

AFAIC anyone who invokes the Anthropic Landscape has not made it as a physicist. I am not directing that just at Susskind.

Maybe I should have phrased it differently. Try "is demonstrating that wisdom does not necessarily come with age."

80. **Cheeky Bastard**
September 5, 2007

Chris, I think you should show some consideration for poor old guys who never made it as programmers and became professional physicists.

81. **Chris Oakley**
September 5, 2007

What – like Richard Feynman?

82. **sanity**
September 5, 2007

One question that was raised was whether string theory requires SUSY GUTs. The answer is no; string theory requires neither low energy SUSY nor GUTs; indeed, although this is not covered accurately in the article, the Bousso-Polchinski mechanism and several frameworks for moduli stabilization apply (and are in some ways actually simpler) also at higher scales of SUSY breaking. Phenomenological clues do hint at low energy SUSY, which would be very interesting to discover. But it is important to recognize that its absence does not affect the status of string theory as a theory of gravity; in fact many of the most important developments and open questions in this area, such as those involving spacetime singularities, involve supersymmetry breaking scales of order the KK or string scale.

83. **chris**
September 6, 2007

hi Chris Oakley,

to some extent i agree with you. i myself can't reconcile antropic reasoning with the very nature of physics. but you know, science has strange ways of progressing.

i always have to think about kepler, e.g. whose middle age mystic speculation about the harmony of spheres ultimately led him to meander his way to find the 3 laws.

for suskind in particular, i (as a lattice physicist) am confronted with one of his brilliant insights on an almost daily basis. even if he decides to become a spiritual medium tomorrow it does not annul this particular achievment.

so, yes, i don't buy any of the stuff he is doing at the moment, but he has definitely 'made it as a physicist' no matter what.

84. **Anders R**
September 6, 2007

i don't understand how you cannot understand something that doesn't exist. the ultimate string theory must be constructed by humans, and if it hasn't been constructed yet it doesn't exist.

85. **Anders R**
September 6, 2007

this was regarding the witten quote:

"It's incredibly rich and mostly buried underground. People just know bits and pieces at the surface or that they've found by a little bit of digging, even though this so far amounts to an enormous body of knowledge…"

86. **Bee**
September 6, 2007

Hi Anders R: That's actually an interesting question. I guess it greatly depends on what one means with 'existence'. In how far does a mathematical structure 'exist' before it is understood by humans? Does something 'exist' that doesn't have any (known) relation to 'reality' (another ambiguous word)? Does something 'exist' that is only an idea, or maybe not even yet an idea, or maybe a not even wrong idea? I think it matters in this context what one is trying to dig out there… Best – B.

87. **Anders R**
September 6, 2007

yeah i guess that if you see mathematics as a sort of structure that mathematicians find out more and more about then it makes more sense.

88. **dan**
September 8, 2007

I understand that string theory does not require SUSY GUT's, but if LHC does detect SUSY, this would presumably imply some sort of SUSY GUT, which presumably could be embedded in some sort of string theory, and all string theories have a quantum gravity sector. String theorists do not commit themselves to low-energy SUSY phenomology that will be seen at LHC, of course, but should SUSY be seen I'm not sure that calling string theory unification scenarios are failures in that remote event.

Does string theory succeed as a theory of quantum gravity? I am aware of objections that it is not background independent, nonetheless it does have gravitons.

89. **Peter Woit**
September 8, 2007

dan,

String theory unification will remain a failure as long as it can't predict anything, and seeing SUSY at the LHC by itself won't change that. The only way it will change is if you see SUSY, together with a SUSY breaking pattern that is naturally explained by a specific class of string theory backgrounds. That's what string theorists are hoping for, but I see zero reason for it other than wishful thinking.

The debate about background independence and string theory has been carried on at this blog and many others upwards of 100 times by now. Unless there's something new about this, please don't start the same discussion all over again here.

90. **dan**
September 23, 2007

Dear Peter,

What do you think is the most promising solution to the hierarchy problem if you don't believe in SUSY? Technicolor models and top quark condensates don't seem any better than SUSY.

thanks
Regards
Dan

91. **Peter Woit**
September 23, 2007

dan,

Actually I've never been convinced by the arguments about the hierarchy problem. For one thing, we have no strong evidence for a GUT scale. For another, given our lack of knowledge about quantum gravity, we don't even know that the size Newton's constant necessarily means that quantum gravity happens at the Planck scale. So, it's not even clear there's a problem. To me the real problem has always been that of actually understanding what is causing electroweak symmetry breaking. Once we know that, let's see if we still have a "hierarchy problem". Hopefully the LHC will set us on the right track….

92. **dan**
September 23, 2007

Peter,
thanks for sharing that with me, I think that your view is why some string theorists disagree with you so strongly. While proton decay hasn't yet been observed as required by GUT's, stringers believe the matter/antimatter symmetry and violation of baryon number implies some sort of GUT, and that the most popular SUSY-GUT can be embedded in a string theory framework.

Dan

93. **Eric**
September 23, 2007

Dear Peter,
It seems that you've never heard of radiative electroweak symmetry breaking which occurs in supersymmetric theories, in particular 'no scale' supergravity models. The large top quark mass was anticipated 25 years ago when this mechanism was first discovered.

No compelling evidence for SUSY? How about:

1) Solution to the hierarchy problem.
2) Gauge coupling unification.
3) Well-motivated dark matter candidate
4) g-2 for the muon
5) Dyamical electroweak symmetry breaking.

It's clear why you're in the math department and not even a real
particle physicists.

94. **dan**
September 24, 2007

Eric,

Peter does address 1-3 in NEW (though I didn't realize reading NEW that he "never been convinced by the arguments about the hierarchy problem")

you may factually disagree with PW, but he does state in NEW, if you bothered to read it, that "Gauge coupling unification" comes off 10 percent too high, and that SUSY "Solution to the hierarchy problem" has its own problems (i.e 105 extra parameters, u problem, symmetry breaking mechanism, ad hoc introduction of R-parity, vacuum energy and cc too high, flavor changing neutral currents, lepton flavor changing, potentially large cp violation). If you bothered to read his book you'd know this.

DM is compelling evidence for anything.

Still, PW, I don't recall you addressed in NEW
points 4 & 5

4) g-2 for the muon
5) Dyamical electroweak symmetry breaking.

regards
Dan

95. **Peter Woit**
September 24, 2007

dan,

I was going to resolve to stop wasting time responding to string theorist trolls like Eric who seem to think that posting bad arguments and personal attacks on me helps their cause.

Besides the book, one of many places I've discussed the issue of supersymmetry is here:

http://www.math.columbia.edu/~woit/wordpress/?p=97

It's a discussion of a talk by Witten I attended on exactly this question. Unlike Eric, Witten did not claim that there is "compelling" evidence for supersymmetry. He gave several very tentative points of evidence for supersymmetry, together with several tentative points of evidence against. He certainly didn't include Eric's ridiculous claim that the g-2 discrepancy is compelling evidence for supersymmetry (it isn't, even assuming it is really there, which is not clear, there are many, many ways of getting such a discrepancy other than supersymmetry). There are various claims about a "prediction" of the top mass from supersymmetry, but this is based on various assumptions and never was much of a "prediction". I'd have to go look up the history, but from what I remember most discussion of this appeared after the top quark was already discovered. I'm pretty sure that there was never a point at which any supersymmetry partisan ever announced that supersymmetry was wrong if the top mass didn't have a certain value.

96. **Eric**
September 24, 2007

Dan,
Peter's arguments against gauge coupling unification are incredibly misleading. He says that it comes out 10% wrong on the strong coupling if you start out at the estimated unification scale and run the RGE's to the electroweak scale. However, this ignores the fact that there is an inherent uncertainty (of about 1%) on the actual unifcation scale, as well as an uncertainty on the value of the strong coupling constant at the electroweak scale. Thus if you start at the high scale, you are merely compounding the same uncertainty multiple times.

As far as the 'wild-claims' that SUSY + radiative electroweak symmetry breaking predicts a large top quark mass, this is standard knowledge which you will find in every textbook on the subject. The prediction of the large top mass was done in the early 1980's, well before there was any other reason to suspect it to be so large.

97. **Peter Woit**
September 24, 2007

Eric,

If you can produce a reference from the period before the top quark mass was measured in which a supersymmetry advocate said that supersymmetry was wrong if the top quark was not in a definite mass range (rather than just that one of many supersymmetry scenarios gave a possible mass range), please do so.

98. **Eric**
September 24, 2007

Peter,
As an example, have a look at

S. Ferrara, D.V. Nanopoulos, and C.A. Savoy, Physics Letters B 123:214,1983.

and various successor papers. Also you might have a look at a textbook published in 1989, 'Particle Physics and Cosmology' by Collins, Martin and Squires, or the popular science book by Gordon Kane on supersymmetry.

This work on dynamical electroweak symmetry breaking in no scale supergravity is very well known. In fact, all computer programs such as Isajet, SuSpect, etc. which calculate the Higgs mass and low energy superpartner spectrum use this.

99. **Peter Woit**
September 24, 2007

Eric,

Sorry, but you are really wasting my time. I made the mistake of looking at the paper you mention. It doesn't contain anything like what I asked for. It's just the same sort of unsuccessful model that you are now, a quarter century later, still working on, and still promoting as "supersymmetry predicts the fermion masses". This wasn't true then, and it isn't true now, for reasons that people have repeatedly pointed out to you.

100. **Eric**
September 24, 2007

Peter,
You should be embarassed by your complete ignorance of particle physics and phenomenology. This is a very basic result which is widely used in just about every calculation used today and for you to not even be aware of it is apalling.

101. **Peter Woit**
September 24, 2007

Eric,

I'm not ignorant of that calculation, I just don't think it's compelling evidence for SUSY. I asked you to provide a reference claiming that this was a definite prediction of SUSY (as opposed to something model-dependent), and you responded by quoting something that doesn't do this at all and continuing to insult me. If you were arguing against string theory I would long ago have put you on my block list as someone ill-informed who added nothing but misinformation and/or hostility to the comment section here. Since I don't want to be accused of censorship, I guess I'll continue to allow your misinformation and stupid personal attacks to appear here. But you're really not doing a good job of representing advocacy for string theory…

102. **Eric**
September 24, 2007

Peter,
You're just playing games to avoid having to concede the point on this issue. Everyone knowledgable knows this result and it is a standard (generic) part of SUSY phenomenology. For the record, I do have a Ph.D. in high-energy physics and am intimately familiar with the current status of the subject. Certainly, more so than you.

On the subject of personal attacks, I seem to recall being rererred to by you a few comments back as a troll. Care to answer for that?

103. **Peter Woit**
September 24, 2007

Eric,

I'll stand by the "troll" comment, see:

http://en.wikipedia.org/wiki/Internet_troll

104. **Eric**
September 24, 2007

Peter,
I hardly think pointing out errors in your statements as deliberately posting comments to stir up controversy. The fact remains that you don't seem to be aware of basic developments in a subject for which you pass yourself off as an expert. Dyanmical electroweak symmetry breaking is just one example. You argument regarding gauge coupling unification is also completely wrong. It's hard to say whether you just don't know what you're talking about or if you're just fundamentally dishonest, but the net result is that many people end up being mislead by your comments.

105. **alex**
September 24, 2007

Peter:"If you can produce a reference from the period before the top quark mass was measured in which a supersymmetry advocate said that supersymmetry was wrong if the top quark was not in a definite mass range (rather than just that one of many supersymmetry scenarios gave a possible mass range), please do so."

I think that the answer is obvious in the context of MSSM. Indeed, if the top were light, there would be no REWSB and extra stuff would have to be added to the MSSM to accomplish this. And indeed, all the standard MSSM packages automatically incorporate this to generate the higgs mass etc.

Eric, Peter has asked you a carefully worded question to which there is an obvious answer – "many supersymmetric scenarious", whatever they are, don't predict a heavy top.

Supersymmetry by itself is just a framework and, of course, such a specific prediction (heavy top) without a concrete model is impossible and Peter knows this and that's why he asked you this ridiculous question.

106. **Peter Woit**
September 24, 2007

alex,

Thanks for the clarifying comment.

107. **Eric**
September 24, 2007

Alex,
Yes, I know that Peter was just playing word games to avoid the issue. The bottom line is that in the MSSM and similar models, the electroweak symmetry breaking scale is determined dynamically. For this to work a large top mass is required, and this was realized in the 80's long before the top was discovered. Peter's tactic is to play ignorant and try to obfuscate because he knows that this completely undermines his arguments that there is no evidence for SUSY.

108. **Coin**
September 25, 2007

Hi,

What does "dynamical electroweak symmetry breaking" refer to in this context, and why are Dan and Eric considering it to be evidence for supersymmetry?

109. **Peter Woit**
September 25, 2007

Eric,

Alex was pointing out to you that your claim that supersymmetry requires a large quark mass is incorrect. This is a claim about certain models, it's not true in others.

110. **Chris Oakley**
September 25, 2007

Eric,

"I can construct supersymmetric models in which the top quark must be heavy. Therefore supersymmetry requires a heavy top quark". If a child presented you with this kind of reasoning then you might feel duty bound to correct them. I certainly would. The fact it seems to be perfectly acceptable amongst particle physicists now just shows how far the subject has fallen. It seems that what was once the hardest of hard sciences is now just a mushy neverland where optimism matters more than fact, hype more than reasoning, and who you suck up to more than the substance of your research. You are welcome to it. All of it.

111. **Eric**
September 25, 2007

Dear Peter and Chris,
You guys are really into convoluted bs and self-deception. What we're talking about it the MSSM, and a heavy top mass is required in the MSSM to radiatively break the electroweak symmetry. I'm not sure what other supersymmetric models you're talking about that wouldn't require a heavy top. Any model which includes the standard model and TeV scale supersymmetry will have this feature. So, stopping misleading yourselves and others with your desperate attempts to deny any evidence for supersymmetry. It's just sad.

112. **Peter Woit**
September 25, 2007

Eric,

Perhaps you should stop insulting people long enough to ask someone about this who actually knows what they're talking about. Your claim

"Any model which includes the standard model and TeV scale supersymmetry will have this feature."

is just not true, as Alex tried to point out to you:

"Eric, Peter has asked you a carefully worded question to which there is an obvious answer – "many supersymmetric scenarious", whatever they are, don't predict a heavy top."

113. **Eric**
September 25, 2007

Peter,
What Alex has said is incorrect. It is simply not true that many supersymmetric scenarios don't predict a heavy top. Well, it might be true if that scenario does not include electroweak symmetry breaking or if your model doesn't include TeV scale SUSY or the standard model.
For your reference, here are publications you should look at if you want to educate yourself:

Ibanez and Ross, Phys. Lett. B110, 215(1982)

L. Alvarez-Gaume, M. Claudson and M. Wise, Nucl. Phys. B207, 96(1982)

K. Inoue, A. Kakuto, H. Komatsu and S. Takeshita, Prog. Theor. Phys. 68 927(1982)

As Alex pointed out, this is a standard, generic feature of SUSY phenomenology and is a feature of every computer program used to obtain low-energy SUSY and Higgs spectra. Why do you suppose the uncertainty in the top mass is so important in calculating the expected Higgs mass?

Again, I would expect any real particle physicist to be well aware of this, so either there are large holes in your education or you are deliberately being deceptive.

114. **Peter Woit**
September 25, 2007

Eric,

You just continue to do the same thing endlessly: posting comments that are a combination of insults and misinformation. Alex, who I suspect has no great sympathy for my point of view, has tried to politely explain to you that you're wrong. Maybe someone else wants to try their hand at this, but it's rather obviously a complete waste of time.

115. **Eric**
September 25, 2007

Peter,
I think you have misinterpreted Alex's post. He was not being supportive of your postition. Read it more carefully.

116. **anon.**
September 25, 2007

This discussion is ridiculous. The physics here is quite simple: if you start out with non-tachyonic masses for the Higgses in the MSSM, you have to drive one of them tachyonic to get EWSB. How can that happen? Well, if you look at the RGEs, it's the contributions from Yukawas that push the mass terms toward being tachyonic. So yes, you need some large Yukawas to get radiative EWSB. No one disagrees with that, right? Anything else is semantics.

117. **observer**
September 25, 2007

> need some large Yukawas to get radiative EWSB

but how large is "large"? A top at 30 GeV would be considered "heavy" w.r.t. to the other quarks, but that's not a prediction of the real top mass.

118. **anon.**
September 25, 2007

observer: the statement that you need large Yukawas for radiative EWSB in the MSSM is a very general one. To get a precise numerical prediction, you need a model.

119. **observer**
September 25, 2007

As usual, the devil is in the details… Thanks!

120. **non-a**
September 25, 2007

"To get a precise numerical prediction, you need a model."

So what. Given the cornucopia of free dimensionful parameters in the MSSM it's hardly surprising some of them can be adjusted to get a heavy top.

121. **Eric**
September 25, 2007

non-a,
There's no need to adjust any parameters to get a large top mass in the MSSM. One needs a large top mass to obtain EWSB, so the two things are related generically.

122. **alex**
September 25, 2007

Eric, I just wanted say that you fell into Peter's trap by using the loose language and saying that the heavy top is evidence for supersymmetry while referring to the MSSM. We all know you were not talking about N=4 SYM when you referred to supersymmetric models. The bottom line is that there is plenty of indirect evidence for MSSM and it will be exciting when the superpartners are discovered.

123. **alex**
September 25, 2007

Eric, I have a question to you since we're having this discussion. If you take split SUSY with scalar masses at about the GUT scale or slightly lower, is there enough RGE running to drive (m_hu)^2 negative? If not, how do they achieve EWSB?

Thanks!

124. **Eric**
September 25, 2007

Alex,
I'm not an expert on split SUSY, and where I come from we would not discuss such models in polite company, but here goes. My understanding is that they use the 'little Higgs' mechanism where strong dynamics at some high (few TeV) scale are employed a la technicolor for EWSB. Such models also give up solving the hierarchy problem, although they can apparently manage to maintain gauge coupling unification. In my humble opinion, split SUSY is very contrived and artificial which is the result of giving up a large amount of SUSY.

Of course you could always consider super split supersymmetry, which would have no way of explaining the top mass, EWSB, or the hierarchy problem, since this is just the normal standard model. Peter Woit would probably use this an example where a supersymmetric model doesn't predict a large top mass. 😉

125. **anghe**
September 25, 2007

Eric,

if we conducted a poll among the CDF and D0 collaborations that discovered the top and measured its mass for the first time, how many of them, do you think, would be convinced that the top quark mass was predicted by SUSY theorists before their discovery?

126. **Eric**
September 26, 2007

Anghe,
Most CDF and D0 colloboraters would agree that a large top mass was anticipated from radiative EWSB, and the fact that the top turned out to have such a large mass as one of the reasons for them to pay attention to SUSY.

127. **anon.**
September 26, 2007

Eric wrote:

My understanding is that they use the 'little Higgs' mechanism where strong dynamics at some high (few TeV) scale are employed a la technicolor for EWSB.

Your understanding is completely wrong. (Doesn't anyone ever look things up before talking about them on a blog?) If you want supersymmetric-looking unification with a split spectrum in a *natural* theory, you might try something like that. But split supersymmetry is just the MSSM with a split spectrum.

128. **Peter Woit**
September 26, 2007

Eric,

Have you checked this with "most CDF and DO collaborators"? Just a wild guess, but I would suspect that they might tell you that a "large" top mass was anticipated not because of SUSY, but because the top was not seen at "low" mass.

129. **Eric**
September 26, 2007

Anon,
I think it would depend on the amount of splitting in the spectrum. I'm sure there are split models where you can get EWSB and others where it isn't possible and you need something else. In any case, split SUSY is inherently unnatural since I can't think of any reason why some supersymmetric partners would have large GUT scale masses and others wouldn't. This only works if you believe in fine-tuning which leads you to anthropic reasoning.

Peter,
The several CDF and D0 collaborators that I know as well as those at CERN were well aware that a large top mass was anticipitated by SUSY. As has been pointed out to you now by several people, this is a very well known result. Using exactly the same idea it's pretty easy to calculate that the Higgs mass should be in the range 114-121 GeV using the current top mass of 170.9 +/- 1.8 GeV. All of the experimentalists know this.

130. **Chris Oakley**
September 26, 2007

> they might tell you that a "large" top mass was anticipated not because of SUSY, but because the top was not seen at "low" mass.

A fine piece of reasoning. This is the same kind of inexorable logic that explains why you don't find many termite nests near places where anteaters hang out.

Is There Intelligent Life On hep-th?

September 5, 2007
Categories: Uncategorized

There are yet more hep-th articles on the anthropic principle this week, following recent ones devoted to the implications for fundamental physics of the heights of giraffes and sizes of brontosaurus brains. The TASI summer school designed to train particle theory graduate students this year featured talks by Raphael Bousso expounding the anthropic landscape pseudo-science as a "solution" to the CC problem. His lecture notes are now available. In them he does refer to one problem that plagues this subject, that of how to identify the intelligent observers whose probability of existence everything depends on:

> The problem of characterizing observers, especially in vacua very different from ours, remains challenging.

Last night a new paper on this subject appeared on the arXiv, by Maor, Krauss and Starkman, making the point about anthropic arguments that:

> arguments of these sort (see for example) strongly rely on the assertion that we must be typical observers, an assertion without sound fundamental scientific basis at the current time.

The authors end with a conclusion about what you can learn from anthropic arguments:

> Finally, the correlations illuminated by anthropic reasoning imply that what we ultimately learn from anthropic arguments is that the existence of us and the existence of the observed value of Lambda do not contradict each other. That is nice, but hardly surprising.

In their acknowledgment section they thank Bousso for "lively discussions". He thanks lots of people in his acknowledgments section, but not them. I don't know about this question of intelligent life in other pocket universes, but the question of whether there's intelligent life on hep-th these days seems to still be open.

Comments

1. **Alfonso Martinez**
   September 5, 2007

   Even shorter, "correlation is not causation".

   If only David Hume could witness what sort of science we do nowadays! Not to speak of the use we give to the money provided by our funding agencies, of course.

2. **locrian**
   September 5, 2007

   Thanks for the quotes from the Maor paper. That last one was perfect.

   It's a shame they need quoting, though.

3. **SnarkFest**
   September 5, 2007

   When people who have demonstrated an attitude towards philosophical reflection ranging from dismissiveness to outright contempt have philosophical ideas of their own (whether or not they acknowledge them as such) the results can generally expected to be crap.

   This is just another case in point.

   (Of course this is not to say that crappy ideas, and execrable *formulations* of ideas, can't originate with professional as well as amateur philosophers.)

4. **Greg Egan**
   September 5, 2007

   Another good paper on this topic is "Are We Typical?" by Hartle and Srednicki:

   > Bayesian probability theory is used to analyze the oft-made assumption that humans are typical observers in the universe. Some theoretical calculations make the *selection fallacy* that we are randomly chosen from a class of objects by some physical process, despite the absence of any evidence for such a process, or any observational evidence favoring our typicality. It is possible to favor theories in which we are typical by appropriately choosing their prior probabilities, but such assumptions should be made explicit to avoid confusion.

5. **Jim Clarage (astonished biophysicist)**
   September 5, 2007

   I admit the quick skim of Bousso's lecture notes got my attention (section 7) where he reports that his developments have

   > changed the status of string theory: the theory has made contact with experiment

   But as I read more carefully I am shocked that reasoning such as,

   > Moreover, it is reasonable to suppose that regions without galaxies do not contain any observers.

survives unchecked in any university who's lectures (they are lecture notes afterall) are attended by other disciplines, e.g., biologists, psychologists, cognitive scientists. As I've posted here before, even most modern theologians would blush at such anthropocentric reasoning. It genuinely goes beyond anything Ptlolemy or any other pre-Copernican cosmologists might have guilty of about Man's central place in the universe and its laws.

6. **Ori**
   September 6, 2007

   So why wouldnt you send some intelligent paper instead of writing content-less postings on the blogosphere ?

If you are so smart you must have some good ideas (with equations and not just words)

7. **chris**
September 6, 2007

because he is woit the destroyer, not woit the constructor.

oh, you still need formulas these days to go on hep-th :-)? a yes, the giraffe's height is related to plancks constant by more than words i forgot.

i wonder, if one could formulate a meta-antropic principle:
given any kind of universe, if an inteligent observer evolves (s)he will always develop a theory of why the universe has to be such as to support this particular form of intelligent observer.

8. **dragon**
September 6, 2007

What I also find startling about Bousso's lecture notes is the style, the way he heaps scorn on people who are stupid enough to disagree with him. I'm told that this is indeed his personal manner, but to see it coming out in "lecture notes" is a bit of an unpleasant surprise.

9. **D R Lunsford**
September 6, 2007

You know, there is a symmetry that may have been overlooked – the giraffe can face any direction and still maintain his height. So there should be a gauge theory of giraffe perambulation. No lion'!

10. **Shantanu**
September 6, 2007

Peter, forget about all this. Did you find anything interesting from
the Lepton-photon symposium(slides now online). also what do you think
about the "Beyond Einstein" decision, now that it is out.
Thanks

11. **Peter Woit**
September 6, 2007

Shantanu,

As far as I can tell, there was nothing really exciting announced at lepton-photon, just lots of solid progress. Rumors of hints of a Higgs didn't pan out…

As for "Beyond Einstein", I just don't know enough to have an informed opinion.

12. **Jack**
September 7, 2007

Nowadays these physicists have gone to a different field (philosophy). Physics concerns, in fact, what is measurable.

It is also clear that this kind of philosophy has no more scientific foundations that the hypothesis that there is a God, who has built the Universe and all that exists.

13. **oxo**
September 8, 2007

If these guys are correct, then LQG has been measured..

http://www.arxiv.org/abs/0708.2889

14. **gravitonto**
September 8, 2007

> http://www.arxiv.org/abs/0708.2889

I think naive dimensional analysis and order-of-magnitude guesstimates are not the most solid possible basis for such a revolutionary claim as the authors make. But, what the heck, J. Ellis is the second most cited author in HEP, so I guess it must be true: quantum gravity has finally been experimentally discovered. hoooo-rrrraaaaayyyy!!!

15. **woit**
September 8, 2007

oxo and gravitonto,

You folks are in the wrong posting, this was discussed a while back, see

http://www.math.columbia.edu/~woit/wordpress/?p=591

16. **gravitonto**
September 8, 2007

Sorry about that. I guess I should have known that preprint couldn't possibly have gone unnoticed and undiscussed here…

Updates on Plagiarism Scandal, Journal of K-theory

September 5, 2007
Categories: Uncategorized

Plagiarism Scandal

Today's Nature has an article by Geoff Brumfiel with more details on the plagiarism scandal described here. At last count it involves 15 authors, 67 papers on the arXiv, of which about 35 were refereed and published, in 18 different journals. The arXiv has set up a special page with information about this. As far as I can tell from checking a few examples, most of the published papers are still available online at the journals, with no indication of their plagiarized nature. One exception is the plagiarized paper at JHEP, which has now been removed, with the notation

> This paper has been removed because of plagiarism. We regret that the paper was published.

As far as I know, neither JHEP nor any of the journals has given any indication of an intent to change their refereeing procedures because of this scandal.

Journal of K-theory

The editors of the new Journal of K-theory have issued a public statement, explaining in detail their plans for how to handle papers submitted to the older journal, K-theory, where they had resigned as editors.

Comments

1. **Thomas Love**
   September 5, 2007

   It does make me wonder about the quality of the refereeing.

2. **Jon Lester**
   September 6, 2007

   The way the review process is applied in physics is a scandal.

   Jon

3. **chris**
   September 6, 2007

   Then do you have any suggestions on how to improve it? remember: referees are not payed, they take time off from pursuing their own work and, this is the most important point i never see properly expressed, they are there to check the scientific soundness and impact of the work. they are not there to check spelling, grammar, fraud or plagiarism. when i get a paper to referee, i assume that the authors were honest. if i don't, i wouldn't even know where to start. should i redo the whole work or what to see if it is reproducible? sure, the key argumentation and drawing of conclusions are tractable, but if someone says, this and that is the outcome of a particular experimental setup or a one year calculation on a supercomputer reveals this number as a result – how can you as a referee challenge that? you have to rely on the honesty the authors.

   it is similar with respect to plagiarism. ideally, of course, you should know all the literature in the field of the paper that you are refereeing. but honestly, there are certain topics that are pursued by only one group of people worldwide and unless you want them to self-referee, someone a bit outside has to be chosen. you can't seriously expect them to dig thru all the literature in search of plagiarism. this is not what referees are supposed to do!

   and on a final note: why the revelation of plagiarism such a scandal for the refereeing system? it just shows, that basically it works. the culprits have been identified and you can be quite sure that their career is over. and given the fact that in order to be of any relevance, a paper has first to be noticed, it just absolutely floors me how these people think they could ever get away with it and have some advantage from plagiarizing. as soon as the work really becomes known, the plagiarization is soon uncovered.
   the same by the way is true for fraud. remember the guy claiming to have produced element 117 (or was it 118?)? he stated an experimentally falsifiable wrong statement. just by common sense there are only 2 future prospects for such a statement: either nobody cares in which case you have to ask yourself what the motivation was for cooking up the fraud in the first place. or people are interested and will inevitably uncover the fraud.

   so i would say that what we witness here is good proof that science is healthy and has self-correcting mechanisms that work.

4. **prague_phys**
   September 6, 2007

   Look at the webpage of ALİ HAVARE,

   http://www.mersin.edu.tr/apbs.php?id=335

   one of the persons involved. Most of his (former) students, such as Yetkin, Aydogdu, Salti and Korunur were involved as well. Wonder who was the head of the gang.

5. **Elisha Feger**
   September 6, 2007

   The K-Theory journal situation still makes my head hurt, no matter how much I read up on it.

6. **matt**
   September 6, 2007

   Elisha, can you check the reference number 25, page 343 in K-theory Volume 36 (2005) in the printed version (not online version)
   to get an example of the `seriousness' with which Springer has been treating the manuscripts of K-theory!!

7. **Peter Woit**
   September 6, 2007

chris,

I don't see how this is evidence of a healthy system at work. If the authors had bothered to change the wording and notation when they plaigiarized, no one would be the wiser.

One of the main roles of the referee is to determine whether the result claimed in a paper is not just correct, but original. If a referee knows nothing about whether the main result claimed in a paper is something that has been done before, and they don't want to take the time to look into this, they shouldn't be refereeing the paper. What this scandal shows is that getting unoriginal (and uninteresting) work published in most theoretical physics journals is almost trivially easy. One reason for this is that the results are of such little interest that no one other than the referee is likely to actually read the paper and notice that it isn't original.

The journals should either find a way to do the kind of peer review that they are claiming to do (and charging lots of money for), or admit that it just can't be done any more and give up. In the meantime, it might be a good idea to deal with the current situation by putting warning labels on these journals saying something like "the editors haven't been able to determine if these papers contain original research or not".

8. **chris**
September 6, 2007

hi peter,

actually i agree with you. and for all practical purposes, these warning labels are already there i would say. because from personal experience i conclude that what counts (in a positive sense) is the recognition of a paper and not journal reference (on the negative, having a preprint without journal reference is a very big warning sign). i think there is consensus that a lot of published work is not worth the paper it was printed on. but i think there is equal consensus, that it is more worthwhile to push ones own research than debuking others unless they make very strong claims or do something that affects you personally.

i am not saying that this state of affairs is ideal. but i see it as the prize to pay for the ease of information exchange. what it ultimately boils down to is that in order to judge a papers merits you actually have to read and understand it yourself.

so in all honesty, classical journals in my opinion are outdated already. they do have some merit, but the speed of todays research just makes a close to 100% identification rate of 'good' papers illusionary. the problem in my opinion comes in when what they do publish is taken as gospel. when selection committees count the number of papers rather than reading the 3 topcited ones. but i see this as a problem on the recipient side. a judgment based on metadata of a persons publication record is just not foolproof. today probably less than decades ago.

for plagiarism specifically i can only repeat my claim, that the only way it can stay undiscovered is when nobody cares about the research and nobody has suffered negative consequences. it is kind of sad that people exist who wish to populate this corner. but i doubt that much more resources of serious scientists should be spent to explicitly search for them in cases where their plagiarism has next to no effect.

but to be constructive, let me ask what you think journals or referees should do?
since refereeing can only be sensibly done by active researchers, this implies that more thorough refereeing will leave less time for research.

9. **Jon Lester**
September 6, 2007

Peter,

What makes me feel sad about the peer review system in physics is that good ideas may fail to go through while rubbish, just because is well recognized fashion, can easily get published on the most important journals. What is worst are the reasons for rejecting a paper that are generally unsound, but now, besides the reviewers, publishers tend to hide also the editors. No person takes on responsibility for the large number of errors the system is badly doing in this historical period.

A paper of mine was rejected by a DAE of PRL because "His work has had no response by the community. I do not understand what he is doing". Other "reasons" like these can be found as I have a large file of published papers and a lot of unpublished ones and it would be really fun to get the reports of such reviewers known, after so long time, to see how badly they turn out to be wrong. I think there is a lot of people out there in similar situations but we are all silent because we fear to have our other papers no more published.

I worked in almost all field of physics but the absolutely worst situation is in particle physics. A referee claimed that "QCD lattice computations do not reflect reality" to reject a paper of mine. So, there is a lot of people out there wasting time, money and resources!

There is again a lot to say. For the moment I stop here. But I would like to discuss what could make a paper publishable and what should mean "important", a criteria largely questionable and deemed to the taste of the single person. In this way is truly easy to suggest rejection on questionable personal feelings.

Jon

10. **chris**
September 6, 2007

hi jon,

did you try to submit said paper to another journal than prl and did it make it?

honestly, i think that every paper which is not totally meritless will certainly find a journal these days.
and even if that should happen, if the paper reaches 50 or 100 citations it doesn't matter that much anymore. people will get curious as of why it didn't make it. and if it doesn't recach that, well, chances are nobody would have cared anyways.

11. **hard gluon**
September 6, 2007

> when i get a paper to referee, i assume that the authors were honest. if i don't, i wouldn't even know where to start.

Then you shouldn't referee. If you don't know the field well enough to know whether a result is original or not, accepting to referee is dishonest on your part.

12. **Jon Lester**
September 6, 2007

Hi chris,

Yes, I did it and I get it accepted in a few days by the editor. I think (my personal judgement) that the paper does worth that.

Jon

13. **Eugene Stefanovich**
September 6, 2007

hard gluon said:

"Then you shouldn't referee. If you don't know the field well enough to know whether a result is original or not, accepting to referee is dishonest on your part."

I think your judgment is too harsh. In our age of narrow specialization, there could be only 2 or 3 people in the world (including the author) who know exactly the background of each particular manuscript. Often these people are either collaborators or rivals, in which cases it doesn't make sense to ask them to review the paper.

For the rest of us it could be almost impossible to read all the references in the reviewed work, to repeat all calculations, or redo the experiment. So, it is impractical to ask the referee to give a 100% "seal of approval". If that would be possible and only "correct" papers appeared in print, then scientific journals would be 100 times thinner than they are now.

This is not only unrealistic, but also dangerous, because increasing the barrier for publication may prevent novel non-mainstream ideas from being published. My attitude is that "s**t happens", and that one or two plagiarized papers will not have any effect, except for the embarrassement to their authors. There are things much more dangerous for the health of science. String theory and anthropic groupthinks are high in this list. We should be thankful to Peter for keeping focus on these areas.

Eugene.

14. **hard gluon**
September 6, 2007

> I think your judgment is too harsh.

Maybe it is, hence my nickname :). Besides, nobody is infallible and plagiarism may be hard to detect. Yet, take for example the paper "Brane-world black holes and energy-momentum vector". I'm sure there are many people out there who are involved sufficiently in the field of black holes in brane worlds to realize whether that paper is lifting its results from some other recent papers. After all, twenty years back nobody was studying brane worlds.

> to repeat all calculations, or redo the experiment.

That is obviously something a referee should never do. If there are obvious (to an expert) mistakes, those should be pointed out. But if the results reported in a paper look consistent and plausible enough to an expert eye, no further checking should be necessary. It's the author's business, I think, to take care that their results are correct. It is their professional reputations that is at stake.

Having said this, I must say that once a referee found a factor 1/2 wrong in a complicated equation for a cross section in a manuscript I submitted. He/she thought it was a typo. Well, it wasn't, it was a calculational mistake, and to this very date I have no idea how that referee caught it… This happened some time ago, I'm not sure that kind of quality refereeing happens very often these days.

September 6, 2007

Hi Peter,
I happen to be from turkey originally so I know the environment there quite well. These folks in question hardly know any english at all. If you asked them to give a 10 minute presentation in english about anything, they wouldn't be able to. The system gives promotion based on bean counting in turkey these days so the strategy is "publish as many as you can" without any regard to quality. That is why most of the papers in question are published in obscure journals. Nobody cares where you publish. Turkey as a country is yet to publish one single paper in science or nature.

16. **Ian**
September 6, 2007

when i get a paper to referee, i assume that the authors were honest. if i don't, i wouldn't even know where to start. should i redo the whole work or what to see if it is reproducible?

One thing I've started doing with every paper I review is pick a handful of phrases, from the intro, the discussion, the results, and just run them through Google. It takes less than five minutes but has at least a chance of picking up plagiarism. (So far, thank God, I haven't found any, and I hate to think of what I'd have to do if I did.)

You're right, you can't repeat experiments. If you're lucky, you have experience with a close-enough system to notice if something is plausible or not. You can also take a few minutes to mentally work through a protocol; there's a well-known instance where a reviewer caught a case of fraud because he realized the experiment as described would have taken thousands of tissue-culture flasks.

Editors are supposedly looking at figures more closely nowadays, including using some automated techniques that will pick up simple fakes. (I'm in biology, and I don't know if other fields have similar approaches.) I do look with a skeptical eye at figures, but I'm not sure that I'd pick up any but the crudest forgeries.

17. **Highly Cited Researcher**
September 7, 2007

Ali,

It's the same all over the Mediterranean (Spain, Italy, Greece, etc.). Promotion depends on the count of papers weighted by impact factor. The more self-citations the better. Governments and universities looking for `objective' criteria for evaluation impose such requirements. The commercial journals depend on this to survive; the journal is outrageously expensive, but can count on a large number of mediocre scientists looking for `impact' to submit their articles. That the publisher produces three journals in the same area is no surprise either; the author and his friends rotate journals, citing each other into the university administration. Once there they see to it that more `objective' criteria for promotion are imposed, favoring ambitious mediocrities like themselves, because such people are incapable of challenging them scientifically, and are easily made dependent.

18. **chris**
September 7, 2007

hi ian,

"One thing I've started doing with every paper I review is pick a handful of phrases, from the intro, the discussion, the results, and just run them through Google."

that actually is a really good suggestion!

19. **prague_phys**
September 7, 2007

Highly Cited Researcher, we have similar system here in eastern Europe. My opinion is that if bureaucrats wants numbers, then total number of citations and determination in which decile the author is in terms of citations in his subfield would be much much better than what we have, though still far from ideal.

20. **la dernier fois**
September 7, 2007

Just like that googling idea, isn't it natural to suggest a similar service from the arxiv? A referee would get a candidate-to-be-paper, run a quick search there (arxiv), if too many similarities come up, well… then she/he's done already!

but, wait… there's really nothing similar already?

because, if there isn't, well… I guess plagiarism is just being asked for…right?

21. **ali**
September 7, 2007

Highly cited researcher,
I am aware of it. It would be more appropriate if people paid attention to the journal the article was published as well. For instance, in china, government pays 1000 dollars per impact factor of the journal the article was published. If you publish one article in science, you receive 30K from the government so there is an incentive to publish in high reputation journals. In countries like greece and turkey, there is no such thing. People can barely speak english, let alone write articles about black holes.

22. **Anonymous Referee**
September 7, 2007

Coincidentally, I was just asked to referee a paper (not found on the arXiv) by different Turkish authors (although from one of the institutions involved), which was also plagurized. However, in this case, the stealing was obvious merely from following up on the paper's references. It looked like the authors had no idea they were doing anything wrong! I'm not sure what to make of this, except that all this plagurizing must be emblematic of a serious misapprehension of scientific ethics in some corners of the Turkish physics community.

23. **Ingwer Angström**
September 7, 2007

Ali i take it that you have some idea about the status of the status of the physics community in turkey but please don't extrapolate it to greece. There are many good greek researchers and people actually do speek english. On the other hand it's true that the greek (i guess the turkish too) goverment prefers to buy weapons (20000 million € in the next 10 years) than to seriously invest in research. That's sad but it will not change soon.

24. **Anon.**
September 8, 2007

"For instance, in china, government pays 1000 dollars per impact factor of the journal the article was published. "

Is this true?! Does anybody know?

25. **Paul**
September 23, 2007

I agree totally with you about Berlinski. His 'tour of the calculus' might be the worst book I've ever read. One more reason for me to buy yours…

26. **Ilja**
September 30, 2007

Peter Woit Says "What this scandal shows is that getting unoriginal (and uninteresting) work published in most theoretical physics journals is almost trivially easy. One reason for this is that the results are of such little interest that no one other than the referee is likely to actually read the paper and notice that it isn't original."

What do you expect in a world of "publish or perish"? If people are forced to publish, they will publish. Even if they don't have anything interesting to say.

27. **JDR**
October 1, 2007

Trust me, it's not just physics that publishes rubbish. It's a huge problem that needs to be solved. As Ilja implied, publish or perish needs to be changed and it needs to be changed by us. If you don't have anything worthwhile to say, don't say it. If we all exercise restraint and only publish what is really worth something (and we all know when that happens, and it doesn't happen that often) we can start to change things.

Yes, it may mean not landing the coveted "position", and it may mean teaching in community college or non-tenure positions. But isn't it worth the price to be able to say " I may have only published X number of papers, but they really meant something". I can't help but feel this is a personal responsibility issue (as most are).

Book Reviews

September 7, 2007
Categories: Book Reviews

Note: For a Romanian translation of this post, see here.

Felix Berezin

Misha Shifman has edited a wonderful book about the mathematician Felix Berezin, which recently appeared with the title Felix Berezin: Life and Death of the Mastermind of Supermathematics. Berezin was a Soviet mathematician largely responsible for many new ideas about “supermathematics”, working out the analog for anticommuting variables of many standard concepts in analysis. Path integrals for fermions crucially use an analog of the standard integral that is now known as the Berezin integral.

Berezin began his mathematical career working with Gelfand on representation theory. While Gelfand thought very highly of him, at some point the two of them had a falling out, which is alluded to without any details in several of the contributions to this book. Since Berezin’s mother was Jewish, his professional life was often difficult due to the anti-semitism that was prevalent in the Soviet mathematical establishment. Between this and being on the outs with Gelfand, he had continual problems with things like getting his papers published, as well as being able to travel or effectively communicate with people in the West.

Tragically, Berezin died at the age of 49, under somewhat unclear circumstances on a trip to Siberia he took with a geological team. The largest segment of the book is a wonderful and touching piece by Elena Karpel, who lived with him for many years (they had a daughter together, Natasha). Karpel describes their life together in detail, as well as the circumstances following his death. It is a moving portrayal of a complex relationship of two highly intelligent and cultured people, with one of them, Berezin, extremely seriously devoted to his work, one cause of stress in his relations with Karpel. Together with contributions from his colleagues, the book gives a fascinating portrayal of the mathematical culture that Berezin was an important part of.

With his interest in quantum mechanics, quantum field theory, path integrals, and anticommuting variables, Berezin helped to transform the field of mathematical physics into something much more modern. His book written during the sixties, *The Method of Second Quantization* remains one of the classics of quantum field theory. I remember being especially impressed by his paper with Marinov *Particle spin dynamics as the Grassmann variant of classical mechanics*, which gives an amazing interpretation of the physics of a spin-1/2 particle by invoking anti-commuting variables in a very simple way. The book contains a summary of some of Berezin’s scientific work by Andrei Losev, and this article is available on-line.

The Mathematician’s Brain

Princeton University Press seems to be trying to corner the market on popular books about mathematics, bringing out in quick succession a novel about mathematics (A Certain Ambiguity), a book about The Pythagorean Theorem, and two books trying to explain what it is that mathematicians do: How Mathematicians Think by William Byers, and The Mathematician’s Brain by mathematical physicist David Ruelle. The Ruelle book is the only one of the four that I’ve had a chance to read.

The New York Sun recently published a review of *The Mathematician’s Brain* by David Berlinski. It’s one of the great mysteries of the popular science book business why anybody publishes the writings of Berlinski. His recent claim to fame is as an affiliate of the Discovery Institute, critic of Darwinism and proponent of Intelligent design, but he has also authored various popular books, including some on mathematics. Some web-sites claim that he has a Ph.D. in mathematics from Princeton, but it appears that the truth of the matter is that he was in the philosophy department there, writing a doctoral thesis on Wittgenstein. His writings on math and science that I’ve seen over the years have always struck me as singularly incoherent and confused.

Berlinski actually doesn’t do that bad a job with the Ruelle review, picking up on one of the things that might interest mathematicians and physicists about the book, the part about Alexandre Grothendieck (I confess to skimming some of the material explaining what mathematicians do, since I spend far too much of my life watching them do it). Ruelle has some interesting stories to tell about Grothendieck and the IHES, where they both worked for many years. The IHES was founded in the late 1950s by Leon Motchane, who had studied mathematics before going into business. Ruelle describes well the IHES during the 1960s, including the various conflicts which existed between Motchane and the IHES members, one of which ended up leading to Grothendieck’s resignation.

Ruelle also has quite a lot to say about the structure of power in mathematics, and how the desire for recognition and honors motivates people. His portrayal of mathematicians is a very well-rounded one, examining not just how they do mathematics, but how they live their lives, noting that:

> But one should not forget that, besides beautiful mathematical ideas, there are many more obscure things that crawl in the mind of a mathematician.

Many of the footnotes in the back are well worth reading, such as one that tells us:

> As my wife puts it, there are fewer bastards and fewer frauds among mathematicians than in the general population, but maybe also fewer amusing people!

Ruelle also tells a favorite anecdote I’ve heard from several mathematicians. The version I’ve heard is somewhat different than Ruelle’s, and goes:

> At the Institute for Advanced Study in Princeton, a visitor once came up to Armand Borel and asked him
>
> “Do you know about algebraic groups?”
>
> Borel answered that, yes, he did. The visitor then went on
>
> “Good. Can I ask a stupid question then?”
>
> to which Borel responded:
>
> “That’s two already.”

La Theorie des Cordes

A colleague brought me back from France a science fiction novel written by the Spanish writer Jose Carlos Somoza. In French the book is called *La Theorie des Cordes* (String Theory), but the Spanish and English versions have the title Zig Zag. The plot revolves around a discovery about string theory that allows physicists to look back into the past. It begins with some promise, describing the world of theoretical physics as seen from Spain, with references to Witten and other theorists. But it soon degenerates into a long tale revolving around a threatened attractive young female scientist. The string is somehow responsible for forcing her into sexual depravity and the prospect of nearly infinitely long and horrific bloody torture, with time suspended and no end in sight. OK, I guess maybe this does have to do with present-day particle theory, except for the sexual depravity part…

Reviews by Atiyah in the Notices

The October Notices of the AMS contains very interesting reviews by Michael Atiyah of two books about Bourbaki: Bourbaki: A Secret Society of Mathematicians by Maurice Mashaal, and The Artist and the Mathematician by Amir Aczel. Atiyah speaks from personal experience, knowing many of the members of Bourbaki and their work well, and having attended one of the Bourbaki gatherings where they hashed out the text of one of their books. He gives an excellent summary of the Bourbaki story and its place in recent mathematical history, finding the Mashaal book to be both highly readable and reliable on the facts and personalities involved. As for the Aczel book, he's much more dubious. Aczel tries to claim an important impact of Bourbaki on sociology and structuralism via Claude Levi-Strauss, but Atiyah is not convinced by this, and takes issue with what Aczel has to say about Grothendieck, someone Atiyah knew well. Atiyah's characterization of Grothendieck goes as follows:

> I greatly admired his mathematics, his prodigious energy and drive, and his generosity with ideas, which attracted a horde of disciples. But his main characteristic, both in his mathematics and in social life, was his uncompromising nature. This was, at the same time, the cause both of his success and of his downfall. No one but Grothendieck could have taken on algebraic geometry in the full generality he adopted and seen it through to success. It required courage, even daring, total selfconfidence and immense powers of concentration and hard work. Grothendieck was a phenomenon.
>
> But he had his weaknesses. He could navigate like no one else in the stratosphere, but he was not sure of his ground on earth—examples did not appeal to him and had to be supplied by his colleagues.

He ends with the following critical remarks

> Aczel's total endorsement of Grothendieck leads him to make such fatuous statements as: "Weil was a somewhat jealous person who clearly saw that Grothendieck was a far better mathematician than he was." Subtle balanced judgement is clearly not Aczel's forte, and it hardly encourages the reader to take seriously his confident and sweeping assertions in the social sciences.

Comments

1. **chimbote**
   September 7, 2007

   I share your appreciation for Berezin's book and his paper with Marinov. Those were among my first reading assignments when I started my phd.

2. **Jason Starr**
   September 7, 2007

   You might also mention another quote from Atiyah's article, which seems to be a pronouncement on EGA (among other things):

   "Where I part company with Aczel is in his assertion that Bourbaki made a fatal mistake in his not taking Grothendieck's advice and rewriting its foundations in the new language of category theory. Aczel believes that Bourbaki had turned its face away from the future in not following Grothendieck. I doubt whether history will come to this verdict. Grothendieck's own EGA, as well as the general fate of the over-confident universalists, might suggest otherwise."

3. **Thomas Love**
   September 7, 2007

   It is easy to check if someone has a PhD in math. I went to the mathematics geneology website:

   http://www.genealogy.ams.org/

   and checked out David Berlinski. He isn't listed. Neither are you Peter, because your PhD is in Physics. There are two Thomas Loves. How weird is that.

4. **Moeen**
   September 7, 2007

   Thomas,

   Keep in mind that while the Math Genealogy website is a good resource, it is not comprehensive since all of the information on their database is entered voluntarily by individuals. So not only is it likely not comprehensive, but may even be wrong in some cases.

5. **John Baez**
   September 8, 2007

   The anecdote about Armand Borel only makes sense if you know his specialty was algebraic groups. He's the author of the well-known book *Linear Algebraic Groups*.

6. **Arun**
   September 8, 2007

   The anecdote about Armand Borel only makes sense if you know his specialty was algebraic groups.

   One can deduce that from the anecdote and the fact that it is worth repeating.

7. **Peter Woit**
   September 8, 2007

   In my experience, the anecdote is invariant under the interchange of Armand Borel and Andre Weil, as well as substitution of various fields of mathematics. In Ruelle's version it is Weil, and his is the streamlined, one question version: "may I ask a stupid question?" "You just did"

   Jason,

   I also was struck by that comment of Atiyah's, but I guess it's not too surprising. I wouldn't have guessed that he'd be a big fan of EGA.

8. **Chris Oakley**
   September 8, 2007

   Reminds me of this, concerning Dirac:

   > One famous lecture he gave in Canada: at the very end of the lecture during questions one of the members of the audience stood up and said, 'I don't

understand the equation you have written on the top right-hand of the blackboard'. Dirac was silent. People were waiting. And then one of the chiefs in the front row said, 'Professor Dirac would you care to respond to the member of the audience'. And he said, 'Well that wasn't a question it was a comment'.

9. **Clark**
September 9, 2007

Subject to being deleted for being utterly off topic, some of you may not have noticed that in last summer's Clay Institute, there were 3 self-contained lectures by Manin from the ground to the frontier. As an aside there were some very funny moments such as when he admitted that he could never remember how the weights are specified in modular forms.

http://www.uni-math.gwdg.de/aufzeichnungen/SummerSchool/SummerSchool_20060809-1600_Manin/avi/SummerSchool_20060809-1600_Manin_xvid.avi
http://www.uni-math.gwdg.de/aufzeichnungen/SummerSchool/SummerSchool_20060810-1430_Manin/avi/SummerSchool_20060810-1430_Manin_xvid.avi
http://www.uni-math.gwdg.de/aufzeichnungen/SummerSchool/SummerSchool_20060811-1430_Manin/avi/SummerSchool_20060811-1430_Manin_xvid.avi

10. **gaspard**
September 9, 2007

About the Aczel book: the only connection I have heard of between mathematicians and Claude Levi-Strauss is that a PhD student of Levi-Strauss had to stop ethnological trips for health reasons and then turned to math. His name is André Avez, who among other things coauthored a book with V.I.Arnold on Ergodic Theory in the 1960s. Perhaps there have been interactions with Bourbaki too, but I don't know them.

11. **David Berlinski**
September 9, 2007

I have never claimed to have a Ph.D in mathematics from Princeton University. My Ph.D. from Princeton is in philosophy. This is what my resume says; it is how I am described at the DI website; and it is how I am described on the dust jacket of my books. If there is a website that claims otherwise, I revile and denounce it. As long as I am correcting misapprehensions, I might add that I am a critic of intelligent design and not one of its supporters. In this regard, you might consider my essay "Has Darwin met his Match," in the December 2002 issue of Commentary. It is devoted perceptively to attacking Johnson, Behe and Dembski. I cannot say that my friends at the DI were pleased to see what I wrote, but they were made wiser by reading it. My feelings toward intelligent design remain what they have always been: Warm but skeptical. Nonetheless, I regard the general hysteria about these issues as intellectually disgusting. As for the question why so many editors are interested in publishing what I write, I suspect that this is because so many readers are interested in reading it.

12. **James Milne**
September 9, 2007

I was at IAS at the time of the "Borel" anecdote, and knew all the people involved. I believe my version is the most accurate.
http://www.jmilne.org/math/apocrypha.html

13. **Mike**
September 9, 2007

David Berlinski,

Thanks for answering the question, I am one of your readers, and find your "humor" interesting. You might have noticed a pattern of, as Dan says, " baseless ad hominem" !

14. **Peter Woit**
September 9, 2007

David Berlinski,

One of your most prominent on-line biographies

http://www.anova.org/bio/berlinski.html

starts off

"Berlinski (Ph.D. in mathematics, Princeton University) is a lecturer and essayist."

Another

http://www.researchintelligentdesign.org/wiki/David_Berlinski

starts off

"David Berlinski (born in 1942 in New York City) is a mathematician. He is the author of works on systems analysis, differential topology, theoretical biology, analytic philosophy and the philosophy of mathematics.."

and yet a third

http://www.coldwatermedia.com/berlinskireviews.shtml

claims that you were a "Fellow of the Faculty in Mathematics" here at Columbia. I don't know what this refers to since presumably it was long before my time (I've been here about 20 years).

You've done an excellent job of convincing people you're a professional mathematician, including PZ Myers who writes:

"This is a guy who is a competent mathematician with a degree from Princeton"

I'll stand corrected about your views on "Intelligent Design", but direct people to the same post by Myers for a discussion of your views on the theory of evolution:

http://pharyngula.org/index/weblog/comments/berlinski_i_cant_believe_im_wasting_time_on_this_guy/

And, to anyone who would like an excuse to start arguing about evolution here, don't even think about it.

15. **Peter Woit**
September 9, 2007

Many thanks to James Milne for the source for the more accurate anecdote, as well as the link to the web page of other ones. Anyone who is not aware of his web-site

http://www.jmilne.org/math/index.html

and the fabulous array of high-level expository writings about mathematics there, should definitely take a look.

16. **Peter Woit**
September 9, 2007

Gaspard,

Andre Weil did contribute an appendix (entitled "Sur l'etude algebrique de certains types de lois do mariage") to Levi-Strauss's book "Les structures elementaires de la parente"

17. **David Berlinski**
September 9, 2007

Thanks for the links. Of the three you cite, the first is incorrect. I shall correct it, The second and third are correct:

Witness

On Systems Analysis: An Essay on the Limitations of Some Mathematical Methods in the Social, Political and Biological Sciences, The MIT Press, 1976.

The Rise of Differential Topology, LITP, Universite Paris, 7, 1980.

My essays about theoretical biology, catastrophe theory, model theory (with Daniel Gallin), epistemic logic, and philosophy are scattered in various journals. Just look around: You'll find them. If not, I'll be happy to send them to you.

I am now more than sixty five years old, and a great many things in my life took place before your time. I was a Fellow of the Faculty in the department of mathematics — courtesy entirely of Lipman Bers — in 1973. I did nothing of value and achieved no distinction. I have never suggested otherwise.

I have made no effort to convince anyone of anything. On the other hand, I have taught mathematics for many many years, both in the United States and in France, and I have written more than eight books about mathematics. I regard myself as a writer — nothing but, but if anyone asks, I know a lot about mathematics.

I am quite sure that P.Z. Myers disapproves of my views concerning Darwin's theory of evolution. I have been exhilarated by his criticisms.

18. **Peter Woit**
September 9, 2007

Thanks for the clarifications about your mathematics activities. I suppose I should know about why readers are interested in your books since at one point a copy of "Black Mischief" was on my bookshelves (can't seem to find it, maybe it didn't survive one or another move over the years). Good luck with the Darwin denialism business…

19. **Mike**
September 10, 2007

I can't believe you found that link, Peter, lol.

And David, very much looking forward to "The Devil's Delusion" !

20. **Patrick Orlando**
September 10, 2007

I disagree with Prof. Woit's comments on Dr. David Berlinski's popular math books. I have read them all and he is an excellent writer able to describe the heart of the mathematical ideas in plane language. His style is very readable and his made up converstions with historical figures are very good. I only have a B.S. in Physics from Columbia so I guess they are on my level.

21. **The man**
September 11, 2007

I take two issues with Atiyah's comments on Grothendieck. First, his comment "both of his success and his downfall" betrays a nasty petty streak in Atiyah. I doubt Grothendieck, or a lot of other people, see his path after IHES as "downfall". In fact, Grothendieck, very courageously, resigned and went his own way because of his ethics and morality. Sticking to what you feel is right is not called "downfall", as least not in the ass-kissing power-hungry circles I'm guessing Atiyah moves in (given how far up the non-academic ladder he's gone). This phrase pretty much betrays Atiyah's worldview. Similarly, I'm sure Atiyah would classify Grothendieck's turning down Crafoord (or Perelman's decision) as blunder etc, however not the way others would see it.

Second, his comment that Grothendieck didnt deal with examples is meaningless if it doesnt interfere with Grothendieck's ability to do good correct maths. So he should have given some examples where Grothendieck was led to publish incorrect math cause of it.

22. **Peter Woit**
September 11, 2007

The man,

Your attack on Atiyah is really uncalled for. From my personal experience with him and everything else I know about him, he's an extremely decent and responsible person. He has gotten where he is through his fantastic mathematical achievements (which are at the level of Grothendieck's), and his encouragement of other people's. You claim that you are "sure" he would be critical of Grothendieck and Perelman for turning down prizes says more about you than him. I've never heard any evidence that he was critical of them for this, and I doubt that that would be his attitude at all. His comments about Grothendieck's style of mathematics not being grounded in examples, and his uncompromising nature being part of the reason he stopped doing math at the level he was doing it during the 50s and 60s are not at all controversial, but rather widely-held opinions by mathematicians who know the subject and its history. His comments on Grothendieck seemed to me well-balanced, recognizing his amazing achievements while not engaging in hero-worship.

23. **The man**
September 11, 2007

Peter,

You missed my point. I agree that he was not doing mathematics at his earlier levels post ’70. What I’m disagreeing is whether it should be called his “downfall”. For example, if some mathematician stops doing mathematics to address political issues or protest nuclear armament etc., that’s his priority (which some would call a very nobel one). Calling it a “downfall” is 1. very demeaning to the person, and 2. betrays your own priorities. If Atiyah’s priorities are not with urgent political issues, there is no reason to demean others whose are.

24. **woit**
September 11, 2007

The man,

I don’t think that Atiyah was specifically calling the decision to stop doing math and do other things Grothendieck’s “downfall” or criticizing his priorities. He was referring explicitly to Grothendieck’s “uncompromising nature”. If you read accounts by friends and allies who were very sympathetic to his political activities, I think you’ll find that many of them feel that the way he went about such activities was unproductive or even counter-productive, exactly because of this “uncompromising nature”.

I found “Recoltes et Semailles” a fascinating document to read, but at the same time a sad one. Grothendieck’s “uncompromising” personality unfortunately evolved in later years to something that could be described as paranoid and delusional, and I think this is actually what Atiyah had in mind by referring to a “downfall”.

25. **Jonathan Vos Post**
September 11, 2007

From the second of the AMS Notices articles on Alexander Grothendieck.

One striking characteristic of Grothendieck’s mode of thinking is that it seemed to rely so little on examples. This can be seen in the legend of the so-called “Grothendieck prime”. In a mathematical conversation, someone suggested to Grothendieck that they should consider a particular prime number. “You mean an actual number?” Grothendieck asked. The other person replied, yes, an actual prime number. Grothendieck suggested, “All right,take 57.”

26. **shameless ass-kisser**
September 13, 2007

The man,

I think you at least partly misinterpret Atiyah’s use of `downfall’. I understood that Atiyah was speaking about Grothendieck’s mathematics as much as anything else – the next paragraph he speaks explicitly of Grothendieck’s `weaknesses’. I warrant Atiyah feels he is as good a mathematician as Grothendieck, and in a position to point out weaknesses as well as strengths of the man’s approach to mathematics; moreover, there is a tendency (cultlike?) to idealize the math and the man, and Atiyah may be gently (I think he speaks gently) suggesting that neither is healthy. He later refers obliquely to the failure of EGA; this can only be taken as a judgment by a very serious mathematician that EGA did not attain its own goals. Atiyah also calles Grothendieck a `phenomenon’ and refers to his courage and concentration. Nowhere in these paragraphs does he refer to Grothendieck’s lifestyle or politics, except to say that Grothendieck’s failures as a mathematican, and his failures as a man, were both rooted in what Atiyah calls an uncompromising nature. And we should remember that Grothendieck was, at least, a terrible father.

27. **Carl Brannen**
September 21, 2007

Woit:

I may not like your blog, but I loved your book and couldn’t put it down. I recommended it to my father who bought it quite some time ago, but it sat around on his shelf. He has a PhD in math. His comment in an email today:

Started on “not even wrong”. I like the perspective
it gives.

La Faillite de la Theorie des Cordes?

September 11, 2007
Categories: Uncategorized

It appears that the release of the French edition of Lee Smolin's book (entitled Rien ne va plus en physique ! : L'échec de la théorie des cordes) has stirred up quite a lot of attention to the string theory controversy over there. A correspondant wrote to tell me that this month's edition of the French popular science magazine La Recherche has the controversy over string theory on the cover (*La theorie des cordes dit-elle le vrai?*) and four articles on the subject inside. Unfortunately I don't have a copy of the magazine or on-line access to the articles, but just to an English language summary. It's hard to tell from this exactly what's in the articles. One of them is an interview with the historian of science Peter Galison, who seems to describe string theory as having "initiated a new way of seeing, crucial for the future of physics." No idea what that is about, but I hope it's not about the string theory landscape….

The string theorists of the Paris region have a web-page, which recently has acquired a defensive section about *La faillite de la theorie des cordes?* It encourages people to read Polchinski's review of my book and Smolin's (my response to this is here), as well as papers critical of LQG. The same web-page also has links to other information sources about string theory, including to two blogs. Personally I don't think Jacques Distler's blog is much of an advertisement for the subject, but sending people to Lubos Motl's is a pretty funny thing to do….

Comments

1. **Jean-Paul**
   September 11, 2007

   From Amazon.fr:

   Biographie de l'auteur
   Chercheur en physique à l'Institut Perimeter (Canada), Lee Smolin a été baptisé " nouvel Einstein ".

   So French will take it seriously. They take anything written by Americans very seriously.
   By the way, there are no serious superstring defenders in France, so it's a completely different battle ground than elsewhere.
   Unlike in Germany, students are able to escape to more interesting research areas.
   You will see talk-shows trashing strings etc — it will be really amusing…

2. **Bee**
   September 11, 2007

   Faites vos jeux, Ladies and Gentlemen, rien ne va plus.

3. **Coin**
   September 11, 2007

   It encourages people to read… papers critical of LQG

   Actually, I'd be curious what those are.

   What are the papers that critics of LQG would be likely to recommend on the subject? I lack the french skills to effectively tease this out from the link.

4. **Peter Woit**
   September 11, 2007

   Coin,

   To find the papers you just need to click on the links in the relevant paragraph. Don't worry, no danger that you'll hit a link that is not critical of LQG…

5. **SnarkFest**
   September 11, 2007

   Peter Galison was interviewed recently for the **Scientists' Nightstand** (*American Scientist*). His acknowledged influences and recent reading are somewhat revealing.

   More on Galison from Steve Hsu:

   > Both my friend and I are great admirers of Galison. After earning his doctorate in the history of science, he wrote a second dissertation in particle theory under Howard Georgi while a junior fellow at Harvard. Other than particle theorists turned science historians like Sam Schweber or Abraham Pais (see here and here), I can't think of anyone more qualified to work on the (underdeveloped) history of modern physics.

6. **Who**
   September 11, 2007

   in case anyone is unfamiliar with *la faillite* the website name translates to

   The Bankruptcy of String Theory?

   and this is a damage control website concerned with defending the self-respect and self-importance of the string theorizing community.

   this must be that the idea of string bankruptcy is already current in
   people's minds, so therefore the defenders wish to challenge
   this prevalent notion, so they put a question mark on it and call
   their site: String Bankruptcy?

   a kind of Enron case judging by this interesting French reaction.

7. **chris**

September 12, 2007

“Actually, I’d be curious what those are.

What are the papers that critics of LQG would be likely to recommend on the subject? I lack the french skills to effectively tease this out from the link.”

read this: hep-th/0501114

really fun and good to see on what kind of shaky assumptions LQG is built, too. my personal favorite: the ‘pulverization’ of space to obtain vanishing inproduct of graphs on different support.

8. **Lee Smolin**
September 12, 2007

The issues raised by those Nicolai et al were not new and were well understood already in the LQG world many years ago. They are the main reason many workers switched to formulating dynamics in a path integral formulation in the late 90s, and they do not apply to those formulations of dynamics. They also do not apply to the currently studied approaches to the hamiltonian formulation of dynamics such as the master constraint formulation. Thus, the criticisms of that paper ignore roughly the last ten years of work in the field.

There have been several responses to that paper, including arXiv:hep-th/0608210 and arXiv:0705.2222. This has also been discussed in previous blog entries, which I assume you can find by searching.

The vanishing of the inner product between states of different support is not an assumption and not shaky, by the uniqueness theorem proved in gr-qc/0504147 and math-ph/0407006 it is a necessary consequence of the requirement of having a diffeomorphism invariant measure on functionals of a connection.

Lee

9. **Christophe de Dinechin**
September 13, 2007

I subscribe to La Recherche, and have read this article. There is not much in there that you won’t know already. I would guess that this is mostly a news article related to the French translation of Lee Smolin’s book, which was recently published here.

The first part that is essentially an interview of Lee Smolin with a bit of historical background and context. The second part is an alternative viewpoint entitled “4 successes of strings”, these being: a quantum description of gravity, the possibility to unify all forces, better understanding of astrophysical phenomena, beginning of an answer on the nature of space-time. The third part lists various competing space-time theories, unfortunately omitting a pet favorite of mine (Nottale’s scale relativity), but referring to LQG, CDT and non-commutative geometry. Finally, part 4 is an interview with Peter Gallison on the criteria to judge a theory, where he essentially answers that a good theory is one we can apply, like Newton’s laws, even after we realize it’s wrong…

About “faillite”, while “Who” is right that this word in French may translate as “bankrupcy”, it may also translate as “failure”, and that’s how I personally read it in that particular context (as I suspect most other French natives would).

I have made a quick reference to that article in a recent post on [my own blog](), although this is not the main topic of the post. Peter, feel free to delete that last paragraph if you feel it’s off topic.

10. **Who**
September 13, 2007

That’s interesting Christophe,
how would you translate this phrase in the French title of Smolin’s book which Peter gave in the original post?
L’échec de la théorie des cordes

Does *faillite* convey a different flavor from *échec”?

11. **Peter Woit**
September 13, 2007

Who,

“Echec” is more like “defeat”, or incomplete defeat, as in “setback”. The word comes from chess (“check”, but not necessarily “mate”).

“Faillite” is well-translated as “failure” in this context (same root), but also specifically is used to mean bankruptcy (economic failure), so carries some of that connotation.

12. **Christophe de Dinechin**
September 13, 2007

Hi Who,

Peter seems to know French pretty well. I would add that “faillite” also conveys a sense of lost credibility, and in that sense, it may be a better translation of the original intent.

13. **Who**
September 14, 2007

Thanks both Peter and Christophe. I was interested in how you hear that.
Trying to understand the French context better I just checked amazon.fr and found Smolin’s book (which has a preface by Alain Connes) had salesrank 2021, while for comparison the two Brian Greene books in French translation had ranks 13,720 and 22,437. I could find no other string books with better sales than those two. So it appears that if a French reader picks up a book about string theory it is most apt to be the one by Smolin.

Peter mentioned the etymology of *faillite* so I glanced in the the Petit Larousse (the Webster’s analog, not a French-English dictionary) which gives the primary meaning as the commercial one, bankruptcy in other words. Larousse explained the etymology by saying the word came into French from the Italian FALLITO. This has the primary meaning of bankruptcy in Italian, same root as “default” I suppose. It also has the secondary figurative meaning of failure. Thought you might like to know the French word does not derive from the French verb faillir “to err, to miss, to fail etc”, but instead was brought over from Italian and was originally applied specifically to commercial collapse: bankruptcy.

I agree with Peter that *echec* has a much less drastic connotation. Setback is very good. To hold an enemy force in echec is to hold it “at bay” rather than destroy it. The word is more like “unsuccess” than failure or collapse.

So the book subtitle merely suggests that string has stalled and is not making progress, while the website name uses the actual word for bankruptcy, connoting collapse and, as Christophe suggests, loss of credibility.

It’s interesting how words sound to different people. Thanks again for “lending me your ears.”

14. **Peter Woit**
September 14, 2007

Who,

I don’t think it makes sense to compare sales figures for books that have come out recently with ones that have been out for a long time. I’m quite pleased with how well my book sold, and Lee’s sold even better, which is great. At least in the US though, I don’t think either of our books came anywhere near doing as well as Brian’s, and suspect the situation in France isn’t that different.

In any case, no matter what the sales figures, the two books have done remarkably well in terms of getting attention for the issues that both of us were trying to raise, and providing a counter-balance to the overly optimistic story about string theory that was dominant until recently.

15. **Who**
September 14, 2007

My goodness! I see that the French edition of your book is due to be released in a couple of weeks—-3 October 2007.
http://www.amazon.fr/M%C3%AAme-pas-fausse-th%C3%A9orie-question/dp/2100503936/r

MÊME PAS FAUSSE

and they arent even doing hardbound first, they are going right to the paperback edition for the, as it were, mass market. Market should be ripe.

Looks like old one-two punch. French Smolin comes out in April and French Woit in October.

Hope you take some earthly pleasure in this, Peter.

16. **T.**
September 15, 2007

About “Même pas fausse”, yet another frenchman’s opinion:

Unfortunately, I’m not sure “Not even wrong” can really be translated in french without conveying a childish meaning.

This is because in france “Not even true” is a phrase that is really only used in playgrounds. It’s a 100% clue that the person who said that is a child. So “Not Even Wrong” has a very strong childish argument flavor, and is less powerfull than in english.

But I hope I’m wrong and it will sell, cause the book is great.

17. **Who**
September 15, 2007

T. please give an example of a situation in which the phrase might be used.
Peter sorry if this is off topic, I’m curious to know how the phrase comes across in French.

18. **T.**
September 15, 2007

mm, well it would go something like:

Child 1: “You looser !”
Child 2: “Not even true ! You’re the looser !”

I insist that no adult would ever use “même pas vrai”, except if he deliberately wanted to look childish for some reason.
So “Même pas faux” is funny and smart, but still is associated to an argument taking place between children. (in my humble opinion)

19. **Christophe de Dinechin**
September 15, 2007

I agree with T. It’s also associated in my mind with another childish phrase, “même pas mal” (I’m not even hurt), which a three years old would typically say after falling from the cupboard where he was trying to steal forbidden sweets.

All in all, I find it’s a rather good title, but with a very different connotation from the original “Not even wrong”, even if it’s a litteral translation. Funny.

20. **Hendrik**
September 17, 2007

Another review of “The trouble with physics” just appeared on the ArXiv at:

http://xxx.lanl.gov/abs/0709.1728

21. **Coin**
September 17, 2007

Hm. Are book reviews on the ArXiv common?

Various and Sundry

It seems that if you're a Fields Medalist, you now have to have a blog. The latest of these is a new blog from Timothy Gowers. His blog will also function as a blog for the upcoming Princeton Companion to Mathematics that he is editing, and he has started a discussion about the possibility of a wiki devoted to "mathematical tricks".

Rigorous Trivialities is another new mathematics blog, one of the rare ones not being run by a Fields Medalist.

Mathematics will now have its own "rumor mill" to gather information about job searches, to be called the Mathematics Job Wiki. It appears to have been set up by Greg Kuperberg, "who however recuses himself from handling confidential e-mail and is not the wiki moderator". All we are told about the moderator is that "someone without a current tenure-track appointment will read e-mail sent to the Wiki Moderator."

Gerard 't Hooft has translated his lecture notes on Lie Groups and Physics from Dutch into English, increasing by about two orders of magnitude the number of people who can read them.

Math and physics geeks are now certifiably cool, as the TV show Numb3rs goes into yet another season, and is joined by The Big Bang Theory. New York magazine got together a group of Columbia physics grad students to take a look at the show and discuss.

The early history of string theory is getting lots of attention these days, especially because of a conference on the subject last May. Some related articles have now appeared on the arXiv, from Di Vecchia and Schwimmer, Ramond and Schwarz. At Caltech, an Oral Histories project has made available the transcript of a long interview with Schwarz.

Hendrik, a commenter here, pointed out that there's more of the latest string theory hype concerning results from the MAGIC telescope, originally discussed here. Now New Scientist has weighed in with an article entitled Finally, a MAGIC test for string theory? According to the article, Mavromatos and collaborators say that their (non-critical) string theory model "predicts the 4-minute delay exactly". Polchinski is quoted to the effect that this would falsify (critical) string theory. LQG is completely cut out of the deal, with no mention of it at all. They really need to do a better marketing job. The way things are now, any supposed evidence of quantum gravitational effects is automatically evidence for string theory, in one version or another.

For the latest attempt to market string theory to astrophysicists, see this new article on astro-ph. The abstract begins not by acknowledging that string theory can't make any predictions about cosmology, but by claiming instead that the problem is

> Attempts to connect string theory with astrophysical observation are hampered by a jargon barrier, where an intimidating profusion of orientifolds, Kahler potentials, etc. dissuades cosmologists from attempting to work out the astrophysical observables of specific string theory solutions from the recent literature.

Update: Slashdot has a thoroughly worthless article about this last paper, based on the New Scientist article about it.

   « 1
   This lecture course was originally set up by M. Veltman, and subsequently modified and extended
   by B. de Wit and G. 't Hooft.
   »

   The notes are not 't Hooft's lecture alone.

2. **Thomas Love**
   September 11, 2007

   The Princeton Companion to Mathematics articles are great. Thanks for the link.

3. **Hendrik**
   September 11, 2007

   Dear Peter, thanks for having a look at the NewScientist MAGIC-string article. NS seems to be giving a bit of limelight to strings at the moment;- there are two more recent string + cosmology items at:

   http://space.newscientist.com/article/mg19526204.000-heretical-cosmologist-does-away-with-the-big-bang-.html

   http://space.newscientist.com/article/dn12628-can-string-theory-accommodate-inflation.html

4. **Peter Shor**
   September 11, 2007

   Amusingly enough, in his book Smolin says that some of the first people to propose doubly special relativity were studying non-commutative geometry, which has been completely left out of the current race for credit (or blame?).

5. **Luboš Motl**
   September 12, 2007

   LQG is cut out not because their marketing is weak – e.g. Smolin's marketing would instantly allow him to work in the Amsterdam's Red Light District – but because the physicists who work on this "theory" are not serious scientists.

6. **gunpowder&noodles**
   September 12, 2007

   Well, Lubos, I would guess that it is *far* safer to patronize the girls in Amsterdam than to rely on the services of some *free-lance* harlot. If you see what I mean.

Anyway, I hope that PW is not insinuating that critical and non-critical strings are on the same plane. Clifford Johnson claims that they are, but Lubos set him straight on that one: non-critical strings, lke non-critical humans, are definitely inferior to the critical variety. So a falsification of critical strings would be a heavy blow to most string theorists.

7. **Johan Couder**
   September 12, 2007

   "Gerard 't Hooft has translated his lecture notes on Lie Groups and Physics from Dutch into English, increasing by about two orders of magnitude the number of people who can read them."

   Now, now, Oppenheimer learned Dutch in 6 weeks and even lectured in the language ! Not that difficult for a theoretical physicist.

8. **Peter Orland**
   September 12, 2007

   Oppenheimer was already fluent in German
   (he worked in Goettingen), and with six weeks
   and a good mind, it doesn't seem impossible
   to learn Dutch (the two written languages are
   rather similar). I wonder if this comment will
   anger any Dutchmen out there.

9. **chris**
   September 12, 2007

   "LQG is cut out not because their marketing is weak – e.g. Smolin's marketing would instantly allow him to work in the Amsterdam's Red Light District – but because the physicists who work on this "theory" are not serious scientists."

   says who? your infailable papal highness? this is the kind of quality contributions we need for constructive discussions. thank you.

10. **Warren**
    September 12, 2007

    Did you want to give a link to that astro-ph article in the last paragraph?

11. **Peter Woit**
    September 12, 2007

    Thanks Warren, link added.

    It's the same paper that got promoted in New Scientist, the second of the two links Hendrik gave. The point of the paper is just to show, for one special version of string theory and the simplest possible choice of a Calabi-Yau, that the moduli fields don't give you the kind of scalar potential you want for inflation.

12. **spring theorist**
    September 12, 2007

    hey lubos, it seems that this blog is the only game in town… 🙂

13. **D R Lunsford**
    September 12, 2007

    Thanks for the t'Hooft lectures. Those things are always fun to read. His presentation is startlingly clear.

    -drl

14. **Bee**
    September 12, 2007

    Reg. MAGIC, see also: [MAGIC's observation of gamma ray bursts]

15. **jkowalskiglikman**
    September 12, 2007

    Peter Shor was kind enough to mention the non-commutative side of DSR.

    However DSR based on non-commutative kappa-Minkowski space and kappa-Poincare algebra does not predict any sizable modification of GZK cutoff (and it seems that we have been right in that) and also no energy dependent speed of light (so that if the MAGIC result is confirmed we are out of business.) Thus there is no reason for us to take part in the race for credit in this case.

16. **Amitabha**
    September 12, 2007

    It's a sad year for strings if Warren Siegel doesn't write a parody even after the end of the Strings conference.

17. **Who**
    September 12, 2007

    The only QG approach I think likely to gain credence if the MAGIC result is confirmed is Martin Reuter's QEG, with its surprise finding that gravity is renormalizable. Dispersion can arise from the running of the action at high photon energies, and the corresponding running of the metric. This paper, for instance, only considers dispersion of massive particles, not photons, but can nevertheless give some idea
    http://arxiv.org/abs/gr-qc/0607030
    Modified Dispersion Relations from the Renormalization Group of Gravity
    F. Girelli, S. Liberati, R. Percacci, C. Rahmede (SISSA and INFN)

(In reply to Bee's post with link to MAGIC discussion at her blog, and also to Jerzy Kowalski-Glikman's comment that confirmation of MAGIC result would put DSR out of business. It certainly **might** be confirmed and there ought to be at least one approach that would prosper from this. :D)

18. **Hendrik**
September 18, 2007

On "The Edge" at:

http://www.edge.org/3rd_culture/einstein07/einstein07_index.html

there is a debate between Brian Greene, Walter Isaacson and Paul Steinhardt where the loose subject is Einstein's scientific values. However, after the first third of the debate, the main topic very much becomes string theory, with some pretty sharp criticisms aired against string theory (mostly known to the readers of this blog). I'm not sure that those points are satisfactorily answered, but at least Brian Greene does admit there are problems.

19. **Peter Woit**
September 18, 2007

Thanks for pointing that out Hendrik, I suppose I should write a short posting about it…

20. **Hendrik**
September 20, 2007

Thanks Peter, I enjoyed your review. It seems to be hard to keep the monster of the Anthropic "principle" under control;- at the moment Steven Weinberg is embracing it at NewScientist at: http://www.newscientist.com/blog/space/2007/09/is-there-human-link-to-dark-energy.html#nbicomments

21. **Aaron Bergman**
September 20, 2007

Embracing it? He started it.

22. **LDM**
September 29, 2007

"*Now, now, Oppenheimer learned Dutch in 6 weeks and even lectured in the language ! Not that difficult for a theoretical physicist*"

…you may wish to know that Oppenheimer, upon learning that two of his friends were reading Dante in the original, also spent a month to learn enough Italian to read Dante outloud to them.
Dirac was unimpressed, and told him he was wasting his time. Indeed, Dirac one time refused a couple of books that Oppenheimer offered him since "reading books interfered with thought".

The one language, other than English, that would be essential for a physicist to learn is German, since there are so many great physics papers, in German, that have not been translated to English.
As example, Sommerfeld's ingenious treatment of the diffraction problem, solved exactly using images on a Riemann surface, in his 1894 paper, was *just* recently translated into English in 2004.

Einstein's collected papers became available in 1987 in English (prior to that you could get Einstein's works in Russian, however 😉)

Physics World on String Theory

September 13, 2007
Categories: Uncategorized

Despite my abusive treatment of his article Stringscape here recently, Matthew Chalmers was kind enough to send me a copy of the September issue of Physics World, which contains three shorter pieces about string theory (available on-line only to subscribers).

One of the articles is by Fred Goldhaber and entitled *Scientific faith put to the test*. It's a scathing attack on the anthropic string theory landscape program, describing it as "antiscience" (rather than my favorite, "pseudo-science"). Goldhaber characterizes this sort of research as "antiscience of the left", with its adherents promoting the idea that we can't ever understand some things since they are due to chance. He contrasts this to the "antiscience of the right", which promotes the idea that we can't understand things because they come from supernatural origin, and finds both attitudes equally unscientific. As for where antiscience comes from, he has this to say:

> On the left, I think that it stems from arrogance ("If *I* can't figure it out, no-one ever will"). On the right, I think it comes from defensiveness ("If science is right, religion must be wrong, and that can't be"). In the end, antiscience on both side boils down to vanity. While we need to stay alert for the vanity of those advocating antiscience, we also should guard against vanity in the name of science.

He ends on a more optimistic note, writing that he does see a difference in those on the "left". They remain physicists, and if someone finds a "promising route to picking out the right solution to string theory", they would leap to pursue it. He doesn't speculate on what they would do if someone shows that string theory just inherently can't ever predict anything…

Philosopher of science Steven Weinstein has a piece with the title *Philosophy pulls strings*, which tries to make the case that string theory is leading to some new interaction between physics and philosophy, since it "forces us to tackle issues that cross both disciplines." As far as one of his topics goes, the anthropic pseudo-science, the main role I see for philosophers is to forcefully point out to the scientists involved that they are doing something intellectually highly disreputable and should stop. He also discusses a much more non-trivial and interesting topic, that of the philosphical questions about space and time raised by quantum gravity, a subject where philosophers may or may not end up having something quite useful to contribute.

Philosphers Nancy Cartwright and Roman Frigg contribute a very interesting article about how scientific theories are evaluated, entitled *String theory under scrutiny* . The make the important point that immediate experimental testability of a theory is not all there is to deciding whether something is science or not. When scientific ideas are new, they often are not understood well enough to be able to extract definitive predictions from them. Theorists are generally engaged in research programs, the end result of which is supposed to be something experimentally testable. In order to evaluate a research program, you can't just note that it isn't predicting anything, you have to evaluate its prospects for reaching its stated goals. They describe good research programs as "progressive":

> Good research programmes are those that are progressive, i.e. those whose theories get better and better, even if individual theories face serious difficulties at certain times.

The fundamental problem with string theory is that, as far as its central goal of unifying physics goes, over the last nearly 25 years it has not only not made any progress toward explaining anything about particle physics, but, quite the opposite. Everything that has been learned about string theory makes it more and more clear that the original hopes for getting unification this way were just misguided and can't work. The derivative here is the wrong sign.

There are areas in which string theory has had successes, notably in mathematics and in strongly-coupled gauge theories. But these are really different research programs, and the fact that progress has been made in them doesn't change the facts about the colossal failure of the unification program. Cartwright and Frigg try and put various other "dimensions" on the string theory research program, including that of "elegance and simplicity", writing that:

> Radical string critics would then conclude that string theory is progressive only in the dimensions of elegance and simplicity (in the sense that the theory only contains one class of basic objects – strings – from which all the basic particles and forces follow), while being largely stagnant in the other dimensions.

As a "radical string critic", I don't see things this way. According to M-theory, "string theory" is not a theory of "one class of basic objects". Strings are just part of a hugely complicated picture, one which at the moment is neither elegant nor simple. String theorists hope that there is some elegant and simple underlying theory, but they have not been able to come up with it despite a huge amount of work. Whatever underlies M-theory, it may be something very complicated. Perhaps M-theory is just a rather obscure corner of a story very different than what string theorists are hoping to find, one that may tell us some interesting things, but just doesn't have anything to say about how to unify particle physics.

Comments

1. **M**
   September 13, 2007

   Now I understand why Lubos hates the anthropic string landscape: it is "antiscience of the left".

2. **R**
   September 13, 2007

   The article by Cartwright and Frigg is available here.

3. **Jon**
   September 13, 2007

   Hi Peter,

   While your views do have merit, I don't think the current string-theory situation will change any time soon. Supposing string theory *is* found to lack in its substantive goal of unifying physics, what other alternatives do you think has the same degree of appeal… I'm not aware of any. (Certainly LQG and the host of other programs don't carry the same intellectual appeal and challenge to grad students and postdocs).

   In short, either strings or nothing.

4. **Peter Woit**
   September 13, 2007

   As for what has the same degree of appeal as a failed idea that has become a pseudo-science (the landscape), well, actually just about anything at all….

More seriously, I've always said that the problem is not that there are good ideas about unification being ignored, but that there aren't good ideas (at all, string theory now clearly isn't one). So the question is how to change the reward structure to encourage people to come up with new ideas. I don't see any evidence that particle theorists of any influence are taking this problem seriously. At the moment the attitude seems to be that the best thing to do is to hide one's head in the sand and wait for experimental results from the LHC to save us. From what I've been hearing lately, people may have to keep their heads in the sand longer than they expected….

5. **Elegant Simpleton**
   September 14, 2007

   Is Yang-Mills field theory elegant or simple? To see the elegance one needs to have studied for many years, both geometry and physics. To see the simplicity – well I don't see that it's all that simple – unless one sees it within the context in which it arose – in which case one needs to know a lot already.

   The criteria of elegance and simplicity are aesthetic judgments made within the context of expertise. To find a particular treatment of Galois theory elegant one has to first know several treatments of Galois theory, understand them, and have thought about the difficulties involved in describing the theory coherently. Not everyone has the preparation to do this. To someone without the preparation, no approach appears either elegant or simple.

   Pauli's way of handling tensor algebra was neither elegant nor simple, though it worked.

6. **Kasper Olsen**
   September 14, 2007

   Peter,

   Nancy Cartwright and Roman Frigg are philosophers; they are able to throw names like Kuhn, Lakatos and Popper into the stringscape, but not much else.

   If you tell them, that e.g. the mass shell condition is this and that, they will have no idea what you mean; if you tell them, that the string sigma model is this and that, they will have no idea what you mean; and if you tell them, that the string tension is related to the Regge slope parameter by a certain relation, they also will have no idea of what you mean.

   Elegant Simpleton is correct here in saying, that "The criteria of elegance and simplicity are aesthetic judgments made within the context of expertise" and therefore their views on a string is of little interest. Except for other philosophers, I guess.

7. **dragon**
   September 14, 2007

   The record of philosophers intervening in physics is mixed. Sometimes it has been worthless; other times it has made more sense than what physicists have said about the same issue. The most extreme example of this that I know is the case of work on the arrow of time. Huw Price

   http://www.usyd.edu.au/time/price/

   has made genuine contributions to our understanding of this. Whereas Lubos Motl claims that the arrow arises from the structure of language, from the way we ask questions. That's right, LM thinks that a postmodernist analysis is the only way to go. In short, if you want real philobullshit, an over-confident physicist is the man to ask. So the views of philosophers on physics should not be dismissed out of hand.

8. **Chris Oakley**
   September 14, 2007

   > So the views of philosophers on physics should not be dismissed out of hand.

   Being less crazy than LM is not really setting the bar very high.

9. **Thomas Love**
   September 14, 2007

   I'm not comfortable calling string theory "Antiscience", it is more specialized, so call it "Antiphysics". "Certainly Repulsive AntiPhysics".

10. **tytung**
    September 14, 2007

    The relation between philosophy and fundamental physics is subtle and complex. Remember, Einstein himself is more philosophical, and less mathematical, than most of his contemporary physicists.
    That the philosophers are not equiped with detailed physics knowledge doesn't mean that they are unable to give valuable insights into it.
    As I see it, all science is to investigate nature within a set of assumptions, philosophy attempts to step outside and examine them.

11. **Christophe de Dinechin**
    September 15, 2007

    I liked the observation that bad science can stem from arrogance. I believe that there is a big gap between what is actually being delivered and what is actually known when you look in the details.

    I've tried to put that in a humoristic way, imagining what would happen if MacOS X had been introduced by Brian Greene instead of Steve Jobs. I'm not sure anybody other than me will find it funny 😉 but I thought I'd share anyway.

12. **dragon**
    September 16, 2007

    "Being less crazy than LM is not really setting the bar very high."

    But a lot of people respect his views on technical questions in physics [if in no other field]. So he provides an example where someone supposedly competent in physics has been led into serious error, in *physics*, by doing philosophy badly.

13. **Eric**
    September 16, 2007

    There's nothing wrong with LM's knowledge or views on physics. However, he just appears to be very intolerant of those with views which differ from his. In regards to those with crackpot views (and let's be honest, there are a lot of these types populating the blogs), I can sympathize. However, he can also be extremely rude and insenstive to even those who are not crackpots.

Of course, in regards to his views on other subjects, LM is clearly a crackpot himself.

14. **Kris Krogh**
September 16, 2007

The philosopher Grete Hermann correctly identified a fatal error in John von Neumann's pivotal "proof" of the impossibility of hidden variables in quantum mechanics. While that proof was widely cited, she was totally ignored for twenty years, until John Bell took up her case. She is still little-known, since the history of physics is written by physicists. (Usually ones with a preference for the Copenhagen interpretation of quantum mechanics.)

15. **lisistrata**
September 17, 2007

> There's nothing wrong with LM's knowledge or views on physics.

If you're talking about his published work, I believe you. I've not read it, so there's no reason for me to doubt your words.

If you're talking about his views on physics as they appear in his blog, then I strongly disagree with you. Statements like the SU(2) symmetry group of weak interactions can be derived from unitarity, or that the existence of neutrinos can be deduced from the existence of charged leptons, or that experimental results are neither important nor needed, that's what I would call plain ignorance both of physics and its history…

16. **Kasper Olsen**
September 17, 2007

Kris,

Grete Hermann was also a mathematician, and this alone made it possible for her to understand the math involved; just being a philosopher would not have been enough to identify this "error" in von Neumann's argument.

17. **Kris Krogh**
September 17, 2007

Kasper,

Yes, Grete Hermann was also a mathematician. But I think Tytung has a point:

As I see it, all science is to investigate nature within a set of assumptions, philosophy attempts to step outside and examine them.

She avoided an assumption of von Neumann's, which David Mermin describes as "silly." (Maybe I would use a different adjective.) Why, in twenty years, didn't physicists notice a silly mistake in a fundamental proof?

We need more people willing to think outside the box, like Einstein and Bell.

18. **notaphilosopher**
September 17, 2007

Eric said: "There's nothing wrong with LM's knowledge or views on physics."

I think you are missing dragon's point. He is referring [I think] to an argument LM had with Anthony Aguirre [a genuine expert] about the origin of the second law of thermodynamics. To everyone's surprise, LM went all philosophical and claimed that the low entropy at the beginning of time does not need to be explained because when we ask questions, we always ask about the future based on what we know about the past. *Therefore* there is nothing to explain. Here is a concrete example where LM was talking nonsense *about physics* because he got the philosophy wrong. Of course everyone who disagrees is an idiot, is "humiliating Boltzmann" etc etc all the usual crackpottery, but that is just the icing on the cake: the point is that LM became a *physics* crackpot, at least for the time being, because he thinks he can play philosopher. Of course Kasper O might argue that LM might have avoided making a fool of himself by staying away from philosophy altogether and trying to think about a physical basis for the arrow of time…….

US/LHC

September 13, 2007
Categories: Uncategorized

Yesterday a new web-site was launched by the DOE and NSF, called US/LHC, which will be devoted to the role of the US in the LHC project. Besides news and descriptions of the science and the experiments, it will also include blogs by several physicists involved in experiments at the LHC. This new web-site joins several other similar ones, most notably one devoted to the ILC, and an umbrella one for US particle physics called Interactions.

I've sometimes wondered whether this huge publicity onslaught for the LHC is a good idea. Just as this new web-site is coming on-line, I'm starting to hear unconfirmed reports of possible very serious delays in the LHC startup, ones which may push back the beginning of experiments by a year or more. The current schedule includes no extra time for cooling down sectors of the machine which have to be warmed up to deal with one problem or another, and this cooling is a tricky months-long process. If these rumors turn out to be true, this will be good news for the Tevatron, which will have the energy frontier to itself for longer than expected. But it will definitely be very bad news for CERN and for particle physics in general, both of which have just about all of their eggs in this heavily publicized basket.

Update: From the comments here and e-mail I'm getting, it appears that others are hearing these same rumors: the first physics runs are likely to be in 2009, not 2008, due to problems that have shown up as they have started cooling down some sectors of the machine.

Update: Peter Steinberg at the US/LHC site blogs about the conundrum of whether he should be dealing with "gossip from unverified or anonymous sources", and decides he'd better not. I suspect one consideration is that his blogging role puts him in a sort of unofficial spokesman capacity, which is rather incompatible with rumor-mongering. On the other hand, I don't have this problem…

An informed commenter reports in the comment section about details of some of the problems that have cropped up in the last month, and that the "best guess" for the delay that these will cause is about two months. This would move the start of a physics run from next July to next September.

Update: Via the Resonaances blog, here's the video of a September 13 colloquium talk by Lyn Evans about the LHC commissioning. Evans describes in detail two of the problems that have shown up that motivated some of the rumors: leaks that have appeared during the first cool-down of certain sectors of the machine, and problems with some of the plug-in modules that interconnect the magnets. It remains unclear if these problems will cause slippage in the schedule, and if so, how much. News about what is going on with these problems is posted here.

Comments

1. **Paul Guinnessy**
   September 13, 2007

   My story in this month's Physics Today magazine Multiple problems push LHC start to next spring might answer some of your questions.

2. **Peter Woit**
   September 13, 2007

   Thanks Paul,

   I did see your article, and what I've been hearing recently involves some of the same problems you describe there. But what I've heard is that the problems are more serious than originally thought, and that the startup date of next July will have to be pushed back. Maybe this is wrong, so I'd be curious to know if your sources for that article are still saying that things are on track for next July.

3. **A quantum diaries survivor**
   September 14, 2007

   Hi Peter,

   I also am hearing of about one year of delay of startup (pilot run end 2008, first data end 2009), due to some structures that may have broken during cooldown and need replacement. Yours is the fourth source of more or less the same information, so I would say it may well be not confirmed, but it is a pretty solid piece of bad news.

   Cheers,
   T.

4. **Thomas Larsson**
   September 14, 2007

   This is sad news. However, Tevatron II also had a lot of initial problems, not to mention the SSC debacle. The CERN people have spoiled us with a track record of completing their projects on budget and ahead of time.

5. **Coin**
   September 14, 2007

   So these USLHC blogs. Should we expect them to be more or less independent? Or will the DOE or somebody be looking over their shoulders every moment monitoring the content?

   I really like this idea of scientists on big projects like this blogging, because it seems like potentially a great way for the public (i.e. me) to get interesting and unusual information about the experiment as it progresses. Unfortunately, this potential seems to be in direct conflict with the NSF/DOE's likely goal in setting up this web page in the first place– that is, as a vehicle for generating publicity for the experiment, probably positive publicity.

   Let's say the most pessimistic comments on this page turn out to be right, and the LHC has some delays coming. Will we see candid posts from the USLHC scientists about the delays and what they mean as they happen? Or will these blogs be only for reporting *good* news?

6. **A quantum diaries survivor**
   September 14, 2007

   Coin,

I can't answer your question, but what I can say is that I am blogging, I work in CDF and CMS, and I am rather erring on the side of dispersing more news than I should, according to many of my colleagues. That is because I believe outreach is more important than obsessing about what the funding agent could read in distorted press reports.

So the bottomline is, read it in my blog!

Cheers,
T.

7. **Peter Woit**
September 14, 2007

Coin,

An interesting question. If these reports turn out to be accurate and serious delays are ahead, it will be interesting to see how the bloggers and the website handle it. It looks like the website itself will be maintained by people hired specifically to do outreach for the project, and their job depends on putting out whatever those responsible for running the project want to be made public. On the other hand, the bloggers are scientists. I doubt they are being paid much if anything to do this, so they have freedom to write about what they want to, although also presumably will feel some obligation not to embarrass the sponsors of the web-site.

In any case, it you want relentlessly upbeat blogging about how wonderful everything is in this area of science, there are some very prominent blogs you can go to for this, and they aren't even sponsored by the DOE or NSF.

8. **anonymous**
September 14, 2007

I don't know of any rumours about a delay in starting LHC. What I do know is that CERN is presently in the process of choosing a new director general who will take over in Jan 2009.

9. **peter**
September 14, 2007

we've known for a long time now that the LHC will come on line on April 21,
2009:

http://www.sfwriter.com/scff.htm

"

Day One: Tuesday, April 21, 2009

A slice through spacetime . . .

The control building for CERN's Large Hadron Collider was new: it had been authorized in A.D. 2004 and completed in 2006. The building enclosed a central courtyard, inevitably named "the nucleus." Every office had a window either facing in toward the nucleus or out toward the rest of CERN's sprawling campus. The quadrangle surrounding the nucleus was two stories tall, but the main elevators had four stops: the two above-ground levels; the basement, which housed boiler rooms and storage; and the minus-one-hundred-meter level, which exited onto a staging area for the monorail used to travel along the twenty-seven-kilometer circumference of the collider tunnel. The tunnel itself ran under farmers' fields, the outskirts of the Geneva airport, and the foothills of the Jura mountains. …

10. **Yatima**
September 14, 2007

> choosing a new director general

But that is not correlated with the rumors about delay, right? Delay may be a good thing. Hearing about the compressed schedule to go live next year with no preliminary testing made me cringe. These tricks never work out, except – maybe maybe – if you know exactly what you are doing (i.e. you are doing it for the fifth time or so).

Now… will politicians head for the door upon hearing this or is LHC funding still assured? On the other hand, I probably don't understand the funding thing. Paul writes: "Construction of a new $150 million injector will start in 2012 when CERN finishes paying off the loans it took out to build the LHC".

They took out loans? With what collateral?

11. **Coin**
September 14, 2007

Dorigo, I do read your blog and it's a great example of what I would say we can hope for from blogging experimentalists, off the top of my head it would be that or the kind of thing that John Conway (but not *that* John Conway, apparently?) occasionally posts at Cosmic Variance. If the USLHC blogs manage to occasionally give us that level of insight into the project I'll be ecstatic. Of course, I'm not picky, I guess *anything's* better than trying to get one's science news from the popular press?

> [CERN] took out loans? With what collateral?

Perhaps if the loans are not paid, the banks will repossess the rights to the Z Boson. I mean consider how many Z Bosons there are in active use, the licensing revenue from those things must be enormous.

12. **JoAnne**
September 15, 2007

By international treaty, CERN recieves a fixed stipend each year from each member country. These stipends form their budget for current operations as well as R&D and construction of future facilities. In order to build the LHC in a timely manner (rather than having the constuction stretched out for more years), CERN took out loans against their future stipends. Each year after the LHC construction is finished, CERN will repay part of the loans with the fraction of these fixed stipends that is not used for current operations. Given the fixed amount of these stipends, it is known (and set by agreement) that the full amount of the loans will be repaid in 2011. Thus in 2012, there will be money available from the fixed stipends for new projects. This is a fantastic and stable funding model. Sure wish we could fund science in the US this way!

I haven't heard any rumors about further delays yet, but would not be surprised. In fact, I think we should anticipate a certain amount of small issues to arise as they commence operations. It is much better than they turn on the machine carefully and correctly!

13. **Less of a dreaming optimist than JoAnne**
September 15, 2007

"It is much better than they turn on the machine carefully and correctly!"

–> I hope the previous commenter does not imply that there are other ways to start running a 14 TeV proton accelerator, whose beams carry the energy of an aircraft.

Unfortunately, it is not because of care and attention to detail that the thing will probably be delayed. Rather, there are things that need servicing along the tunnel – many of them – and even figuring out where they are isn't easy! Imagine being in the situation when it does not seem that silly the plan of running tennis balls through the beam pipe to figure out where a few hundred among 4000 pieces blocking the path are, and having to dream of teams of grad students cycling around the tunnel to find out. It's just that bad.

No, I would not give the picture those soft rosy tones JoAnne likes to paint. The further delay, if confirmed, is a disaster to a large number of people who were counting on real data first at the end of 2007, then in 2008, then "a little in 2008 – 1 or 10/pb, and then 2-3/fb in 2009 – but we'll publish W and Z cross sections end 2008!", and now apparently not more than minimum bias until late 2009. For a theorist and assistant professor, sure, no hurry. But for a grad student who spent the last few years building things in the hope to finish his PhD in glory, it is a hammer blow. And it is not much less so for a fresh post-doc who has been hired to do data analysis and will instead spend three years doing Monte Carlo studies, not publishing anything meaningful.

Let's just hope that the rumors coming from CERN have been amplified through the echo of the caverns.

14. **Ellipsis**
September 15, 2007

Here is what I hear (gosh, why is there no better public source for these things than a blog by a mathematical physicist which is supposed to be about the problems with string theory?):

There are two problems which have cropped up in the past month:

1) Vacuum leak in arc 8-1

2) Problems with the "plug-in modules," which are the interconnects between dipoles. About 1% of them (in sector 7-8) failed and were damaged during the cooldown recently.

It is not clear how much time fixing these will add to the schedule, although apparently a year would be extremely pessimistic. Unless other problems crop up (not unlikely), the best guess (and it is a guess at this point — that is why you're not hearing any official statements) for the amount of time this will add to the schedule is approximately 2 months or so. That's a guess. Apparently the CDF spokespeople have announced they thought the delay would be longer, but remember that CDF is looking for an extension on Tevatron running time (and its spokepeople are not the most knowledgeable about this situation). Relax and wait until the people who know, know better.

As for the US LHC blogs, personally I certainly wouldn't worry about any active censorship or anything like that. I might be a little more concerned about them just becoming boring "corpora-blogs" because of their restricted mission and focus. Wait and see.

15. **JoAnne**
September 16, 2007

Dear Less of a dreaming optimist than JoAnne:

I have been waiting for data at the TeV scale since the summer of 1983. That was my first summer of doing research and was when it was announced that the US was going forward with the SSC. Fast forward, past all the super-collider calculations I did, to the Fall of 1993 when the SSC was cancelled and my paycheck was being paid by an SSC Fellowship.

You have no idea what it means to wait. I have most likely been waiting longer for data at the TeV scale than you have lived. Believe me, you and your career will survive the waiting. Life (and physics) as we know it will not end.

Yes, the LHC is already delayed and likely will be delayed more. But, after waiting 25 years, the very large numbers of people that have worked so hard and have waited so long already will find that it is OK to wait another year or so. And yes, the waiting will be because the people in charge of starting operations are careful. They will only test one segment at a time, carefully, so that a catastrophic event does not occur. And a safe startup will happen, precisely because of attention and care to detail.

16. **Less of a dreaming optimist than JoAnne**
September 16, 2007

JoAnne,

sorry, but I am older than you figured, I have a job, and it does not depend too much on LHC turning on or being canceled. I do, however, feel concerned for the tens, maybe even O(hundred), people that do not have the luxury option of waiting, and have to drop out of the field because they have to go on with their lives rather than living through 10-year PhDs. Seeing physics at the TeV scale is sure nice, but I do not shed a tear if our children will do it rather than us. There are sociological implications that to me are more important.

17. **Ellipsis**
September 16, 2007

I don't think anything related to these current issues has the remotest chance of turning a 5-year PhD into a 10-year one. Agreed that it is clearly somewhat of a concern when startup has been "a year from today" for a year now, but there haven't been any true disasters … yet. This is life, and funding agencies, employers, and just about everyone working on the projects have anticipated this level of issues. I think you should save the major complaints for when the beampipe gets a vacuum leak inside the CMS silicon, or when joule heating breaks the rest of the PIMs, or something like that. There are plenty of things that could go majorly wrong, and might — you're early (if ever). And that will be life too if it happens. How else do you suggest science progress?

18. **Ellipsis**
September 16, 2007

Furthermore, even if a disaster does occur, in that case it is likely that the Tevatron would be kept running until things improve. Most people working on the LHC also work on another project, partly because of the possibility of these kind of issues. It is fundamentally different than the SSC. I think very few will have to leave the field, even if a disaster occurs. Students can be shifted to a different project if necessary. People are more careful this time around.

19. **observer**
September 16, 2007

Pessimistic,

whining about a (possibly inexistent) one-year delay is ridiculous. Such delays are to be expected, with a certain probability, so anybody working on this should know what their chances are and take appropriate precautions. If someone is betting their phd on a certain date and time for the start of operations, they're making the wrong bet.

To extend JoAnne's description of the consequences of the SSC cancellation, I know many people who went into finance and computing in those days, who didn't even work in SSC physics. At least one who didn't even work in particle physics proper, but in astroparticle physics. There was a big crunch in the job market and everybody paid a price.

20. **Less of a dreaming optimist than JoAnne**
September 16, 2007

I confirm what I said above: it is not this -not yet confirmed- delay by itself what makes things bad. It is the addition of a small series of them.

Imagine you are a grad student who started in 2003 with the idea of finishing in 2008 with a thesis including enough data to see low-mass SUSY. As the delays pile up, you find your planning fall to pieces, and you are now looking at a thesis plan that will only be concluded in 2010-2011 -if everything else goes well-, when you originally thought you would be a post-doc, with a decent salary, and maybe a life. You are forced to consider bailing out.

And there are countries where PhD cannot be extended: they last three or four years, period. You started two years ago, and now you know your work will not make a dent, because you will only include Monte Carlo studies in it.

Further, there are problems with opening new positions for data analysis at LHC: in some countries the delays may end up causing a hole in the time profile of openings.

I am not a catastrophist: I first of all hope things will not turn out to be as bad as I heard claimed. Second, I think solutions can be found – especially to funding issues, which as far as CERN is concerned JoAnne has well explained aren't real troublesome. But I insist that the concern is sociological first of all. JoAnne has waited for 20 years, with a salary ? She can wait three more, and we with her. Younger people might be in more trouble.

21. **Peter Woit**
September 16, 2007

Ellipsis,

Many thanks for the helpful informed comment about the LHC status.

I agree that the problem with blogs sponsored by the labs or funding agencies is not likely to be censorship, but that the writers may try and avoid anything controversial to avoid embarrassing their sponsors. And, due to their official connection, rumor-mongering is problematic since what the bloggers write will be seen as having some semi-official status.

On the other hand, with no such connections myself, I'm more than happy to engage in (responsible) rumor-mongering, and encourage informed sources who want to let the rest of the world know what is going on to take advantage of this. Either with their names attached, or not, depending on which is more appropriate…

And this applies not just to depressing news about delays, etc. If you have information about a new Higgs signal or some-such, that would be even more welcome.

22. **Ellipsis**
September 16, 2007

Hi Peter,

Thanks. Note that all LHC hardware status info is in principle completely public — you can get all the dirty details at http://hcc.web.cern.ch/hcc (see especially the nonconformities section). Understanding what is really a big problem and what is more easily fixed requires some detailed knowledge, the vast majority of which I need explained to me as well (and was, thanks to a chain of people). You can bet that I will *not* be releasing any rumors about the Higgs or any other premature info that is not supposed to be public before release (for good reason). Physics results are fundamentally different than hardware status. When physics results are released they are meant to be definitive statements about nature and the universe. Leaking physics results which may or may not be correct confuses the ultimate goal of teaching the public the workings of the universe. I think that's something to be avoided. I definitely think Steinberg's statement (which I saw too) is overly restrictive if he means that they won't even talk about the most recent hardware status, which is public info. Hopefully his/their self-imposed restrictions will not reduce them to just posting what they had for lunch.

23. **Peter Woit**
September 16, 2007

Ellipsis,

I had poked around the site you mentioned, surprised to see how much detailed information is available about how the project is going. But I'd also quickly realized that you need an expert to tell you which problems are serious and which aren't.

I understand the distinction between the LHC status info and physics results, which are a different question. But even there, I personally don't see a problem with discussion of rumors of in-progress experimental analyses, as long as this is a discussion aimed at physicists and makes clear that this is work in progress and no claims are yet being made. The tricky part of this of course is the public nature of blogs, which, even when they are aimed at other scientists, are monitored by science journalists who are likely to try and report preliminary results to a wide audience, with the caveats getting sometimes lost in the process.

Theorists don't seem to suffer from this problem, with many of them seemingly happy to have highly misleading versions of their work reported, perhaps since the general misfortune of the theorist is to almost never have anyone pay attention to what they are doing. I agree that it wouldn't be a good thing to have the typical level of New Scientist reporting on theoretical work spread to reporting of experimental results.

24. **Peter Steinberg**
September 17, 2007

Ellipsis – I will never report on my lunch on the US-LHC site (you can check my non-LHC blog for that here)! Of course, I will pass along any substantiated information I come across, but I remain reluctant to pass along non-trivial interpretations of information from anonymous bloggers who heard things from insiders, which was the issue in my Conundrum post.

25. **woit**
September 17, 2007

Peter,

Just to insist on precision of terminology: if a blogger is someone with a blog, there aren't any anonymous bloggers involved here. There are anonymous blog commenters, one of whom (Ellipsis, whose identity is not known to me) gives good evidence of knowing what he or she is talking about.

Other than that correction though, I don't think there's anything wrong with your decision not to discuss these rumors on your blog, since it is part of the official LHC outreach effort, and information confirmed by those responsible at the LHC is not yet available. As for the rest of us though, I see no reason not to blog about information coming in either from reliable sources I know the identity of, or credible information from anonymous sources.

Steinhardt on the String Theory Crash

September 18, 2007
Categories: Uncategorized

The Edge web-site has something new up they call [Einstein: An Edge Symposium] (thanks to commenter Hendrik for pointing this out). It's an exchange between Walter Isaacson, Paul Steinhardt and Brian Greene, nominally about Einstein, but ending up turning into a discussion of whether and how string theory has "crashed".

Steinhardt forcefully makes the same point I've made *ad nauseam* here: the anthropic string theory landscape is not a valid scientific research program, but simply the kind of thing you end up with when a speculative idea fails.

> In my view, and in the eyes of many others, fundamental theory has crashed at the moment. Instead of delivering what it was supposed to deliver—a simple explanation of why the masses of particles and their interactions are what they are—we get instead the idea that string theory allows googols of possibilities and there is no particular reason for the properties we actually observe. They have been selected by chance. In fact, most of the universe has different properties. So, the question is, is that a satisfactory explanation of the laws of physics? In my own view, if I had walked in the door with a theory not called string theory and said that it is consistent with the observed laws of nature, but, by the way, it also gives a googol other possibilities, I doubt that I would have been able to say another sentence. I wouldn't have been taken seriously…
>
> But what angers people is even the idea that you might accept that possibility—that the ultimate theory has this googol of possibilities for the laws of physics? That should not be accepted. That should be regarded as an out and out failure requiring some saving idea…
>
> What I can't accept is the current view which simply accepts the multiplicity. Not only is it a crash, but it's a particularly nefarious kind of crash, because if you accept the idea of having a theory which allows an infinite number of possibilities (of which our observable universe is one), then there's really no way within science of disproving this idea. Whether a new observation or experiment comes out one way or the other, you can always claim afterwards that we happen to live in a sector of the universe where that is so. In fact, this reasoning has already been applied recently as theorists tried to explain the unexpected discovery of dark energy. The problem is that you can never disprove such a theory … nor can you prove it.

Steinhardt dismisses attempts to hypothesize that maybe the landscape is somehow predictive as follows:

> Do you mean as derived from string theory? I don't believe that's true. I don't believe it's possible…
>
> Well, I believe that if you came to me with such a theory I could probably turn around within 24 hours and come up with an alternative theory in which property X wasn't universal after all. In fact, you almost know that's true from the conversation that's been happening in the field already, where someone says, these properties are universal and these others are not. The next day, another theorist will write a paper saying, no, different properties are universal. There are simply no strong guidelines for deciding…
>
> If a version of string theory with a googol-fold multiplicity of physical laws were to be disproved one day, I don't think proponents would give up on string theory. I suspect a clever theorist would come up with a variation that would evade the conflict. In fact, this has already been our experience with multiverse theories to date. In practice, there are never enough experiments or observations, or enough mathematical constraints to rule out a multiverse of possibilities. By the same token, this means that there are no firm predictions that can definitively decide whether this multiplicity beyond our horizon is true or not.

After some prodding, Steinhardt makes clear that he is not claiming that string theory as whole has crashed, that it is just the landscape that is the crash. While insisting that people need to acknowledge that the landscape is simply a scientific failure, he holds out hope that some fix to string theory may still be found:

> …it's that point of view which is a crash, and needs a fix. I am not arguing that string theory should be abandoned. I think it holds too much promise. I am arguing that it is in trouble and needs new ideas to save it.

There's also some discussion about what Einstein would have thought of string theory and the landscape, with Steinhardt of the opinion that Einstein would have liked string theory with its unification via geometry of extra dimensions, but that he would have rejected the landscape:

> Einstein took gravity and turned it into wiggling jello-like space, and now string theory turns everything in the universe, all forces, all constituents into geometrical, vibrating, wiggling entities. String theory also uses the idea of higher dimensions, which is also something that Einstein found appealing.
>
> What I was commenting on earlier was where the string program has gone recently, which I described as a crash. I can't say for sure how Einstein would view it, but I strongly suspect he would reject the idea.

[Three years ago] I expressed the opinion that the promotion of the anthropic landscape would make Einstein gag, which so upset Joe Polchinski that he used this to argue that trackbacks to my blog should not be allowed on the arXiv (even though this was not about an arXiv paper, but a Scientific American article). At one point I regretted having used that expression, feeling it was somewhat over the top and inappropriate. In retrospect, seeing what has happened over the past three years, I've changed my mind. The kind of thing that would make Einstein gag has moved from popular science articles to regular appearance in the lectures and scientific articles of leading figures in particle physics. This would probably not just make him gag, but send him into a serious fit of depression.

   "Every absurdity has a champion to defend it."
   — [anti-religion website]

   I had a conversation with [Wolfgang Haken] a few yrs ago

   [UIUC mathematician (whose father was Max Planck's PhD student) who proved the 4-color theorem with K. Appel, using computer] who was working on cosmology in his retirement. He was very vocal about the "infinity of solutions" curse, & thought the scenario was hopeless! This, from someone who solved a famous combinatorial math problem.

He mentioned something very interesting:

"If you have not made a mistake, you have not been a great scientist!"

He pointed out "Even David Hilbert was wrong!". The moral of the story is "You have to try a lot of ideas" (shotgun approach, as per L. Pauling). This mirrors D. Gross statement "You have to try" (the W. Churchill quote).

I think what P. Woit & L. Smolin are saying is that ST (over 20+ yrs) isn't getting it done ("crash"), & it's time to admit failure. Move on.

"An honest man can make a mistake, but only fool persists in doing so"

"No matter how far you have gone down the wrong path, turn back."
— Old Turkish proverb

September 19, 2007

An interesting discussion, and this part seems potentially explosive!:

GREENE: […] But just so I understand; you're saying that this one particular way in which one may think about string theory—for which the endpoint is many many universes—is unacceptable.

STEINHARDT: Right. I claim it needs to be fixed.

GREENE: But you also agree—just so it's clear—that's not a crash in string theory per se; that's a particular way of approaching the theory that you would not advocate because the endpoint would be unacceptable. You need to go further…

STEINHARDT: That's right; so it's just what you were saying; some people say that is the endpoint, and I'm saying that's not acceptable. If you believe that, it's time to abandon it.

GREENE: But it's those people who've crashed.

Wow, take that Susskind & Co!

4. **tytung**
September 19, 2007

Regarding the points raised by Steinhardt…I think it need to be made more clearly. An ultimate theory may allow certain physical facts as something that is selected by chance, and other universe, if allowed to exist, may take other possibilities. The candidates are the values of physical constants. I can't even imagine that these values can be determined in some ultimate theory, free of any constants.

5. **mclaren**
September 19, 2007

Since the Uncertainty Principle made Einstein gag, this criterion should not be used as a measure of the measure of a physical theory.

6. **chris**
September 19, 2007

tytung,

i think this is not the point. of course a theory with no constants to fix would be the ideal one. but take e.g. QCD. how many free parameters does it have? one plus the quark masses? how about the 3 in the SU(3) gauge group? why not 4? is that a free parameter?

i think the trouble with the landscape is quite different. imagine, that QCD would not directly lead to the hadron spectrum or confinement (let's assume for now, that they are sufficiently well established). let's assume that we only have an effective theory of hadrons and we conjecture a fundamental theory behind it that first needs to break the ground state symmetry down to a subgroup in a very specific way. and let's imagine that there are zillions of other plausible patterns that we are not able to exclude because of either internal consistency or experiment.

now, even if the fundamental theory would have only one free parameter (or zero, if you want), the unsatisfactory feature is, that it leaves you with *no prediction*. only if you pile additional external assumptions upon the theory (how the symmetry is broken) can you arrive at a descriptive theory.

the point with the landscape is exactly this. your fundamental theory may be nice (assuming it can ever be formulated correctly), but unless you pile 'anthropic reasoning' on top of it (=invoke god at this point) it does not predict anything. it just does not.

it totally floors me to see how string theory can claim to have improved the state of affairs in quantum gravity. the original problem was lack of predictiveness. at this level, quantum gravity (the QFT with the einstein-hilbert action) is just doing fine! well, it is nonrenormalizable perturbatively (on first inspection), but what the heck. if you fix an infinite number of parameters, it is just fine. and even you can in principle fix them all with observations.
even more so, there is strong evidence piling up that the QFT of gravity is nonperturbatively renormalizable. so it seems, that the original problem of nonpredictability will eventually turn out to be an intermediate technical difficulty.

now compare that to the currently claimed nonpredictability of the antropic string landscape. the only reason i can imagine that this is not dead as a valid candidate for a physical theory is that too many people have spent too many years hunting the phantoms and won't admit they went the wrong way. it is just absurd.

7. **milkshake**
September 19, 2007

Chance selection in the Ultimate theory: How many chance-selected parameters would you be willing to accept?

"A multiverse encompassing every alternative compatible with our theory is possible according to the theory – so it could have been a combinatorial process that picked the winning numbers in our corner of the multiverse"

This is just productive as saying: “Our creator is a mysterious dude who laid out the universe according to his subtle wisdom”.

In both cases you can fit all the known facts in, with the help of scriptures and some scholastic reasoning.

8. **Thomas Larsson**
   September 19, 2007

   Mr Academic Failure Motl now decrees that the [Albert Einstein Professor in Science at Princeton University]() is an incredibly stupid crackpot. It is really funny when AFM says that one of the leading theorists responsible for inflationary theory say “many breathtakingly dumb and bitter things about inflation” 🙂

9. **Thomas Love**
   September 19, 2007

   Peter said: “The kind of thing that would make Einstein gag has moved from popular science articles to regular appearance in the lectures and scientific articles of leading figures in particle physics. This would probably not just make him gag, but send him into a serious fit of depression. ”

   From what I’ve read about Einstein, he would neither gag nor become depressed, he’d be laughing his head off. As am I.

10. **King Ray**
    September 19, 2007

    To quote Einstein from his book The Meaning of Relativity:

    “More complex field theories have frequently been proposed. They may be classified according to the following characteristic features:

    (aa) Increase of the number of dimensions of the continuum. In this case one must explain why the continuum is apparently restricted to four dimensions.

    (bb) Introduction of fields of a different kind (e.g. a vector field) in addition to the displacement field and its correlated tensor field g_ik (or scriptg^ik).

    (cc) Introduction of field equations of higher order (of differentiation).

    In my view, such more complicated systems and their combinations should be considered only if there exist physical-empirical reasons to do so.”

    From this one might deduce that Einstein would not favor additional dimensions unless there was empirical evidence for them, which there is not. Also there does not seem to be a good explanation for why the continuum appears to be 4 dimensional insteand of some other number.

    Once you give yourself too much mathematical freedom, there are too many possible theories and you end up with a mess like the landscape.

    (I had to double the letters because it was turning the c in parentheses into a copyright symbol)

11. **King Ray**
    September 19, 2007

    I should also add that almost all of Einstein’s 30+ year search for a Unified Field Theory was confined to four dimensions. He rejected the Kaluza-Klein idea using higher dimensions.

12. **Thomas Love**
    September 19, 2007

    But the use of higher dimensions goes back even further.
    Robert S. Cohen wrote a fascinating introduction to the 1956 Dover reprint of Heinrich Hertz’ The Principles of Mechanics. :
    In the writings of Descartes, there is sketched just such an
    efficiently running world-machine, devised without forces or energies, built of rigidly connected space-time atomic entities. Although he was an advocate of the mathematization
    of physical reality, Descartes was driven to admit the inadequacy of ordinary space-time geometry to explain inertia and gravitation. These two properties of bodies, perhaps to be supplemented by other non-geometric properties in later investigations, seemed to require more than the pure mathematics of Euclidean geometry, but Descartes asserted that they should be analyzed by a higher geometry of many dimensions. “By dimension,
    I understand nothing else than the mode and aspect in respect
    of which a subject is considered to be measurable. Thus, it is not only length, breadth and depth which are dimensions; gravity is also a dimension, speed is a dimension of motion…
    and so on with innumerable other dimensions of this sort”
    (Rules for the Guidance of our Mental Powers, Rule xiv, tr. N. K. Smith).

    Thus, according to Descartes, we need a dimension for each physical quantiy we can measure!

    There iare certainly “physical-empirical reasons to do so”

13. **sophia**
    September 19, 2007

    Peter,

    Forgive me for even contributing here. I’m not a scientist, just an interested observer. But I do have a question that may be relevant.

    I followed the link and began to read. After a while I began laughing and then wincing and then, yes, gagging. Why? Well, stand back and survey the scenery: three intelligent men, two of them credentialed scientists, wondering what a dead man would think, because they have reached (sorry) a dead end. That’s not so pathetic it’s funny? To me it is.

    Don’t get me wrong: I revere Einstein as much as the next good American does, but dudes, he’s dead. Wondering what he would think is ludicrous. What is this, science or a seance?

    I gave up here:

    “I think most of us in the field absolutely will never have faith that this approach is right until we do make contact with data, but it would be great to have the insight of the master as to whether he feels that this smells right."

What does it matter what Einstein would think? What matters is what Brian Greene and Paul Steinhardt think!! What are THEIR insights?? And what is this business about "contact with the data", as if "the data" are alien beings that we conjecture about but have never met??

OK, that's three questions.

14. **JPL**
September 19, 2007

Hi Sophia,

Sorry to barge in but Einstein is quite alive, at least, a lot more so than the String Theory landscape! I am sure that this sounds silly to you, 3 grown (but living) men speculating about what a dead one would think, but in Physics this is hardly what it seems. Einstein is one of the few figures whose own sense of proportion and aesthetics has impacted the discipline enough that one can justifiably refer to it some 60 years after he passed and thus the argument makes sense and can be consistently addressed and narrowed as you see above.
I would dare add that what Einstein would think matters much more than what Steinhardt, Greene or Isaacson think, otherwise they would not think to add that bit to their own opinions, now would they?

15. **Peter Woit**
September 19, 2007

Sophia,

I agree that the "What would Einstein think?" question is kind of silly. He is rightly revered for his contributions to physics, but the greatest of these were from a very different time a century ago, when physics was facing very different challenges. This kind of question functions like "Would Jesus drive an SUV?" questions, as a rhetorical device for people to invoke what they see as high principles by embodying them in a prestigious figure.

Of course, I'm personally convinced that Einstein would strongly dislike string theory, and I'll construct a long, detailed argument about why this is true. Well, maybe not today…..

16. **Glenn**
September 19, 2007

In my more depressed moments, when pondering this topic, I wonder, "What if they're right?"

That is, what if the fundamental nature of the universe really is the unprovable 'landscape' or some other critter we can't disprove?

If that's true, we're doomed to an endless search for a 'truth' that lies outside the area we're willing and able to search, like the drunk in the old joke who lost his keys in a dark alley, but is looking for them next to the street because the light's better over here.

I can only hope that "Science" isn't about to hit then end of a centuries-long winning streak…

17. **King Ray**
September 19, 2007

Cheer up, we are just in a long period between paradigms, if you believe Kuhn's The Structure of Scientific Revolutions.

They say that a camel is a horse designed by a committee. I think string theory is physics designed by a committee. The efforts of a large group can never match the aesthetics of a single extraordinary genius like Einstein.

It will take a new idea, probably by a single person, to make the breakthrough needed to have a successful theory of quantum gravity and a unified field theory.

18. **Changcho**
September 19, 2007

Paul Steinhardt said "…if I had walked in the door with a theory not called string theory and said that it is consistent with the observed laws of nature, but, by the way, it also gives a googol other possibilities, I doubt that I would have been able to say another sentence. I wouldn't have been taken seriously…"

Steinhardt is, of course, right. A 'theory' that gives you "a googol other possibilities" isn't scientific, simply because a good science (at least good Physics) puts limits on what is and isn't possible.

19. **anonymous**
September 19, 2007

"This would probably not just make him gag, but send him into a serious fit of depression."

But that's not saying much; it was also true of Einstein and QM.

20. **Eugene Stefanovich**
September 19, 2007

anonymous said:

"But that's not saying much; it was also true of Einstein and QM."

As far as I know, Einstein never questioned the correctness and usefulness of quantum mechanics. He just thought that it is not the ultimate description of nature and that there should be a more fundamental underlying theory. That's why he was reluctant to work on QM.

String landscape is different: it does not explain or predict anything. So, it is questionable whether it belongs to science.

Eugene.

21. **Belizean**
September 19, 2007

And we should not forget that virtually every competent theoretical physicist alive today understands general relativity better than Einstein ever did.

22. **King Ray**
September 19, 2007

Belizean said:

"And we should not forget that virtually every competent theoretical physicist alive today understands general relativity better than Einstein ever did."

That's an arrogant statement. I know of at least one very prominent string theorist who couldn't even write down the formula for the Christoffel symbols in terms of the metric tensor when he was teaching a class on GR.

I don't think anyone today understands GR as well as Einstein did; he invented it, after all. It takes a lot more intelligence and insight to make a discovery than to understand it after the fact. Standing on the shoulders of giants doesn't make you a giant.

23. **Thomas Love**
September 19, 2007

Thanks for the link to the Edge Symposium. For me, the most interesting statement was :

ISAACSON: There's a wonderful book that Einstein wrote called The Evolution of Physics with Leopold Infeld in 1938, which is not easy to find. I've gone over it again two or three times because I just love the way it was written. It was written to make money for both of them, because it's the 30s, and Hitler, and refugees and stuff. It's a popular book, but it has a deep philosophical argument, and the publisher is reissuing the book because I was pushing them to get it out there.

The deep philosophical argument is that it will be a field theory approach that will work. It starts with Galileo; he talks about matter and particles, and just makes the argument that in the end it is all going to be reconciled through field theory. It's about whether there is going to be a great distinction between a field theory and a theory of matter.

24. **Anders R**
September 19, 2007

i wonder if einstein would have gone into theoretical physics at all if he was a 16 year old student who was about to make a choice for college.

26. **Mr. Mustela**
September 19, 2007

The fundamental issue seems to be that no progress has been made in the last 20-30 years on those fundamental questions. The anthropic principle succeeds as a theory by explaining **that failure**, if not much else. As such, it is probably a step in the right direction.

The Woit-Smolin alternative rejects that theory, and instead blames part of the academic system for the failure. Personally, I believe that if there is no promising idea today (as Peter said a few posts ago) then it is unlikely to be the failure of the system. The system is bad, but not that bad. A good idea wouldn't be ignored for that long. Stolen? yes, no problem. But not ignored.

To me, a better approach would be to think of **better** explanations as to why we are making so little progress. If possible, ones with a backdoor to be able to validate them, of course.

In this light, it seems to me that the true value of the anthropic principle has been overlooked. Sure, it is awful from the point of view of getting an explanation of concrete phenomena. But as an attempt to explain the limits of our current methods, it works better than not.

27. **a quantum diaries survivor**
September 19, 2007

Sophia,

you should read "Conversations with Einstein's brain" in "The mind's I" by Daniel Dennett… Appropriate for the current conversation!

Cheers,
T.

28. **Coin**
September 19, 2007

*The anthropic principle succeeds as a theory by explaining **that failure**, if not much else. As such, it is probably a step in the right direction.*

Seems to me like more of an excuse than an explanation, frankly…

But as an attempt to explain the limits of our current methods, it works better than not.

Well, for what reason must we conclude that our current methods have limits at all?

29. **tytung**
September 20, 2007

Chris,

I was trying to say that one should distinguish those features of our world are to be explained in an ultimate theory from those that should not (because they can not). Regarding predictability, I think if it postulates some entity like string, then in principle the theory allows these to have observable effects, albeit one that is technically unavailable.

30. **chris**
September 20, 2007

"The fundamental issue seems to be that no progress has been made in the last 20-30 years on those fundamental questions"

this is definitely false. see e.g. http://relativity.livingreviews.org/Articles/lrr-2006-5/
or also see how far LQG has come. i think we are on the verge of proving the renormalizability of quantized GR. and it might not take a genius but hundred people working out the tedious details in a decade long struggle. better to abandon romantic views of heureka moments that come out of nowhere.

31. **Thomas Larsson**
September 20, 2007

One important thing that Steinhardt points out is that the Landscape is really at odds with observation. If the laws of physics fluctuate throughout the multiverse, there might be some fluctuations already in our observable universe. However, no such fluctuations are observed…

Of course, this is not a hard argument. The fluctuations may take place on length-scales that are much larger than the size of the universe. Nonetheless, this fits well into the standard pattern: whenever some experimental signature is suggested by string theory (susy, extradimensions, laws-of-physics fluctuations, …), you can be sure that it is not observed. Maybe the Lord is trying to tell us something by that.

OTOH, if string theory does not predict a Landscape, it is difficult to see how it can accomodate a nonzero cc 30 orders of magnitude below the Planck scale. So in that case string theory is probably ruled out by observation anyway.

32. **dan**
September 20, 2007

Dear Peter Woit,

How do you feel about Briane Green's contribution, for example,

"…..When you look at the framework within which the standard model of particle physics sits, namely relativistic quantum field theory, you do find that there are a google, if not more, possible universes that that framework is capable of describing. The masses of the particles can be changed arbitrarily and the theory still makes sense, it's internally consistent; you can change the strengths of the forces, the strengths of the coupling constants….."

"…..So how is that any worse than string theory?…."

http://www.edge.org/3rd_culture/einstein07/einstein07_index.html

33. **sophia**
September 20, 2007

Peter,

Sometimes I feel that no matter what I say on a comment, it's misleading.

I wasn't 100% clear, so let me rephrase.

I have no objections to anyone, in any discipline, getting iinspiration in a general way from the great practitioners of their field. So, in that limited sense, "what would Einstein think?" is no big deal. If that helps grease your mental wheels, go for it.

But I do not think that's what's going on here. What is going here is bullshit, desperation and non-thought. It's actively anti-science- not even non-science.

The invocation of the numinous name of Einstein is the dead giveaway. I've noticed that with physicists there's a tremendous amount of prophet-wannabeism, and there are two favorites whose names always seem to pop up when all else fails: Einstein and Feynman. Somehow, Dirac doesn't do the trick….

I don't want to get off a nitpicky thing about Jesus, but since you mentioned him, I'll respond to it, because it underscores further my problems with "what does the master think"-ism.

Invoking Einstein's name when you are out of ideas is much worse than asking whether Jesus would drive an SUV or vote Democratic, because no one knows exactly what Jesus said, there are canonical and non-canonical sources, and so on.

But everyone knows what Einstein said. He left a recorded, written body of work that is unambiguous and free for all who care to, to access.

And that's the reason the business about making "contact with data" and having "the insight of the master as to whether he feels that this smells right" drove me so crazy.

If one of your students said that to you, what would you say to him or her?

If someone came to me and said that, I'd say, "Forget about channeling Einstein. Think your own thoughts. Come to your own conclusions. Make your own damn contact with the damn data. No contact? No data? Think some more."

Am I making any sense to you?

34. **Peter Woit**
September 20, 2007

sophia,

I pretty much agree with you. I don't think the "what would Einstein think?" question is an interesting or useful one.

In my experience, it's not actually a question physicists spend much time thinking about. It's the sort of thing that comes up when someone is looking for a hook that will get the public's interest. Basically Einstein gets dragged into any discussion of any kind about physics, no matter how inappropriate, because people figure that makes the discussion something the public can relate to. It's not a good thing, but relatively harmless compared to lots of other things…

35. **Arun**
September 20, 2007

Peter,

I think Einstein gets dragged into the whole thing because he is supposedly the exemplar of figuring out something about the world purely by power of thought. The implicit assumption in today's research programs is that it is possible to perform similar feats and bootstrap ourselves from Standard Model QFT + GR to a way more comprehensive theory. Whether a given line of inquiry is fruitful is now a matter of taste, and Einstein becomes the arbiter of taste.

36. **Peter Woit**
September 20, 2007

dan,

I really should write up a FAQ and include this issue of "QFT and string theory are on the same footing, lots of both.." Sure, by choosing arbitrary gauge groups, particle representations, etc, you can get an infinite number of QFTs. But the reason QFT makes predictions is that one of the simplest possible such choices works just about perfectly. If simple choices of QFT disagreed with experiment, and you had to go to extremely complicated sets of choices in order to avoid contradicting experiment, never actually getting to anything that you could test, then QFT would be in the same situation as string theory. It's not as simple as just noting the "number of theories".

37. **Anders R**
September 20, 2007

regarding what you've said sophia, i definately agree about the prophet wanabeeism, especially within theoretical physics. i think there seem to be large amounts of name dropping going on, especially among string theorists.

38. **Eric**
September 20, 2007

Simple choices of QFT do disagree with experiment. For example, wouldn't it be simpler for the weak interactions to be described by SU(2) rather than SU(2)xU(1) as originally proposed by Glashow? However, this is not how nature is working. And isn't this whole symmetry breaking business horribly complicated? Wouldn't nature prefrer unboken symmetry since it is simpler? Or shouldn't physics be described by SU(5) instead of SU(3) x SU(2) x U(1)? And why are there three generations when one would be much simpler, and for that matter why doesn't the Standard Model predict the masses of each generation? QFT only makes predictions because there is experimental data available at the low energies at which it is valid. The problem with string theory is that it is a theory which is valid at very high energies, at which experimental data is sorely lacking.

39. **Arun**
September 20, 2007

The problem with string theory is that it is a theory which is valid at very high energies, at which experimental data is sorely lacking.

What high energy experimental data are you looking for? Assume I can accelerate protons and anti-protons to Planck scale energies and collide them. What are the predictions?

40. **Peter Woit**
September 20, 2007

Eric,

Last I heard, string theory was supposed to be valid at all energies…

Very convenient to have your scientific research be on a theory which is not valid at any energy scale we'll ever be able to reach.

I don't claim that the Standard model is the simplest possible choice among gauge theories, I do claim that it is one of a relatively small number of the simplest ones, so one can compare to experiment by looking at a small number of possibilities (not 10^500), which is exactly what people did in discovering the standard model during the 1960s and early 70s.

41. **ScienceLover**
September 20, 2007

> [calling Einstein] is not a good thing, but relatively harmless compared to lots of other things…

That's why it is funny as if it were some sort of a sketch: 3 men are discussing theoretical physics. Then they get stuck. Silence. They look at each other and after a while one of them breaks the silence: "What would Einstein say?" The discussion recovers and although it was at a dead end one of them claims that Einstein would be certainly impressed by the great theory he and his colleagues worked out.

42. **Eric**
September 20, 2007

Peter,
If you read my comment very, very closely you'll see that I state that string theory is valid at high-energies as well as low energies where it should reduce down to conventional QFT. What string theory does is unify QFT with a perturbative formulation of quantum gravity. As such it is much more ambitious than QFT. However, the situation today is no different than if you had a formulation of QFT, but didn't know anything about the weak or strong interactions. There is no possible way to deduce the standard model from QFT alone.

43. **Peter Woit**
September 20, 2007

Eric,

No, you can't deduce the standard model from pure thought about QFT alone. You have to learn how to calculate things in tractable QFTs, compare to results of experiment, identify the right QFT, then make predictions and test them.

In string theory what you are doing is doing calculations in tractable string theories, comparing them to experimental results, seeing they don't agree, trying for 25 years to find some way around this and failing, then, instead of giving up and trying something else, telling everyone that the problem is just that it's "too early to tell", you need to do more calculations (10^500), and then maybe it will work. And trying to also tell people that the problem is those damn low energies, that surely at unmeasurably high energies your calculations would agree with experiment.

44. **Eric**
September 20, 2007

Peter,
You are presupposing that experimental data exist to guide you to identify the right QFT. The problem for the last 25 years has been a lack of any experimental data at energies a magnitude above the EW scale. Once this data is available, hopefully from LHC/ILC, this situation will change drastically. I sometimes wonder if this isn't why you seem so excited anytime there is a rumour of a delay in starting up LHC. Such a delay gives you that much more time before things come crashing down.

45. **Peter Woit**
September 20, 2007

Eric,

There's plenty of experimental data out there to guide people trying to do unification, the problem is string theory can't reproduce it.

Funny how you think the electroweak scale is the problem, that string theory has something to say just above the electroweak scale, but not below it. That's nonsense.

I in no way think a delay in the LHC is a good thing. Quite the opposite. Any delay just delays the date at which the standard nonsense about finding evidence of string backgrounds in LHC data comes crashing down.

46. **Eric**
September 20, 2007

Peter,
Yes, string theory can describe the current low-energy data below the weak scale and there is at least one string model which does so. The question of whether or not such models may uniquely predict the parameters of the standard model is presently unanswered. For this, the problem of moduli stabilization must be completely addressed and this is where a lot of the current work is focused. In this respect, string theory is currently no better than QFT.

47. **Anders R**
September 20, 2007

"You are presupposing that experimental data exist to guide you to identify the right QFT. The problem for the last 25 years has been a lack of any experimental data at energies a magnitude above the EW scale"

maybe the experimental data is there, but the theoretical phycisists who are working on it right now just aren't competent enough to work out what it is.

48. **Anders R**
September 20, 2007

sorry peter i didn't see that you wrote almost the same thing

49. **David B.**
September 20, 2007

Dear Peter and Anders:

Saying there is plenty of data out there to guide people trying to do unifcation is not accurate. The current situation is like trying to find New York City by the following algorithm:

it's not London, it's not Paris, It's not Geneva,…

Any model of high energy physics will impact the low energy physics by the addition of non-renormalizable couplings. This is at best an indirect measurement. Most of these are beyond current experimental bounds (meaning experiments are consistent withthe standard model), and this fact only indicates that either the unification scale is too high to see, or the correct theory has a huge conspiracy to cancel all possible signatures in the low energy physics.

As it stands, this does not give you any information on what the theory is, but it definitely gives you a lot of information on what it is not.

50. **Amos Elberg**
September 20, 2007

Einstein got "dragged" into the thing because the thing is a symposium about Einstein. An Einstein tribute. I think its entirely appropriate during such a symposium to ask other physicsts what Einistein would have thought. The ensuing discussion is pedagogically useful.

51. **Peter Woit**
September 20, 2007

Hi David,

My point about unification wasn't that there's a lot of information about beyond the standard model physics. There certainly isn't, and that's a huge problem. But the standard model itself is both extremely well tested, and has quite a few features that we don't have an explanation for. All I meant is that any idea about unification should explain one or more of these features in a convincing way. The fact that string theory doesn't do this, but instead has turned into a set of excuses about why it's impossible to explain such things, is for me the main reason to be skeptical about it.

52. **dark-matter**
September 20, 2007

We now have Prof Steinhardt, a scientist of considerable stature, clearly stating the string landscape of googles is unacceptable to science. The implication of this to string theory itself has been laid out in this thread. He knows he is speaking to the large community of string theorists. He should also know he is indirectly speaking to the funding agencies. The message is: if you believe it is unacceptable, then you should do the right thing. If you are a researcher, move on. If you are responsible for funding, also move on. He is on your side.

53. **?**
September 21, 2007

Prof. Steinhardt may have considerable stature with some people, but after his ekpyrotic and cyclic clowning, it isn't with serious particle or gravitational theorists. He is actually selling his own competing "theory" in his rants against string theory.

54. **Eugene Stefanovich**
September 21, 2007

? said:

He is actually selling his own competing "theory" in his rants against string theory.

Is it a bad thing? Isn't it the job of theorists to produce and sell theories?

Eugene.

55. **chris**
September 21, 2007

for those of you who claim that over the last 25 years there has essentially been no discoveries in experimental hep, let me briefly remind you about the following:
.) discovery of W and Z
.) discovery of the t quark and its mass
.) lower limit on SM higgs of 115 GeV (beyond treelevel susy!!)
.) flavor mixing in the b meson sector
.) neutrino masses and mixing (making a perturbatively renormalizable SM contradict experiment!!!)
.) cmb fluctuations
.) measurment of the deceleration parameter, baryonic and dark matter/dark energy densities
.) measurment of muonic g-2

that's a lot i would say.

56. **chris**
September 21, 2007

oh, and i forgot the spectacular LEP Z-pole data.

57. **Peter Orland**
September 21, 2007

Chris,

Most of these experimental results were anticipated. I think the only one on your list which does suggest some really new physics is neutrino mixing (whose details are not yet fully determined). Maybe muonic g-2 could also lead to something.

Exciting experimental discoveries are those which nobody or only a few people expect. I am not denying that it is necessary to look for anticipated results, but they don't make me jump up and down.

58. **chris**
September 21, 2007

dear peter,

i largely agree with you. but i want to point out, that the absence of new particles per se is not always totally unexciting. for example, would you really have anticipated, that all the LEP Z-pole data and b-meson CP violation would be compatible with the SM? in 1983, would you really have made a bet that the higgs was heavier than 115 GeV? that the top was even heavier? that there will be no baryon number violation detected at all?

of course in some way this is anticlimactic, but it is extremely surprising (at least to me) that the SM describes data so well.

59. **Arun**
September 21, 2007

On the other hand, the SM does not describe the majority of the mass/energy in the universe.

60. **Brett**
September 21, 2007

The detailed data is surely very interesting, and it does tell us quite a bit that we didn't know before. However, most of what it is telling us is that the theory we already had worked out is good to quite a bit higher energy scales than we might have expected. We learn a lot about physics at higher scales, but what we learn is that there isn't anything new there. Hence, the experimental data, while providing information, provides no positive guidance about what the new physics should be.

For what it's worth, the particular measurements that I would pick out as telling us useful negative information about low-scale new physics are: the stability of the proton (which is a really strong condition on GUTs), CP tests with B mesons (which find nothing other than CKM effects, strongly constraining superweak theories), the large masses of the top and Higgs (since they place strong constraints on supersymmetric unification), and neutrino oscillations. The last one may sound odd, since it is really evidence of new physics, but the new effects are limited to the neutrino sector. The smallness of the observed neutrino masses suggests (via the see-saw mechanism) that the scale at which new fundamental physics enters is large.

61. **dark-matter**
September 21, 2007

To: ?

Prof Steinhardt joins the group that says string theory biggest 'prediction', an infinite solutions of physical reality for our single universe, is not only clearly dead end, it is absurd. It is not science and implies those who continue to pursue it is folly. Of course, every expert has all the rights to choose to be folly. But not on taxpayer's money. Prof Steinhardt credibility, his scientific output, and his various professional engagements, are such that it is folly of me to engage seriously with your assertion.

62. **David**
September 21, 2007

Arun made an interesting comment about the SM not describing dark matter/energy. I can't see how we can have a TOE at least until we have more information about dark matter/energy. Have I missed something?

63. **Coin**
September 21, 2007

I can't see how we can have a TOE at least until we have more information about dark matter/energy. Have I missed something?

I'm really not the person to ask, but I think the idea is that hopefully a TOE today would *predict* what the information about dark matter/energy is eventually going to tell us, once we have the technology to collect that information– or, at least, the TOE might offer us some *possibilities* about what sort of thing dark matter/energy might be, which we would then be able to select among.

This might be a little too optimistic, but it's maybe worth a shot. Occasionally in the past theoretical physics has managed to jump ahead of theoretical physics in a similarly spectacular fashion, and anyway, we do have *some* indications about dark matter/energy's nature, if not its details.

64. **hyans**
September 22, 2007

> Three years ago I expressed the opinion that the promotion of the anthropic landscape would make Einstein gag, which so upset Joe Polchinski that he used this to argue that trackbacks to my blog should not be allowed on the arXiv (even though this was not about an arXiv paper, but a Scientific American article).

So this is, then, the solution to the trackback mystery? I don't know if it was reported before here or elsewhere, but it's probably news to many people besides myself. Interesting story. Probably interesting only at the anecdotal level, but interesting nevertheless.

65. **Peter Woit**
September 22, 2007

hyans,

Can't say that I really know what the "solution to the trackback mystery" is. I was referring to the blog comment of Polchinski here:

http://golem.ph.utexas.edu/~distler/blog/archives/000760.html

Privately I've heard that there is more to the trackback mystery than that Jacques Distler hates me because of my criticism of string theory. And if you take a look at the trackbacks attached to papers promoting the anthropic landscape, I don't recall noticing any critical ones being allowed. Somehow though, I doubt that this effort at censorship is particularly effective, since anyone who reads physics blogs has probably come across me explaining my views on this far too often.

Anyway, I've long ago given up on fighting this particular issue, on the grounds that it's a waste of time. The amount of dishonesty exhibited by the people involved was quite an eye-opener for me.

66. **Ori**
September 22, 2007

Peter said

" But the reason QFT makes predictions is that one of the simplest possible such choices works just about perfectly. If simple choices of QFT disagreed with experiment, and you had to go to extremely complicated sets of choices in order to avoid contradicting experiment, never actually getting to anything that you could test, then QFT would be in the same situation as string theory "

This is complete nonsense. According to what you decide that SM is amongst the simple gauge group ? it is actually one of the complicated ones !! There many many theories, much much simpler than SM and they don't describe nature. It is not 5 or 10 theories simpler than the SM , it is infinty !

For instance, if we say that a guage theory is simple if its perturbative expansion is simple, which is pretty well defined criterion than clearly infinitely many SUSY theories are much simpler than the SM.

There are severe inconsistencies, like the one I point out here, in all Peter's claim. I wonder what Einstein would think of Peter 🙂

67. **Marion Delgado**
September 22, 2007

If that's your criticism, you shouldn't imply with the title of your book and blog that you're depending on Popper's criterion. I realize it started with Pauli, but the fact is that in the modern era saying something is not even wrong in science usually denotes a "falsifiability" criterion. There are some common uses of "not even wrong" that don't apply to string theory, as well.

The "moribund research programme" approach is pegged to Lakatos, and his model of H&SS is very different from Popper's. I think it's particularly well-suited to string theory. There are some things that would have falsified string theory, as well as other theories we regard as more parsimonious. Moreover, it may be that the earliest formulations have basically been falsified, which is a secondary reason (behind the desire to cover more territory) why the paradigm (not really AN hypothesis or A theory) had to morph so many times.

Actually the old saying that i think fits better is that it has ideas that are original and valuable. But the ones that are original aren't valuable and the ones that are valuable aren't original (or unique to string and brane theories). Like intelligent design, string theory now has become a follower – faced with a success by a competing theory, it says, we can model that, and does so. Every once in a while it cannot, at which point more degrees of freedom are introduced.

68. **Peter Woit**
September 22, 2007

Ori,

I guess we'll just have to disagree about whether SU(3)xSU(2)xU(1) is among the simplest possible choices of gauge groups. But what there is no way to argue about is that the Standard Model is the most accurately predictive physical theory ever, and string theory predicts absolutely nothing at all. If you want to explain why this is really very much the same thing, go right ahead…

69. **Ori**
September 23, 2007

Peter, I did not meant to argue what is the simplest gauge group (that was a typo). This is not a good physical question. It makes much more sense to argue what is the simplest physical theory. Namely, which one has the most elegant structures. Of course, there are many many QFTs with various non trivial constraints on their perturbative and non perturbative phenomena, so they are much simpler than the SM. There infintely many such theories.

Hence, the whole argument of Peter does not make any sense.
Now a different issue is that the SM fits experiment, that's of course correct. However, suppose there were no experiments during the 70's and early 80's, then there would be some PW who would claim that QFT does not make predictions, since it proposes infintely many consistent universes, and many more parameters have to be tuned. Of course, the only constraint, lacking experiments would be that the theory has to include QED. That is rather easy to do, so there are still infinty possibilities.

This is exactly the situation in string theory, no significant experiments (besides one – the cosmological constant) and many models, some consistent others not.

70. **Peter Woit**
September 23, 2007

Ori,

In your analogy, you're assuming that we had QED, the simplest gauge theory, which was extremely successful experimentally. There is nothing like that in string theory. If the simplest version of string theory accurately described most physical phenomena to 10 decimal places, we wouldn't be having this discussion.

71. **Ori**
September 23, 2007

My analogy does not assume anything.

I used QED as an example for the fact that although people knew it is there, there were still infinitely many QFTs consistent with that. Thus, PW would claim that QFTs don't make predictions since there are infintely many consistent examples, non is testable at present etc.

In string theory there is a perfect analogy : string theory PREDICTS that the low energy theory, whatever it is, contains QFT. Yes Peter, it is a prediction of string theory whether you like it or not. Moreover, it actually is a YM theory. However, there are infintely many examples in string theory which reduce to QFT and in particular the SM but there is no experiment to tell which one is correct.

I assure you all that logically the situation is one and the same, what is different is that in one case experiments could decide quite fast what is the correct theory among the infintely many good choices and in the other case, it may take longer, and nobody knows how longer, and also in QFT, it could in principle take much more time before people discovered which microscopic theory gives all these non renormalizable operators.

72. **Peter Woit**
September 23, 2007

Ori,

Again, sure, if you look at all possible gauge theories extending QED, you're not going to get predictions. If you look at gauge theories extending QED, and restrict attention to the simplest ones, you get a finite number of possibilities, ones you can analyze and compare to experiment. It turns out one of them is a huge and fantastic success.

The problem with string theory is that the simplest string theory doesn't look anything like the real world. You can't start with it. Instead, you have to keep adding complexity to it to get agreement even with the gross features we observe. The state of string theory now is that, just to avoid basic contradiction with experiment, people have been forced to look at such complicated versions of string theory that they are looking at essentially infinite classes of theories, of such complexity that they can't accurately calculate much of anything. This is a failed research program, failed because it tried to do what theorists always do when they investigate a new idea, but it didn't work. What theorists always do with a new idea is look at the simplest versions of it, the ones they can analyze the implications of, then compare to experiment. Sure, if they get disagreement, they try and look at more complicated versions. But, sooner or later, if things just get more and more complicated and you never predict anything, you have to give up and admit failure. The only unusual thing about this story is the refusal to admit failure.

I'm sorry, but I really think that some string theorists such as yourself have gone over the deep end. You are claiming that two opposite poles of science, spectacular success (the SM), and utter failure (the landscape), are logically the same thing. This is only true in the sense that black is a version of white.

73. **?**
September 23, 2007

Actually what theorists do (at least the good ones) is try to describe something about the world, that seems interesting.

In a totally different subfield (to avoid the usual idiotic bickering about string theory), condensed matter theory, theorists have worked now for 25 years to try to understand high temperature superconductivity. They have, by and large, failed. That is because it seems to involve numerous intricate behaviors that doped cuprates can exhibit, which may require an understanding of dualities, dynamics, and materials that we don't have yet.

This doesn't mean that the subject of condensed matter theory is a failed, dead end. It means the theorists are struggling with a hard problem.

I suspect the same is true of string theorists.

74. **D R Lunsford**
September 23, 2007

?,

Good point, and you make Peter's, because that field, like the standard model, is phenomenology backed up by hard observations and a tractable theoretical expression. Like the SM, the limits of phenomenology show up – without a fundamental model, there is little to suggest which way to turn. Phenomenology is by its nature exhaustive – it uses up its good start and eventually bumps up against its inherent limits. That doesn't make it wrong – it makes it honest. It doesn't make it a failure. It just means there is more work to do.

-drl

75. **observer**
September 23, 2007

> I assure you all that logically the situation is one and the same, what is different is that in one case experiments could decide quite fast what is the correct theory among the infintely many good choices

And what is, exactly, the experimental data that would be needed to decide what is the correct *string* theory?

76. **chris**
September 24, 2007

ori,

"For instance, if we say that a guage theory is simple if its perturbative expansion is simple, which is pretty well defined criterion than clearly infinitely many SUSY theories are much simpler than the SM."

this is another piece of priceless anthropic argumentation. there are so many out there in hep. let's recount a few:

.) the gut/planck scale is so high up that we can't reach it in laboratories. extra dimensons bring it down to a convenient few TeV. this is a success of extra dimenions.

.) gravity seems to have a non-gaussean uv fixed point. but we really can't deal with nongaussian fixed points. let's just abandon the approach and invent something else.

at least in qcd, we have sucessfully defeated this nonsense. qcd is firmly established in the nonperturbative sector and techniques have been developed to deal with it. we no longer need phony fundamental strings or s-matrix theory with nothing behind.

your statement is firmly in this category. it's difficult to compute, so let's just take a simpler to compute theory.

let me tell you, that i do think exactly the opposite of what you stated. a theory that is structurally simple but has a host of interesting phenomena (like e.g.QCD) is a much more promising candidate than a theory that adds extra degrees of freedom just to make it more convenient for the hotshot theorists to crank out paper after paper with minimal effort of developing new techniques/insights/understanding.

77. **Coin**
September 24, 2007

> In a totally different subfield (to avoid the usual idiotic bickering about string theory), condensed matter theory, theorists have worked now for 25 years to try to understand high temperature superconductivity. They have, by and large, failed.

This seems kind of different considering that we *know*, experimentally, that high-tc superconductors exist.

78. **non_linear**
September 24, 2007

High Tc Superconductivity is one of the most interesting cond. mat. phenomena but this doesn't mean that every con.mat. theorist deals with it. There is so many topics in con.mat. where there have been major advances in the last 25 years. Spin glasses, Bose-Einstein Condensation, nano physics, non-linear effects etc. etc. And at least we do have a very well microscopic theory (BCS) that explains
low -temp superconductivity ….
I miss anything similar to the achievements of cond.mat. theory in string theory so i'd be cautious do draw analogies between these two fields.
But again many string theorists seem to actually believe that string theory actually can explain superconductivity (Polchinksi being the most prominent i think) so I 'm actually waiting for a cond.mat. paper with title "Non-perturbative M-theory of the cuprates" or so to have a good laugh …

79. **Peter Shor**
September 24, 2007

As somebody who knows information theory, I want to say that I don't think it makes any sense to say that there are an infinite number of theories less complicated than the Standard Model, unless you have some fairly contrived definition of "less complicated." The Standard Model can be described (assuming adequate mathematics and physics background) in just a few pages. Using the Kolmogorov complexity criterion for simplicity, any simpler theory would need to have a shorter description. This still leaves lots and lots of theories with shorter descriptions (although many of these are not consistent), but only a finite number of them.

I suspect you could come up with a definition of "less complicated" in which any string theory measures up as less complicated than the Standard Model, but in this case you are definitely stacking the deck.

80. **?**
September 24, 2007

I would say we know that gravity and quantum mechanics exist
and are looking for a way to reconcile them as well. The fact that
the high-T_c guys have much more data, can do hands on
experiments, and still are stuck, just shows how hard the problem
high energy theorists are grappling with is. Luckily, there will
be new experimental data very soon.

81. **Thomas Larsson**
September 24, 2007

Ori (Ganor?), there have been a lot of significant experiments testing string theory signatures, e.g. supersymmetry (SPS, Tevatron, permanent electric dipole moment, muon g-2, proton decay) and extradimensions (deviation from Newton's law at short scales). It is just that these experiments haven't found anything. Like the Michelson-Morley experiment didn't find the ether wind.

82. **observer**
September 25, 2007

> I would say we know that gravity and quantum mechanics exist and are looking for a way to reconcile them as well. […]Luckily, there will be new experimental data very soon.

"?", what experimental data will allow us to reconcile gravity with QM? I guess by "very soon" you must be referring to the LHC. Will the LHC, according to you, provide enough data to unify gravity and QM?

83. **Eric**
September 25, 2007

Observer,
If LHC discovers supersymmetric partners, then one can look at local supersymmetric models, otherwise known as supergravity which naturally finds its home within string/M theory. Is this not a unification of gravity with QM (in fact the only viable unification currently known)?

84. **Thomas Larsson**
September 25, 2007

> If LHC discovers supersymmetric partners…

Ah, but supersymmetry will not be discovered at the LHC. I have given a rigorous proof showing that it is impossible. Didn't you know that? 🙂

85. **David**
September 29, 2007

Hey, been reading your site for awhile now Peter Woit and I was wondering what theory you favour ?
Is there any credible scientist out there who believe in ONE universe and not MWI/String/Mtheory etc?

86. **JE**
October 1, 2007

Slightly off-topic, but I saw Steinhardt, Ovrut and Turok explaining their ideas on cyclic cosmology late on Saturday night as Malcolm Clark's 2002 "Parallel Universes" BBC documentary was broadcast on Spanish TV. Besides their train ride to London, where they came up with the idea of a cyclic universe (which they characterized as a sort of cathartic moment of artistic creation, as if they had effectively uncovered some hidden truth), it was amazing to see how Lisa Randall's climbing skills were mixed up with the quest for the 11th dimension, brane collisions, the multiverse idea and other tentative proposals to produce such a piece of hype for string theory, supergravity, braneworld scenarios and speculative physics in general. Not that anything in all that mix-up of ideas can not be found to have any connection with the real world in some very distant future, but the dishonest way in which all this stuff was sold off, without even adding the word "tentative" or "speculative" before dispatching it to the layman, really appalled me.

The Wall Street Journal on the Tate Conjecture

September 25, 2007
Categories: Uncategorized

This is not a very timely posting, since my readers let me down by not telling me about this when it came out. Last month the Wall Street Journal ran a piece by Lee Gomes about a workshop on the Tate conjecture held recently at AIM, the institute now housed in Palo Alto behind Fry's Electronics, at some point to move to its own castle. The piece was entitled Math Whizzes at Conference Prove Just How Exciting The Tate Conjecture Can Be, and it gave a good feel for what a math workshop looks like to an outsider. The full piece is not available on-line, but the MAA *Math News* has an article that quotes much of it.

I noticed two inaccuracies in the piece. It begins with:

> One is tempted to feel sorry for mathematicians. In contrast to, say, physicists, mathematicians don't have their own Nobel Prize; they rarely get hired by hedge funds; they don't have grand toys like particle accelerators to play with; and their work is usually so recondite that not even their families understand it.

This is pretty accurate except for the part about hedge funds. I know quite a few mathematicians who have gone to work for them, and at some of them mathematicians form a sizable fraction of the people holding so-called "quant" jobs.

At the end of the piece there's the news:

> Progress, though, was made. V. Kumar Murty, of the University of Toronto, said that as a result of the sessions, he'd be pursuing a new line of attack on Tate. It makes use of ideas of J.S. Milne of Michigan, who was also in attendance, and involves Abelian varieties over finite fields, in case you want to get started yourself.

Milne has recently posted an article on the arXiv (also available on his web-site here) that corrects this, noting

> This becomes more-or-less correct when you replace "Tate" with the "weak rationality conjecture".

Milne's article is actually a write-up of his talk at the AIM workshop, and it does an excellent job of surveying the state of what is known about questions related to the conjecture.

I was going to try and put together some explanation of what the Tate conjecture says and how it relates to other parts of mathematics, but since this is a tricky business, and since experts who really understand this have already done a better job elsewhere than I could ever do here, I'll mostly just provide links.

The Tate conjecture is an analog for varieties over finite fields of one of the Clay Millennium problems, the Hodge conjecture, which deals with the case of varieties over the complex numbers. For a popular discussion of this, there's a nice talk by Dan Freed on the subject (slides here, video here). In the number field case there's another Millennium problem analog, the Birch and Swinnerton-Dyer conjecture. For a popular discussion of this, there's a video of a talk by Fernando Rodriguez-Villegas (who has a blog here).

These conjectures all revolve around the idea that it should be possible to relate three apparently different mathematical objects associated with an algebraic variety:

- The space of algebraic cycles in the variety, modulo some equivalence relation
- Certain cohomology groups associated to the variety
- The order of a pole in the zeta-function of the variety

There's no evidence we're close to a proof of these conjectures, but there are many partial results and the conjectures can be proved in certain special cases. Experts seem convinced of the truth of these conjectures despite the lack of proof, one reason being that they fit nicely into the general philosophy of "motives" first promulgated by Grothendieck. One expert on the Tate conjecture, when asked about the probability of it not being true, responded something like: "Don't be silly. It's true."

For more about the Tate conjecture, there are two documents put together for the AIM workshop that may be helpful: an expository piece for a wide audience here, and a technical summary of the workshop here.

Comments

1. **Clark**
   September 25, 2007

   Thank you for your reference to the talk of Prof. Milne, to whom it is always worth paying attention .

   I note from this source that he is not convinced of the validity of the Tate Conjecture, at least in full generality:

   "ASIDE 6.4. The Hodge conjecture is known for divisors, and the Tate conjecture is generally expected to be true for divisors. However, there is little evidence for either conjecture in higher codimensions, and hence little reason to expect them to be true. On the other hand, Deligne expects his conjecture to be true. "

2. **JP**
   September 25, 2007

   Tate conjecture?

   Seems like esoteric mathematics … probably doesn't have much to do with theoretical physics. But thanks anyhow for the post.

   JP

3. **Matt Daws**
   September 26, 2007

   "they rarely get hired by hedge funds". Yep, as you say, the writer clearly has never heard of Jim Simons for example.

4. **Thomas Love**
   September 26, 2007

   Since I had already read this entry, I decide to check out the links you provide in the right hand column. I went to each of the sites under String Theory Weblogs and found discusisions of The Bionic Woman, How to do slide shows, The Beijing Jazz festival, A proposal for a new theme new website, The Cosmic Climate link, a site last

updated on Dec 5, 2006, The fun of cleaning up, another
site last updated on Dec 5, 2006, and a site in Spanish, which I don't know. I have to conclude that there is not much progress being made in String Theory. Surprise, Surprise, Surprise.

5. **Jim Clarage**
   September 26, 2007

   The video link to Dan Freed's talk didn't work for me. The link to it from the main Clay video page:

   http://www.claymath.org/video/

   does appear to work.

   ps,. thanks for the respite from the landscape. These popular/survey links are always appreciated.

6. **woit**
   September 26, 2007

   Thanks Jim,

   Link fixed. Now if only my postings on things like the Tate conjecture would draw 100 comments…

7. **SnarkFest**
   September 26, 2007

   Jim Simons wasn't *hired* by a hedge fund. He *started* one. Right?

8. **Tom Whicker**
   September 28, 2007

   Instead of String Theory, it should be "The Susskind Conjecture".

From Fermilab to Equivariant Cohomology

September 28, 2007
Categories: Uncategorized

Various things of interest, ordered in terms of increasing mathematical content:

This week Fermilab has hosted a P5 meeting and an annual program review.

At the P5 meeting, Fermilab director Pier Oddone made the case for planning to keep running the Tevatron through FY 2010. He pointed out that the current LHC schedule has "no float" for any possible delays in putting the hardware together, and only allows for 3 months between first beam and physics collisions, drawing the conclusion that it was unlikely the LHC would have physics results competitive with the Tevatron before the currently planned closure date of September 2009. Presentations from D0 and CDF claimed that, if the machine runs through FY2010 and provides them with a projected luminosity of 6.8 fb^{-1}, they should be able to exclude the possibility of existence of the Higgs at 95% confidence level over almost the entire possible range of Higgs masses (if it isn't there!) or find 3 sigma evidence for its existence in some mass ranges (if it is).

At the program review, there was an overview of particle theory at FNAL from Andreas Kronfeld, and a presentation about the LQCD lattice gauge theory project from Paul MacKenzie. Several interesting documents reviewing the state of the lattice gauge theory work are here.

Over the last few months I've often told myself that I should learn more about Howard Georgi's ideas concerning "unparticles" and try and write something about them. Sabine Hossenfelder has saved me the trouble, you can learn about this here.

Last month there was a symposium at Durham on Twistors, Strings and Scattering Amplitudes, a subject which has seen some exciting activity recently. Zvi Bern reviewed progress on computing multi-loop amplitudes in N=4 gauge theory and in gravity theories. He noted that the recently found unexpected one-loop cancellations in N=8 supergravity (leading to the so-called "no triangle hypothesis") are not due to supersymmetry and are already there in non-supersymmetric gravity. This leads him to conjecture that other gravity theories will be perturbatively finite, he explicitly mentions N=6 supergravity. Nathan Berkovits discussed multi-loop superstring amplitudes in the pure spinor formalism, ending up by noting that there are possible problems caused by needed regularization of ghosts in this formalism, and they affect high-energy contributions to the 4 point 3-loop amplitudes. Not that I'm saying I think this will happen, but it would be pretty damn funny if it turns out that multi-loop superstring amplitudes aren't finite, multi-loop supergravity ones are…. There's also a talk by Jacques Distler, who continues his ceaseless quest to figure out how to make physics available over the web in a form that no virtually no web-browser can display properly.

Finally, I strongly believe in advertising equivariant cohomology as much as possible, for mathematicians and for physicists. The new lecture notes by Matvei Libine are a good place to read about it.

Comments

1. **JC**
   September 28, 2007

   Could it be that the pure spinor formalism is just showing its limitations and shortcomings, as opposed to the string multiloop amplitudes being genuinely nonfinite?

2. **Peter Woit**
   September 28, 2007

   JC,

   Sure, it could just be a problem of the formalism, and in any case maybe even within that formalism it can be dealt with. What's interesting though is that, at higher loops, the standard ideology "string amplitudes finite, (super)gravity infinite" may very well be wrong. Hard to be sure until, in both cases, the amplitudes are better understood.

3. **JC**
   September 28, 2007

   If somebody ever calculates the correct 3-loop superstring amplitude (or higher) expilicity and it is shown to be genuinely nonfinite, then I wouldn't be surprised if this ends up being the last nail in the coffin for string theory.

4. **DB**
   September 28, 2007

   Nobel Laureate Martin Veltman gave an interesting public lecture (not sure how old it is – doesn't appear to have been mentioned here before, my apologies if it has) where he offered his highly sceptical opinion (in decreasing orders of scepticism) on string theory, supersymmetry, the cosmological constant and the Higgs mechanism in the context of a proposal to motivate the construction of an 800GeV linear collider in Hamburg as a successor to the LHC.
   It doesn't require specialist knowledge and contains interesting remarks about the US direction in particle physics. A video of it is here:

   http://pauli.physics.lsa.umich.edu/w/arch/som/sto2001/Veltman/real/n001.htm

   It makes for an interesting comparison with his co-laureate and student Gerhard 't Hooft (who also gives excellent public lectures, by the way) who is quoted in the recent Physics World article as advising physicists to keep such debates out of the public arena.

5. **Thomas Love**
   September 28, 2007

   "Unparticle" physics remind me of the uncola. But it makes me think that perhaps string theory should be called particle "unphysics".

6. **Peter Orland**
   September 29, 2007

   Thank you, DB.

   I checked out Veltman's lecture. Though I think his momentum-space
   suggestion is totally wrong, he has framed the current state of physics
   and its problems in a very sensible way.

7. **Kris Krogh**
September 29, 2007

That Veltman lecture was 2001, before this blog existed. Courageous stand against string theory for that time. Peter, I know cosmology doesn't interest you as much, but I hope you also heard his remarks on that topic and general relativity.

8. **Kris Krogh**
September 29, 2007

If you use this link, you can view the video and slides for Veltman's lecture simultaneously.

9. **Luzo**
October 1, 2007

Veltman also makes some nice comments at a lecture I once saw at the CERN library. He was very vocal and corrosive regarding string theory. He basically said that he only trusts things that calculate things (something like this).

I don't know whether these comments were made before or after this lecture.

10. **Bee**
October 1, 2007

Hi Peter,

Thanks for the link, I only just noticed. Yes, the unparticle stuff is a fairly weird development. I'm not planning on looking closer into it though. Some of the comments to my post are also interesting in this regard.

Best,

B.

11. **Doug Natelson**
October 1, 2007

I have a silly, naive question from a condensed matter person…. It seems like "unparticles" are the HEP equivalent of a condensed matter phase that simply isn't well-described in terms of quasiparticles. For example, when Fermi liquid theory fails in some strongly correlated electronic materials (e.g. the "local moment" phase in heavy fermion compounds), there appears to be no simple description of the low energy excitations of the resulting phase, at least not in terms of weakly interacting quasiparticles with simple quantum numbers like momentum and angular momentum. Is that basically the idea here?

12. **JE**
October 2, 2007

Concerning the searches for Higgs and supersymmetry at the Tevatron, the D0 and DF teams have just submitted a joint paper about their status. As stated in its conclusions, "the `hint´ of an MSSM Higgs boson at m_a around 160GeV obtained by CDF was not confirmed by D0". In other words, no Higgs or SUSY so far. This is the link:

http://arxiv.org/PS_cache/arxiv/pdf/0710/0710.0248v1.pdf

13. **a quantum diaries survivor**
October 2, 2007

JE,

the proceedings you point to do not include the most recent results. CDF has a new result for MSSM Higgs blessed for both the bbH->bbb(b) and the H->tau tau searches. These update previous results based on half the statistics.

As far as the former goes, it is reported in my blog – I wrote about it a month ago. The latter, although blessed, is not accessible online yet to my knowledge. I did write about it today, but I left out the results, because I prefer to leave a chance to the authors to do that first. In any case, your conclusion does hold.

Cheers,
T.

14. **Shantanu**
October 3, 2007

DB, thanks for the link to Veltman's talk . He certainly has non-conventional povs about validity of GR and there are also interesting discussions at the end.
Peter , what do you think of the talk? Has Veltman read your book or have you
corresponded with him regarding string theory?
Thanks

15. **Peter Woit**
October 3, 2007

Doug,

I was hoping someone knowledgeable would answer your question. I haven't looked closely at what Georgi is doing, but assume you're basically right, that the point is that there are field-theoretic phenomena not describable by particle-like excitations.

Shantanu,

Haven't had a chance to look at the Veltman talk. I corresponded a little bit with him when I was trying to get the book published, and he was quite sympathetic. I'd suspect my more mathematical point of view is not to his liking, but that's he'd agree with much of the critique of string theory. I had the pleasure of meeting him once when I was a postdoc at Stony Brook, and found him to be quite an impressive character.

Scientists Ask Congress To Fund $50 Billion Science Thing

September 28, 2007
Categories: Uncategorized

The latest issue of the Onion has some HEP-related coverage. It includes a nifty graphic, and has this inspirational message from one of our congress-people

> “Now, I’m no science major, but if I’m being told by a group of people that the protons, neutrons, and electrons need unifying, then I think we owe it to the American people to go in and unify them,” Rep. Mark Udall (D-CO) said. “After all, isn’t a message of unity what we want to send to our children?”

Comments

1. **Chris Oakley**
   September 28, 2007

   The graphic looks like a Tokamak to me. So all that High Energy Physicists need to do is to claim that Synchrotrons, like Tokamaks, are a stepping stone to solving the world’s energy problems and funding will be secured.

2. **Yatima**
   September 28, 2007

   People actually have time to read the Onion?

   Well, this is clearly the International Torus Experimental Reactor (ITER):
   http://www.sbf.admin.ch/htm/themen/international/euratom_de.html

   You can even see a loop or glowing closed string in the cavity. I will get my coat now.

3. **Paulo Guerra**
   September 28, 2007

   Hi, I’m from Brazil and I thought only brazilians politicians give declarations like that.

4. **hmmm**
   September 29, 2007

   This is a must read for all high energy physicists.

   I don’t think it’s funny. I think it’s a good look in the mirror for a lot of people who have forgotten that; ultimately, we serve at the pleasure of the public.

   We won WWII and fueled myriad technological advancements. We deserved the MASSIVE govenment welfare programs we currently enjoy (NSF, DOE, national labs….).

   When high energy physics lost contact with the real world, and even the hope of gaining any tangible benefits started to fade….the funding started to fade.

   Now HEP is lost in the multiverse….WTF.

5. **retardigrade**
   October 2, 2007

   “While expense is something to consider, I think it’s very important that we have this kind of scientific apparatus, because, in the end, I have always said that science is more important than it is unimportant,” Committee chairman Rep. Bart Gordon (D-TN) said. “And it’s essential we stay ahead of China, Japan, and Germany in science. We are ahead in space, with the NASA rockets going to other planets, so we should be ahead in science too.”

   “These scientists could trim $10 million if they would just cut out some of the purple and blue spheres,” said Rep. Roscoe Bartlett (R-MD), explaining that he understood the need for an abundance of reds and greens. “With all of those molecules and atoms going in every direction, the whole thing looks a bit unorganized, especially for science.”

   “Now, I’m no science major, but if I’m being told by a group of people that the protons, neutrons, and electrons need unifying, then I think we owe it to the American people to go in and unify them,” Rep. Mark Udall (D-CO) said. “After all, isn’t a message of unity what we want to send to our children?”

   “Fifty billion dollars to buy atoms is too much,” Rep. Tom Feeney (R-FL) said. “Frankly, I don’t understand why they don’t just gather up all the leftover atoms in their test tubes and Bunsen burners. I think the scientists should have to use those up before getting new ones.”

   By gumbo, but we’re a sharp bunch, aren’t we? With smart cookies like that leading us, our superiority in science is assured.

6. **a quantum diaries survivor**
   October 2, 2007

   Retardigrade, Peter, all:

   There is clearly a pattern here. I seriously think these people are making it up. I cannot conceive somebody uttering such idiocies. Rather, I think they want to convey the message that they are ordinary people who watch football and don’t understand science.

   Whether that is the case or not, I feel for you guys. I guess you did not deserve such a government.

   Cheers,
   T.

7. **a.k.**
   October 2, 2007

..one has to note that this is a brilliant text, it is brilliant as only satirical texts can be, it even refers to 'self-referentiality' ('I've always said that science is more important than it is unimportant'), which is clearly a non-trivial problem both in mathematics and physics, this '..where science will ultimately occur..' on the other hand links with an evil undertone to the fact, that the LHC will -possibly- force more scientific concepts to vanish or to remain shady areas of speculation than to transport them to a surface where they could 'ultimately occur', but anyway: the combination of dumb every-day belief and scientific arrogance and impenetrability is too typical for western societies not to be matched by satirical intelligence.

8. **retardigrade**
October 2, 2007

a quantum diaries survivor says, "There is clearly a pattern here. I seriously think these people are making it up. I cannot conceive somebody uttering such idiocies. Rather, I think they want to convey the message that they are ordinary people who watch football and don't understand science."

Yeah, okay, seriously. There IS a clear pattern here. I would submit that even in the event they are (ALL of these quoted) "making it up…in order to convey the message that they are ordinary people who watch football and don't understand science" is sufficient testimony for the existence of idiocy. Whether you can or can't conceive of people "uttering such idiocies" is entirely irrelevant. (I have trouble conceiving the possibility myself…it means nothing). The net idiocy, however, remains.

In fact, the conscious masquerade of deception which you propose as an explanation for such foolish statements that can impinge on the future of the country is arguably tantamount to unpatriotic behavior, if not treason. In terms of government, I can't conceive of anything more idiotic than that. In a supposed "democracy", such behavior becomes downright ludicrous.

NO. I don't buy it. I really DO think these people ARE actually that stupid. But I ALSO think they revel in their culturally-instilled bragging-rights for stupidity.

They don't need to pretend to be smart or stupid, but that doesn't absolve them of their ignorance where it is most painfully apparent, nor does it mean we should let them off the hook just because they feel a need to build an affinity with common folk who enjoy, say, football.

I enjoy a good football game too, but I don't feel any need to act like an idiot in an attempt to ingratiate myself to other enthusiasts. Such an approach I THINK would be insulting to my fellows. At the very least. I'll continue to assume they are smart, and respect them for it, thank you. Similarly, I'd just like to see reps and senators start acting like we aren't nearly as dumb as they evidently think we are.

What in the world would it take for our political leadership to HONESTLY espouse and promote the merits of scientific literacy and public education in general, for the authentic good of the country, if not the world, with the same (deceptive!) zeal they apply to getting reelected? What the flaming heck do these people think the purpose of their job is???

Yes, I know those may be construed as rhetorical questions. We all "know" what politics is ultimately all about, right? Sure. But they still need real answers. The trouble is, hardly anybody has the guts to ask the hard questions anymore.

9. **anon.**
October 2, 2007

This is the funniest comment thread I've seen in quite some time.

10. **Lowenergy**
October 2, 2007

According to wikipedia, the Onion is a US parody newspaper. This mean that politicians have still some road ahead of them! 🙂

11. **non-a**
October 2, 2007

> I guess you did not deserve such a government.

Mmmmhh… talking about congress people, would Cicciolina have done better? But, on second thought, at least there was one thing she demonstrably did very well. That's probably more than can be said about any other politician anywhere…

12. **anonymous**
October 2, 2007

This is a (very funny) satirical article from a well-known satirical paper. Has anyone considered the possibility that the dumb comments from the congressmen (on whose smartness I have few illusions anyway) were just made up by the writer?

13. **parmenidis**
October 2, 2007

I 'm kind of perplexed here, did anyone of you took the article really seriously ?
Uhm anyway there is another one which I find even more funny

"Evangelical Scientists Refute Gravity With New 'Intelligent Falling' Theory"

http://www.theonion.com/content/node/39512

Peter you are right it's not string theory that unifies physics.
…..It's jesus

14. **D R Lunsford**
October 2, 2007

My browser can't display extra dimensions. Do I need a new plugin?

-drl

15. **Chris Oakley**
October 3, 2007

Hi Parmenidis,

You could be on to something here. God may have created String Theorists to formulate non-predictive theories, so that mankind would never cease to be in awe of the wondrousness and incomprehensibility of the universe.

16. **a quantum diaries survivor**
October 3, 2007

Fascinating hypothesis Chris. My own is that God himself does not understand the universe. He was experimenting with singularities when the whole thing blew him off. In that sense we resemble Her: and string theorists even a tad more.

Anyway, I rather wanted to answer retardigrate here:

"What in the world would it take for our political leadership to HONESTLY espouse and promote the merits of scientific literacy and public education in general, for the authentic good of the country, if not the world, with the same (deceptive!) zeal they apply to getting reelected? What the flaming heck do these people think the purpose of their job is???"

I think you are giving for granted something which is not – i.e., that everybody agrees that scientific literacy is good for the world. That assumption is a deadly sin. Many of those who can't spell quark actually think science is just a pastime.

Cheers,
T.

17. **Arun**
October 3, 2007

God just has to make itself unambiguously apparent for mankind to be in permanent awe of the mysteriousness and incomprehensibility of the universe; no need to mess around with string theory.

Anyway, re: string theory, it is amazing that we think we have all the physical principles at hand to specify physics at the highest energy.

18. **rob**
October 3, 2007

Great. But the all-time classic onion physics story is this one:

http://www.theonion.com/content/node/38718

If anyone mistook that one for a real story, I'd be awfully surprised.

19. **Changcho**
October 3, 2007

I suppose it is very telling (mostly about the US political leadership) that some could not tell that the story is a parody…

20. **Anon**
October 3, 2007

Actually, it's very telling about the general readership of this blog. Woit's rants against string theory and science in general only gain traction because such people exist.

21. **non-a**
October 4, 2007

> gainst string theory and science in general only gain traction because such people exist.

Which leads us back to the old wisdom that anyone doubting string theory is an anti-science moron with an IQ lower than 10.

Frankly, ST supremacists don't seem to have any new ideas. May that be because they are string theorists?

22. **Anon**
October 4, 2007

Actually, a good fraction of the people who closely follow this blog are 'alternative scientists' who are against string theory essentially because it represents 'the establishment'. Woit essentially exploits these people in order to gain a following.

23. **a.k.**
October 4, 2007

..well, I know, and they are leftist, self-righteous 'non-producers' who are mainly interested in following their path into eco-phantasizing foreagers' liefstyle, while leading comfortable lives on the cost of all the others who are following the thoughts and ideas of others, as it is adequate for serious scientists. If these latter, serious scientists however, run into trouble with their department, they invert their views from constant praising to qualifying their former colleagues as being 'parasites' etc., as if one behaviour would naturally induce the other. Anyway: I strongly recommend Horkheimer/Adorno: 'Die Dialektik der Aufklaerung', this should give enough material for some TOE-reflections.

24. **Marty Tysanner**
October 4, 2007

"Anon" says,

> Actually, a good fraction of the people who closely follow this blog are 'alternative scientists' who are against string theory essentially because it represents 'the establishment'.

This could be true, but what is the factual basis for saying it? Even granting the possibility that the comment may be valid for the range of commenters, "Anon" is surely aware that many more people read blogs than comment in them, and there is no obvious correlation between the viewpoints of those who leave comments and those who don't.

"Anon's" comment could equally apply to any number of other blogs, for example Cosmicvariance (as a perusal of comments on string theory related topics there indicates). The comment would probably be equally correct if it were rephrased along these lines: *A good fraction of the readers who closely follow [insert ST-oriented blog name here] are string theory partisans essentially because it represents 'the establishment'*. That could also be true, but so what? Observations like these are basically content-free and irrelevant to whether the blog itself is valuable.

"Anon" (and others with similar views) appear to want consumers of their derogatory comments about *Not Even Wrong* to associate skeptical views of mainstream research directions in HEP with being "uninformed" or "contrarian for its own sake." That is a very simplistic view of skepticism, one that itself seems very uniformed. It is also very insulting to the apparently significant number of serious scientists and mathematicians who at least occasionally visit this blog. Perhaps "Anon" should talk to physicists from a variety of disciplines before deciding that skepticism about string theory indicates a contrarian world view.

Finally, the "observation" that

> Woit essentially exploits these people in order to gain a following.

is much different than my own perception. I don't see Peter cunningly marshalling the forces of the ignorant and anti-establishment folks to bolster his case. Perhaps "Anon" has overlooked Peter's repeated pleas to stop the stream of uninformed or repetitive anti-string theory comments, or his judicious pruning of many such comments…

Frankly, given the apparent ignorance and simple-minded analysis that is evident in "Anon's" comment, it is quite understandable to me why he/she wishes to remain anonymous.

25. **Arun**
October 5, 2007

Re: God (joke by Gerry Porter, rec.humor.funny)

(UPI) Heaven. God has lost Her NSF grant. The National Science Foundation cited three reasons in deciding not to renew the Holy Grant.

1. Although God has done good creative work in the past, there has been no recent evidence of creativity.

2. No one as yet has been able to reproduce Her experimental results.

3. She has only written one book, and it has never been subject to peer review.

26. **Arun**
October 5, 2007

Phillip W. Nabours:

This actually happened, I didn't make this up.

Prof: Some people have proposed using Krypton gas in scintillator detectors.

Grad Student: Won't that scare away the superstrings?

A New Subfield of Physics…

October 3, 2007
Categories: Uncategorized

Things are not going well for string theory on the public relations front. Someone just pointed me to the poll at Wired magazine they call [String Theory Smackdown](), where the side arguing for string theory is losing the voting by more than 3 to 1.

The argument that seems to be carrying the day with the public is the simple one that a supposedly unified theory that can't make a single testable prediction, despite more than twenty years of work, must have something really wrong with it. Many string theorists acknowledge that this is the situation the theory is in, but make the case for what they see as promising aspects of the theory that justify continued work on it.

Unfortunately, some string theory partisans have chosen to react to recent criticism not by acknowledging the fact that string theory can't be tested, but by making misleading claims that the theory does make predictions and is testable. On Monday here at Columbia, Gordon Kane gave a colloquium talk of this kind, with the title *String Theory and the Real World — a "new" subfield, string phenomenology*. Kane began by quoting David Gross as being highly skeptical about the whole idea of string phenomenology, arguing "we don't know what string theory is, how can it have a phenomenology?". Kane's claim that "string phenomenology" is a new field is rather peculiar, since it was an active subject back in the early 1990s. It is however true that, for better or worse, it has become a more active one the past few years, as string theorists have reacted to their colleague's complaints that they do mathematics, not physics, by trying to sell themselves as "phenomenologists".

Kane mostly actually ignored string theory, concentrating on supersymmetry, which he has been promoting for more than 20 years (he had an article about "Is Nature Supersymmetric" in Scientific American back in 1986). He described seeing supersymmetry as essential, pretty much the only way of getting a "window to the Planck scale". There was some mention of the idea that string theory makes predictions about cosmology, but the "prediction" was just that in "most" string theories, the size of B-mode polarization in the CMB is unobservably small. He put up plots from [this]() recent paper, claiming that one could distinguish different string "backgrounds", by their "footprints" on LHC data. Looking at the paper, it appears to be based upon a large number of assumptions (e.g. that one just gets the MSSM), designed to provide enough constraints so that one could not get absolutely anything, but not so many as to be forced into contradiction with experiment.

For another exercise of this kind, take a look at Kane's 1997 Physics Today article entitled *String theory is testable, even supertestable*. This included an impressive looking detailed, specific spectrum of the masses of superpartners, implying that it was the sort of thing "predicted" by string theory. Only problem is that by now it looks to me as if these "predictions" are almost all in disagreement with experiment. Back in 1997 Kane was arguing against John Horgan that string theory really was testable, that it "would predict a specific spectrum of particles and superpartners that can be compared with experimental data". He seems to have backed off on that claim, there were no such spectra mentioned in his talk this week. About the landscape and its exponentially large number of possibilities, he had little to say except that we "have to learn how to think about this".

He repeatedly made the claim that "String theories DO give predictions" and "String theory is falsifiable", giving as an example work by 3 graduate students of Mary Gaillard that showed that one specific heterotic string compactification scheme gave no light neutrino masses and thus led to models incompatible with experiment. Another repeated point was that the problem with string phenomenology was just a lack of manpower. If more people (especially graduate students) were doing these calculations, great progress would be made. In the question session, asked about the CC, he said that there were lots of ideas about how to solve it, what was needed was just more people doing calculations.

Evidently many agree with him, since the IAS has just announced that next year's summer program for graduate students and postdocs will be on [Strings and Phenomenology]().

I decided not to ask any question in the question session, having the overwhelming feeling that arguing with "string phenomenologists" is now just wasting one's breath. They have made it clear that, no matter how dubious the arguments needed, they're going to keep promoting this field as predictive and highly relevant to the LHC. The intellectual "dead zone" of "string phenomenology" will be with us no matter what and perhaps even come to dominate particle theory until LHC results are in. May they stay as close as possible to schedule! (Kane estimates first physics collisions next September).

Comments

1. **mclaren**
   October 3, 2007

   Dr. Woit remarked:

   > [In] the poll at Wired magazine they call String Theory Smackdown…the side arguing for string theory is losing the voting by more than 3 to 1.

   String theorists make an excellent point when they note that the laws of nature are not subject to a popular vote. We're going to have to wait for the LHC and see. In that connection, new calculations taking into account the latest hadronic PVES experiments apparently place tighter constraints on physics beyond the Standard Model: http://www.jlab.org/div_dept/theory/highlight/beyondSM.html

   Of course if no exotica beyond the SM show up in the LHC it's easy to predict that the string contingent will simply move their predictions to higher energies, as usual.

2. **Demagogue**
   October 4, 2007

   Let's put quantum mechanics to a popular vote. If it fails we'll discard it as a theory and replace it with something that gets more votes, like angels. That's they way to do science – popularity contests.

3. **Peter Woit**
   October 4, 2007

   I wasn't suggesting that the results of a vote like this have anything to do with the validity of a theory. But the fact that string theorists have been losing the public debate does explain some of the tactics they are now adopting in this debate. You don't hear any more the argument for string theory that "it has triumphed in the market of ideas".

   I'd be curious to know what similar numbers would be if you asked not visitors to the Wired site, but Ph.D. physicists. My suspicion is that they wouldn't be very different. About the only population where the results would go the other way would be if you asked string theorists. And even there, I'm not so sure, they seem pretty discouraged these days…

4. **Demagogue**
   October 4, 2007

Maybe string theorists are a large part of the population competent to comment on the matter at all.

There's no reason to expect an experimentalist working on optics to have any more of an idea about string theory than an algebraic geometer.

5. **Visitor**
October 4, 2007

And because science is not a popularity contest, there is no reason to think that that the opinion of string theorists themselves have any bearing on the correctness of string theory either. And might even have LESS, to the degree that their jobs and reputations are built on string theory.

6. **a quantum diaries survivor**
October 4, 2007

Hi Peter,

indeed I think this new delay of LHC schedule was greeted by string theorists as new breathing air…

Cheers,
T.

7. **DB**
October 4, 2007

The "String Phenomenology" codology is an attempt at brand repositioning. When your consumers tell you they don't want your product, instead of reworking the product you go for a re-branding exercise and try to find new applications and markets. New ad campaign, new logo, the works. The alternative is to shut down those factories and layoff all those highly trained workers. Unfortunately, when the product is fundamentally unfit for purpose, you're onto a loser.
The lads at the IAS have been running their string theory show every second year since 2002. They try to attract students from the ICHEP conferences – also biennial. Now ICHEP is where all the action is in experimental HEP but string theory always gets short shrift there, presumably because these people are actually concerned with testing real theories, not mathematics masquerading as physics.
In place of gimmicks, string theorists should take a lead from Witten's approach – use insights from mathematical physics to make new discoveries in pure mathematics – of which his latest paper on Geometric Langlands provides yet another eloquent example.

8. **King Ray**
October 4, 2007

I think that Occam's Razor has slit String Theory's throat.

9. **Kris Krogh**
October 4, 2007

Hi Mclaren,

String theorists make an excellent point when they note that the laws of nature are not subject to a popular vote.

That's ironic, given that so far the success of string theory has been measured mostly by its popularity. Doesn't seem they are really against voting, but have concerns about who should be allowed to vote.

Or maybe the point is that instead of voting on poorly understood ideas, we should vote on people. Edward Witten is chosen "most likely to succeed." A videotaped incident at the KITP comes to mind, where a string theorist proposes a vote on whether Lee Smolin is a crackpot.

10. **Roger**
October 4, 2007

For better of worse, public engagement in the issue has happened and is largely the result of yours and Lee's spur.

As a particle physics experimentalist I have little real knowledge of string theory. Certainly, not enough to form anywhere near an informed opinion as to whether your arguments about string theory making little progress are valid. If I feel unqualified to judge – and I'm trained to a reasonably high level in particle physics theory – then the average politician certainly won't have a clue.

This is what troubles me. I am persuaded by the idea that it is better to keep this debate out of the public arena. Politicians like simple messages. If the prevailing message is that theorists have wasted a lot of money doing stupid things (I know this isn't your message but may be message they get) then it is conceivable that they will cut funding for theoretical physics, irrespective of the topics under study.

The LHC may well provide new directions for the theoretical community which would reduce the influence of string theory. I think it would have been better to wait for the data before starting this debate, especially now that the issue is getting its own momentum and will soon be out of the hands of you and Lee.

11. **Analyzer**
October 4, 2007

Maybe string theorists are a large part of the population competent to comment on the matter at all.

You don't have to be a string theorist, or even a physicist, or even a scientist, to appreciate the scientific method. When you say you can make predictions, and then you don't, your audience doesn't have to be Wittens and Susskinds and Motls to know whether something is wrong.

12. **mo**
October 4, 2007

Roger wrote:

It may be difficult for a non-string theorist to understand WHY so little progress in string theory has been made, but it does not take fine sense of discrimination to

ESTABLISH lack of progress. It takes almost no brains to figure out that string theory keeps to promise a lot and delivers very little on the promises.

Yes, the average politician is well trained to sift the wheat from the chaff, even though he/she may be unable to tell one kind of wheat from another. Remember the cancellation of the superconducting supercollider? The project died largely because of delays and cost overruns, but also because of the associated hype (e.g., the promise of cure for cancer) and DOE's deceptive claims.

13. **Changcho**
October 4, 2007

"When your consumers tell you they don't want your product, instead of reworking the product you go for a re-branding exercise and try to find new applications and markets. New ad campaign, new logo, the works."

Of course:

Pre-owned – > Used
Private security contractors -> Mercenary
String Phenomenology -> String Theory

and many others…

I strongly disagree. People shouldn't shut up out of fear that some stupid politician misinterprets their words and cuts funding. Quite opposite. The duty of scientists is to educate laypeople and politicians. Open and honest debate is a part of that education.

Eugene.

15. **A.J.**
October 4, 2007

Mo,

What do you think the promises made by string theorists are, and what do you think a reasonable time frame for delivery on these promises would be?

16. **dan**
October 4, 2007

Dear Peter,

Briane Greene once said string theory is the only game in town.

In NEW you yourself pointed out that one reason string theory was popular in early 80s was there were few unresearch seemingly promising ideas left to address the shortcomings of the SM.

What do you think will happen to string theory and to string theorists should LHC fail to find evidence for SUSY? Or, in otherwords, what would most string theorists today (i.e Witten, Greene, Randall, Susskind) work on (both HEP and QG) in an era where LHC does not find evidence of SUSY in the next few years? Will those string theorists interested in QG continue to work on strings or would they switch to LQG?
Do you think those string theorists interested in HEP might jump on Smolin's/Sundance preon braiding bandwagon? Or will string theorists continue to do stringy research ignoring a LHC null result.

Dan

17. **amused**
October 5, 2007

If smart people genuinely think they can get something worthwhile out of this string phenomenology business then good luck to them. But they should have the same obligations to demonstrate interesting and important progress as the rest of us. If they are able to make such progresses, let them "prove it" by publishing them in PRL. And if they can't get published there then the rest of us will draw the obvious conclusion. I'm not personally qualified to assess the worth of research on this topic, but I trust in the capability of the referees and editors of PRL to do so.

18. **Quixotik**
October 5, 2007

"There's no reason to expect an experimentalist working on optics to have any more of an idea about string theory than an algebraic geometer."

Wrong! An experimentalist working on optics would have to know the theory behind her experiments. And she'd therefore know if string theory had been formulated such that it could reduce, under certain conditions, to the those standard theories. And if it hasn't been thus formulated, she knows string theory is far from complete and usable.

That is much more than an algebraic geometer knows, unless the algebraic geometer also happens to have a working knowledge o physics.

19. **Quixotik**
October 5, 2007

And another thing.

The public's job is not to decide whether string theory is valuable or not. The public's job is to decide whether or not string theorists should each be given over a hundred thousand dollars per year to sit around with paper and pencil thinking about string theory. And even an unintelligent uneducated member of the lay public can ask, "What's in it for me?” And if no one can give him a satisfactory answer, he has the right to withdraw his tax money from the paychecks of the string theorists. And if that happens, it doesn’t mean string theorists have to stop working on string theory. They can get a day job and do string theory at night if they’re so convinced it’s a blockbuster.

20. **chris**
October 5, 2007

dear roger,

let’s assume that someone to whom nonabelian gauge theories are a total mystery would need to be convinced of the correctness of qcd. do you have to carry that guy thru the proof of renormalizibility? does he need to know how to compute the beta function?

no. you show him the bjorken scaling plots in the pdb an that’s it.

how about the SU(2)xU(1) weak theory? do you need to understand the higgs mechanism for gauge boson mass generation? no. just look at that picture from UA1 and there is the W and the Z. and you can understand the higgs mechanism better than higgs himself and still there is this shadow of doubt if it is correct at all because we have not seen the particle yet.

every reasonable person is qualified to judge scientific theories, that’s the beauty. they make predictions that either get validated or not.there is a certain time lapse of course. in 1960 the big bang theory was fine even without direct experimental proof. it would be hard to defend today if no CMB would have been found yet. it is equally hard today for steady state fans to argue against the big bang – even if the hardcore ones still do so.

for string theory the clock is just ticking. and they are on the move.

21. **David**
October 5, 2007

when oh when, will you stop being so negative and grace us with your brilliant alternative so we can put that to a vote……

22. **mo**
October 5, 2007

A.J. Says:

“Mo,

What do you think the promises made by string theorists are, and what do you think a reasonable time frame for delivery on these promises would be?”

Speaking in the simplest possible terms, it is better to point out past promises that became claims:

1) they claim they have a theory, but string theory (or more accurately M-theory that substituted it) doesn’t really exist yet;

2) they also claim string theory provides a unification of all of fundamental physics, but it doesn’t even predict the Standard Model parameters.

Re: time frame. Let’s look at comparable projects. It took Einstein about ten years to formulate general relativity. It took 16 years to complete the electroweak theory, from Yang-Mills (1955) to Glashow-Salam-Weinberg (1960s) to t’Hooft (1971). So I would expect that by now we should have had a complete formulation of string theory.

23. **Roger**
October 5, 2007

Interesting responses.

I stand by what I wrote that dragging this into the public arena at this stage is not sensible, especially with the LHC around the corner. Were there to be no LHC then it would be more appropriate to begin the debate now. As it is, should the LHC discover new physics then my money is on the theorists trying to understand the new phenomena quantitatively i.e. chasing the Nobel prize. If string theory is not fit for this purpose then it will naturally ebb away to an extent. Others may have different opinions of how future events will pan out. However, nobody knows anything for sure other than that we have experiments waiting to come on-line which stand a fighting chance of changing the direction of physics research. In this situation it is sensible to hold back – after all we’ve already waited twenty years.

Unless I missed it then nobody responded to my main point which is that sending the message that theoretical physicists are a useless bunch who can’t be trusted with the public’s money is a dangerous message to send. This is the message which is being sent. With every popular magasine picking up this debate, the qualified and carefully worded criticisms become more and more distorted.

As for string theory having made no progress, I’m not going to restate the string theorists arguments, which are well known.

The issue of hype was also mentioned. The LHC has probably been hyped as much as string theory. According to every popular science magasine I’m taking part in an experiment which will explain mass (well not really since most observable mass comes from the strong force), explain dark matter (let’s hope that the hierarchy problem is as serious as we think and we get new TeV physics), and also allow us to somehow unify the fundamental forces (such is the message getting through). The fact is that every science field hypes its work in order to get the public and policy makers on board.

I don’t have any particular love for string theory. My own opinion, for what its worth, is that theoretical physics research may have gone down a blind alley for the past twenty years and needs to learn lessons to avoid repeating this behaviour in the future. However, I’m not convinced that the current blog wars and bringing the fight into the public arena at this stage is the most sensible way to achieve continued funding and future excellence in research, which has to be the final aim.

24. **DB**
October 5, 2007

Roger,

Your position resembles that of Gerhard ‘t Hooft, and is, I believe, the majority view held by physicists, whether they be theoreticians or experimentalists.
It is a traditional stance and can be summarised as “don’t wash your dirty linen in public”.
The problem, as has been repeatedly explained by Smolin and Woit, is that until recently very little debate has taken place either within or without the physics community, and string theorists have had free reign to hype their theories to the public while establishing hegemony over much of theoretical physics research in the US.
The fact that the physics community allowed this to happen shows that the ‘t Hooft approach doesn’t work. That much of the debate has had to be stirred by an outsider (Woit) only highlights a twenty year failure of the physics community to address this issue internally.
Your expectation that the LHC will further diminish string theory status exactly mirrors the prevailing view, i.e., that we can trust to experiments to sort the wheat from the

chaff. There is no evidence that string theorists will take a blind bit of notice of any negative outcomes from the LHC.
The physics community's ostrich mentality will have serious consequences for future physics funding when, not if, the string theory program collapses. Because we didn't put our house in order when we had the chance to do so, outside forces will do it for us, and we only have ourselves to blame.

25. **Roger**
October 5, 2007

You say there is no evidence that there experimental data will sort the wheat from the chaff. This is a statement of the obvious – we haven't taken data yet. Nobody knows what will happen. The only certainty is that we have experiments about to start which have a fighting chance of changing the face of physics. That hasn't been the case for many years. Being hot-headed now is somewhat absurd given the risks of inflicting lasting damage to the reputation of the field.

I'm very sceptical that the damage created by this messy public debate is less than if string theory "internally" collapsed. Funding and the general health of science relies on public trust – with every magasine article this trust is being eroded. One has to be damn certain before opening a public debate and washing dirty linen in public. I've yet to see any evidence that the approach you're advocating is any more constructive than my favoured option which is to wait several more years and see how the LHC influences the field before opening the can of worms.

Its very easy to start a public debate, its not so easy to control it. The end result of all of this may well be unsatisfactory for string and non-string enthusiasts alike.

Note, by the way, a lot of qualifications in my statements. I don't know what will happen. This is why I strike a note of caution. I'm not convinced that any of the posters here have any more prescience than me and the certainty and, at times, fanaticism with which both sides push their view is very worrying.

26. **DB**
October 5, 2007

Roger,

I did not write "there is no evidence that there experimental data will sort the wheat from the chaff". I wrote "There is no evidence that string theorists will take a blind bit of notice of any negative outcomes from the LHC." That is based on the assumption that they will continue to behave as they have to date when faced with inconvenient and unanticipated experimental outcomes, witness the use of anthropic arguments when faced with the lambda-CDM cosmology.
Proposing that public debate be closed down is just an argument for a restoration of the status quo pre Smolin and Woit. Well, that's not going to happen. Either the community resolves this internally or funding authorities will do it, with knock-on implications for the reputation of all physicists, especially in the HEP sector.

Once again, I point out that it is this blind faith in experiment as the arbiter of string theory's demise or success which is the Achilles heel of the community's response to date. It's cosy, convenient and a recipe for doing nothing. It ignores the fact that the LHC is incapable of falsifying string theory as things stand. So what if LHC doesn't find supersymmetry? Not to worry, check higher up. Oh you can't, well, build a bigger machine and in the meantime we'll do some more calculations.

When string theory eventually collapses, its practitioners can go back to doing what many of them are eminently qualified to do, making fine contributions to pure mathematics, as Witten does, or diversifying into other areas of mathematical physics. The physics community will be left holding the baby.

27. **Roger**
October 5, 2007

You know nothing about what will happen in the theoretical community during the LHC era and nor does anyone.

Tell me, why does the community need the public debate *now* and not, for example, in 4-5 years time when the data could already have led to other promising approaches and a greater diversity emerging ?

28. **Miso**
October 5, 2007

«And even an unintelligent uneducated member of the lay public can ask, "What's in it for me?"»

Please. The average joe is not qualified to judge the best clothes to wear on a rainy day and you want them to make these decisions about prospects that are anything but clear?

Some people's faith in humanity never ceases to amaze me.

29. **Thomas Larsson**
October 5, 2007

*why does the community need the public debate *now**

Woit's original evaluation, [physics/0102051]() appeared in 2001. Glashow's (Nobel 1979) and Ginsparg's attack on string theory, [Desperately seeking superstrings](), appeared in Physics Today in 1986. 2001 and 1986 are hardly "now".

What is happening now is that string theorists no longer have the power to suppress critique. A generation of physicists has spent 20 years on the receiving end of unchallenged string theory propaganda can no longer be ignored.

30. **DB**
October 5, 2007

I know that the LHC it will not be able to falsify string theory as things stand today, because no predictions are made that can eliminate the theory if they are not found. Phenomena may be discovered which are tough to reconcile with string theory, but that has never been an unsurmountable obstacle.

The HEP community needed this debate many years ago, and has crouched behind the bogus LHC "messiah" argument for long enough. It has painful lessons to learn.

Feynman blasted string theory publicly back in the mid-1980s, and was ignored. Twenty years on, do you believe we are better off?

31. **Peter Woit**
October 5, 2007

Roger (and others),

Thanks for the thought-provoking comments. I have been thinking about these issues as this debate has become a public one over the last year or two.

There are two answers to “why now?”. One is that it’s already way too late. Much of this debate could have and should have taken place 20 years ago. I got involved in 2000, after many years of frustration that the obvious issues were not being addressed, attempting unsuccessfully to get something published in Physics Today, addressed not to the public, but to the physics community. That was stopped, and the piece ended up being published in American Scientist, getting an audience of not just physicists. The book was written a couple years later, and an editor at Cambridge University Press was interested in publishing it. Again, string theorists put a stop to that, which just delayed the publication and forced me to go to a publisher much more in the business of marketing to a wide public. All of this was going on at a time when LHC results were still quite a few years in the future.

The other answer to “why now?” is that much of this is already over: the “dirty linen” has already made its public appearance, with the heaviest public attention to this taking place last fall when my book and Smolin’s appeared in the US around the same time. At this point, the cat is out of the bag, with a widespread perception that string theory is a subject in trouble. If string theorists want to respond to this by saying “yes, things are not going well, let’s see what the LHC says”, there’s not much to debate. If they decide to go to the press claiming that Smolin/Woit are all wrong, everything is fine, and keep publicly fighting a debate they have so far been losing, that’s their choice, but I think not a smart one.

As far as the effects of this on funding of particle physics, it’s not so simple. People calling up their elected representatives to demand defunding of particle theory is not the way the world works. The FY2008 proposed DOE and NSF budgets contain quite healthy increased funding for HEP, both experimental and theoretical. I can see why string theorists are not happy to lose the status with the public that years of hype had bought them and have to live with a more realistic one, but funding questions are in the hands not of the public, but of a much smaller and better-informed group. It undoubtedly is a tougher sell these days to use string theory to get private funding from philanthropists, but I can’t say I think that’s a bad thing. Much of the funding and health of particle theory is based on the decisions of other physicists, who are making the decisions about whether to hire particle theorists in their departments and advising the NSF about how to allocate resources. The main problem for particle theorists is this possible loss of support not from the ill-informed public, but from their much-better informed colleagues.

As far as this danger goes, the main problem is just the too-obvious lack of progress in the subject. When people see nothing new coming out of a field for a long time, they start thinking that resources are better allocated elsewhere. As far as the effect of my book and Smolin’s, I think they gave many physicists a more realistic awareness of what the state of HEP theory is, and what the level of string theory hype has been. This is uncomfortable for many theorists, but I don’t see the argument that it’s a bad thing. From talking to many people, I actually think the worst damage to the interests of string theory has come from the behavior of string theorists themselves. Lubos Motl, aided by significant support from other string theorists, personally did a huge amount of damage to the perception of the subject. Lenny Susskind and others promoting the anthropic principle (through books and articles for the public) have done even more. When I talk about the problems of string theory with physicists and mathematicians who don’t know much about the subject, they generally have a prejudice in favor of the idea that things can’t be really that bad, given how smart some string theorists are and how many people work on it. When they see Susskind or others going on about the anthropic principle, I often see a strong reaction of visceral disgust and a lot of sympathy for the idea that there really is a big problem here.

So, as far as the “public debate” goes, particle theorists should be worrying not about the public, but about their colleagues and specifically about the damage that promotion by prominent theorists of pseudo-science is causing. Allowing this to go unchallenged is a huge mistake. As far as the wider debate about string theory goes, I think it would have been a lot smarter for string theorists to react in public the way many of them react privately: acknowledging that the problems of string theory are very real, and that the subject is in a difficult state. Instead of going to the public with claims that Smolin/Woit don’t know what they’re talking about, everything is fine, they would do a lot better by acknowledging problems, and telling the public that this is how science is done: much if not most of the time ideas don’t work out as hoped.

My own worry about HEP theory funding is a different one. I see physicists drawing the conclusion that what went wrong here was too much emphasis on mathematics, that if theorists had just stuck to “phenomenology” and not gone off into mathematically sophisticated formal investigations then there wouldn’t have been a problem. The problem with string theory is not that it’s too mathematical, it’s that it’s a wrong physical idea about unification. What I see happening now is not a defunding of particle theory in general, but an abandonment of the kind of deep, long-term investigation of difficult issues that is needed, in favor of often outrageous attempts to claim “real world” applications of string theory. To some extent this is being justified by the idea that the LHC is going to save the day, that all theorists need to do is get up to speed on how to analyze collider data. Maybe this will work out, but I don’t think the way all eggs are being put in that basket is wise.

32. **amused**
October 5, 2007

David wrote: “when oh when, will you stop being so negative and grace us with your brilliant alternative so we can put that to a vote……”

Actually there are quite a few interesting alternative topics to ST in formal particle theory. Reasonable string theorists don’t seem to have any problem acknowledging this; Jacques Distler even listed some of them here. I suspect these alternatives would do quite well if put to a vote…

Regarding Roger’s points: I agree it is potentially damaging that the string theory punch-up has led to the public getting a negative impression of the state of physics in general. The solution imo should be to give the public a more accurate picture of present day physics research. Unfortunately they have been brainwashed into thinking that the only interesting problems are quantizing gravity and “unifying the forces”. Even the LHC is being partly sold to them as something that is supposed to give insights into these things. If the public realized that most of what goes on in physics (including much of HEP) takes place through conservative, uncontroversial, bottom-up approaches, and that these are generally doing fine and continue to produce important advances in physical knowledge, then I don’t think they will want to pull the plug on physics just because they hear about a relatively small segment of physicists getting bogged down in a metaphysical multiverse.

The seeds of the current public airing of dirty linen were sown a long time ago by string theorists who for some bizarre reason felt that the public absolutely had to know all about their speculative research program, extra dimensions and all, without it having a shred of experimental evidence or having reproduced the standard theories we already know are correct at low energies. If it hadn’t been for this the current airing of dirty linen probably wouldn’t be in the public domain (they wouldn’t know about it).

Finally, a question for Roger: What do you think about string theorists continuing to put out misleading press releases about “tests of string theory”? Is it really best to just ignore these for the time being, to avoid letting the public get a bad impression?

33. **Eric**
October 5, 2007

Dear Peter and others,
One question that I would like to pose to you is, suppose that the string landscape is true and there are really 10^500 possible vacua. Do you claim that of these 10^500 vacua that there is not one which corresponds to our universe? If so, how would you know? Unless you can prove that there is no such vacuum, then your claim that string theory cannot make any predictions is baseless.

Essentially, the purpose of the field of string phenomonelogy is to find this vacuum from a ‘bottom up’ approach. Now, we may or may not be able to explain why this particular vacuum is chosen, but that is a seperate question.

34. **Peter Woit**
October 5, 2007

Eric,

I've already gone on about what I think about this point far too many times, here and elsewhere. If "string phenomenologists" want to make the case for their subject by saying that they're going to keep at it and not give up until every one of the 10^500 vacua has been investigated and carefully examined to make sure it doesn't agree with experiment, they can do that, but this is just going to convince people that the criticisms of the subject are valid.

35. **Eric**
October 5, 2007

Well, Peter is no different that the state of particle physics in the 1950's when there was an elementary particle zoo rather than a string landscape. I suppose it's a good thing that the phenomenologist of the time 'kept at it'.

36. **Peter Woit**
October 5, 2007

Eric,

One minor difference: the "elementary particle zoo" was experimental data, the "string landscape" isn't.

37. **Eric**
October 5, 2007

Peter,
The point is that there was no fundamental theory which could explain the plethora of elementary particles. There was no Standard Model and it was far from clear that QFT was the correct description of elementary particle physics.

Regarding the string landscape, the data that we hope to have soon is the superpartner spectrum from which it is hoped that the pattern of soft masses may be deduced. Since the soft masses are calculable in string models, as opposed to the MSSM where they must be put in by hand, it may then be possible to zero in on a particular class of vacua.

38. **dan**
October 5, 2007

Eric,
what if LHC doesn't find any SUSY partners?

39. **Peter Orland**
October 5, 2007

Eric,

Your line of reasoning is very curious. You are trying to make an analogy between 1) complicated experimental data, and the need for a theory to simplify that data and 2) complicated possibilities from a theory, and picking out one of many possibilities with the aid of experiments.

These two situations are not analogous.

40. **cosmologist**
October 5, 2007

I'm no expert in string theory but I think the fact that no one has been able to get a string theory land scape based inflation model which produces gravity waves is a very important thing to keep in mind. Over the next few years cosmic microwave background polarization experiments should be able to detect gravity waves if the scale of inflation is not too low. If they do, my impression is that the landscape is going to be in big trouble. Another way cosmology could make life very difficult for the landscape is if the dark energy is shown to have a time varying equation of state. The landscape based solutions predict an equation of state equal to -1 (a cosmological constant).

41. **A.J.**
October 5, 2007

mo,

I'm not sure I agree about the time frame, or about the statement that GR and Yang-Mills theory are comparable projects. Trying to simultaneously unify particle physics and construct a theory of quantum gravity strikes me as vastly more difficult than either of these. I suspect that a reasonable time frame might be something more like a century or two. (This is a somewhat pessimistic take on Witten's comment that strings was a piece of 23rd-or-whatever century physics.)

How do you judge progress in a project on such a long time frame? I don't really know. The best answer I have is that you look for spin-off, good ideas that are applicable elsewhere. There's some precedent for this: many of the techniques used to study gauge theories were first developed in early attempts at quantum gravity.

42. **Peter Woit**
October 5, 2007

A.J.,

I think the way you evaluate any ambitious project is whether, as you learn more, you are moving towards your goal. The problem with the idea of unification via string theory is that since 1984, as people learn more and more about it, they find more and more problems with it. Instead of producing even some minimal explanation about the standard model, it has instead led to the reductio ad absurdum of the landscape.

I think one can argue for continued research on string theory based on hopes for spin-offs, but it's not a good idea to be pursuing a failed project purely based on such hopes. You're more likely to get spin-offs from trying something different than from continuing to work on something that has already failed.

> In the question session, asked about the CC, he said that there were lots of ideas about how to solve it, what was needed was just more people doing calculations.

Crackpot. Noun: crackpot 'krak`pót. … In physics: those who promote extravagant ideas before having accomplished the calculations necessary to check the validity of such ideas.

44. **anon.**
October 5, 2007

cosmologist: the Lyth bound suggests that measuring a large tensor-scalar ratio is problematic in field theory, not just in string theory…..

45. **Eric**
October 5, 2007

Peter O,
The situations are exactly analogous. Suppose it is 1959 and you have experimentally the elementary particle zoo and you have QFT. In this situation, would there not be a complicated set of possible QFT's which you could construct in order to try to explain the data? There is no priniciple inherent in QFT which would uniquely lead you to the Standard Model. Thus, what was done is to construct phenomenlogical models which then can lead us to the correct description.
With string theory, we are looking to experimental data in the form of information about the supersymmetry breaking soft terms which will guide us to the correct string theory description.

Dan,
If no supersymmetric partners are discovered at LHC, then it's still possible that string theory might be right. However, since in this case there is very little chance of ever making contact with experiment I would expect interest in the subject to dwindle. However, there must be some new physics at the TeV scale one way or the other. We shall see.

46. **Arun**
October 5, 2007

Eric wrote:

With string theory, we are looking to experimental data in the form of information about the supersymmetry breaking soft terms which will guide us to the correct string theory description

The situation with not analogous to 1959 because we don't know that supersymmetry is real. Your example is, to put it crudely, we are waiting to find out the size of an angel, so that we can figure out how many can dance on the head of a pin.

47. **Eric**
October 5, 2007

Well, Arun we find out if supersymmetry is realized in nature very soon.

I would like to remind you that the idea of quarks were introduced to simplify the particle zoo, however there was no evidence for these for many years just like in the case of supersymmetry. In fact, most physicists did not accept their existence since they had never been observed.

48. **David B.**
October 5, 2007

I am dismayed by the attitude that various commenters of this Blog have. They are suggesting that all research in string theory should stop. In particular, there is this idea permeating various posts that string theorists are being payed enormous ammounts of money to do fluffy landscape metaphysics with no connections to reality.

It is important to remember the following:

Models of light strings at the TeV, or 10 TeV scale have not been ruled out experimentally. They might be diisfavoured by certain theoretical prejudice, but they are not ruled out. We have to wait for the LHC data before we say that strings are not relevant for the TeV scale.

String theory is not just about unification of the standard model with gravity and predicting the couplings of the standard model. That is just one of the goals that the program of string theory as a whole is trying to pursue.

String theory is also (at the very least) a toy model of quantum gravity where many questions about the nature of black holes and geometry can be answered. This alone is sufficient justification to keep the program runing in the eyes of many scientists (not just string theorists).

Via the AdS/CFT correspondence, string theory ideas offer a unique insight into strongly coupled phenomena of gauge theories. Considering that QCD was proposed over 30 years ago and that it has not been solved (even with the most powerful computers and the efforts of thousands of people in the lattice QCD program) it seems ridiculous to toss away a formalism that gives you some analytic handle on strong coupling phenomena just because some other aspects of the string program are not satisfactory at the current moment. This is like tossing away the Ising model for being unrealistic. As a matter of fact, calculations using black holes in higher dimensions are still the best theoretical match for certain measurements that have been done in the RHIC experiment. There is a lot of cross-talk between experimentalists, string theorists and QCD experts at the moment, and it is centered on data.

To all of you with this intense anti-string prejudice: get back to reality and research the field and its current status before you start making pejorative statements just because you have a grudge.

49. **Cecil Kirksey**
October 5, 2007

David B.:
"String theory is also (at the very least) a toy model of quantum gravity ….". This I believe is a statement that no string theorist would support. What happen to the statement : "string theory is believed to be the only consistent theory of quantum gravity"?

October 5, 2007

Eric wrote:

> Well, Arun we find out if supersymmetry is realized in nature very soon.

Well, there's one I've been wondering about, actually. Should we really expect supersymmetry to imply that supersymmetry will be found at the LHC? I mean, we apparently don't see any supersymmetry under 1 TeV. Why must we see it under 15 TeV? Is there anything special about that particular factor of 15 that causes us to expect it to bring the superpartners into visibility range?

I've seen it expressed previously that if we don't see SUSY at the LHC, then probably SUSY is false. Is this fair, and is there any particular reason for this argument? What is the constraint that makes it unreasonable that the lightest superpartner would be massed at greater than 15 TeV? *Why* should we expect that we'll find out whether supersymmetry is realized in nature very soon?

Meanwhile, people seem to generally act as if they're expecting the Higgs to be found before any superpartner. Let's say this in fact happens. Should we then conclude that ALL the superpartners are heavier than the lightest Higgs? If it turns out that all superpartners are heavier than the lightest Higgs, does this tell us anything? Would this be viewed as unusual, predictable, mere coincidence?

51. **Eric**
October 5, 2007

Cecil,
We except supersymmetric partners of the TeV scale because this is required for SUSY to solve the gauge hierarchy problem. Since the Higgs is a fundamental scalar, it's mass should recieve corrections which diverge quadratically. Introducing a fermion which is the partner to the Higgs cancels these divergences and stabilizes the Higgs mass.

As far as your statement that SUSY hasn't been yet been seen up to the TeV scale, this is wrong because this energy has yet to be probed by any experiments. LHC will be able to probe this regime, and if LHC doesn't find SUSY then SUSY must not be the solution to the hierarchy problem.

Eric, thanks for the clarification.

54. **Jock Distiller**
October 5, 2007

I'm a bit surprised to see PW still saying that the Landscape is pseudo-science. Jacques D explained why that is not so over in the "infinte thread" on CV:

"I've explained why I think it is likely that, when we manage to find a family of vacua which bear more than a passing resemblance to the Standard Model (so far, we haven't), they will have a sparse distribution of values for the parameters — both those which have already been measured (which can, if you want, be used to further prune the vacua which bear looking at) and, more importantly, of the parameters we have not yet measured.

Since we haven't yet found the family of vacua we are looking for, my argument can hardly be called ironclad*. But it is a good deal more persuasive than the mere assertion than "You can get anything you want on the Landscape."

In any case, if you're going to go around repeatedly making the latter assertion, then you have to explain why the above argument is wrong. "

Well, I have to admit that I don't like his attitude any more than you do, and I did have a good laugh at your jibes at his weird obsession with typesetting. Rising above all that, however, the man has made a point — not every flux on a CY manifold contributes to renormalizable SM couplings; in fact, generically, very few do. So it is just not true that "anything goes" except for a few things like the cosmological constant.

What is your response? I'm not trying to score points here, I just thought it was an interesting point that certainly bears further discussion.

55. **Arun**
October 5, 2007

I thought it was clear that string theory as THE theory of everything, the one and only game in town, the language in which God wrote the universe, etc., has so far gone nowhere; and is the one that is being derided; there are other much less grand, but more scientific, uses of string methods; by all means pursue them. And maybe one day, string theorists may even have the last laugh.

56. **Peter Woit**
October 5, 2007

Jock,

I've already responded to this multiple times elsewhere, explaining exactly what my argument about the landscape is. Jacques and others typically ignore my actual detailed argument, take one phrase out of it like "you can get anything you want" and insist on just arguing with that. I'm not claiming that the landscape can be disproved with 6 words, and I don't know whether zero, a finite number or an infinite number of supposed vacuum states of string theory will match to experimental accuracy all the standard model parameters. I am claiming that all hopes to get real predictions out of it are based on massive amounts of wishful thinking, and wishful thinking is not science. It's up to people like Jacques who claim the landscape is science to come up with the standard sort of scientific evidence for this, which is something more than "if we could just do certain computations which are now completely hopeless, the results would be certain very complex constraints on real world data which might be true". You can't just assert this, but have to come up with some evidence for it.

David B.,

If you read blogs regularly I'm surprised that you're "appalled" to find that some blog commenters are not extremely well-informed about some topics. Funny that you only seem concerned by ill-informed commenters who aren't happy with string theory. What about ill-informed commenters like Eric who are promoting string theory, do you think they're also a problem?

I notice you've completely ignored the content of my posting.

57. **Eric**
October 5, 2007

Dear Peter,
I think I know a thing or two more about both particle physics and string theory than you, so I think I would be careful about who you are calling ill-informed. So please go back to studying representation theory or whatever it is you pretend to study in order to create the impression that you're a scientist and not just some computer administrator.

58. **Peter Woit**
October 5, 2007

Eric,

And David and Moshe wonder why so many people have acquired a low opinion of string theorists…

59. **amused**
October 6, 2007

David B,

"I am dismayed by the attitude that various commenters of this Blog have. They are suggesting that all research in string theory should stop."

Well, that's not my suggestion. And I don't think it is Peter Woit's suggestion either.

"String theory is also (at the very least) a toy model of quantum gravity where many questions about the nature of black holes and geometry can be answered. This alone is sufficient justification to keep the program runing in the eyes of many scientists (not just string theorists)."

I agree completely. Not obviously inconsistent theories of quantum gravity are few and far between, so when one comes along then of course people should study it and learn all they can about it, within reason.

I have to take exception to your comments about AdS/CFT and QCD though. I think what irks many people about this is the way string theorists present it as a dramatic great breakthough that revolutionizes our understanding of QCD. That's simply not the case at the moment. Firstly, AdS/CFT gives at most an effective theory description for QCD in certain regimes. And as far as I'm aware it isn't even clear at present whether, and to what extent, this really is a valid effective theory for QCD. Secondly, and more importantly, the impact of this on QCD theory research as a whole is not very big. (One way to quantify this would be to count the number of PRL publications on QCD theory in recent years and see what fraction of them involve AdS/CFT.) Afaik it has made no impact on central topics such as understanding the QCD dynamics responsible for confinement, realistic calculations of hadronic mass spectra, and calculations of the various operator matrix elements relevant for studying the weak interactions and thereby testing the Standard Model. Contrast this, e.g., with the large impact that the theoretical breakthough in formulation of chirality on the lattice has made. It is of course very welcome that AdS/CFT is able to say something about regimes of QCD where lattice methods fail (e.g. at high density, due to the sign problem at nonzero chemical potential), assuming that the effective theory description it provides really is valid. But this hardly justifies the hype. There has been much progress in nonperturbative QCD theory in recent years. AdS/CFT is just one of a number of interesting developments. Despite the impression that you and other string theorists try to give, it does not tower above the others in it's significance and impact. If anything it is of lesser significance so far, especially considering that its status as an effective description of QCD is still up in the air.
Finally, since you emphasized that the AdS/CFT approach is analytic, let me just mention that the lattice approach can also be done analytically in certain limits, most notably the strong coupling limit where Wilson's original (analytic) derivation of the area law was carried out. Analytic studies of QCD in the lattice and other formulations continue to this day; you shouldn't imagine that the AdS/CFT approach is at all special in that regard.

60. **Geon**
October 6, 2007

I just can't wait until LHC turns on.

61. **Roger**
October 6, 2007

Amused –
Finally, a question for Roger: What do you think about string theorists continuing to put out misleading press releases about "tests of string theory"? Is it really best to just ignore these for the time being, to avoid letting the public get a bad impression?

Its a very difficult question to answer. In an ideal world the string theorists would desist from their extraordinary claims. However, it looks like the opposite is happening. Whether the right response *at this time* is for another group of scientists to stand up in public and say "they're talking nonsense, are fools, and have wasted money" – the message absorbed by the public – is the right one is something history will judge.

We shouldn't forget we're in unchartered territory here, both in terms of the physics under debate and the power of mass media. The only equivalent major spat over science which I can think of which has spilled into the public area is over global warming. I don't think for one moment that this issue will get anywhere near the level of hysteria and press-coverage as the greenhouse effect. However, it is a salutory warning of what can happen given a mix of genuine, concerned scientists, scientifically illiiterate journalists and crackpots with websites.

62. **Anon**

THE ONLY LOGICALLY POSSIBLE PROPOSALS I HAVE SEEN FOR LANDSCAPE PREDICTIONS ARE STATISTICAL ONES. I PERSONALLY DON'T BELIEVE THESE MAKE SENSE (YOU CAN NEVER KNOW THE MEASURE).

–PW

63. **Peter Orland**
October 6, 2007

David B.,

I have not now, nor have I ever suggested work in string
theory should stop (I'd conceivably be working on it myself, were
I not occupied with other matters). Nor has Peter W., I think.
Nor did some of the other commenters on this thread.

Eric,

I am looking at your response to my comment from yesterday
and some of your further remarks. I am still not persuaded
(if anything, even less so) that your analogy is right.

As I understand it, you are trying to make the following analogies:
1. the space of field theories is analogous to the landscape.
2. the standard model is analogous to one string theory solution.

These are not analogous. Nobody claimed in the sixties that
the SPACE of ALL field theories was something emerging from fundamental theory of nature. The Holy Grail (except to the
large community of S-matrix advocates) was ONE correct field
theory. People searched for one theory which would explain the
data. They did not search for a solution of what they wished
would be the correct theory consistent with data. There is a
difference between a scientific theory and a particular solution.
They aren't the same – think about it.

On another matter, trying to pull rank on Peter W., by saying you
know more than he does, undermines anything valid you might
have to say.

64. **Peter Woit**
October 6, 2007

Anon,

If you want to discuss what I actually think you need to respond to what I write here. The tactic of ignoring what I write in favor of pulling out of context phrases from some other discussion is a tedious one.

65. **a.k.**
October 6, 2007

..since some commenters demanded to go 'back to reality': not anybody in this blog seemingly denied the mere *possibility* the landscape could bare at least a family of solutions which could match a given set of known parameters of the 'real world', the subtle point is exactly the interpretation whether the situation is analogous and is being transported to be analogous to the situation of QFT in '1959', I would agree to Eric if the landscape wouldn't reach the measure of confidence with which it seems to be correlated: a parameterized model made to be constrained by experimental data which could eventually fail.

So, as someone whose physical interests remain that of a mathematical observer: why *do* physicists, i.e. Suesskind et al. claim, a set of mathematically 'valid' models could represent a set of 'possible universes', which mathematical concepts, as it is obvious not to rely on experimental data, force this interpretation? Is it possible to *prove* strong belief in the possible validity of a constrained set of models without any sufficient constraint data? Did someone, and Lubos at least seemingly could not deny this possibilty, exclude the perspective that for *any* given energy scale there will be, if at all, a family of models which matches the given data, but can only be distinguished beyond the given scale, implying any predictions beyond a given, experimentally observed, scale would be impossible, as long it wouldn't be the Planck scale?

66. **Peter Orland**
October 6, 2007

a.k.

There are a lot of possibilities which I can't deny out of hand. I'd
like evidence, however, or at least a solid motivation for a possibility before seriously considering it. That's the problem with the landscape
– there is nothing simple or compelling about it. So why launch a
research program to attempt to parametrize the world with it? After
all, there are plenty of other ways to parametrize the world (say, by using the particle data table).

67. **LDM**
October 6, 2007

I wasn't suggesting that the results of a vote like this have anything to do with the validity of a theory. But the fact that string theorists have been losing the public debate does explain some of the tactics they are now adopting in this debate. You don't hear any more the argument for string theory that "it has triumphed in the market of ideas". – PW

The latest issue of Physics Today has a free, excellent letter ("American physics implosion"), discussing NEW and TTWP, in which this notion of "market of ideas" is refuted and points out a disturbing trend in American physics. For anybody interested, the letter URL is:

http://ptonline.aip.org/journals/doc/PHTOAD-ft/vol_60/iss_10/16_2.shtml

Nature does not shop at our market place of ideas…she is the way she is — and only reveals herself through honest inquiry and experiment, rather than hype.

68. **Quixotik**
October 6, 2007

So please go back to studying representation theory or whatever it is you pretend to study in order to create the impression that you're a scientist and not just some computer administrator.

October 6, 2007

Don't be so rude!

Wikipedia

70. **David B.**

October 6, 2007

Dear amused (and others)

I'm not saying that lattice QCD has not solved many problems in the theory of the strong interactions. I'm actually very supportive of using whatever it takes to solve a theory of nature.

Even if with lattice one can see the area law, there are various things that are beyond computation because we do not have infinite resources. For example, getting the Regge behavior observed in nature and the unstable resonances in the meson spectra is beyond what can be done
on the lattice. If there has been a recent development that solves this problem I will be very glad to see it.

Regarding confinement, in toy models based on strings this can be understood as a geometric transition (topology change). This gives you an easily identifiable order parameter in the AdS realization. A lot of the papers where this was understood have about 500 citations and I would claim that that is a successful set of ideas.

You should also read the recent papers by Alday and Maldacena on scattering of gluons in conformal field theories. This is a very interesting new development.

My point of not tossing the Ising model for being unrealistic is exactly that: there are many situations where string models provide a lot of insight into strong coupling phenomena, even if not directly on QCD yet. One has to keep things in perspective.

I also don't see what the number of PRL's has to do with success in high energy theory. If you present a very long computation, it is hard to reduce it to four pages. I've gotten a few papers published in PRL, and it is usually a lot more work than what it is worth (I've had situations where the paper goes back and forth with the editors and reviewers five times and the whole process took over 8 months). If instead your result is a number with an error bar, that is a lot easier to package in the required format.

Regarding my coment of strings as a toy model of quantum gravity, I subscribe to that point of view and I am considered a string theorist.

We (as a string community) do not all agree on the various merits of various phenomenological approaches to the standard model. I am less optimistic than some others regarding predictivity, but I'm not going to tell people who are trying very hard to match with known experimental data to stop working on what they are doing because I'm prejudiced against some set of ideas.

I hope this has clarified my (very personal) point of view.

71. **Anon**
October 6, 2007

"If you want to discuss what I actually think you need to respond to what I write here. The tactic of ignoring what I write in favor of pulling out of context phrases from some other discussion is a tedious one."

So we're not allowed to examine individual propositions in your argument, and decide whether they are true or false? Or to see whether one statement follows logically from the others?

72. **woit**
October 6, 2007

Anon,

You can do whatever you want. But if you just take something I wrote on another blog out of context, try and make some point here with it, ignoring the fact that I already responded to that same point already on that blog, and ignore what I actually write here in response to you, it's really hard for me to believe that what you're interested in is a serious discussion. Somehow I get the idea that any time I decide to spend responding to you is just wasted. The fact that you are doing this under multiple anonymous pseudonyms, some juvenile, means that I have no idea who you are, why you are doing this, or any indication of seriousness on your part.

73. **Peter Woit**
October 6, 2007

LDM,

Thanks. The same issue also has

http://ptonline.aip.org/journals/doc/PHTOAD-ft/vol_60/iss_10/12_1.shtml

which features anectdotal evidence about what is happening to students doing theoretical phds these days.

74. **amused**
October 6, 2007

Dear David B,

I'm certainly not suggesting that AdS/CFT isn't interesting and should be tossed, and I agree that it would be akin to tossing the Ising model. My beef is with with the impression that you and other string theorists seem to be trying to create that AdS/CFT towers above other QCD theory developments in its significance and impact.

I'm aware that it provides an interesting model with a deconfining transition that might be related or similar to the one in finite temperature QCD. But does it have anything to say about the specific confinement mechanism in QCD and features of the QCD vacuum that give rise to it? E.g., does it give any insight into whether the picture of confinement based on dual Meissner effect is correct? Or why the deconfinement and chiral symmetry restoration transitions occur at more or less the same critical temperature? My impression, maybe wrong, is that AdS/CFT doesn't have much at all to say about these central issues in QCD theory.

"You should also read the recent papers by Alday and Maldacena on scattering of gluons in conformal field theories. This is a very interesting new development."

Ok, I'll try to find time to take a look. And while I'm doing that you should read Lellouch and Luescher's paper hep-lat/0003023 on weak transition matrix elements from finite volume correlation functions, which was also a very interesting development of continuing importance as well as a technical tour de force. And if you have some more spare time you should think about how to develop a Hamiltonian formulation for overlap/Ginsparg-Wilson lattice fermions, resolve the apparent difficulty with CP symmetry (see hep-lat/0501010), and prove Osterwalder-Schrader positivity for this formulation so as to put it on a secure theoretical foundation. These are very important issues that deserve your attention.

"A lot of the papers where this was understood have about 500 citations and I would claim that that is a successful set of ideas..[…]..I also don't see what the number of PRL's has to do with success in high energy theory…."

It’s kind of amusing that our views on the significance of citations vs PRL publications are diametrically opposite… But I think your insinuation that it’s easier to publish papers whose “result is a number with an error bar” is no less silly than the view of people who say that the real reason string theorists reject PRL publication as a measure of value is because if they accepted it then it would be possible to measure the value of ST work against the value of work on other topics and that comparison would lead to a conclusion that was uncomfortable for string theorists’ egos. At any rate, my experience and impression of PRL is quite different from yours. My papers in there are all on formal theory topics; the results were not “numbers”, in fact none of the papers contained a single physical unit. Moreover, the results in several of the papers were based on lengthy calculations that would have exceeded the PRL page limit n times over if written out in full. But as with all letter publications, as I’m sure you know, the thing to do in these situations is simply sketch the main steps in the calculations and state and explain the result. (And there is nothing unique about my PRL experiences; it’s been the same in quite a few other cases that I know of.) I can’t believe there should be any special difficulty for string theorists in this, especially considering the apparent ease which they summarize their work in press releases and press articles for the general public.

75. **David B.**
October 6, 2007

Dear amused:

Unfortunately I don’t know your name. You can on the other hand probably figure out who I am rather easily as I don’t hide behind a pseudonim.

When I have an idea that I think fits in the PRL format I make an effort to publish there. Also, when I spoke about numbers with error bars, it was not meant in any derogatory sense. I know very well how hard it is to produce a number with an error bar, as I have been recently doing exactly that and it has taken me over eight months of work to learn how to do it properly. I’m stating that it is a lot easier to put that type of calculation in a PRL format than other theoretical speculations. Don’t take it personally.

I feel that you are extrapolating assumptions about my personna and stereotyping me without bothering to know me or my scientific output.

I have never said that the string community has a compete handle on QCD, nor have I ever stated that the other developments in QCD are not important. I was trying to put the work of some segment of our community in perspective. It is very hard to get the point across that many of us actually care very deeply about real physical phenomena, to then be accused of making claims of the type “my field is better than yours”.

In fact, I am very glad for all the effort that has gone into the lattice QCD program and I think that some of the results in that field are outstanding. I’m also very glad that you pointed me to the work of Lellouch and Luscher on Weak transition matrix elements. This still does not explan the Regge behavior nor the strong decay matrix elements of unstable resonances which is the point I was trying to make. I hope this clears this apparent confusion.

Now, regarding citations versus publishing in PRL, that is a question of objective criteria to determine the quality of a paper and will certainly satisfy various bureaucratic bean-counters.

What counts as having made more impact on physics? A paper with 500 citations (which is a huger number by any measure), or managing to put a paper in PRL format?

I think you are over-reading the tea-leaves regarding my opinions in this matter.

I certainly hope this has clarified things a bit.

76. **amused**
October 7, 2007

Dear David B,

I’m sorry if you are bothered by my anonymity but there are good reasons why someone might prefer to remain anonymous in blog discussions…I have no idea who you are either.

Regarding publishing in PRL, from what I’ve seen the main consideration that people make in deciding whether to aim for it is whether or not their results satisfy the interest and importance criteria. That’s where the real challenge lies. I don’t think it’s at all difficult to put a more formal theory paper into PRL format (it can be a pain, but I wouldn’t say it’s hard).

“It is very hard to get the point across that many of us actually care very deeply about real physical phenomena, to then be accused of making claims of the type “my field is better than yours”.”

I don’t doubt your sincerity, but the way string theorists present the potential application of AdS/CFT to QCD often comes across as aggrandizement and misleading advertising (e.g. the lack of caveat about whether it really gives a valid effective theory for QCD in some regimes, which isn’t known yet). Maybe there’s a clash of cultures here.

Regarding citations, having a huge number of them is no doubt a sign of good work, as is a large number of papers in PRL. But beyond that I can’t really take it seriously as a measure of anything. It seems that papers that catch a wave of research activity at an early point can ride it to become highly cited without necessarily having made a major contribution. This happened (on a lesser scale) for one of my papers once, through dumb luck. There was nothing particularly great about it, and others which I consider to be much better have hardly any cites.

Anyway, thanks for taking the time for this discussion, hopefully we understand each others viewpoints better as a result.

77. **chris**

78. **chris**
October 8, 2007

dear david b.,

i would like to point out that a) there is no effective string description of QCD yet and b) that the sheer viscosity is a quantity that every model – no matter how crude – seems to get correct. i see it more of an interesting question as to why this quantity is so insensitive to the underlying theory or approximation methods than anything else. and by the way, there are accurate lattice predictions of this quantity as well.

regarding the lattice QCD results i am willing to make the following bet: we will have the complete meson and baryon specrum calculated with 3% precision before you will even have a dual string description of QCD.

oh, and of course these papers will hardly be topcite 500. our community is just that much smaller. but we have learned to live with this renormalization factor. it is also not too bad when you think about it. today a paper that does a rough order of magnitude estimation in a toy model does get 5 times more citations than the actual ab initio calculation. but in 50 years, i wonder which of these 2 numbers will end up in a textbook about qcd.

79. **JDR**
October 10, 2007

One thing I find troubling is the suggestion that “a computer programmer or an analytical chemist or a forklift operator” can not do or think about theoretical physics (or anything else for that matter). One does not need an advanced degree (or even a degree) to be able to pick up books, read information, work out the math, draw their own conclusions, and maybe provide some insights into a topic. Lets not forget the gentleman (and gentlewomen) scientists of an earlier era who did important work.

Deep Beauty

October 6, 2007
Categories: Uncategorized

I spent Thursday down in Princeton attending talks at the second day of a symposium on mathematics, quantum mechanics and the legacy of John von Neumann, organized by Hans Halvorson of the Department of Philosophy. A blurb about the symposium is here, and a list of talks is here. There were quite a few interesting people there that I enjoyed having the opportunity to talk to, including John Baez, who gave the keynote presentation (available on his web-site). Most of the talks were pretty far from my own interests (an exception would be that of Stephen Summers, on the vacuum state in algebraic quantum field theory), but it was interesting to see what sorts of things people interested in quantum mechanics, mathematics and philosophy are up to. At the end of the day I joined a group of people on a trip to visit von Neumann's grave, which was nearby.

One of the topics that some people at the symposium are working on is that of reformulating quantum mechanics using topos theory, an idea promoted by Chris Isham. For more about this, see an article here from the FQXI web-site. I have to say that, like 't Hooft and Dijkgraaf who are quoted in the article, I'm skeptical about this kind of thing, since topos theory is such a general formalism that I don't see how it is going to provide the sort of non-trivial new idea that people are looking for. But, you never know, something unexpected may come out of it. The article also describes Isham's "somewhat mystical view of reality" and the fact that he likes to "take part in interesting meetings on the twilight zone between physics and religion." At one earlier this year about "God and Physics", he speculated that "a logic of partial truth might be useful in comprehending the Trinity."

As you might have guessed, the Templeton Foundation is deeply involved in funding all of this, from the "God and Physics" meeting, to an FQXI grant for Isham, to the symposium on von Neumann itself. Besides the event I was at, yesterday and today they're also sponsoring two other events at Princeton: a panel discussion on Budapest: The Golden Years, Early Twentieth Century Mathematics Education in Budapest and Lessons for Today and a program called Living in von Neumann's World: Scientific Creativity, Technological Advancement, and Civilization's Accelerating Dilemma of Power.

At lunch I got to meet and chat a bit with Chuck Harper, who is in charge of much of Templeton's grant-making in the scientific area. The mechanics of the symposium were very ably organized by him and others, and they were all quite friendly to me. Either they're pretty oblivious and unaware of my vocal criticism of Templeton's activities, or just extremely gracious. I'm guessing the latter.

Templeton wasn't funding my day-trip down to Princeton, but they were paying for the dinner I consumed that evening in some very enjoyable company. Among other topics our dinner conversation included a long discussion about our hosting organization and what significance its activities and funding have for the sciences. Some people are concerned about involvement with an organization led by someone (John Templeton Jr.) known for his evangelical Christianity and devotion to funding right-wing political organizations (this article in the New York Times mentioning Templeton's involvement in "Freedom Watch", a new group that has done things like run ads suggesting Iraq was responsible for 9/11). As far as I can tell, the Templeton Foundation is careful to keep the right-wing politics out of its activities. However, they unambiguously are devoted to trying to bring science and religion together, and that's my main problem with them. Their encouragement of religion seems to be of a very ecumenical nature, not pushing especially the evangelical Christianity of Templeton Jr. Still, more influence from a religious world-view seems to me to be the last thing that physics in particular needs right now, especially with the on-going challenge to the scientific method represented by the anthropic landscape, a topic that Templeton has strongly encouraged work on through funding various conferences and other activities.

Others pointed out to me correctly that Templeton wasn't solely to blame for the anthropic landscape, that the real problem was its popularity at the top level of the physics establishment, leading to funding and influence mainly from other sources. The symposium I attended had not a trace of involvement of religion in it, and it seems that Templeton is careful to keep this out of some of the things that it funds as pure science, with another good example being the FQXI organization. They appear to have a serious commitment to the idea of funding things in physics that can be considered "foundational". People working in some such areas often are considered out of the physics mainstream and so find it hard to get their research funded. For them, Templeton is in many ways a uniquely promising funding source.

So, it was an interesting day, I'm glad I went, and so have to thank the Templeton people (and Halvorson) for the work they did in organizing the event. I remain concerned though about the significance for physics of this large new source of funding, out of scale with other such private sources, and with an agenda that seems to me to have a dangerous component to it.

Update: John Baez writes about the symposium here, including (courtesy of Jamie Vicary) a picture of a bunch of us standing behind von Neumann's grave trying to look suitably solemn.

Update: Thanks to many people for interesting comments, I especially recommend reading the one from Klaas Landsman here. Klaas both explains some of the motivations of recent work on topos theory and physics, and has interesting comments on the issue of Templeton funding. He notes that even a proposal by 't Hooft for funding foundational research on QM was rejected by conventional sources, making clear that the less conventional Templeton source of funding is one of the few alternatives open to people in this field.

Comments

1. **Matt**
   October 6, 2007

   I think one has to be careful to distinguish between the aims of a funding organization and what they require from the scientists that they fund. Historically, patrons of science have not always been bastions of morality, but have been responsible for funding some very good scientists. Today, a large part of science funding in the US comes from the defense department and it would be almost impossible in my field (quantum information) to conduct normal scientific activities without receiving some funding from them. They sponsor almost all the major conferences for example. I would think that this should be a greater concern than a few misguided religious people, but so long as they don't require me to unconditionally support all US military action, or to work on weapons research, it doesn't bother me too much.

   I have a similar attitude towards organizations like Templeton. Provided I am free to declare my atheism, and they are not going to use my work to promote religion, I would accept funding from them. The minute this changes I would cease from doing so. Of course, a certain amount of credibility is given to the whole organization by the fact that scientists are accepting their money, but shouldn't this be an even bigger concern with military funding? Isn't there a double standard involved in singling out Templeton for criticism?

2. **Peter Woit**
   October 6, 2007

   Matt,

   The fact that all money comes with some agenda is certainly true, and I recall Lee Smolin making the same point about military/government money. It's not even clear how much of a distinction one should make between DOD and DOE money, they both are coming from the same source, just different agencies.

   But, if the military started significantly funding particle theory, emphasizing one part of the subject that I thought was troublesome because they thought it might lead to better ways of killing people, I'd be criticizing them too…

3. **nork**
October 6, 2007

Is the Templeton physics funding that significant? I would have assumed it's a small drop compared to other sources.

4. **Peter Woit**
October 6, 2007

nork,

I think the initial round of FQXI grants totaled $2 million. To get some sense of scale, the DOE budget for particle theory at universities is around $20 million, NSF $10 million. So, it's not a huge fraction, but it's not a small drop.

Keep in mind that most government grants are continuing grants going to the same groups all the time. The amount of "new" money that someone who doesn't have a grant but wants to try and get one can compete for is much smaller than the $30 million total. The FQXI money was all new money.

I understand that Templeton has annually been funding projects totaling $60 million, and recently doubled its endowment and is planning on perhaps doubling their spending. I don't know how much of this they intend to devote to pure science or science/religion. Traditionally they don't make grants to experimental groups that require expensive equipment, so their money is going to theorists, whose other funding levels are much lower.

My impression is that in the area of academics working somehow on an overlap of science and religion, the amount of funding in this area available from Templeton completely overwhelms any other sources.

5. **Kea**
October 6, 2007

…since topos theory is such a general formalism…

If *general* applies to the level of abstraction, perhaps, but the theory is a very well developed branch of mathematics, computer science and logic, and quite capable of providing new computational tools.

6. **Yatima**
October 6, 2007

Topos theory in computer science? Really? Haven't heard of it yet, and I am generally keeping my ears open. I will hit The Googles but would you have any references straight away?

7. **Yatima**
October 6, 2007

And, speaking of the John Templeton Foundation ("Supporting Science – Investing in the Big Questions"), I open the print edition of The Economist and – what do you know – find a two page advertisement of said Foundation, with the title "Does the Universe have a Purpose?". Seven personalities are holding forth on the question: Lawrence M. Krauss, ("Unlikely"), David Gelernter ("Yes"), Neil deGrasse Tyson ("Not Sure"), Owen Gingerich ("Yes"), Jane Goodall ("Certainly"), Christian de Duve ("No"), Elie Wiesel ("I Hope So"). The advertisement rates are not publicized on The Economist website, but this can't be cheap.

8. **Chris Oakley**
October 6, 2007

Peter,

All this fraternising with the enemy. I would not now be surprised to hear about you getting drunk with Lubos at the Pilsen brewery in Czechia, or going on a cattle drive with Jacques Distler in Texas.

9. **Peter Shor**
October 7, 2007

It has always appeared to me that some of the people promoting the anthropic principle are in some sense trying to remove the last vestige of possible divine influence in physics. That is, they are trying to deny God His last remaining privilege; that of, e.g., setting the parameters in the Standard Model.

10. **Peter Woit**
October 7, 2007

Yatima,

Same two page spread in today's New York Times, also not cheap. Available online here

http://www.templeton.org/questions/purpose/

11. **Alex Rivero**
October 7, 2007

The two definite "no" in the spread come not from physicists but from chemists. Interesting.

12. **Andreas Doering**
October 7, 2007

Peter,

what you forget to tell your readers concerning topos theory and physics is the fact that you did not hear the two talks on this subject (by Klaas Landsman and me, where I was reporting on my work with Chris Isham), since they took place on the first day of the meeting when you were not there. Both Klaas and I included a lot of conceptual discussion besides the technical aspects, since this meeting seemed right for that. There also was some interesting discussion following the talks.
Listening to the talks would have provided a minimal basis for an assessment of the topoi-and-physics ideas, reading the papers would obviously have been better. The

FQXi article you give as a reference is completely non-technical and surely not a source for a serious discussion of these subjects. Moreover, the one day you were at the meeting, you made no attempt to talk to me about topos theory or anything related. (Maybe you discussed with Klaas or Chris Heunen, his PhD student?)

As you say yourself in your post: "The symposium I attended had not a trace of involvement of religion in it, and it seems that Templeton is careful to keep this out of some of the things that it funds as pure science, with another good example being the FQXI organization." To spell out the obvious: Chris and I welcome any serious discussion of our work – and criticism, of course! If you do not want to engage in that, please just let it be; I am not advertising here. But mixing an uninformed criticism of technical work that has absolutely nothing to do with religion with whatever beef you may have with the Templeton Foundation is deeply unfair. The remarks on Chris's activities beside his scientific work come very close to a personal attack, since these remarks are obviously intended to put him in a somewhat dubious light. Chris was not even at the meeting, and our work has nothing to do with religion whatsoever, so what is the point here?

I would think that this kind of rhetoric is something with which you have had a lot of unpleasant experience yourself, so I am surprised to see you employ this. I still hope that we may have a constructive discussion of physics some time.

Sincerely,

Andreas

13. **rob**
October 7, 2007

Andreas,

I think you're overreacting a bit here. I'm a relativist, and Isham has been a personal hero of mine for well over a decade, despite his apparent religious proclivities. But I really don't see how anything Peter said could be read as "very close to a personal attack." In fact, I read the post as a statement of puzzlement over the fact that the Templeton foundation, an organization that most physicists seem to distrust, is nonetheless funding (in part) real science by great scientists.

You may be annoyed that Peter expressed skepticism over your program of research, but surely you're used to that by now. I'm a huge fan of the idea of applying Topos theory to QM, and I'd love to see someone evangelizing it on a blog, but this is Peter's blog, and it's not his job to evangelize your work, especially if he doesn't happen to believe in it.

14. **Steven H. Cullinane**
October 7, 2007

Rhetorical question: What *is* "deep beauty"? See also a rhetorical answer.

15. **Peter Woit**
October 7, 2007

Andreas,

Unfortunately I wasn't able to come to the first day of the symposium since I was teaching that day. I would have liked to have heard your talk, as well as several of the others from that day, and undoubtedly would have learned something from the discussion there. Klaas sent me his paper before the conference, I did read that, and took a look at yours. But I'm certainly not well-informed on the subject of work on topos theory and physics, and I don't think I made any pretense of being so, or even capable of giving a serious explanation of the subject, with links to appropriate references.

I do know something about what a topos is, having spent a fair amount of time trying to understand and assimilate the Grothendieckian point of view on topology and algebraic geometry in which the concept originally arose. But I don't know much about the kind of attempts to reformulate physics using this that you are involved in. I don't think that it's controversial to characterize such a program as highly speculative, or inappropriate to mention that, despite not being well-informed about the program, I'm skeptical that it will work (while acknowledging that my skepticism could turn out to be misplaced). Everyone thinking about physics and mathematics in a fundamental way has their own prejudices about which directions are most promising to think about. I've got mine and they seem to me rather different than those of people working on toposes in physics. Quite possibly I'm wrong about mine, quite possibly we're both wrong. All ideas out there at the moment about new ways to understand fundamental physics are highly speculative, without much evidence to back them up.

I certainly in no sense intended what I wrote as any sort of attack on Chris Isham. The main reason I linked to the FQXI article was that, while mentioning the skepticism of 't Hooft and Dijkgraaf, it seemed to me a sympathetic description of him and what he is trying to do. I don't know Isham personally and know very little about his recent work, but earlier in my career I spent a fair amount of time reading articles of his, especially about geometry and quantization, and as a result have a great deal of respect for him.

The other reason that I linked to the FQXI article is that it mentions Isham's attitude towards the science/religion issue, which is very different than mine. You couldn't pay me enough to sit through a conference of talks on science and religion, while Isham says he enjoys this kind of thing. To each his own. It sounds to me like his point of view is a lot closer to that of the people running Templeton than mine, so he is a good example of what they would like to fund. As I hoped I made clear, my views about what Templeton is funding are mixed. The science/religion stuff I don't think is very worthwhile, but it's harmless if kept completely separate from real science. That Templeton is, through FQXI and things like the Princeton symposium, funding serious work about foundational issues in physics (including that of Isham on toposes and physics) is great, but the fact that their agenda includes a very different aspect seems to me very much worth keeping in mind.

16. **mo**
October 7, 2007

Andreas Doering Says:

"Listening to the talks would have provided a minimal basis for an assessment of the topoi-and-physics ideas, reading the papers would obviously have been better."

I read with sympathetic eye most of the papers relating to categories/topoi and physics as I think it is a great idea and am curious to know what may come out of it. So far the progress was meagre. I believe this whole line of thought has been initiated by F. Lawvere who tried to apply topos theory to dynamics, chaos, entropy, continuum microphysics, and even engineering (unfortunately his lecture notes on algebraic foundations of physics and engineering are not published yet). As it turned out the most serious obstacle on this path is how to introduce time and evolution into a static framework of the category/topos theory. Lawvere tried to do it but I don't feel he was successful.

Isham and his coworkers laid the foundations of "topoical physics" (let me call it this way), but it was never clear to me how it would work in real life, whether it categories in general or topoi in particular. And then Jamie Vicary (a rising star of categorical physics?) posted his groundbreaking article on arXiv:

A categorical framework for the quantum harmonic oscillator
http://arxiv.org/abs/0706.0711v2

At last we have a simple, but real-life quantum system for which categorical computations have been pushed through to some kind of end and we can perform a comparative evaluation. I really appreciate Jamie's yeoman's work, but one immediately notices that titanic effort and much space (44 pages) did not accomplish a lot–Schroedinger and Heisenberg did it better. Jamie himself (or herself?) concludes on p. 41:

"However, there are many issues which are still unclear. Philosophically, perhaps the biggest problem with the existing framework for categorical quantum mechanics is the lack of any nontrivial categorical description of dynamics. For this reason, it is questionable whether the system under study in this paper deserves to be called the harmonic oscillator at all: without a description of dynamics, all that has really been defined is the state space,
but many different systems have isomorphic state spaces."

That damn problem of time again!

Obviously, categorical physics isn't yet ready for prime time.

I skip our neighbors from n-Category Cafe (J. Baez et al.) to Louis Crane who, in my opinion, is the only person doing research in categorical physics that is well balanced between physics and mathematics. His most recent survey paper (which is heavy on topoi) is available here:

Categorical Geometry and the Mathematical Foundations of Quantum General Relativity
http://arxiv.org/abs/gr-qc/0602120

And by the way, to my knowledge, LC is the founding father of categorical physics:

Categorical Physics
Authors: Louis Crane
http://arxiv.org/abs/hep-th/9301061

17. **Coin**
October 7, 2007

Kea, if you don't mind me asking, I also would be curious what the connection you allude to is between topos theory and computer science. Or do you just mean that category theory in general is of relevance to computer science?

18. **Amitabha**
October 8, 2007

Not the right thread, and perhaps too close to the event, but would you or anyone else make any prediction about tomorrow's Nobel Prize?

19. **Urs Schreiber**
October 8, 2007

By the way, we had quite a bit of discussion of Doerin-Isham's work on topos-theoretic quantum theory on the n-Category Cafe, in case anyone is interested.

It starts here

http://golem.ph.utexas.edu/category/2007/03/a_topos_foundation_for_theorie.html

and here

http://golem.ph.utexas.edu/category/2007/04/topos_theory_in_the_new_scient.html .

A transscript of a talk by Andreas Doering is here:

http://golem.ph.utexas.edu/category/2007/07/physical_systems_as_topoi.html
http://golem.ph.utexas.edu/category/2007/07/physical_systems_as_topoi_part.html
http://golem.ph.utexas.edu/category/2007/07/physical_systems_as_topoi_part_1.html

20. **John Sidles**
October 8, 2007

Many disciplines claim von Neumann as one of their own; this includes atomic-resolution microscopists, as foreseen by von Neumann in this little-known 1946 letter to Norbert Wiener.

21. **John Baez**
October 8, 2007

Just so everyone knows, religion wasn't on the agenda at the *Deep Beauty* conference. As far as I can tell, none of the speakers is even very interested in the relation of religion and physics. Freeman Dyson is, but he merely sat in on the last talk of the first day, and came to dinner afterwards. I would be very uneasy attending a physics conference if I felt it was pushing religion somehow, but I didn't get that feeling.

I suspect that while the Templeton Foundation is interested in promoting religion, garnering the good will of academia is too important to their plans for them to deliberately do anything that stirs up lots of hostility. Look how they dropped the Discovery Institute like a hot potato after that controversy erupted.

By the way: I hope to say a bit about the recent work on topos theory and physics in This Week's Finds, pretty soon.

22. **Jamie Vicary**
October 9, 2007

If Chris Isham ever said "a logic of partial truth might be useful in comprehending the Trinity", then it was certainly intended as a joke! 🙂

It was a real pleasure to be at the conference and hear all of these ideas from their creators' mouths. Something that might not be clear to an outsider reading this thread, though, is that the 'topos quantum mechanics' approach (D\"oring, Heunen, Isham, Landsman, Spitters) is currently quite different to the 'quantum mechanics in symmetric monoidal dagger-categories' approach (Abramsky, Baez, Coecke, Duncan, Morton, Paquette, Pavlovic, Selinger, Vicary). The latter looks to the category of Hilbert spaces for inspiration, and tries to axiomatise its important properties. The former provides a more flexible context in which to describe theories of physics, which then come along with a tailor-made realist interpretation. This works, in particular, for quantum physics, which famously lacks a realist interpretation when formulated in a more conventional way. So, although both approaches are 'categorical quantum mechanics', and people give talks about them at the same conferences, they're really quite different in both style and short-term goals. (Although, of course, one hopes that in the medium term they'll prove complementary, on the road to a long-term goal of quantum gravity!)

The realist interpretation of quantum physics that emerges from the topos-theoretic approach is often not mentioned in high-level descriptions of the research, which seems a shame to me. This is a hugely important part of its philosophy and motivation. Perhaps this angle might make it more attractive to you, Peter?

23. **Benni**
October 9, 2007

the project sponsored by tempelton that scares me mostly is this here:
http://www.quantum.at/uploads/media/Templeton_Fellows.pdf
This is a project from the famous quantum physicist Anton Zeilinger who is well known for his work on entangled states (several nature papers).
Templeton foundation makes it possible to fund some theologists for a one year period, that will, according to the proposal, work together with the quantum optics group from Zeilinger.

That is: some people really look up into the holy bible how to collapse a wavefunction……
It is scary that the interpretation of physical formulas and experiment data which is the sole domain of theoretical physicists, is now taken up by theologists on a religions basis.

24. **Peter Woit**
October 9, 2007

Thanks Jamie,

Glad to hear that the Trinity comment was intended as a joke, I was hoping so…

I'm afraid that I don't especially have any prejudices one way or another about whether a realist interpretation of QM is desirable. My own prejudices are fueled by a belief that deep ideas about physics and deep ideas about mathematics are often closely related, and the interpretation question is kind of independent of this. My skepticism about topos and category-theoretic ideas is just based on the feeling that they seem to be such general frameworks that, while they may be useful for formulating all sorts of different kinds of theories, they aren't likely to help one with the problem of identifying the specific mathematical structure that governs our word. But, as I keep pointing out, I'm all in favor of people with different guesses about what will be fruitful following those and seeing where they lead.

25. **Chris Heunen**
October 9, 2007

Yatima, you will want to look for `the effective topos'; it is very much related to computability and recursion theory. Invented by Martin Hyland in the 1980s, it also happens to be the best example (that I know of) of an elementary topos that is not a Grothendieck topos, i.e. a logical structure that allows full internal reasoning but could not have arisen in a geometric setting.

26. **tytung**
October 9, 2007

Hi Jamie,

I wonder if you can describe a bit on the realist interpretation of quantum theory as seen from a topos formulation?

27. **Klaas Landsman**
October 10, 2007

1) Topos theory

Though a proponent of the use of topos theory in physics myself, I would agree that so far very little has really been achieved in this direction; the program largely rests on hope, on the excitement of having a relatively new and profound mathematical formalism at one's disposal, and on a few technical indications that we might be on the right track (it would be ironic if topos theory indeed turns out to be relevant to physics, since its founder, Grothendieck, abhorred physics and physicists as he held them responsible for the atomic bomb). The reformulation of the Kochen-Specker Theorem in sheaf-theoretic language by Butterfield and Isham, see arXiv:quant-ph/9803055, (which for me and others was the original reason to get interested, spurred by friendship with and intellectual admiration for these authors) is certainly nice, but by no means shows that topos theory is genuinely relevant to physics. The papers by Doering and Isham, in particular section 4 of their second paper at arXiv:quant-ph/0703062, formed a second source of inspiration for me, notably their idea of reformulating the pairing between observables and states so that it takes values in the subobject classifier of a suitable topos (instead of in the interval [0,1]). Here the goal is to derive the usual probability interpretation of quantum theory from a deeper multi-valued truth assignment, but it has to be stated quite clearly that this goal has not been achieved so far (there are clear indications that it can be achieved, though). In fact, even the meaning of the multi-valued truth assignment in question is pretty unclear. Thirdly, the work of Heunen and Spitters at Nijmegen, see arXiv:0709.4364, appears to be the first mathematically rigorous and truly satisfactory version of Bohr's version of the Copenhagen Interpretation, especially his Doctrine of Classical Concepts and his Principle of Complementarity (see my Handbook article, arXiv:quant-ph/0506082, for a modern though pre-topos reading of these notions). I distance myself from any reference to Heidegger (instead of Bohr) by Doering and Isham at this point.

I would say that the essence of topos theory resides in its natural link with geometric logic, a fragment of intuitionistic logic deemed relevant to observational theories. As I said at the Deep Beauty meeting in Princeton, the statement that fundamental physics ultimately rests on geometric logic seems to me to be the correct version of the common informal idea that quantum gravity is "finite", combined with the observation that quantum mechanics seems to cry out for intuitionistic (as opposed to classical) logic.
The notion of a geometric morphism is highly attractive and might be the right home for the functoriality of quantization, an idea I wrote a number of papers about and which so far has lacked the link with the classical limit that the inverse image part of a geometric morphism could perhaps provide.
As topos is a branch of category theory, it also deserves to be mentioned that there is increasing evidence for the relevance of category theory in physics, not merely as an organizing principle behind the maths behind physics, but more directly, too (cf. work by Graeme Segal, John Baez and others).

Despite the somewhat preliminary nature of topos-related work in the foundations of physics so far, I was a bit surprised to see Gerard 't Hooft's dismissive comments on topos physics at the fqxi website
(see the link "Topos or not Topos" at http://www.fqxi.org/community/). Indeed, 't Hooft, myself and a few others recently submitted a large research proposal on the foundations of quantum mechanics, general relativity and quantum gravity to FOM, a branch of the Dutch Science Foundation responsible for the funding of physics research, in which topos theory (with reference to Isham et al) was explicitly mentioned as both promising and appropriate to the Dutch research landscape (for example, Ieke Moerdijk is a leading expert on topos theory and logic with close ties to myself, initially because of our joint interest in groupoids and lately also because of our view that the philosophy of mathematics should
be relevant to the philosophy of physics). Now, believe it or not – 't Hooft is widely regarded as one of the most eminent theoretical physicists in the world, having won the Nobel Prize in 1999 for work done in the 1970s and since then still thriving with deep and original ideas, such as the holographic principle –

our proposal was not even shortlisted! Such is the funding climate for foundations research outside of the Perimeter Institute.

Which brings me to my second theme:

2) Science, religion and the Templeton Foundation

The John Templeton Foundation takes a sympathetic eye towards foundational research in physics and is funding an increasing part of it. First, it has to be mentioned that controversies of the type we are dealing with here seem heavier in the US than anywhere else; even technical disagreements about the K12 Math curriculum are referred to as "wars" (see Suzanne M. Wilson, California dreaming: reforming mathematics education, Yale UP, 2003). As a case in point, rumour has it that the Deep Beauty meeting had to be held at the Nassau Inn instead of at Princeton University because the latter refused to be host to an event sponsored by the Templeton Foundation (and this despite the fact that the Chair of the conference, Hans Halvorson, is a professor of philosophy at Princeton University). Apparently, it was never a problem for Princeton University to host researchers receiving grants from a Government involved in the Vietnam war or in the invasion of Iraq, not to mention all the other illegal operations practically any US Governments has been associated with in the past and the present.

On a somewhat different note – trading the illegal for the legal – the Dutch Government receives part of its income from taxes paid by the producers of animal porn movies, the production of which is perfectly legal in the Netherlands (we do live up to our reputation). Indeed, 75% of the world production of animal porn comes from the Netherlands. Such movies do not display the intercourse of animals among themselves, which perhaps would be offensive enough if exploited commercially, but the rape of women
by dogs and goats etc. Although it is hard to think of something more disgusting and humiliating, I have never heard of anyone returning his or her research grant to the Dutch Government for this reason Indeed, neither have I).

The mission of the Templeton Foundation, on the other hand, is: "to serve as a philanthropic catalyst for scientific discovery on what scientists and philosophers call the 'Big Questions.' Ranging from questions about the laws of nature to the nature of creativity and consciousness, the Foundation's philanthropic vision is derived from Sir John's resolute belief that rigorous research and cutting-edge scholarship is at the very heart of new discoveries and human progress."

Sir John apparently hopes and expects that the answers to the Big Questions will involve God one way or the other, but so did Isaac Newton and I see nothing objectionable in this. No commitment in this direction whatsoever is required from grantees of the Foundation, and even the research funded by the Foundation need not contain any religious theme (and indeed much of this research does not).
It seems to me that much of the hostility to religion I read in typical comments on the Templeton Foundation by secular scientists is fuelled by fear of Bush and the Christian right. I am a secular scientists and I share this fear, but I do not see why it should read to a rejection of the Templeton Foundation (or indeed of its grantees).

In fact, I believe atheists or naturalists should be honest enough to admit that science has not given us a clue about the question why there exists a Universe at all, or, equivalently, why there exists something rather than nothing. I once closely followed research on the "wave function of the Universe" and other attempts to explain how the Universe could have been created from nothing, and in honor of our host Peter Woit I can safely tell you that such research is Not Even Wrong. We haven't got a clue.

In conclusion, I felt no qualms in receiving my expenses and honorarium cheques from the Templeton Foundation, I am going to apply to the Start program (which is funded by the Foundation) and I would not hesitate in the slightest to apply to the Templeton Foundation itself in the future, e.g. for a large program on determinism. I think we should be grateful to this Foundation and its executives for funding foundational research that Goverments typically refrain from supporting, and for doing so without asking anything in return but high quality.

28. **Andreas Doering**
October 10, 2007

Peter,

thanks for the clarifications. It is good to keep the assessment of scientific work apart from the political (like questions about funding), as usual. And, as also said by some other participants, the Deep Beauty meeting was free of religious under- and overtones, and that is how it should be for a science meeting.

I am happy to see that there is some interest for the work on topos theory in the foundations of physics. Every thoughtful criticism may be very useful. Klaas, John, Jamie and Urs give some valuable hints to the literature and some background information – thanks for that! -, and it is easy to find in the ArXiv the four papers (from March) that I have written with Chris.

tytung,

an explanation of the `neo-realism' achieved by the topos formulation of quantum theory is not easily done in a few lines. I would like to point you to the papers. If you like, contact me via email with questions.

29. **a.k.**
October 10, 2007

..let me say that it is certainly true that 'any money comes with an agenda', still the questions remains, to which degree the formulated aims interact with the content. While the US government is far from being without scientific agendas regarding their funding, someone mentioned quantum information, its funding still permits 'diverging' opinions, as the example 'string theory' and its opponents clearly shows.

One could read, one year ago, some concerns regarding the Templeton foundation in the german weekly magazine 'die Zeit', where it was shown to what extent the Templeton foundation already interacts with certain themes in the non-exact sciences, here the Foundation actively engaged, as an example, in psychological projects to show the effect of 'prayer' and 'forgiveness' on health status and life-expectance, the evidence for both effects was rather small, by the way, this new area is called 'neuro-theology'. The question remains how, especially in times of decreasing financial support for the non-exact sciences, a Foundation with a certain religious and explicit ideological agenda could influence the neutrality and freedom and possible critical views towards religion in the non-exact sciences or could even be involved in questioning certain achievements of critical rationalism as an organizing principle in society. A good example for such a questioning, as it was mentioned, would be to punish 'non-spiritual', 'non-moral' behaviour as pornography or even 'animal porn' by identifying it naturally with a criminal act, disregarding the highly differentiated categories of modern societies leading to tolerate these behaviours, given they are acts of free choice.

Regarding the exact sciences, Templeton's agenda is to accelerate a certain characteristic any progress has regarding the myths it evaporated: to become an even more powerful myth in its own. Since from the beginning, especially the exact sciences tended to develope a 'vertical' character which implied some ressemblance with monotheistic religious concepts, the question remains, if Templeton will be involved in a development which naturally converges to an anti-emancipating 'scientific god', that it will help to substitute the scientific method to be the culmination point of universal belief for anyone who is not part of a small, neo-religious elitistic circle, called exact scientists, even today certain parallels between ancient religious symbols and the particle accelerators are undenieable. To conclude, one could judge it doubtful to isolate Templeton's actions on physics and mathematics, where their agenda is far from being clearly religious, one has to consider the effect on science and society in general, i.e. in that era of religious fundamentalism that we are going through.

30. **woit**
October 10, 2007

Thanks Klaas, both for the lucid explanation of some of the motivations of the work on toposes, and the comments on the Templeton funding issue.

31. **chris**
October 11, 2007

a.k.,

once we reach the point at which the templeton foundation – or any other private sponsor for that matter – is the main source of funding in a certain area of science it would be time for society to react. react by outdoing the private source and thus claiming the research topic in question firmly back into the public domain.

if society chooses to be oblivious – well – then so be it. research in that area will then not be driven by public interest but by private interest. ultimately it is just a reflection of the value commonly assigned to a specific field.

what i hope this will ultimately achieve is to ring the alarm bell in society that no private organization should take over research funding and direction.

if this will not happen – well – then we are kind of lost anyways. and funding no matter what agenda behind is still better than no funding, since i firmly believe that ultimately the truth (i.e. true statements about reproducible empirical relations) will ultimately prevail and nothing else.

32. **Steven H. Cullinane**
October 11, 2007

Chris says *the* truth consists of “true staements about reproducible empirical relations.” He should read William Golding’s Nobel lecture: “When I consider a universe which the scientist constructs by a set of rules which stipulate that this construct must be repeatable and identical, then I am a pessimist and bow down before the great god Entropy. I am optimistic when I consider the spiritual dimension which the scientist’s discipline forces him to ignore.”

33. **Stephen J. Summers**
October 11, 2007

If I may interject a clarifying remark: while at the conference, I spoke with Hans Halvorson about why the conference was moved from the campus to the Nassau Inn. It was not the University, but rather one senior professor in the physics department (I will suppress the name), who made it clear to Hans that he would prefer the change of venue, as he did not want to place the Physics Department’s imprimatur upon anything associated with the
Templeton Foundation. Indeed, in connection with this von Neumann celebration there were major talks given on the Princeton campus which were also funded by the Templeton Foundation (and this fact was prominently displayed on the advertising placards placed all over the campus). So, Princeton University did not distance itself from the Templeton Foundation in the least.

Lubos on Lenny

October 8, 2007
Categories: Uncategorized

Last night a new paper by Lenny Susskind appeared on the arXiv, carrying the title The Census Taker's Hat. It seems that Lubos Motl stayed up much of the night reading it, with a long posting on the subject appearing before 8 am in the Czech Republic.

Now that he's no longer employed within the string theory academic community, Lubos feels free to treat Susskind in much the same way he did Lee Smolin, characterizing Susskind and collaborators as a "gang" of "leftists", and making fun of the central notion in Susskind's paper (that of a preferred observer called the "Census Taker") by referring to it as "Stalin the daddie". He gives a detailed section-by-section critique of Susskind's paper, here's some of the flavor:

> Well, this is about 7th assumption that seems obviously wrong to me – this one is really bad – but let's go on reading. I still haven't understood what question he exactly wants to be answered. Equally seriously, I don't understand whether he thinks that his speculation about the location of the central committee is a hypothesis with some evidence, a nice hypothesis without evidence, God's ad hoc decision, or why does he exactly believe it.

Unlike Lubos, I haven't tried to follow the details of Susskind's 65 page argument, but did try to figure out how he addresses the central problem of any multiverse scenario: how do you test it? If you can't test it, it's not science. Susskind describes exactly two possible ways that information about the "Ancestor" universe to ours may be accessible.

- The sign of the spatial curvature should be negative. This just predicts one bit of information about the universe, and there's a paper claiming that you can also get the other sign, so that even this one bit is not there.
- If the number of slow-roll e-foldings is "minimal", then tensor fluctuations of the CMB would be there, but just in the lowest harmonics. Funny, but last week I was told in a colloquium talk that string cosmology predicts no observable tensor fluctuations…

Susskind begins by claiming that "To many of us, eternal inflation, bubble nucleation, and a multiverse, seem all but inevitable", but goes on to note that the fact that one has an infinity of universes that one doesn't know how to count means that "the inevitable has led to the preposterous". A reasonable person might decide that this means that things weren't so inevitable, but Susskind feels that one must soldier on, although "In my opinion, this situation reflects serious confusion, and perhaps even a crisis." This paper is his attempt to address the crisis.

Susskind quotes Bjorken as having told him that the Multiverse is "the most extravagant extrapolation in the history of physics". He seems rather proud of this, but somehow I suspect that Bjorken didn't mean this as a compliment…

Comments

1. **Jack**
   October 8, 2007

   This is off-topic, but I can't still believe that Lubos left academia. What went wrong? Can anybody tell? What is he going to do next?

2. **IMHO**
   October 8, 2007

   What went wrong with Lubos??????

   Have you ever read his blog? Have you read this post? And I would call this post tame compared to the usual….I think it's now common knowledge that his mouth is a big part of what happened.

   Either way, no matter how much I disagree with his opinions, I have to respect his dedication to the truth (as he sees's it)…consequences be damned!!! Also, you have to be impressed with his ability to debunk a 65 page Susskind paper in one evening.

3. **Jack**
   October 8, 2007

   Again off-topic, but let me tell that only after reading Peter's current post I came to know that Lubos had left academia. I searched on the net including wikipedia but the reason why he did it remains unclear. Now I see he had mentioned about this decision at other blogs but so far the only hint he had given is: he wants to leave institutionalized science. He is extraordinary no doubt otherwise he would have not become a faculty member at Harvard. I am waiting to know what he is going to do next.

4. **Chris Oakley**
   October 8, 2007

   > Dear Lubos, I think you should know that this time you've really outdone yourself. Normally a very negative review will induce me to go see for myself (because of my contrarian streak), but this time I'll have to fight a real sense of repulsion in order to do so. Congratulations.

   This was the first (anonymous) comment following Lubos's review.
   I agree entirely.

   As for Lubos leaving Harvard, I thought that it was common knowledge that he was driven out by an unholy alliance of feminists, communists, climate change scaremongers and anti-science crackpots.

5. **Dan Fitch**
   October 8, 2007

   In the last paragraph, you note "Susskind quotes Bjorken" when I'm pretty sure you mean "Lubos quotes Bjorken".

6. **Dan Fitch**
   October 8, 2007

   Actually, they both quote the same thing. Never mind. I still think you mean to address Lubos taking it as more of a compliment than intended.

7. **Peter Woit**
October 8, 2007

Dan,

No, it is Susskind, in his paper, and he's the one I'm guessing took it as more of a compliment than intended. Bjorken is Susskind's colleague at Stanford and presumably they've discussed this issue in person.

8. **IMHO**
October 8, 2007

I just reread Lubos's post…and all I can say is WOW. Irregardless of whether or not he is correct; it's almost as if he has spent his entire life in a book and has no concept of social acceptance or appropriate social interaction.

9. **Ted**
October 8, 2007

Anyone else forced to ctrl-alt-del out of Lubos' site?? Happens to me every time now …

10. **Ted**
October 8, 2007

Tried FoxFire, works ok … never mind.

11. **Garrett**
October 8, 2007

Heh. If you try to follow Peter's link to Lubos' blog, you'll get a redirect stating visitors clicking in from NEW aren't welcome. In defense of this snub against PW and his readers, he cites non-other than the esteemed Professor Susskind. Apparently the enemy of his enemy is… his enemy.

12. **F.**
October 8, 2007

No, Susskind is not treated by Lumo as his enemy. He just happens to think that Lenny is wrong in this new paper. Thats different.

13. **David**
October 8, 2007

This is off topic, but I think Lubos' blog and the comments there have become largely irrelevant. I can't see anybody taking it seriously. The comment stream no longer contains any serious comments by people in science. Given where he once was, it's all a bit sad.

14. **Eu**
October 8, 2007

Regarding "may or may not", I doubt these stylistic constructions don't exist in other romance languages given that Portuguese and Castellian have them. They are not used very often but they do exist together with "for what it's worth", which ironically isn't worth anything.

Lubos' site is heavy on the javascript with all sorts of junk and it cripples some browsers to their knees. Just disable it either globally or just on that site. You won't loose much. Alternatively use an rss feed reader.

To follow links to TRF from NEW just disable the referer (some browsers allow this in the privacy settings). Lubos isn't a magician and doesn't know where you come from unless you tell him.

This time Lubos actually surpassed himself, even with the leftist metaphors.

15. **chris**
October 9, 2007

"This is off topic, but I think Lubos' blog and the comments there have become largely irrelevant. I can't see anybody taking it seriously. The comment stream no longer contains any serious comments by people in science. Given where he once was, it's all a bit sad."

well, if someone makes a habit of deleting critical remarks, that's what you get.

16. **Aleksandr Mikunov**
October 9, 2007

May sound slightly off the topic, but keep on reading 🙂

1) It is ironic to read how Lubos M. is demoting Susskind's work whereas his own stuff is just a generic blah-blah-blah [E.g. look at LM's PhD: http://arxiv.org/abs/hep-th/0109149. Semi-trivial math and not a single physically meaningful calculation].

2) I wonder if the IQ level of contemporary theoretical physicists is even comparable to what t. physicists had back in the pre-string era, say in the 40-60-s [Although, LM insists it's by ~40 pts higher than average – I doubt it]

3) To LM and other "above-the-average-IQ" physicists: The field is dead, so become programmers (the good ones :).
Believe or not but becoming an !expert! in C++/Windows/Linux takes years of *extremely* hard work.

(BTW, Not as simple as calculating Green's functions 🙂
E.g try digesting this book: http://www.amazon.com/Modern-Design-Generic-Programming-Patterns/dp/0201704315)

(Note that here we are simply talking about *digesting* this stuff. You won't be able to come up with anything similar of that level for a long time 🙂

17. **Hendrik**
October 9, 2007

No one has commented on the fact that Witten has a new paper on the ArXiv at:
http://xxx.lanl.gov/abs/0710.0631

titled “Gauge Theory And Wild Ramification”.
I suppose it takes a bit longer to digest.

18. **fulo**
October 9, 2007

> Semi-trivial math and not a single physically meaningful calculation

According to the abstract, the results in his thesis were obtained “for the first time in history”. It’s just childish…

19. **Peter Woit**
October 9, 2007

I’d like to discourage further criticism of Lubos here, on grounds that it’s too easy, kind of boring, and at the moment he’s just a guy with a blog in Pilsen. Crazy as he is though, in this case he makes a lot more sense than Susskind, who’s somehow a leading figure in particle theory…

20. **Mr. Mustela**
October 10, 2007

Interesting. So we have a Census Taker, and scenarios with a “sense of inevitability” about them. I think I have an hypothesis on why the Templeton foundation is pouring money into theoretical physics.

21. **Peter Orland**
October 10, 2007

Oh, and Peter, sorry about contributing to an off-topic tangent in this
thread.

22. **Paul**
October 15, 2007

Lisa Randall mentions Lubos in Warped Passages – not for physics, but for slagging off female physicists!

23. **IMHO**
October 16, 2007

‘slagging off’ … Sounds British. What does it mean.

24. **Chris Oakley**
October 16, 2007

slag off (v.t.) – to denigrate

cf. slag (n.) – a loose woman, normally unattractive

25. **CM**
October 16, 2007

Harvard never ever gives junior profs tenure-this is a problem in lots of elite places. That is why LM left academia, the blog and his big mouth is an excuse that we all knew he would use once tenure was denied, people have been guessing this this would happen for years.

Latest From The LHC

October 8, 2007
Categories: Experimental HEP News

The LHC web-site contains a wealth of up-to-date information about how things are going there as they are commissioning the machine. In particular, one can follow the latest news about how things are going in each sector here, which may or may not give a more accurate picture of the situation than various rumors.

Today an updated commissioning schedule appeared at the web-site. One can see how things are going by comparing to the previous version (from Aug. 3, still available right now here). Attempts to cool down certain sectors have taken longer than expected, and the new schedule has them cooled to operating temperature 2-3 months later than in the previous schedule. The "Machine Checkout" and "Beam Commissioning" periods have not been changed yet, but it's not clear that the way they are currently listed still makes any sense (can you be commissioning the beam while still doing powering tests on the sectors??). It looks to me as if the present situation is that they are 2-3 months behind schedule now, and if all goes well, physics runs could start not next July as planned, but maybe in September at the earliest.

The CERN director general Robert Aymar issued a statement today that begins:

> In an age of blogs there are seemingly no secrets…

and ends

> All of this is business as usual when bringing a new particle accelerator on-line. There are inevitably hurdles to be overcome, but so far there have been no show stoppers. We can all look forward to the LHC producing its first physics in 2008.

I take the lack of any reference to the July 2008 date to mean that they acknowledge the schedule has slipped, but still think the slippage will only be a few months.

Update: I should also have mentioned this article, which explains how they are trying to deal with one of the most serious problems: using RF transmitters in ping-pong balls blown through the beam pipe to try and find broken copper fingers in the so-called "plug-in modules".

Update: Physics World has a story about this that starts:

> Robert Aymar, the director general of CERN, has dispelled rumours that a series of buckled electrical connectors at the Large Hadron Collider will delay the accelerator's official start-up date of May 2008.

In a technical sense this may be accurate, in that evidently the "official" start-up date has not been changed since the previous schedule. But the new schedule shows that things are two to three months behind where they are supposed to be to make the May 2008 date, so it now seems unlikely that that will be the date when they have a beam, or that July will be when they start doing physics. In his statement Aymar only promised start-up in 2008, so I take this to mean that he was quashing rumors about a delay into 2009, not the ones about a 2-3 month delay.

Update: Nature's Geoff Brumfiel has a new story about this. He quotes project leader Lyn Evans as saying the schedule is now quite tight

> "The next three months are going to be pretty critical," says Evans. "If something unforeseen comes up between now and then, it will slip. There's no doubt."

During this period one will be able to see exactly how they are doing. The cool-down schedule is here, periodic updates on how things are going in each sector are here, and the actual temperature of the magnets can be followed here.

Comments

1. **Paolo**
   October 8, 2007

   > which may or may not give a more accurate picture

   Maybe it's just me (I'm italian) but to date I fail to understand which is the informative content of the "may or may not" sentences, in english. Definitely we don't have an equivalent in italian, neither in spanish and french, I think. Nitpicking…

2. **Peter Woit**
   October 8, 2007

   Paolo,

   I guess it's pretty much pure stylistic affectation, just designed to indicate that reasons could be given for either of the alternatives being mentioned.

3. **a quantum diaries survivor**
   October 8, 2007

   Hi Paolo,

   there is no italian equivalent afaik (pqns 🙂 but there is informative content indeed in what Peter wrote… It casts some doubts while hiding the hand…

   Cheers,
   T.

4. **Yatima**
   October 8, 2007

   What about "peut-être bien que non, peut-être bien que oui", usually given in response to an indiscrete question? 😉

5. **Paolo**
   October 8, 2007

Argh, “peut-être bien que non, peut-être bien que oui” , I didn’t know about that! (honestly I’m not praticing much french these days beyond “Cahiers du cinema” and a few movies from time to time) What a waste of words… what a waste of words… 😉

6. **fulo**
October 8, 2007

> Definitely we don’t have an equivalent in italian, neither in spanish and french, I think. Nitpicking…

“May or may not” in Spanish, “puede o no”. I’d have guessed in Italian it would be the same thing, something like “puodi o non” or “puodi o menos” or some such. But then, I don’t speak Italian… 🙂

7. **Paolo**
October 8, 2007

This is quickly becoming off-topic, sorry to Peter. But, anyway, of course I can say “may or may not” in Italian, the question is whether it’s *common* in italian to say “… blah, blah, may or may not this, blah, blah, may or may not that…”. It isn’t, definitely. I maintain the same is by and large true of other neo-latin languages besides italian. In italian we can certainly say the rough equivalent of “may”, meaning “it is possible”, but it would be considered completely redundant to negate that “may” and add to it. Apparently, however, in english, something special happens, and “may or may not” becomes a single “block”, and, in a sense, native speakers do not instinctively appreciate that if something “may” (vs must) of course logically also “may not” and it’s not necessary do add the negation. That’s my point. That said, each language has its own weird, seemingly irrational, corners, I could mention 1000 in italian…

8. **wb**
October 8, 2007

Finding the damaged rf fingers is very important, but is not the only impediment to smooth sailing. One is left with the problem of the improperly fabricated fingers that are likely to damage in a thermal cycling of the machine.

9. **Ellipsis**
October 9, 2007

Peter (and all):

In fact, the answer to your question, as for what CERN management is officially stating (and which I’m _not_ going to try to defend), is _no_ — the official position is that the schedule remains with a _July 2008 start for beams_, despite the issues (which they believe can be solved without additional delay)…

Here is the talk, fresh from 6 hours ago, from Lyn Evans (LHC accelerator project leader):
http://indico.cern.ch/materialDisplay.py?contribId=85&sessionId=23&materialId=slides&confId=20736

Also of interest may be Peter Jenni’s (ATLAS spokesperson) talk yesterday:
http://indico.cern.ch/materialDisplay.py?contribId=9&sessionId=7&materialId=slides&confId=20736

Here’s what will probably really happen (but it’s not that far from reality, the problems really aren’t as bad as some were stating orginally). See p. 10 of Peter Jenni’s talk. The LHC Inaguration Day, at which multiple “VVIPs” (science ministers, and several European prime ministers and presidents, even a few royals — probably Sarkozy, the Swiss president, German minister of economics & technology, some members of the Dutch royal family(?), maybe Ray Orbach for the U.S., …) will come to CERN for the official inauguration of the LHC, is October 21 of next year. There MUST be a collision or two, or at VERY least storage of (low current) beams, by that date, to show particles colliding to a very large number of dignitaries in the control room.

I think Peter Jenni’s original statement (last month, that he appears to still hold) that there would probably, in the end, be a ~2 month delay is still correct. But the official CERN position is that the schedule remains for July beams next year.

Put your money on 1 or 2 observed proton collisions and corresponding pretty event displays by early October next year. But note that nobody really knows or can predict precisely what problems have yet to occur.

10. **Peter Woit**
October 9, 2007

Thanks a lot Ellipsis,

The idea that there will be a push to have some collisions when the VIPs show up on Oct. 21 sounds plausible. Probably no similar push for the string theorists, who will be there Aug. 18-23 for Strings 2008…

11. **DB**
October 9, 2007

It seems France and Germany are in a position to do some early celebrating: Albert Fert (from France) and Peter Gruenberg (from Germany) have just won the Nobel Prize in Physics for discoveries in magenoresistivity. Maybe String Theory will get it next year!

12. **Christine**
October 9, 2007

Congratulations to the Nobel prize winners and to the Brazilian physicist Mario Norberto Baibich, who was the first author to the 1988 paper.

(I have the feeling that Brazil will never get a Nobel prize.)

Christine

13. **dragon**
October 9, 2007

The usual nobel for trivial advances in solid state. Yawn. Somebody nobody has heard of, together with somebody else nobody has heard of, discovered the ipod. Strong contender for the most forgettable Prize of recent times.

14. **Johan Couder**

October 10, 2007

"The usual nobel for trivial advances in solid state. Yawn. Somebody nobody has heard of, together with somebody else nobody has heard of, discovered the ipod. Strong contender for the most forgettable Prize of recent times."

Where does that cantankerous remark come from ? Theoretical physics isn't the only physics game in town.

15. **Peter Orland**
October 10, 2007

Part of the function of the Nobel Prize is to put physics in context for
the rest of the world. That may not have been one of its original purposes, but today it is the case. For this reason, I think it's good that practical aspects of physics are put into the limelight. The public needs to be made aware that the practical devices they use originated in relatively recent physics research.

The committee's choice may not reflect the interests of the people who read this blog, but it certainly is real physics and is not forgettable.

16. **Peter Orland**
October 10, 2007

Just apologized for being off-topic in the wrong thread. I'm
doing this here again….

17. **SnarkFest**
October 10, 2007

Yes, Dragon. Those "trivial advances in solid state" help pay quite a few bills for those of us with more esoteric interests. And need I mention yet again the cross-over between condensed matter physics and quantum field theory?

18. **Kris Krogh**
October 11, 2007

I'm happy they give Nobel Prizes for research with a demonstrable connection to the real world, and not for playing games that only generate lots of citations.

19. **srp**
October 11, 2007

Didn't Marconi win it more as an inventor than a physicist? If anything, there may be too little credit given to the inventor types versus the academics–wasn't that the crux of the dispute over the Medicine prize for MRI? In any case, device physics is real physics.

20. **Biff**
October 12, 2007

Unless I'm mistaken, the giant magnetoresistance phenomena that Fert and Grunberg discovered is rather more useful than a 'trivial advance'.

In fact it's vital in most hard drives made today, including those used at the LHC. Or isn't that sort of physics real enough for some of you ?

21. **mo**
October 12, 2007

It is completely OK to get a Nobel for an invention as Alfred Nobel's will (see a larger excerpt below) explicitly says that a Nobel in physics should go "to the person who shall have made the most important discovery or invention within the field of physics." I heard many times that it was a long-standing Nobel Committee's policy to award the science prizes for outstanding work that resulted in tangible, practical advancement of sciences and useful arts.

That's why two most visible candidates for "genius" status, Hawking and Witten, never received the prize–and rightly so.

"The whole of my remaining realizable estate shall be dealt with in the following way: the capital, invested in safe securities by my executors, shall constitute a fund, the interest on which shall be annually distributed in the form of prizes to those who, during the preceding year, shall have conferred the greatest benefit on mankind. The said interest shall be divided into five equal parts, which shall be apportioned as follows: one part to the person who shall have made the most important discovery or invention within the field of physics; one part to the person who shall have made the most important chemical discovery or improvement; one part to the person who shall have made the most important discovery within the domain of physiology or medicine; one part to the person who shall have produced in the field of literature the most outstanding work in an ideal direction; and one part to the person who shall have done the most or the best work for fraternity between nations, for the abolition or reduction of standing armies and for the holding and promotion of peace congresses. The prizes for physics and chemistry shall be awarded by the Swedish Academy of Sciences; that for physiological or medical work by the Caroline Institute in Stockholm; that for literature by the Academy in Stockholm, and that for champions of peace by a committee of five persons to be elected by the Norwegian Storting. It is my express wish that in awarding the prizes no consideration whatever shall be given to the nationality of the candidates, but that the most worthy shall receive the prize, whether he be a Scandinavian or not."

October 13, 2007

Nobel Commitee likes to award for narrowly-defined contributions that have a great impact. HEP theorists are naturally at disadvantage.

Polarography got Heyrovsky a Nobel – a very simple-minded potenciometry experiment. (and a method for analyzing metal samples – not exceedingly useful one). It was the first completely-defined and understood system in electrochemistry – one that greatly boosted the self-confidence in the field. It also makes a good textbook chapter.

23. **Sebastian Thaler**
October 13, 2007

Peter,

Off-topic, but the issue of COSMOS magazine with your cover story on string theory has finally appeared on the magazine stand at my local Barnes & Noble. I bought it and am looking forward to reading it.

24. **woit**

October 15, 2007

Thanks Sebastian. I just got a copy of the magazine in the mail, and I'm quite pleased with how the article came out.

The Great Cosmic Roller-Coaster Ride

October 15, 2007
Categories: This Week's Hype

More than three years ago Scientific American ran a feature article by Bousso and Polchinski promoting the then new idea of The String Theory Landscape. Now that this pseudo-science has become well-entrenched in the physics community, this month's issue of the magazine has a feature article on The Great Cosmic Roller-Coaster Ride, describing how

> one of the emerging themes of 21st-century cosmology is that the known universe, the sum of all we can see, may just be a tiny region in the full extent of space

and claiming that this is "stimulating a thorough rethinking of the early universe in terms of string theory." There is quite a bit of defensiveness about string theory in the article, where it is described as the "leading candidate for the foundational laws of nature". The authors note that "String theory has received some unfavorable press of late", and characterize criticism of the theory as due to the fact that it "has yet to be tested experimentally", ignoring the fact that much of the criticism is about string theory's inherent untestability. Not only has it not been tested yet, but no one has any idea how to test it ever. They admit as much when it comes to predictions about particle physics:

> string theory has disappointed because it has not yet been possible to test it experimentally, despite more than 20 years of continued investigation. It has proved hard to find a smoking gun – a prediction that, when tested, would decisively tell us whether or not the world is made of strings. Even the Large Hadron Collider (LHC) – which is now nearing completion near CERN , the European laboratory for particle physics near Geneva – may not be powerful enough.

At the same time, they imply that the answer to string theory's problems is that it will produce testable predictions about cosmology. They describe work of their own and other people attempting to use as an inflaton field positions of branes or moduli parameters describing positions in the Landscape. What predictions do they see coming out of this?

- CMB experiments will continue to not see effects due to gravitational waves. In other words, the prediction is just that CMB experiments won't see anything relevant. Not exactly a distinctive prediction of string theory, and Lenny Susskind lists seeing such effects as the main hope for observational evidence of the Landscape. If such effects are seen, I doubt that string cosmologists will give up on string theory, but just come up with models that do "predict" such effects.
- Cosmic superstrings, observed by their gravitational lensing effects. One can in principle construct scenarios where cosmic superstrings are produced in the early universe in just such a way as to have eluded all observation until now, but such that one will turn up as we look more closely at more galaxies. I don't know of any reason for this other than wishful thinking. If cosmic superstrings don't show up over the next few years, I don't think anyone will take this as evidence against string theory.

I don't think it does much for the public understanding of science or increases respect for scientists when they decide to go to the public in this way, promoting extremely speculative and complex ideas that lack not only a glimmer of experimental evidence, but also any plausible idea about how they can be tested.

Update: There's a new review of string cosmology up on the arXiv tonight. The authors contradict the SciAm article's claim about whether these models can accomodate observed effects of gravitational waves:

> As an example, in many – but *not* necessarily all – string inflation models, the primordial tensor signal is very small.

giving examples of models with detectable gravitational waves (see here).

While the article as a whole is pretty much unadulterated hype for string cosmology, it ends on a downbeat:

> Despite these promising signs, it remains to be seen whether this endeavor will lead to genuine contact between experiment and Planck-scale physics. In many scenarios, inflation is described by a well-controlled, albeit fine-tuned, effective field theory Lagrangian, and inflation lasts long enough to obscure all evidence of a pre-inflationary stage. If we live in such a universe, cosmological observations can, at best, teach us about the nature of the inflaton, but will provide few clues about more fundamental physics, except perhaps through the enduring mystery of dark energy.

   October 16, 2007

   "Not only has it not been tested yet, but no one has any idea how to test it ever."

   This might very well be true, but a good half of your postings
   feature a similar statement. Perhaps you should choose it as a
   caption for the whole blog.

   ..

   However, maybe it can't be said often enough and in fact
   i like your blog anyway.

2. **Coin**
   October 16, 2007

   This might very well be true, but a good half of your postings feature a similar statement. Perhaps you should choose it as a caption for the whole blog.

   Technically, isn't it expressed in the *title* of the blog?

3. **roland**
   October 16, 2007

   i noticed that right after posting.

   but it might as well have been some sort of weird sarcasm.

4. **Kris Krogh**

October 16, 2007

Hi Roland,

Trouble is, string theorists keep coming up with new “tests,” and others cite those without checking them.

See this exchange with Joe Polchinski, items 35, 43, 44. He never responded to the last one.

5. **fulo**
   October 16, 2007

   > See this exchange with Joe Polchinski, items 35, 43, 44. He never responded to the last one.

   Kris,

   I’m very far from sharing Prof. Polchinski’s optimistic view of the landscape, but I think his answer #43 is perfectly sensible. What he says is that having a theoretically tractable model of a strongly coupled non-abelian gauge theory out of equilibrium is important and interesting. It is.

   I think there are at least three reasons why he didn’t answer your comment about quoting a non-refereed talk as a basis for his remarks.

   First, because if you really want references to refereed papers, you just have to look them up in the talk he mentions.

   Second, because he was posting his answer to a weblog, not to a scientific journal, so there’s no need to be so picky about references.

   And third, because actually whether a paper is refereed or not is of no importance at all to any practicing physicist. People download papers right from the arXiv, read them, and decide by themselves whether they believe them or not. You only download papers from journals when they are too old to be found in arXiv or, else, when you are very interested in the figures, which are usually better printed in the published version.

6. **Quixotik**
   October 16, 2007

   This blog is a bit one-note, true, but many good blogs are…if someone ever actually comes up with a universally accepted way to test string theory, this blog will lose it’s *raison d’etre*.

7. **nerd**
   October 17, 2007

   Quixotik, they can test string theory, the whole problem is that there are 10^500 versions to falsify before any alternative ideas can get a look in…….

8. **roland**
   October 17, 2007

   maybe browsing through that math book, they just chose the wrong page. i mean the not even wrong page.

9. **Thomas Love**
   October 17, 2007

   nerd said: “…. there are 10^500 versions to falsify before any alternative ideas can get a look in…….”

   What a horrifying possibility…that would tie up progress in physics for 10^490 years! Or longer! I won’t be able to sleep tonight thinking about that.

Accumulated Links

Various things that I've been wanting to mention:

Steven Hawking has a paper out, on his version of the Landscape story, using amplitudes that don't rely upon string theory or eternal inflation. But just like the string theory Landscape I don't see how his proposal is testable. It completely gives up on saying anything about particle physics, even statistically

> If the volume weighted amplitude for the standard model vacuum is non-zero, it is irrelevant what the volume weighted amplitudes for other vacuum states are. The theory can not predict a unique vacuum state. Instead we have to input that we live in the standard model vacuum.

He ends with

> The amplitudes will be highest for states in which the whole universe is in a single state, rather than a mosaic of different states, as predicted by eternal inflation. There will be no primordial production of topological defects, such as monopoles, and cosmic strings. Not all states in the landscape will have significant amplitudes, but there will be more than one that do, so M theory does not predict a unique low energy particle physics theory. It is implausible that life is possible only in one of these states, so we might have chosen a better location.

John Baez has a new This Week's Finds out, with interesting discussions of the topos-theoretic approach to quantum theory, and the analogy between the integers and three-dimensional space. This semester he is running a seminar on "Geometric Representation Theory" (not clear how close this is to the use of the term by those representation theorists who work with D-modules). Videos and lecture notes from the talks are available, along with some blog postings (see here and here).

As always, Terry Tao's blog has wonderful postings and articles, often of a general expository nature. For some recent examples, see one about the Schrodinger Equation, and another about Jordan normal form.

Besides excellent expository physics postings such as the recent one on single top production, Tommaso Dorigo gives a more realistic view of the academic life than most other blogs. For some understanding of how academics feel about the travel opportunities that conferences present, and what they think about the question of whether their employer should be financing what sometimes feels like a vacation, see his recent posting on Ethical aspects of professional conference-going. I strongly endorse his recommendation of the David Lodge novel *Small World*.

There's a string theory wiki out there, aimed at students trying to learn string theory, which has been set up by the Centre for Research in String Theory at Queen Mary College. Much of the site is a listing of the one thousand or so review and other papers an aspiring young theorist should read and absorb to get an idea of what is going on with string theory. Also listed are various blogs, including this one, that might save students some of this reading…

Comments

1. **John Baez**
   October 15, 2007

   Peter writes:

   > This semester he is running a seminar on "Geometric Representation Theory" (not clear how close this is to the use of the term by those representation theorists who work with D-modules).

   Ideally our seminar will eventually cover such material, taking a new viewpoint that makes it seems a lot less technical and scary than it usually seems. But we're starting with more elementary stuff, e.g. Coxeter groups, Hecke algebras, buildings, Bruhat decompositions, Schubert cells and the like. Again, we're taking a new viewpoint designed to make it less scary than usual… a big emphasis on q-deformation and groupoidification. So far we're just doing the An case – that is, representations of Sn, SL(n) and the like. Later we'll generalize to other Dynkin diagrams.

   The seminar will probably last for at least two years. It's hard to see precisely where it will go.

2. **David Ben-Zvi**
   October 16, 2007

   Geometric representation theory (as I understand it) is a natural extension of classical harmonic analysis in which function
   spaces are replaced with various geometric alternatives, be they cohomology groups, K groups, or categories of sheaves of various
   kinds (such as D-modules, perverse sheaves, coherent sheaves,…).
   There are natural analogs of Fourier transforms and the classical Hecke operators, and all are realized geometrically –
   one of the fundamental principles of geometric harmonic analysis
   (just as for classical harmonic analysis) is that all reasonable operators are realized by "integral kernels", which are themselves geometric objects of the same kind on a correspondence (or span).

   Usually one is studying not just a space but a space with
   a group action so all of the geometry is done equivariantly with respect to that group (or equivalently on the level of stacks or groupoids). Also one often introduces more refined structures (in particular gradings), coming from Hodge theory or Galois theory, leading to q-deformations. When studying semisimple groups in their many incarnations (eg over R, C, finite fields, loop groups, quantum groups etc) the spaces involved are essentially always the same – one studies flag varieties, nilpotent cones, Springer resolutions and variations on the above.

   The themes and structures in the subject are
   surprisingly uniform and conceptual across a broad range of questions. They're also not at all scary or technical intrinsically, though perhaps often presented that way. The fundamental ideas can all be explained in accessible ways, though it is hard to find literature in that spirit (I am trying to collect what informal expository materials I can find on my webpage but there's still a long way to go!)

   In any case it's really great to have John and James's seminar and their excellent explanations publicly available as a resource in the subject and drawing attention to geometric representation theory and I am eagerly awaiting its further developments.

3. **sophia**
   October 16, 2007

You forgot this link from NY mag:

http://nymag.com/guides/fallpreview/2007/television/36554/

"Simon Judes (27, string theory): Like Gob on Arrested Development! We're basically always whining about nothing important. And then we're absurdly happy about tiny achievements.

DK: And in every department I've ever been in, you have the one guy who's essentially lost his mind. Those guys are very weird and would be great comic fodder.

AA: No other field, I think, collects as many crazies. And not just physics crazies—all kinds of crazies.

SJ: Oh, and another thing, the whole Stephen Hawking bit. Stephen Hawking is actually a rather peripheral figure in physics research."

4. **mo**
October 16, 2007

The other day at our physics library, I picked up a new book by Raymond Streater:

Streater, R. F.
Lost causes in and beyond physics
Berlin : Springer, c2007.

I think it should be a required reading for everyone in the topos-theoretic quantum theory business. Streater gives a thoughtful overview of quantum logic and related subjects and concludes as follows:

"Very little physics has resulted from quantum logic, trivalent logic, or Jordan algebras."

Most sections in the book have amusing epigraphs. Here is the epigraph for the section on quantum logic, etc.:

"Science is not that easy."
Lubos Motl

5. **Kea**
October 16, 2007

Very little physics has resulted from quantum logic, trivalent logic, or Jordan algebras.

I saw this book at GRG18 a few months ago – very nice – but this comment is somewhat behind the times.

6. **Peter Woit**
October 16, 2007

Thanks John and David,

More expository sources about geometric representation theory would be a great help. It's a fascinating but too little known area of mathematics, and probably has interesting implications for physics. The efforts of both of you in this direction are greatly appreciated.

7. **Holmes**
October 16, 2007

"Streater, R. F.
Lost causes in and beyond physics
Berlin : Springer, c2007.
"
Of course, if you asked 100 physicists for a good example of a lost cause, 99 would probably cite Streater's work. The best defence really *is* offence…

8. **Eugene Stefanovich**
October 17, 2007

R.F. Streater has a fascinating/humorous/controversial/… web-site

http://www.mth.kcl.ac.uk/~streater/

Highly recommended.

Eugene.

9. **Hans**
October 19, 2007

Peter, in a new article in current nature magazine, it seems that Herrmann Nicolai from the German MPI for gravitational physics somwhat joins your opinions. At least the abstract reads that:

http://www.nature.com/nature/journal/v449/n7164/index.html
String theory: Back to basics p797

"String theory was toutet as a theory of everything"

IT WAS! (and isnt anymore..)

"And now may at last succeed as a theory of something very specific — the interactions of particles under the strong nuclear force."

It MAY AT LEAST succeed as a theory of the strong force.
This implies indirectly that it may never succeed as a Theory of everything.

10. **Peter Woit**
October 19, 2007

Thanks Hans,

I did see that, it's a nice article about developments in AdS/CFT. But my reading of it was that it was very careful to not take any position at all about the controversial issue of whether string theory has failed as a TOE.

11. **zorba**
October 19, 2007

Not directly relevant, but wasn't tbere a big meeting about time at Columbia this week? Did you attend any of the talks?

12. **Peter Woit**
October 20, 2007

zorba,

The meeting wasn't at Columbia, but all the way downtown at the New York Academy of Sciences. Not really my kind of thing, I'm too busy this week, and they were charging a $150 registration fee, so I didn't consider going. They set up a website:

http://arrowoftime.org/

maybe at some point more info about the talks at the meeting will appear there.

13. **zorba**
October 20, 2007

Oh, sorry, whenever I see Brian Greene I think Columbia….yes, $150 is ridiculous.
Anyway I note that Sabine H. was there, and she may write a report on what she heard [about time, not about drunken physics celebrities throwing bread rolls about in the manner of Bertie Wooster……]
Thanks anyway!

Susskind Joins PI

October 16, 2007
Categories: Uncategorized

I haven't been able to confirm Lubos Motl's claims that the Perimeter Institute offered him a job, but yesterday they announced that Lenny Susskind has accepted an offer to join them as an associate member. According to the announcement, this means that "he will spend focused time at PI each year to conduct research activities."

At the Frankfurt book fair, Backreaction's Stefan Scherer took a picture of one of the displays, that featured a large poster advertising Susskind's forthcoming book *The Black Hole War*, which carries the subtitle "My battle with Stephen Hawking to make the world safe for quantum mechanics".

Update: Marcus at Physicsforums points to this interview with Susskind about his forthcoming book:

> For two decades an intellectual war took place between Stephen Hawking, on the one side, and myself and Gerard 't Hooft on the other. The book is about the scientific revolution that the controversy spawned, but also about the colorful personalities and the passions that gave the story its drama. The story starts in Werner Ehrhardt's Mansion in San Francisco, and eventually passes through all seven continents, including Antarctica.

Comments

1. **Who**
October 16, 2007

"My battle with Steven Hawking to make the world safe for quantum mechanics".

what a ham. Hawking as well.

2. **Steven H. Cullinane**
October 16, 2007

That's "Stephen," with a "ph."

3. **Peter Woit**
October 16, 2007

Steven,

Thanks, fixed.

4. **Who**
October 16, 2007

I know, I was just copying how Peter had it.
Given that Susskind once posted something about "Sting Theory" on the arxiv, maybe a little misspelling is appropriate.

5. **Steven H. Cullinane**
October 16, 2007

As noted in a previous comment of mine containing a misspelling, we must all sometimes "bow down before the great god Entropy."

6. **Quixotik**
October 16, 2007

Wow, now theoretical physicists have feuds like rappers.

7. **H-I-G-G-S**
October 16, 2007

Yes Quixotik, and for the same reason: marketing.

8. **stefan**
October 16, 2007

Hi Peter,

thanks for mentioning my visit to the Frankfurt Book Fair – I was curious if anyone would notice that detail of the photo ;-).

The publisher is Little, Brown and Company in the Hachette Book Group USA. I cannot say anything more about the book – the stand was quite deserted on Sunday afternoon, with all books already packed away. On the Hachette Group website, the title is not announced yet. For comparison, the "Geography of Bliss" is scheduled for January 2008, so the "Black Hole War" will probably appear later in 2008.

9. **Greg Egan**
October 16, 2007

> Wow, now theoretical physicists have feuds like rappers.

It would be a brave physicist who declares "If my book doesn't sell more copies than Hawking's *A Brief History of Time*, I'll stop writing papers as lead author and just make guest appearances as pencil-sharpener and LaTex checker for other physicists. So buy ten copies, vote with your wallet, my genius in on the line …"

10. **Chris Oakley**
October 16, 2007

The LS book could be one of a series. Peter: why not write sequel to N.E.W. with a title like:

The Whacko Control War: My battle with Leonard Susskind to make the world safe for particle physics theory

11. **Anders R**
October 16, 2007

leonard susskind 2: the reckoning

12. **Peter Woit**
October 16, 2007

Chris,

Putting Hawking's name on the cover sells books (I should have found a way to work him into the subtitle…). I don't think Susskind's name would have a similar effect.

13. **Quixotik**
October 16, 2007

How did Hawking get so famous anyway? Was it his book, or was he famous before?

14. **LDM**
October 16, 2007

People who read this blog could get the wrong impression. We actually do physics because it is tremendously interesting and intrinsically worthwhile.
Publishing highly speculative work, and then using Hawking's celebrity to OVERSELL it to a scientifically unsophisticated general public, is not a reputation most of us would want. There's nothing wrong with creative and speculative ideas of course, only they must be presented in a balanced and objective manner.

15. **Holmes**
October 16, 2007

The strange thing about the "black hole war" is that nobody but Susskind seems to have noticed it. I mean, of course there has been extensive discussion about whether black hole evaporation violates unitarity, but that has centered on Maldacena's work; most people never heard of "black hole complementarity" until Bousso recently started mentioning it to motivate "observer complementarity". The whole "war" must have been fought in the dark places of the world, far below the world of ordinary physicists……

16. **Aaron Bergman**
October 16, 2007

I mean, of course there has been extensive discussion about whether black hole evaporation violates unitarity, but that has centered on Maldacena's work;

Do I really have to say that unitarity in black hole evaporation is a subject that long predate's Maldacena's work? Recent discussion has centered on Maldacena's work because it finally provides a concrete way to address the question.

most people never heard of "black hole complementarity" until Bousso recently started mentioning it to motivate "observer complementarity".

Speak for yourself.

17. **Anders R**
October 16, 2007

well he said most people so he isn't necessarily saying that you're one of them or himself for that matter.

18. **Holmes**
October 17, 2007

Of course there were papers before Maldacena came along. They were however [a] nearly all by Susskind himself and [b] largely ignored. Hardly what one would call a war, dividing families, devastating innocent civilians, etc etc etc.

19. **John Baez**
October 17, 2007

Quixotik wrote:

> How did Hawking get so famous anyway? Was it his book, or was he famous before?

Among physicists he was famous for calculating how much entropy a black hole has, and before that, for showing (along with Penrose) that black holes are inevitable under certain conditions — the singularity theorems.

Some of this fame percolated down to the general public, and his disabilities helped make him a fascinating character.

But I guess his book was the first thing he wrote that ordinary people could pretend to understand… so it became a best-seller, and he's been a lot more famous ever since.

20. **Hans de Vries**
October 17, 2007

Somehow this gives me a strange pro-wrestling association…

The battle of
"the Master-of-the-Multiverse"
versus

October 17, 2007

Re: Book Cover “marketing”

I’m sure the publisher pressed for the “Hawking” reference, the need a “god-like” figure. “You are who you associate with”, as the saying goes. Just like L. Lederman’s book “The God Particle”, need to tantalize the gullibe (god-fearing) public. Just like G. Smoot/COBE

> Much of the excitement outside of the scientific world stemmed from Smoot’s comment at the press conference that “if you’re religious, it’s like seeing God.”

Just like Morris Kline (interestingly a NYC native like L. Susskind):

> As the author’s wife and sometime secretary, I can testify that Morris Kline was keenly unhappy with the publisher’s choice [“Why the Professor Can’t Teach”]. This book is not an attack on professors but is rather a wide-ranging critique of undergraduate education. Indeed an appropriate, less jazzy title would have been A CRITIQUE OF UNDERGRADUATE EDUCATION.

The above is a really bad case of “sensationalism”, & how scientists have to be really wary of dealing with the media.

I like the way M. Franklin/Harvard puts it:

“Why the NY Times doesn’t get the right spin on on our data”

The “almighty dollar” rules (Law of Business..getting market share):

“People don’t buy Good Products, they buy GOOD MARKETING”

> If you’re going to get caught up in the commercialization of mass culture of excitement, you’re never going to make it. [“Stupidity is Its Own Reward”] & too many people
> get caught up in it,.. You have to be independent individualist, & committed to excellence

— Steven Gould/Harvard

Someone on this blog objected to “pandering to the masses” with high-end Science. I agree. Diluting Science for the purpose of public outreach CAN be dangerous. Timothy Ferris (science writer) is notorious for this, his recent PBS program was a JOKE. Roald Hoffman/Cornell (Nobel Laureate in Chemistry) had a negative comment about Pop Culture & the Masses (PBS TV program).

22. **chimpanzee (aka "joe")**
    October 17, 2007

    Here is the link for the Science Channel program “Hawking Paradox”. Werner Erhardt, et al. I saw the program last year, & it’s been repeating regularly.

    I met & talked with L. Susskind at last year’s SUSY ’06. Very approachable, polite, & willing to talk. Very professional appearance & good speaker. I got the same impression during the TV program. His presentation/exposition is very polished, gives a good public impression of a scientist. Classy. Here’s a good article about him, which makes me like him even more.

    I called L. Motl prior to the conference, for background prep (I’m an outsider, my degrees are in Elec Eng). He was very generous with his time (J. Preskill/Caltech & only a few others have been this extending), & was impressed. Other people have commented on his dedication to students/teaching & charm. Just by accident, I mentioned Lubos (who asked me to say hi to his Rutgers PhD advistor) to Lenny & I got a very interesting response. (reminds me of the fights I had during my PhD days, when my arch-rival called me a “monkey”) I didn’t realize they had a “history”!

23. **Holmes**
    October 17, 2007

    Oh, so now its a “scientific revolution” and not just a mere war. What will LS call it when somebody finally manages to settle the question of unitarity violation for evaporating black holes that look *even vaguely* realistic? The war to end all wars? The mother of all revolutions?

    By the way, the notion that Maldacena’s work was somehow “spawned” by LS’s early-90s lucubrations is, shall we say, stretching a point just a tad.

24. **nerd**
    October 18, 2007

    “Among physicists he was famous for calculating how much entropy a black hole has, and before that, for showing (along with Penrose) that black holes are inevitable under certain conditions — the singularity theorems.” – John Baez

    Not exactly an experimentally confirmed calculation. All theorems based on GR are based to some extent on faulty (classical) approximation, what you need to do is find quantum gravity, and then calculate black hole properties using that.

    The business of calculating details of black holes that aren’t checked yet reminds me of Sir James Jeans’ calculation “proving” that the solar system formed from giant tidal waves on the sun, with popular hype of Jeans (who also wrote popular best-sellers back in the 30s, like Hawking today), and you got popular notions that “the solar system exists, so Jeans must be right!” Wrong, there were subtle errors.

    It’s disappointing for black hole calculations that have yet to be experimentally confirmed in detail, to be hyped and celebrated; kinda misleads people about what is fact and what is speculation.

25. **Bee**
    October 18, 2007

    @ Chimpanzee:

    > “People don’t buy Good Products, they buy GOOD MARKETING”

    One of the sures signs for intelligence is the ability to learn from and avoid mistakes. How come then that a significant fraction of the homo sapiens sapiens on this planet today lives in a society that runs in a downward spiral of deception, lies, and ignorance of facts. How come that intelligent people can point out weaknesses and potential dangers of dramatic failures of the current system, and other allegedly intelligent people don’t even care to listen, because they are too busy worrying about their own career – and how ironic is that if exactly this was the point of criticism.

@Quixotik:

> How did Hawking get so famous anyway? Was it his book, or was he famous before?

The Large Scale Structure of Spacetime
Stephen Hawking and George Ellis, Cambridge University Press (1973)

not exactly a good book (i.e. as you find on wikipedia it's indeed "highly technical and quite unreadable"), but it's one of these books one kind of needs to have. later then (75) the black hole evaporation stuff.

26. **Shantanu**
October 20, 2007

Peter, did you go for

this workshop. If so any report?

27. **Peter Woit**
October 21, 2007

Shantanu,

See my comment about this on the other thread. Evidently Bee was there, see her report at Backreaction, where she promises to write more…

28. **cecil kirksey**
October 22, 2007

Peter:
I was rereading parts of Lenny's book the other night. Near the end he recalls a dinner talk he gave at Strings 1995 about what theoritical physics would be like now based only on the experimental data available up to 12/31/1899. He paints a fairly rosy picture about the abilities of pure thought. Granted both SR and GR probably would have proceeded unabated. But would they have been accepted? Lenny's commit spurred me to start looking at the history of QM in particular QED. A correct theory may…may have been found but so would a lot of equally viable ideas that would be wrong. The correct theories were accepted based on experimental data not the beauty, nicity, the theoorist or other subjective qualities. I think Lenny was wrong then and may be wrong now.

Any comment from anyone on the history of QM and QED?

29. **George Lehtola**
October 22, 2007

From PI's home page:

Leonard Susskind Joins PI
WATERLOO, ON, October 15, 2007 – Canada's Perimeter Institute for Theoretical Physics (PI) is pleased to announce that renowned scientist Leonard Susskind has joined its Faculty as an Associate Member. Professor Susskind is widely recognized as one of the most highly creative researchers in the field of particle physics. He earned his BSc at City College of New York and his PhD in 1965 at Cornell University. He held a number of positions at the postdoctoral and faculty level afterwards before becoming a Professor in the Department of Physics at Stanford University in 1978, where he continues to work as a Professor of Physics.

Leonard Susskind has received a range of honours and prizes, including having been elected to the National Academy of Sciences (NAS), the American Physical Society's prestigious Sakurai Award, as well as the American Institute of Physics' Science Writing Award.

Rob Myers, Interim Scientific Director at PI, remarks, "Professor Susskind has been one of the most creative and influential theoretical physicists in the last four decades. He has contributed important ideas to topics ranging from the theory of quark confinement to black holes in string theory." As an Associate Member, Professor Susskind will spend focused time at PI each year to conduct research activities.

In addition to an outstanding record as a distinguished theoretical physicist, Professor Susskind has a demonstrated interest in communicating science to members of the general public and improving society's awareness of physics, astronomy, and allied science fields. He will share this talent by participating in a special PI Public Lecture panel discussion on December 5, 2007, dealing with the topic of 'Information and Reality'.

About Perimeter Institute
Canada's Perimeter Institute for Theoretical Physics is an independent, non-profit, scientific research and educational outreach organization where international scientists cluster to push the limits of our understanding of physical laws and calculate new ideas about the very essence of space, time, matter and information. The award-winning research centre provides a multi-disciplinary environment to foster research in areas of Cosmology, Particle Physics, Quantum Foundations, Quantum Gravity, Quantum Information and Superstring Theory. The Institute, located in Waterloo, Ontario, also provides a wide array of educational outreach activities for students, teachers and members of the general public across the country and beyond in order to share the joy of scientific research, discovery and innovation. Additional information can be found online at http://www.perimeterinstitute.ca.

30. **Who**
October 22, 2007

Cecil, this sounds like it might be from some other book by Susskind than the one we were talking about. Could it be from "The Cosmic Landscape: String Theory and the Illusion of Intelligent Design" ?

> I was rereading parts of Lenny's book the other night. Near the end he recalls a dinner talk he gave at Strings 1995 about what theoritical physics would be like now based only on the experimental data available up to 12/31/1899…

31. **Physics Professor**
October 22, 2007

Hello all,

I've been following this blog for awhile.

What exactly has Lenny Susskind done in the realm of physics?

I know it says, “Leonard Susskind has received a range of honours and prizes, including having been elected to the National Academy of Sciences (NAS), the American Physical Society’s prestigious Sakurai Award, as well as the American Institute of Physics’ Science Writing Award.”

But what has he done? The Cosmic Landscape seemed highly speculative. Was there physics in it that I perhaps missed?

32. **Peter Woit**
October 22, 2007

Physics Professor,

No, The Cosmic Landscape is pretty pure pseudo-science, but until recent years Susskind was doing very serious science. He does have a legitimate claim to have been one of the first to realize that the Veneziano amplitude could come from quantizing a string. The later work of his I’m most familiar with is the way of handling fermions in lattice gauge theory that goes under the name “Kogut-Susskind” fermions.

Unfortunately, he’s not the only seemingly smart, reputable physicist who seems to have taken leave of his senses the last few years…

33. **Aaron Bergman**
October 22, 2007

SPIRES is your friend.

34. **LDM**
October 22, 2007

cecil kirksey,

I am glad you brought up your question…I too read Susskind’s book when it came out found that chapter interesting.

In particular, Susskind says in The Cosmic Landscape, page 269, the following:

Could theorists have guessed the full structure of the Standard Model? Protons and neutrons, perhaps, but quarks, neutrinos, muons, and all the rest. I don’t see any way that these things could have been guessed

Susskind is correct, since as the history of HEP shows, experiment was essential. Unfortunately, Susskind does not emphasize the point, when in fact it is probably one of the more important statements in the book. If theoreticians could not have guessed the Standard Model without experiment, then a similar statement regarding the final form of a string theory TOE is not unreasonable, and we need only remember string theory has no experimental tests, and is likely never to have any.
It is one thing to make the largest extrapolation in history, but when doing so, at least have the honesty to explain to the laymen that while an *interpolation* of data tends to be safe, *extrapolation* of data is, from a scientific point of view, very dangerous, and often wrong.

35. **Cecil Kirksey**
October 22, 2007

To Who:
LDM has it correct. The book I was referring to was “The Cosmic Landscape”. I was still left with the impression that Lenny fells that the correct model for QM and QED could have been guessed given no new data in the 1900’s. Given the fact that not every physicist took the idea of a quantized EM particle as postulated by EA seriously until the Compton effect was discovered, it is hard to believe that QM and QED could have been developed to the point that they were even up to say 1948-49.

Maybe someone who better understands the historical development of QM and QED can respond.

36. **JC**
October 23, 2007

Cecil Kirksey,

Without any experimental data, most likely QED would have been thrown into the trash as soon as the first calculations were done which (naively) produced infinite quantities. There would have been very little to no motivation for renormalization, if there was no Lamb shift experimental data.

Future Linear Colliders

October 23, 2007
Categories: Experimental HEP News

There are two highly active projects to design a linear collider that would collide electrons and positrons at energies higher than those achieved at LEP. Recently there were workshops discussing the state of the projects.

The ILC is the farthest along of the two and uses more conventional technology. It is a design for a 250+250GeV collider, upgradeable to 500+500Gev. There's a very jazzy new web-site aimed at selling the idea to the US public. This week Fermilab is hosting a workshop on the ILC, talks available here. Michael Peskin gave an introductory talk with an unfortunate title ("The Physics Landscape", I really think serious physicists should not be reminding people of this, especially when they're making a pitch to the public for money). He argues that the LHC will see a spectrum of new particles (in order to solve the hierarchy and dark matter problems), and motivates the ILC as the machine to study these. This of course depends on their existence, at a mass low enough to allow production at the ILC, but high enough to evade bounds from LEP and the LHC (for some new results from the latter, see here). It now appears certain that no decision about building the ILC will be made until results are in from the LHC (2010?) that will resolve whether there are new particles in the mass range that the ILC is capable of studying.

DOE's Ray Orbach gave a talk about the ILC project, emphasizing:

> It is critical that planning for the ILC takes into account the realities of the funding situation, the need to formalize the ILC arrangements between governments, the changing scientific landscape, the scientific capabilities at other facilities, and the health of our national scientific structure.

Orbach seems concerned that the ILC project does not have a realistic schedule ("I judge that these arrangements will require more time than the currently proposed schedule of the GDE") , and does not have commitments from other countries. I'm guessing that he sees financing it out of the current and expected DOE budget is not doable without large contributions from other countries, and a relatively long time-frame. He emphasized that there is now a well-defined process for projects like this: they have to survive a series of "critical decisions". The ILC is not yet ready for the first critical decision "CD-0, Mission Need" and won't be until after the LHC results are in. He also mentions "other planned international projects", and the importance of not duplicating their activities (I take this to be a reference to CLIC). Finally, he is critical of the plan of the ILC project to move to an "Engineering Design Report" that would give detailed engineering plans for the machine, since he sees it as still in an R and D phase.

Over at CERN, the Resonaances blog reports on a workshop devoted to CLIC, a more ambitious and less technologically developed plan for a 1500 + 1500 Gev collider (upgradeable to 2500 + 2500 Gev). If CLIC really turns out to be feasible, and buildable on a time-scale close to that of the ILC, it will not be possible to justify building the ILC, since it would operate at much lower energy.

This week internet access is more iffy, since I'm in Lisbon, for a conference late in the week on "Is Science Near Its Limits?", sponsored by the Gulbenkian Foundation. After it is over, I'll write about it here, and I think I can post a copy of the talk I'll be giving.

Update: Science magazine has a short piece about the Orbach talk, see here:

> Orbach said physicists must follow the department's protocol that requires a large project to pass five critical decision milestones. The ILC has not passed the first, which allows researchers to proceed from basic R&D to design, Orbach said. Previously, DOE officials had been "completely open" to a less formal approach, says Caltech's Barry Barish, who leads the design team. What counts as "engineering design" remains to be determined, he says.

Another piece of this story recently pointed out to me is that the new CERN director is from DESY and associated to the ILC project there. This might cause people at CERN to wonder how hard he'll push for its CLIC projector, which is in some ways an ILC competitor.

Comments

1. **Bee**
   October 23, 2007

   Ah, commitments! How about we just design the next virtual collider and put it on Second Life? Who needs the ILC? 😉 Have a safe trip,

   B.

2. **dan**
   October 23, 2007

   Hi Peter, just a quick question, to revisit an issue before it got derailed,

   you don't think that there is a "hierarchy" problem (requiring SUSY as the antidote to radiative corrections to the higgs, and hence, string theory) I am curious as to whether you think there is a higgs boson and higgs field, and what prevents it from gaining mass from the EW-scale to the GUT scale. Do you think that the higgs boson is fined tune to 32 decimal places and that is the end of that – no SUSY required?

3. **Peter Woit**
   October 23, 2007

   dan,

   This is off-topic, and I don't really want to start yet another discussion of supersymmetry, but, in brief, I've never been convinced by the "supersymmetry eliminates the need for fine-tuning argument", for several reasons:

   1. We don't even know there is a GUT scale. There is zero evidence for such a thing.

   2. We don't know that the Higgs field is an elementary scalar.

   3. If supersymmetry really was going to eliminate all fine-tuning, it would have shown up by now.

4. **a quantum diaries survivor**
   October 23, 2007

   Wow Peter,

for an answer to an off-topic comment you did pretty good 🙂 Let me add my own:

4. Speculating susy exists but was not detected so far because there was some symmetry breaking mechanism making susy particles much more massive than ordinary ones is legitimate, but it stinks. It flies in the face of Occam's razor, which becomes nervous and comes a-slashing.

Instead, why not giving some more tentative credit to Alejandro Rivero's idea that sparticles (bosons) are composites of two fermions ?

Cheers,
T.

5. **Peter Woit**
   October 23, 2007

   Hi Tommaso,

   Yes, supersymmetry is a beautiful idea, until you have to break it…

   The problem with composite models is you have to find some dynamics that doesn't screw up the fact that the standard model works perfectly. The idea that the Higgs field is a composite field of a fundamental fermion field is an old one, well motivated by what happens in superconductivity (Cooper pairs). Technicolor is one way of doing this. People have looked at this, but maybe if they had put as much effort into is as into SUSY, other better ideas might have shown up.

6. **JC**
   October 23, 2007

   It would surely liven up the field again, if the Higgs mechanism, supersymmetry, technicolor, etc … and all of their variations + combinations, all turned out to be complete failures in the end.

   If this indeed turns out to be the case, then I would have no idea offhand what would be a fruitful path to follow afterwards. I suppose one could skim mindlessly through older theoretical particle and/or condensed matter journals, searching for long forgotten ideas to resurrect and try out.

7. **Coin**
   October 23, 2007

   Woit, just to be clear– are you saying you consider it probably the case that the Higgs is *not* an elementary scalar? Or are you just saying that an elementary scalar nature of the higgs cannot or should not be *assumed?*

   Also, more on topic, kind of a dummy question: Why is it that all the big "vacuum cleaner" accelerators, like the LHC and Tevatron, seem to be cyclic/synchrotrons– whereas the new proposed colliders we're seeing described in this post for the lower-power but more "fine-tuned" measurements are all linear? Is there something about a linear collider that makes the fine-resolution stuff easier to do than it would be with a synchrotron? Or what?

8. **Peter Woit**
   October 23, 2007

   Coin,

   Above LEP energies, synchrotron radiation loss is just too high for electrons (goes as fourth power or the energy), so you have to have a linear accelerator.

   I don't know if the Higgs is an elementary scalar or not. If I had to guess, I'd guess not (not asymptotically free, for one thing…)

9. **Coin**
   October 23, 2007

   I see, thanks.

10. **Eric**
    October 23, 2007

    In reponse to Peter's answers to Dan's questions:

    1. It doesn't matter if there's a GUT scale or not. Quantum corrections to the Higgs mass will push it to whatever the next energy scale is, and if there is no GUT scale then this would be the Planck scale.

    2. It's true that the Higgs might be a composite boson. However,
    such Technicolor models were studied very seriously in the 70's and 80's, but were eventually rejected due to some serious shortcomings. Namely, in order to generate mass hierarchies for the SM fermions, one ends up with serious problems with FCNC's. Nevermind that it requires adding another gauge sector to the SM with strong dynamics which would have led to a plethora of technimesons for which there is absolutely no evidence. Occam's razor anyone? Oh right, we only reserve this for things we don't like like SUSY.

    3. The amount of fine-tuning required in the Higgs potential in order to give a large enough Higgs mass is very small and perfectly reasonable. In any case, what Peter's means is that to eliminate all fine-tuning, the Higgs should have been observed by now, not that the superpartners should have already been observed.

11. **Paul Guinnessy**
    October 23, 2007

    Keep your eyes peeled for the November issue of Physics Today, which has an interview with Aymar on the issue of which project CERN will support, CLIC or ILC. Toni Feder also has a good piece on Fermilab's project X (doi:10.1063/1.2800091) in the October issue.

12. **Tony Smith**
    October 23, 2007

    Peter Woit said "… If CLIC really turns out to be feasible, and buildable on a time-scale close to that of the ILC, it will not be possible to justify building the ILC, since it would operate at much lower energy …".

    So, in CLIC's favor is its higher energy.

What about cost?

If ILC were to cost on the order of USA2007$10 billion,
how would that compare with the cost of CLIC ?

If the USA dollar were to continue to decline with respect to the Euro,
how would that affect the cost comparison ?

How would site location (Illinois, Europe, or Asia) affect the cost comparison ?

If CLIC were to be built in Europe or Asia, would the USA get to use it on terms as favorable as the USA has with respect to use of LHC ?

Tony Smith

13. **Tony Smith**
October 23, 2007

Slide 38 of the file CLIC07_JPD.pdf from the CLIC workshop web site shows:

CLIC Old Parameters
Accelerating field – 150 MV/m
RF frequency = 30 GHz
Total cost (a.u.) = much higher than 2

CLIC New Parameters
Accelerating field – 100 MV/m
RF frequency = 12 GHz
Total cost (a.u.) = 1.15

What does a.u. mean ?
(is it effectively a comparison with the cost of the ILC?)

Tony Smith

14. **Coin**
October 24, 2007

What does a.u. mean ?

"Astronomical Units"? 🙂

15. **Peter Woit**
October 24, 2007

Tony,

I don't think anyone has a good estimate of what CLIC will cost. From what I remember, the size they are talking about is similar to the ILC, presumably based on the fact that that should make the cost somewhat similar. Not sure if exchange rates make much difference, although I suppose if the US currency collapses and we become a third-world country, it will be much cheaper to build something here. No matter where it's built, there will be physicists from all countries working on it.

Paul,

Thanks for the heads-up, looking forward to hearing what Aymar has to say about this. I get the impression that it's a delicate issue, with people on both sides choosing their words carefully…

Eric,

We also don't know that the Planck scale is relevant…

See Distler's explanation

http://golem.ph.utexas.edu/~distler/blog/archives/000336.html

of why current bounds on the Higgs mass imply a very heavy stop, and amounts of fine-tuning that are not "very small".

16. **AGeek**
October 24, 2007

Eric, you'd better read http://arxiv.org/abs/0708.3550

17. **conrad**
October 24, 2007

> and if there is no GUT scale then this would be the Planck scale.

Why? Is the desert (susy or not) a well established experimental fact? Has a new physics threshold at, say, 30TeV, been definitively ruled out?

In any case, is it true that we have everything figured out all the way up to the GUT scale, so if it's not there then only the Planck scale is left?

18. **Eric**
October 24, 2007

Conrad,
The expected next scale between the electroweak and GUT scale is the SUSY breaking scale which should be around 1 TeV in order to stabilize the Higgs mass. It's

always possible, in fact likely, that there are hidden sector gauge groups which become strong at some higher scale. However, this would have no effect on the quadratic divergence to the Higgs mass since the Higgs states are doublets of the SM SU(2) and not of the hidden sector groups. Regarding Peter's comment that there is no evidence that the Planck scale is relevant, it doesn't matter. That would just mean there is no cutoff and the Higgs mass becomes infinite.

As far as the fine-tuning in the Higgs potential, this is presently a few percent at most. The problem is if the lower limit on the Higgs mass gets pushed up much beyond 114 GeV, say to around 130 GeV. If the Higgs mass is in the range 114-121 GeV as expected, then the fine-tuning is not a real problem. Also keep in mind that this depends strongly on the top quark mass, which was recently revised downward to ~171 GeV.

19. **Yatima**
October 24, 2007

> Eric, you'd better read http://arxiv.org/abs/0708.3550

Picture a particularly vast, featureless Zen Garden with a gnarly stone at one end. Now meditate.

20. **Andr**
October 25, 2007

T. writes

"4. Speculating susy exists but was not detected so far because there was some symmetry breaking mechanism making susy particles much more massive than ordinary ones is legitimate, but it stinks. It flies in the face of Occam's razor, which becomes nervous and comes a-slashing."

Let me write an analog of this, frequently heard in the seventies:

"4. Speculating gauge symmetry exists but was not detected so far because there was some symmetry breaking mechanism making gauge particles much more massive than ordinary ones is legitimate, but it stinks. It flies in the face of Occam's razor, which becomes nervous and comes a-slashing."

Who turned out to be right then?

21. **Thomas Larsson**
October 25, 2007

U(1) gauge symmetry, i.e. electromagnetism, was understood in the '70s, right? At least in the 1970s. A better analog from the 1870s would be the ether wind: people speculated it existed but was not detected.

22. **moron**
October 25, 2007

Andr, I thought gauge symmetry SU(2) is based on simplicity and elegance and describes the weak force well, and predicted the masses of the W and Z massive gauge bosons in advance of experimental discovery? The reasons I was taught for why the gauge symmetries of the SM are physics (unlike susy) is that they

(1) come from experimental observations of fundamental forces and fundamental particles,

(2) are the simplest known ways to represent physical facts,

(3) predict reaction cross-sections, etc., that make it useful,

(4) predicted W and Z gauge bosons observed at CERN in 1983.

So I don't understand what you are saying. Either I'm a moron or you don't know the difference between fact and fantasy (susy).

Now if you are going to defend susy by saying some really great discovery in physics was suppressed, you need an analogy to a religious belief system that can't make quantitative falsifiable predictions. Try the analogy of susy to epicycles.

23. **conrad**
October 25, 2007

Moron,

what Andr says is correct, both historically and factually. Historically, Weinberg proposed SU(2)XU(1) because it was the simplest possibility consistent with phenomenology, but he didn't know whether it was the correct group. After his famous "model of leptons" appeared, many people (including Weinberg himself, you may want to check Phys. Rev. Lett. 38, 1237 – 1240 (1977) which appeared ten years after his model of leptons) started exploring other groups. It turned out that there are three massive weak bosons, and SU(2)XU(1) was the end of the story. But, also, many people didn't believe in intermediary bosons — until they were experimentally observed. Something similar happened with quarks, gluons, jets, etc, etc

Factually, there is no reason why SUSY shouldn't be there. There is also no reason, IMHO, why it should be. The only consistent argument I've seen for SUSY is naturalness, and I personally don't buy it. But just like with weak bosons, experimentalists will hopefully resolve the mystery soon.

Eric,

my answer to your post was rejected by the server. In any case, thanks for your detailed answer.

24. **moron**
October 25, 2007

'Factually, there is no reason why SUSY shouldn't be there. There is also no reason, IMHO, why it should be. The only consistent argument I've seen for SUSY is naturalness, and I personally don't buy it. But just like with weak bosons, experimentalists will hopefully resolve the mystery soon.'

conrad, the weak gauge bosons were predicted to have a mass around 80-100 GeV.

When you are looking for sparticles 'predicted' by susy, you don't have any predictions of what energies they should have.

Therefore, experimentalists who fail to find sparticles below 1 TeV will then have to continue trying at ever higher, arbitrarily higher in fact, energies. At what point do you say that experiments have finally 'tested' susy? You can go on testing a theory which makes no falsifiable predictions for eternity.

Testing susy is like testing ESP or religious miracles: if you fail after one effort, you can simply go on and on forever. That's not science. It's more like religion. You pray for experimental confirmation by a miracle, but if it doesn't occur, you can keep on trying and believing in the speculations. That's why falsifiability is the criteria that separates religion from science.

25. **Mo**
October 25, 2007

Moron,

You're way off here. First off, the fact that a symmetry should be broken is no argument against having it in the theory. MANY symmetries which we know and love are broken, either by the vacuum or else by excitations.

Second, obviously SUSY is falsifiable as a solution to the hierarchy problem (in fact, it's already under pressure). If you give that up, then you loose one of the strongest motivations for SUSY. Also, SUSY has a DM candidate. It should be possible to determine whether the DM in our universe is the lightest stable SUSY partner. If it's not, then that motivation could get killed too. If these two motivations get killed then a lot of people will loose interest. But, of course, the theory has not strictly been ruled out. SUSY is very predictive, I'm not sure why people here are so keen to argue otherwise. (Also, SUSY is not string theory. We could have the MSSM quite independently of whether or not it's UV completed to some string model.)

If we stuck to theories which are falsifiable in the sense which you're asking for, then we wouldn't have much left to work with. According to your philosophy scalar-tensor gravity is on the same logical footing as religion. You're entitled to think that, but it certainly doesn't reflect mainstream physics.

26. **Eric**
October 25, 2007

Moron,
I should like to add that the superpartners must be less than or equal to the TeV range in order to explain the hierarchy problem, which was mentioned but not emphasized by Mo above. If LHC doesn't see the superpartners, then it means that SUSY is not the solution to the hierarchy problem. Supersymmetry could still be a part of nature even in this case, but then most of the interest in it will evaporate because it would not have any relevance for low-energy physics. The thing to keep in mind is the saying of Feynmann that in quantum mechanics anything which is not strictly forbidden is compulsory. If nature doesn't incorporate supersymmetry, it would strongly violate this principle.

27. **Arun**
October 25, 2007

The thing to keep in mind is the saying of Feynmann that in quantum mechanics anything which is not strictly forbidden is compulsory. If nature doesn't incorporate supersymmetry, it would strongly violate this principle.

This is the most confused thought I've seen around here in a long time. Feynman is turning at 60K RPM in his grave at the extrapolation from

"What is not forbidden in QM is compulsory" to
"What is not forbidden in nature is compulsory".

28. **anon.**
October 25, 2007

The thing to keep in mind is the saying of Feynmann that in quantum mechanics anything which is not strictly forbidden is compulsory. If nature doesn't incorporate supersymmetry, it would strongly violate this principle.

This is the most bass-ackwards reasoning I've ever seen, and a complete misunderstanding of the "totalitarian principle" (which I think is usually credited to Gell-Mann, not 'Feynmann').

29. **Eric**
October 25, 2007

Dear Arun and Anon,
Obviously, neither of you knows anything at all about quantum mechanics. If there is an allowed symmetry of your Lagrangian, it will be realized in nature. End of story.

30. **Andrew**
October 25, 2007

Eric,

So what you're saying is if I wrote down a Lagrangian with a U(17) symmetry it would be realised in nature, because that's allowed by my Lagrangian? I'm afraid not, just take a look at SU(5).

31. **Arun**
October 25, 2007

Eric, quite entertaining!

32. **Eric**
October 25, 2007

Andrew,
You misunderstand me. What I'm saying is that there is a fundamental symmetry between fermions and bosons that will be a symmetry of any Lagrangian which includes fermions and/or bosons regardless of the gauge group.

33. **Thomas Larsson**
October 26, 2007

> Obviously, neither of you knows anything at all about quantum mechanics. If there is an allowed symmetry of your Lagrangian, it will be realized in nature.
> End of story.

Putative terms in the Lagrangian compatible with the symmetries will be generated by radiative corrections and are hence compulsory. This does not imply that any symmetry principle is compulsory.

34. **Eric**
October 26, 2007

Well, I would expect the symmetry between fermions and bosons to be as compulsory as Lorentz symmetry. In any case, it's the radiative corrections involving fermionic partners which stabilizes the Higgs mass…

35. **Andrew**
October 26, 2007

Eric,

If I misunderstood you, it is because you made a generic statement that anything not disallowed is compulsory. Now you seem to be saying something else. OK, thanks for the clarification. So why is the symmetry between bosons and fermions inevitable? You say yourself that you merely expect it (i.e. can't prove it), so why such high confidence in this symmetry?

String Theory’s Next Top Model

October 25, 2007
Categories: This Week's Hype

I’ll write soon about the conference I spoke at today in Lisbon. A few hours ago I participated in an interesting discussion about some of the issues around string theory with two string theorists. One of them was quite vehement that a big part of the problem is things being hyped to the media, and that this is an American disease, something that doesn’t happen to the same degree in Europe.

I think he may be right, since I certainly haven’t noticed as much media hype (either pro or anti-string) from European sources, although I follow US ones more closely. When I got back to the hotel this evening, I noticed that SLAC is promoting on its web-site a news story about [String Theory’s Next Top Model](). The story appears to be about this [paper]() that was just published in Physical Review D. In it, the authors consider three toy models of inflation in string theory and find that they don’t work. Their conclusion:

> This may be an artifact of the simplicity of the models that we study. Instead, more complicated string theory models appear to be required, suggesting that explicitly identifying the inflating subset of the string landscape will be challenging.

So, the gist seems to be that they went looking for toy models of string inflation, didn’t find a workable one, but decided that this was worth a SLAC press release, presumably because “string theory is currently the most popular candidate for a unified theory of the fundamental forces”, so one should go to the press with any result one gets, even if negative. I think the Europeans may be right that this sort of thing doesn’t happen here….

Comments

1. **Who**
   October 25, 2007

   This is how the New Scientist handled that same paper on 11 September.

   http://space.newscientist.com/article/dn12628-can-string-theory-accommodate-inflation.html

   They quoted Mark Hertzberg (I gather the lead author), Max Tegmark (a co-author), and Andrei Linde (who criticized the paper.) Fairly balanced job, to NewSci’s credit. Interesting paper raising interesting question.

   Also quoted Paul Steinhardt:

   > Paul Steinhardt of Princeton University in New Jersey, US, who helped to pioneer the theory of inflation, says the findings are in agreement with work that he and others have done using other versions of string theory.
   >
   > “I think the fact that it is difficult to combine inflation and string theory is very interesting,” he told New Scientist. “It could mean they are completely incompatible, which would force us to abandon at least one of them.”

   This time David Shiga at NewSci comes out looking better than whoever it was at SLAC public relations that talked to Kachru.

2. **DB**
   October 26, 2007

   String Theory Hype is not just an American disease, though clearly that’s where it started and reached epidemic proportions. Britain has also been infected, for years they have been “treated” to breathless expositions from the likes of Kaku and Greene, specially imported to create programs on the subject for BBC’s Horizon series, for example.
   Recall also that New Scientist is a British based publication.
   I don’t believe Continental Europe has succumbed to the same degree.

3. **moron**
   October 26, 2007

   A similar promotion of complexity as advancement happened with the theory of epicycles in about 150 AD. Everytime Ptolemy tried to predict something new with his model, it turned out wrong so more epicycles and more complexity was added to make it work.

   His reaction was always, “Great! I’m discovering more exciting knowledge about how complex nature really is!”

   Ptolemy would then announce the great news about his “Exciting Discovery of Complex New Epicycles” by a press release to the geeky *Novus Scientist* in Londinium.

   My Latin is a little rusty, but the gist of his final press release was: “Ptolemy’s mainstream earth-centred universe theory is obviously true. It’s led to some fantastic maths for working with epicycles, and it’s also the most popular idea around. It’s the only game in town. Aristarchus’s simplistic solar system is crackpotism.”

4. **Who**
   October 26, 2007

   To focus on what we’re looking at, the key paragraph in NewSci was

   The study was carried out by a team of researchers led by Mark Hertzberg of MIT in Cambridge, US. The team tried to produce inflation in three versions of string theory in which the extra dimensions are shaped like a doughnut – the simplest possibility. But they found that the conditions needed for inflation appear to be impossible to achieve in these simple versions.

   In the cases studied, the space required by strings cannot inflate. Which is serious because prevailing cosmology needs inflation to have occurred. What follows in the article are quotes taking various sides on the issue (from Andrei Linde, Max Tegmark, Paul Steinhardt…)

   Nothing as clear and forthcoming as this paragraph occurs in the Stanford press release. My guess would be that issuing the Stanford press release was the idea of Shamit Kachru, who may have chosen not to be quoted in the September article, but who may later have wished an opportunity to put his own interpretation on the group’s findings (without the inclusion of quotes from other authors of the paper).

5. **blogguy**

October 26, 2007

It doesn't appear to be a press release at all. I think it is just an article in the daily SLAC paper, which Peter has decided to call a press release. (I say this because there are profiles of recent work by other SLAC physicists regularly appearing on that site). It would be an odd press release, since it doesn't claim to have discovered something, only to concern a direction of work in progress.

6. **Peter Woit**
October 26, 2007

blogguy,

I actually first saw this at physorg.com

http://www.physorg.com/news112545705.html

a news site where most of the content is items put out by press offices of universities and labs. This article was put out by the SLAC press office, written by one of their staff. You are right though that it is not something they officially call a press release.

Who,

Having two press stories about a paper which quote different authors with opposite spin on the paper's results is kind of odd. It's also odd to have one, much less two press articles about a paper dealing inconclusively with toy models. But then again, the press coverage of string theory has often been odd.

My impression of how these things get written is that it is unlikely that Kachru contacted the SLAC press people asking them to write about this. More likely, what they do as part of their job is to call people at their institution up and ask them if they know of any work going on at their institution that they could write a story about. If a press person calls one up expressing an interest in writing about something one has done, most people won't turn them down.

7. **Stanford grad student**
October 26, 2007

More likely, what they do as part of their job is to call people at their institution up and ask them if they know of any work going on at their institution that they could write a story about. If a press person calls one up expressing an interest in writing about something one has done, most people won't turn them down.

I can personally attest to the fact that this is essentially exactly how many SLAC Today articles work. But SLAC Today is little more than a daily site-wide newsletter. It's handled by the press office, but it's not meant to be cutting-edge, breaking-news, press-release kind of science material.

8. **Coin**
October 26, 2007

> "I think the fact that it is difficult to combine inflation and string theory is very interesting," he told New Scientist. "It could mean they are completely incompatible, which would force us to abandon at least one of them."

So, I was going to ask if this could eventually somewhere bring us within striking distance of a "falsifiable prediction" for string theory (i.e., no inflation), but the same article seems to scuttle that hope:

> Andrei Linde of Stanford University in California, US… says the results only apply to a class of string theory versions called type 2a, which are irrelevant to the real universe because they have been shown to be incompatible with dark energy, the mysterious force causing the universe's expansion to accelerate.

So it looks like more than anything this is turning into another case where String Theory tells us you can have things one way if you choose one model, or another way if you choose a different model, and then there's some other classes of models where we aren't quite sure which way it goes…

On the other hand, if we conclude inflation is too precious to give up, could a serious program of trying to get toy-inflation out of other topologies besides the "doughnut" one finally allow us to "drain" some of that "swampland" I keep hearing about in the string theory landscape? It seems like I was hearing a bunch at one time about how the next step in the landscape program would be to get some of that swampland drained, but if there's been any progress in that regard I've somehow not managed to hear about it.

Does ruling out type IIA string theory, or one particular simple background geometry, rule out any quantifiable proportion of the string theory landscape (if we're assuming inflation)? (Or have we really not gotten anywhere at all, since it's possible that we were just not using a sufficiently complex variant of IIA string theory– as Tegmark suggests in the article to free type IIA from being ruled out on Dark Energy grounds– or possible we were using the wrong type of inflation? (Or for that matter, is it possible I'm just confused here and IIA is a different kind of string theory altogether than the one that produces the oft-discussed "landscape"?))

9. **Eric**
October 26, 2007

Coin,
Usually when talking about the landscape, people are talking about Type IIB flux compactifications, which are T-dual to Type IIA string theories. It's doubtful that they've ruled out inflation for all such possible compactifications. More likely, just for the simplest type of model. In any case, eternal inflation is a principle idea needed to populate the landscape. If most string compactifications cannot inflate, the one might expect the landscape to be lightly populated. In fact, inflation may be 'vacuum selection principle'. If we're lucky, there will be one and only one string vacuum where inflation can work, and this vacuum will contain the Standard Model. But this is just speculation…

10. **Coin**
October 26, 2007

Eric, thanks.

One question, would T-duality be enough to conclude that the Physical Review D results *do* apply to IIB flux compactifications? (Or at least whichever flux compactifications correspond under IIB to the one particular kind of calibi-yau manifold they considered in their IIA analysis).

11. **Annie**
October 27, 2007

I think the New Scientist article did a poor job. They spun the article unfairly, indicating that just because Hertzberg et al couldn't inflate those simplified models, string theory was in trouble. This isn't the case at all. The SLAC article points out their real goal–to find a simplified model for the purposes of understanding string theory and inflation. And as Stanford grad student says, the SLAC Today articles aren't press releases; they're intended for the SLAC community to let them (astrophysicists, particle theorists, engineers, students, construction workers, etc) know what's going on. PhysOrg takes any science article from SLAC Today and puts it on their page, without any prompting from SLAC.

Comment on Technicolor/Extended Technicolor Models

October 26, 2007
Categories: Uncategorized

Robert Shrock of Stony Brook sent me the following to post as a response to one of the comments on the latest posting. With his permission I'm putting it here as a separate posting, since I think it's a valuable informed summary of the current state of technicolor/extended technicolor models.

I would like to respond to Eric's recent comment on Oct. 23 in which he said that "technicolor models were..eventually rejected due to some serious shortcomings. Namely, in order to generate fermion mass hierarchies for the SM fermions, one ends up with serious problems with FCNC's." and that these theories "led to a plethora of technimesons, for which there is absolutely no evidence.".

While it is true that FCNC's are a relevant constraint on technicolor and extended technicolor (TC/ETC) theories and were viewed as very serious before the development of walking TC in the mid-1980's, they do not obviously exclude TC/ETC models where the TC sector has walking behavior. The walking (slow running of the TC gauge coupling over an extended range), results naturally from the presence of an approximate IR fixed point in the renormalization group equation for the TC gauge coupling. This walking has the effect of enhancing SM fermion masses for a fixed set of ETC breaking scales. Indeed, since the mid-1980's, the only viable TC models have been those with walking behavior. This walking allows one to use higher ETC breaking scales and still obtain the same SM fermion masses. It also enhances the masses of (pseudo)Nambu-Goldstone bosons. This was discussed in T. Appelquist and L. C. R. Wijewardhana, Phys. Rev. D 35, 774 (1987); Phys. Rev. D36, 568 (1987) and reviewed already a number of years ago, e.g., in R. S. Chivukula, hep-ph/9503202, hep-ph/9803219 and K. Lane, hep-ph/0202255, as well as more recent reviews such as C. Hill and E. Simmons, hep-ph/0203079 (published in Phys. Repts.) and my brief SCGT06 review, hep-ph/0703050. PNGB's in one-family TC/ETC models may still be a phenomenological concern, but the early estimates of their masses were substantially increased by walking TC.

Let me explain in more detail how TC/ETC models may be able to satisfy FCNC constraints. ETC models generically gauge the generational index and combine it with TC, so a simple SU(N_{ETC}) model has N_{ETC}=N_{gen}+N_{TC}. With three generations of SM fermions, N_{gen}=3 and using the minimal value of N_{TC}, namely N_{TC}=2, this yields an SU(5) ETC theory. The SU(5) ETC symmetry can break to an exact residual vectorial SU(2) TC gauge group in three stages, characterized by three different mass scales, Λ_j, j=1,2,3. The ETC gauge bosons with masses Λ_1 mediate transitions between SM fermions of the first generation and the technifermions, and so forth for the other scales. With the values
$$\Lambda_1 \simeq 10^3\ TeV$$
$$\Lambda_2 \simeq 10^2\ TeV$$
and
$$\Lambda_3 \simeq few\ TeV$$
this model appears to be able to fit constraints on FCNC processes. Consider, for example, one of the most severe such constraints, arising from $K^0 – \bar K^0$ mixing. In early studies in the 1980's, in the absence of an explcit ultraviolet ETC completion, one simply wrote down a generic form for the low-energy effective Lagrangian for this process, $\simeq (c/\Lambda_{ETC}^2)$ times the relevant four-quark operators, where Λ_{ETC} was taken to be "the" ETC breaking scale. But the key observation is the following: in the initial $\bar K^0$, the d sbar pair can annhilate to produce a V^2_1 ETC gauge boson, where the indices are the gauged generational indices. But this cannot directly produce the s dbar pair of the K^0, which requires a V^1_2 ETC gauge boson. Hence, in order for the K-Kbar transition to proceed, the the actual ETC propagator factor is not 1 over the mass squared of the V^2_1 gauge boson, $1/\Lambda_1^2$, but instead
$$(1/\Lambda_1^2)\ \Pi\ (1/\Lambda_1^2)$$
where Π denotes the requisite nondiagonal propagator insertion that takes a V^2_1 to a V^1_2. Using a reasonably ultraviolet-complete ETC theory, in the paper hep-ph/0308061, published as Phys. Rev. D 69, 015002 (2003), Appelquist, Piai, and I showed, via explicit calculation of the ETC gauge boson mixings, that the nondiagonal ETC gauge boson mixing term is generically of order the square of a low ETC breaking scale, essentially as a consequence of a residual approximate generational symmetry in the ETC theory. This suppresses the $K^0 -\bar K^0$ mixing strongly, by a factor like $(\Lambda_3/\Lambda_1)^2$, i.e., the coefficient of the four-quark operator is not $1/\Lambda_1^2$ but the much smaller Λ_3^2/Λ_1^4, which is sufficient to satisfy the constraint from the experimentally measured mixing and resultant $K_L – K_S$ mass difference. In this and a series of other papers, taking account of the mixing between ETC group eigenstates of fermions to form mass eigenstates, we also examined many other FCNC constraints on TC/ETC theories and showed that they appear to be able to be satisfied.

There are also FCNC processes that do not involve mixing of ETC gauge bosons. For example, the (conjugate of the) process $s \rightarrow d\ \mu^-\ e^+$ via exchange of a virtual V^2_1 ETC gauge boson gives rise to $K^+ \rightarrow \pi^+\ \mu^+ e^-$, for which the upper bound on the branching ratio (from the E865 experiment at BNL) is $BR(K^+ \rightarrow \pi^+\ \mu^+\ e^-) < 1.3 \times 10^{-11}$ (90 % CL). This is satisfied with the above value, $\Lambda_1 = 10^3\ TeV$.

Although Eric did not mention the effect that technifermions have on Z and W boson propagators, these also serve as a stringent constraint on technicolor models, especially the electroweak S parameter. However, because technicolor is strongly interacting at the scale of a few hundred GeV, it is not possible to use a perturbative estimate of S, and nonperturbative estimates based, e.g., on spectral function integrals, are difficult to make reliably for a walking TC theory since one cannot just scale up results from QCD. (There have been a number of papers over the years giving estimates on this, and I can send a list to anyone who is interested, but the issue is not resolved yet.)

In the SM, the electroweak symmetry breaking (EWSB) is produced by the vacuum expectation value of the hypothesized Higgs field. But this breaking is simply put in by hand, via an ad hoc choice of a negative coefficient for the quadratic Higgs term. No explanation is given in the SM of why this coefficient was not positive, when, a priori, it could just as well have been. Since the SM give no explanation for this negative sign of the coefficient, it does not provide a satisfactory fundamental explanation for EWSB. Indeed, it is interesting to recall that in both of the previous two main cases where a scalar field was used in phenomenological models for spontaneous symmetry breaking, namely in the Ginzburg-Landau free energy functional for superconductivity and the Gell-Man Levy sigma model for chiral symmetry breaking in hadronic physics, the microscopic physics did not involve the vacuum expectation value of a fundamental scalar field, but instead a bilinear fermion condensate – the Cooper pair in the BCS theory and the quark condensate in the case of QCD. In technicolor theories, it is precisely this type of bilinear fermion condensate – now involving technifermons,- which is responsible for electroweak symmetry breaking. Furthermore, the quark condensate in QCD already breaks electroweak symmetry. Thus, the original construction of technicolor models by Weinberg and Susskind was quite well motivated.

This is, of course, not to say that TC/ETC theories do not face many challenges. They are very ambitious, since they try to explain both EWSB and the spectrum of SM fermion masses, and no fully realistic model of this type has been constructed. Moreover, it is certainly true that far more people are currently working on various variants of SUSY models than on dynamical EWSB approaches such as TC/ETC. But at least readers should know that Eric's comment refers to the old TC theories of the early 1980's, which were, indeed, rejected; the results of more recent work indicate that modern walking TC theories appear to be able to satisfy FCNC constraints. PNGB's and the S parameter are concerns, but, in the opinion of a number of us who work in this area, they do not obviously exclude these theories. In any case, we should know soon from the LHC whether dynamical EWSB via TC/ETC or some other possibility like low-energy SUSY is realized in nature.

   October 26, 2007

   Robert Schrock said:

"… In the SM, the electroweak symmetry breaking (EWSB) is produced by the vacuum expectation value of the hypothesized Higgs field … via an ad hoc choice of a negative coefficient for the quadratic Higgs term. …
Since the SM give no explanation for this negative sign of the coefficient, it does not provide a satisfactory fundamental explanation for EWSB. …
the quark condensate in QCD already breaks electroweak symmetry. Thus, the original construction of technicolor models … was quite well motivated. …".

In addition to technicolor, other types of quark condensate models can account for the Higgs mechanism, and even give reasonable calculations of the Tquark mass and (predictively, and so falsifiably) the Higgs mass. For one example,
Hashimoto, Tanabashi, and Yamawaki say in … hep-ph/0311165
"… in the top mode standard model with TeV-scale extra dimensions, where the standard model gauge bosons and the third generation of quarks and leptons are put in D(=6,8,10,…) dimensions … while the first and second generations are confined in the 3-brane (4-dimensional Minkowski space-time) … the bulk QCD coupling can … become sufficiently large to trigger the top condensation for … D = 8 … We predict masses of the top (m_t) and the Higgs (m_H) … based on the renormalization group for the top Yukawa and Higgs quartic couplings with the compositeness conditions at the scale where the bulk top condenses …
m_t = 172-175 GeV and m_H=176-188 GeV …".

If some people want to work on various superstring landscape models to try to find something realistic, then that is fine and good luck to them.
However,
working with composite Higgs, technicolor, etc (whethet or not supersymmetric) should be equally encouraged by the physics community, especially since examples such as the Hashimoto et al composite model not only calculate a realistic Tquark mass value and give testable predictions of Higgs mass,
and also, if verified by LHC Higgs observations,
would indicate what sort of structures beyond the minimal Standard Model (such as 4 internal symmetry dimensions in the Hashimoto et al model) could be explored in detail by CLIC or ILC,
and
even might indicate whether ILC or CLIC could do a better job of exploration.

Tony Smith

2. **Shantanu**
October 27, 2007

Thanks fo this. Could some answer the following:
1) How do the latest incarnations of technicolor solve the strong
CP problem?

2) Do they predict proton decay?

3) How do they account for non-0 neutrino mass. What is the technicolor
prediction for theta_13?
Thanks

3. **Robert Shrock**
October 27, 2007

Dear Shanatu:

Thank you for your interest and questions. Let me respond to them herewith.

1. Certainly, technicolor (TC) and extended technicolor (ETC) provide a different context in which to study the strong CP problem. One could envision a scenario in which the $\bar \theta$ parameter is promoted from a constant to a dynamically determined quantity, and some dynamics leads to a very small value for it. Two recent papers on CP violation in TC/ETC are K. Lane and A. Martin, Phys. Rev. D 71, 015011 (2005) (hep-ph/0404107) and Appelquist et al., Phys. Lett. B 595, 442 (2004) (hep-ph/0406032). The Lane-Martin paper specifically proposes a solution to the strong CP problem in the context of technicolor.

2. TC/ETC theories, by themselves, do not predict proton decay. This question is related to another, namely to what extent can one grand unify a theory containing the SM and TC/ETC. This is challenging; for a recent discussion, see Christensen and Shrock, Phys. Rev. D 72, 035013 (2005) (hep-ph/0506155). To me, grand unification is very appealing, for all the well-known reasons, so the difficulty of achieving a GUT containing TC/ETC is a concern.

3. On neutrino masses, yes, as I mentioned in my post, there is a mechanism in TC/ETC to that can explain why neutrino masses are so small; see T. Appelquist and R. Shrock, Phys. Lett. B 548, 204 (2002); Phys. Rev. Lett. 90, 201801 (2003). In this mechanism there is strong suppression of the Dirac neutrino masses and, in addition, there are induced Majorana masses which are large compared to the Dirac masses (although small compared with the ETC breaking scales) leading to a seesaw and hence to sufficiently small neutrino masses. Because of the fact that this is a strongly coupled theory, it is difficult to obtain precise numerical predictions for leptonic mixing angles such as theta_{13}.

with regards,

Robert Shrock

4. **Coin**
October 30, 2007

Mr. Shrock:

In any case, we should know soon from the LHC whether dynamical EWSB via TC/ETC or some other possibility like low-energy SUSY is realized in nature.

Quick question, what kind of potential observations would be able to confirm or exclude technicolor at the LHC? Is the idea that the LHC would have to actually detect particles from technicolor's new fermion fields, or could conclusions be drawn more indirectly? If a Higgs is observed, would this falsify technicolor? Are there any other kinds of observations that might exclude technicolor, or at least the new walking technicolor models?

Is Science Near Its Limits?

October 27, 2007
Categories: Uncategorized

The past two days I've been at a conference here in Lisbon organized by the Gulbenkian Foundation on the ostensible topic of Is Science Near Its Limits? The Gulbenkian is probably the most well-known and best-funded cultural organization in Portugal, and it includes a world-famous museum housing the wonderful art collection of its founder, Calouste Gulbenkian, who made his fortune in the oil business early during the last century.

The conference was extremely well-run and well-attended, filling a large lecture hall where there was simultaneous translation of the talks into Portuguese. It was organized by literary critic, writer and polymath George Steiner, who gave the introductory talk. I hadn't known that Steiner had originally started out studying mathematics, but was discouraged from pursuing a career in the subject at the University of Chicago by Irving Kaplansky, which led to his turning to the study of literature and philosophy. Steiner had quite a lot to say provocative to scientists, including questioning whether they had been able to justify to the public the large sums of money being spent on the LHC, and characterizing the lack of testability of string theory as strong evidence that science had hit a limit beyond which it could not progress.

On the whole the rest of the speakers actually didn't have much to say about limits of science, taking the standard view of most scientists that their own field had a bright future, with no limits in sight. The final talk of the conference did return to the limits issue, with John Horgan giving an uncompromising defense of the thesis of his 1996 book *The End of Science* (although he did allow that possible advances in neuroscience such as the decoding of a neural code, could be as revolutionary as previous advances). While the scientists in the audience took Steiner's attacks in stride, partly because he was our host, they were less charmed by Horgan, who got a rather hostile reaction from many of them. I hope he'll write about his point of view on the conference at his blog, or discuss it in one of his Bloggingheads discussions with George Johnson.

I was one of the few other speakers discussing the question of limits, with my talk emphasizing that particle physics is now in a new, different environment than that of the past, one in which progress, even revolutionary progress, is possible, but much more difficult. A written version of my talk is available here. I was paired with string theorist Dieter Lust, who gave a presentation of the case for string theory unification and the Landscape. We were introduced by Gustavo Calstelo Branco of the IST, who emphasized recent advances in our understanding of neutrinos. Also speaking in another session was Luis Alvarez-Gaume of CERN, who gave a very upbeat talk on the prospects for particle physics, taking the point of view on string theory that, like any idea, string theorists will give up on it if it doesn't work out. He already sees a diminishment of interest in string theory among particle physicists, with people moving instead towards subjects that promise some sort of interaction with experimental data. The three of us were brought together later for an interesting small and very lively discussion of the issues surrounding string theory and recent media attention to it. This was taped, and may appear in some form or other in the future.

Update: There's an entertaining conversation between John Horgan and George Johnson about the Lisbon conference now up at Bloggingheads.

   "My critique of string theory over the past few years has made me many fans who are convinced that sophisticated mathematics is not needed to understand fundamental physics correctly, and that this is why string theory must be wrong. They're often unhappy to hear that I strongly disagree with them, that I think particle physics probably needs even more mathematics of a high level of abstraction and intellectual difficulty."

   – http://www.math.columbia.edu/~woit/lisbontalk.pdf (page 5)

   Way to go, man!

   Pythagoras: "Numbers rule the universe".

   Plato: "God ever geometrizes"

   Kepler: "The chief aim of all investigations of the external world should be to discover the rational order and harmony which has been imposed on it by God and which He revealed to us in the language of mathematics."

   Poincaré: "If God speaks to man, he undoubtedly uses the language of mathematics."

2. **Tony Smith**
   October 27, 2007

   Peter Woit's paper excerpt quoted by anon. is indeed something to which people (especially policy-making physicists) should pay close attention. A few more excerpts describe his position in more detail:
   "… Humanity may sooner or later reach the limits of what it can understand about the universe, but there is no evidence that we are there yet. …
   In 1993 Andrew Wiles announced his proof of Fermat's Last Theorem … Just five years ago, Grigori Perelman posted on the arXiv
   preprint server a set of papers outlining a proof of the Poincaré Conjecture …
   Both Wiles and Perelman worked intensively by themselves for
   seven years or more to come up with the advances needed in their work. …
   Wiles and Perelman … showed what kind of long-term effort is
   generally needed to make a fundamental advance against a difficult problem.
   The current organization of research in physics puts the best young people in a position of needing to quickly prove themselves, to produce results on time-scales of a year or two at most if they want to remain employed.
   At later stages of their career, even with tenure, the pressure of grant applications continues to discourage many from making the kind of commitment to an unpopular speculative research program that may be needed to make progress. …".

   As to what sort of physics institutions might be consistent with Peter Woit's recommendations, maybe Alain Connes's remarks made in a Tehran interview might be relevant:
   "… I [Connes] believe that the most successful systems so far were these big institutes in the Soviet union, like the Landau institute, the Steklov institute, etc.
   Money did not play any role there, the job was just to talk about science. It is a dream to gather many young people in an institute and make sure that their basic activity is to talk about science without getting corrupted by thinking about buying a car, getting more money, having a plan for career etc …",
   and
   it may also be relevant that such institutes were the environment that produced Perelman.

   With respect to the USA, I am not sure that it would be politically realistic to get government funding for such institutes, whose freedom for pursuit of unconventional ideas would make them different from current North American “institutes for advanced study” that are smaller and more directed toward currently fashionable approaches such as superstring theory or loop quantum gravity.

Maybe a newly rich nation, such as China, could establish such institutes and so become the source of future major advances in physics based on sophisticated mathematics.

Tony Smith

3. **John Baez**
October 27, 2007

For people who think they can do fundamental physics without much math, the correct answer is not “no!” so much as “I doubt it, but go ahead and try”. Most such people are crackpots and will produce nothing but nonsense, but someone might succeed, and only time will tell.

It’s quite possible that right now theoretical physicists are stuck, not mainly for lack of math, but for lack of a bright new idea that fits together the puzzle pieces that have been handed to us: dark matter (or some failure in our understanding of gravity), dark energy (or some failure in our understanding of gravity), inflation (or whatever makes the background radiation display the patterns it has), the precise detailed structure of the Standard Model, and various other open questions. Right now these puzzle pieces don’t seem to form a nice picture.

4. **Alface**
October 27, 2007

«This was taped, and may appear in some form or other in the future.»

More that taped, I think it was broadcasted live via the Internet (at least Friday it was) and I can’t see why the video isn’t available after the conference’s end.

I was only as the conference on Friday afternoon.
I saw John Horgan’s presentation and can’t agree with your characterization «they were less charmed by Horgan, who got a rather hostile reaction from many of them».

He mainly got a “verbally violent” reaction to his claim that anti-depressants are as effective for the treatment of depression as talk therapies by someone who objected loudly without giving any reason why it was wrong. The others were anything but hostile and the last long rambling in Portuguese was just silly and vacuous.

Horgan’s ideas regarding the end of war seemed out of place in a scientific context but he did do a good job overall.

Unfortunately I didn’t see your lecture and I appreciate that you post the link to the video feed if it ever becomes available.

Dyson gave a very optimistic account but curiously never even glanced over global-warming, a topic that might have had some relevance to the conference. Given his “unorthodox” views it could have been interesting.

As a final note, the Portuguese title was ridiculous meaning “does Science have limits?” which is a milder question than “*IS* Science near its limit?”. The organizers did a very poor job on this account.

5. **Cool Hand Luke**
October 27, 2007

I would like to ask Baez to please refrain from saying things such as, “Most such people are crackpots and will produce nothing but nonsense, but someone might succeed, and only time will tell.”

Saying things such as “Most such people are crackpots,” just because they might value logic, reason, and truth over math, does not advance the culture nor physics.

Arxiv.org is filled with papers that are in turn filled with math–math that has never born any fruit. Reading Woit’s and Smolin’s books, a strong case could be made that today’s crackpots prefer math. Why is it that government-funded mathematical nonesense is deemed superior to truth, logic, physics, and reason?

I hope that Baez someday has an opportunity to read the original papers of Faraday, Boltzman, Maxwell, Einstein, Bohr, Newton, Wheeler, DeBroglie, and Einstein.

You will notice that the simple logic, reason, and motivation are all contained in beautiful words which far eclipse the presence of math. Read Penrose’s THE ROAD TO REALITY, and you will find far more math, but Penrose hasn’t done much in the realm of physics, other than The Emporer’s New Mind.

Indeed, Faraday’s notebooks and papers barely contain any math–he lead with logic, reason, and physics, as did Einstein, and then they both sought out the math that captured the physical reality. Same with Ludwig Von Boltzman, who many called a “crackpot” in his day.

At any rate, none of the Great’s papers nor notebooks nor books spent that much time talking about who were and who weren’t the crackpots of their age. In fact, I have found no mention of the word “crackpot” throughout all their noble, lasting work. And all of their eras produced far more noble and enduring advancements in the realm of physics than has the last thirty years of our era.

Perhaps the time Baez invests in his crackpot contemplations could be better spent advancing physics. There is no need for ad hominem attacks and name-calling, and we should all be humble with regards to the mysterious nature of science. We do not know where tomorrow’s revolution will come from–curiosity cannot be dictated nor legislated; and thus it should never be castigated nor impugned with snarky namecalling. Curiosity must remain free.

And while Baez’s cataloging of “big questions” is fun, all great scientists have ever asked their own questions, following their own curiosity; from Kepler, to Newton, to Einstein, to Feynman.

One certainity is this–those who find the big answers get to ask the big questions. And the questions are ultimately asked in words–not in numbers.

6. **Leonard Ornstein**
October 27, 2007

Peter:

In your beautiful and convincing Lisbon talk you state:

“The main thing that distinguishes mathematics from physics and other sciences is the different role of experiment”.

“As particle theory enters a new environment in which experimental results are much harder to come by, it may need to learn from mathematicians how to work in a much more painstaking way, taking care to see what can be built solidly without reliance on validation by experiment."

"Lacking inspiration from experiment, physicists may find that searching for it in mathematics is one of the few avenues left open."

This seems to reveal your fundamental Platonic Idealism.

But, as you argue, this is pretty much the path that most string theorists now pursue, and you usually criticize them with such arguments as:

"For such a conjecture to deserve to be called scientific, it must come with the standard sort of scientific evidence, or a plausible idea about how one might someday find such (empirical?) evidence."

This seems a bit schizophrenic. Can you clarify this apparent inconsistency with some argument, other than the possible criticism, that string theorists' efforts are simply not "painstaking" enough?

7. **Erik**
October 27, 2007

That's funny, my objection to

"Most such people are crackpots and will produce nothing but nonsense, but someone might succeed, and only time will tell"

was that it might encourage those crackpots with the "but someone might succeed" caveat.

8. **Shantanu**
October 27, 2007

(Sorry for posting this twice). first time, message did not go through.
Peter have you you looked at the slides and talks of the recent QG conference
in Uruguay?
http://qgsciv.fisica.edu.uy/program.html

9. **J.F. Moore**
October 28, 2007

I recall when Horgan's End of Science book came out. Most striking was the strong, emotional, and yet poorly reasoned response from the bulk of scientists who publicly voiced their opinions on the matter. They trotted out the same tired, hoary notions such as the throwback to the state of physics in the late 19th century or the apocryphal 'the patent office shall soon be closed' story. Even worse were the ones who chose to discount the opinion of a mere journalist. Just embarrassing.

Somewhat better, but still wide of the mark, was John Maddox' response book. I don't really understand why Horgan's thesis wasn't met and argued fairly, rather than hysterically. Then again, I don't understand why people like Kurzweil get a free pass for promoting absurd concepts like the 'singularity' in book after book.

Anyway, this conference sounds like it would have been fascinating to attend.

Cool Hand Luke wrote:

"Saying things such as 'Most such people are crackpots,' just because they might value logic, reason, and truth over math, does not advance the culture nor physics."

But math is logic…and "truth over math"? You mean math **isn't true?!**

Math is a collection of **tautologies**, how in the hell **can't** it be true?

11. **Greg Egan**
October 28, 2007

Cool Hand Luke: What we classify as "mathematics" versus what we classify as "logic and reason" is a purely cultural distinction, which varies from place to place and time to time, and to which physics itself is indifferent.

It would be wonderful if everything in the universe could be explained by means of simple imagery, common sense and everyday language, but there's no good reason to expect this to be the case. Feynman did an amazing job explaining most of QED and much of the Standard Model in simple terms in *QED: The Strange Theory of Light and Matter*, and many people have produced nice, intuitive accounts of much of General Relativity (included John Baez, here). But everyday language and intuition are shaped by a relatively small subset of physical reality, and there is a limit to how far beyond that subset we can reach without the tools of formal mathematics.

12. **Chris Oakley**
October 28, 2007

I do not know whether those who say that you can do fundamental physics without mathematics are trolling (trawling?) or not, but let us assume that they are not.

How, I ask them, are you going to get a cross-section (a number) for e+e–>γγγ (a number) if your theory has no numbers in it?

Take your time about answering.

13. **George Jones**
October 28, 2007

John Horgan had an article (available here) in the October 2006 issue of Discover Magazine that updated his views on the limits of science.

14. **Steve Demuth**
October 28, 2007

For people who think they can do fundamental physics without much math, the correct answer is not "no!" so much as "I doubt it, but go ahead and try". Most such people are crackpots and will produce nothing but nonsense, but someone might succeed, and only time will tell.

It's quite possible that right now theoretical physicists are stuck, not mainly for lack of math, but for lack of a bright new idea that fits together the puzzle pieces that have been handed to us

Many of us were attracted to physics, and foundations in particular, by the proposition that some **simple** order underlies and explains reality. Mathematics in physics bolsters that hope, by reducing apparent complexity, to simply stated physical laws. Who, who understands them, can fail to be moved by Maxwell's equations', or Einstein's field equation's, elegance and explanatory power?

But that's the rub – *who understands them*? At some point, the mathematics required by physics has ceased to be in any sense simple. For me, the boundary came between QM and QFT – the former seems to satisfy the need for simplicity, the latter to defy it.

All this is relevant, because at some point, I think we have to contemplate the possibility that the human ability to imagine or manipulate the mathematics required to describe physical reality may simply be insufficient. Insufficient imagination may mean that the fundamental operations our brains can adeptly manipulate, are not the most appropriate fundamental operations for understanding deep physics. Insufficiency of doing may mean that even if we've got the right ideas, too many computations of too great complexity are required to take those "simple" ideas, and make them describe a big universe.

This would be a sad conclusion for physics, of course, but the incredible quantity of talent thrown at finding a unification of GR and the standard model, with little obvious fundamental progress, suggests that we at least entertain the possibility.

15. **Peter Shor**
October 28, 2007

This was very interesting, Peter.

My objection to John Horgan's book was for each discipline, he came up with a different argument about why we've reached the end of science. For some disciplines, he said that we've reached the limit because we've worked everything out, and all that remains is filling a few details (e.g., what many physicists thought was the state of physics at the end of the 19th century). For other disciplines, he said that we understood a lot of the basic ideas, but fitting them together to reach the next level of understanding was impossible (maybe the state of physics in the years before the Standard Model was discovered). For other disciplines, he said that we had no idea how anything worked, but it was too complicated to figure it out (this was for neuroscience).

So basically, you can make the same argument about nearly any science at most periods of history (excepting the few years after a fundamental breakthrough), and only in retrospect can you discover when you were right.

16. **Peter Woit**
October 28, 2007

Shantanu,

Thanks for pointing out the link. I haven't had time to look at the talks carefully, but they appeared to be good summaries of what is going on, if nothing really surprising.

Leonard,

Yes, sometimes I describe my philosophy of mathematics as radical Platonism…

There is a common perception that the problem with string theory is its reliance on mathematics, and for some reason people get the idea that this is what I believe. What I actually think is that this is just completely wrong and I have argued this point many times, most at length in my book: the problem has nothing to do with mathematics, it's that using a string theory in higher dimensions to try and get a unified theory is just a speculative idea that turned out to be wrong. What is needed is other, different speculative ideas, which may involve just as much mathematics, but turn out to be right. The only way to be sure they are right will be if they, unlike string theory, show signs of making progress towards telling us something about particle physics that the standard model itself doesn't tell us.

17. **Peter Woit**
October 28, 2007

Alface,

The negative response to Horgan wasn't so much from people who spoke publicly during the question session, but privately from people near me in the front part of the room. I think he evokes a strong negative reaction from most scientists, since he is challenging one of their most deeply held beliefs of most scientists, who are doing what they are doing typically because of their belief in the possibility of dramatic future progress in their field.

I actually hope the talk itself isn't available on the internet, I wish people would instead read the written version of the presentation. I ended up having only about half as much time to talk as I had prepared material for, so, was just improvising much of the talk on the fly, which didn't work that well. The written version is much more carefully thought out and I hope much clearer.

18. **John Baez**
October 28, 2007

Cool Hand Luke wrote:

> I hope that Baez someday has an opportunity to read the original papers of Faraday, Boltzman, Maxwell, Einstein, Bohr, Newton, Wheeler, DeBroglie, and Einstein.

I have! I haven't read them *all*, of course, but I like looking at original papers.

> You will notice that the simple logic, reason, and motivation are all contained in beautiful words which far eclipse the presence of math.

Hmm. Let's consider Newton's *Principia*. It's interesting to read about contemporary reactions when this book came out around 1687.

According to Richard Westfall's biography, the philosopher John Locke tried to read it, but "since he was not a mathematician, he found it impenetrable. Not to be denied, he asked Christiaan Huyghens if he could trust the mathematical propositions".

The mathematician DeMoivre tried to read it at the age of 21. "But he was surprised to find it beyond the range of his knowledge and to see himself obliged to admit that what he had taken for mathematics was merely the beginning of a long and difficult course that he had yet to undertake".

Of course, nowadays calculus is taught in high school, in a far simpler style than one will find in the *Principia*. But, in its day, it was the peak of mathematical achievement.

Of course Newton *also* had good ideas in physics, not just math. For him the two went hand in hand, inseparable.

I think the same is true of most of the authors you list. Bohr and Faraday may be the two exceptions. Faraday, of course, was an experimentalist. He interrogated Nature directly.

> Perhaps the time Baez invests in his crackpot contemplations could be better spent advancing physics.

It only took me a few minutes to write that post. Surely I'm entitled to a little break from advancing physics now and then? If you wanted me to get back to work, you shouldn't have written something else for me to reply to. This one took a lot longer.

But: my main point was not to lambast crackpots! It was to suggest that physicists may be stuck "not mainly for lack of math, but for lack of a bright new idea that fits together the puzzle pieces that have been handed to us."

So, it's sort of weird for you to reply as if I'd been arguing in favor of the importance of math.

19. **milkshake**
October 28, 2007

There was a very entertainig interview of OMNI mag with Feynman, I think in 1978 or so – and the journalist specifically asked if a matemacically unsophisticated person like Faraday could make a significant contribution nowadays – and Feynman said no.

(To paraphrase: We got out of simple mechanical models as much as we could have already – and since the natural rules and language of universe is so strange and remote from the everyday experience, we need careful abstraction to translate it into things we comprehend, hence lots of math is needed.) In that interview Feynman also said that math can be threatening to somebody who didn't study it but it is no harder than a normal person can handle.

20. **ScienceLover**
October 29, 2007

I don't think C H Luke wants actually ban mathematical physics but he doesn't believe an advancement in the foundations of physics has to be expected from mathematical "problem puzzling" but requires a conceptual advancement originating from ideas which can be explained without formalism.

As far as Horgan is concerned, it's like a Pascalian bet: he might be correct but it is more promising when he is wrong. After all it's just a journalist hypothesis and the only way he tries to "proof" it is leading interviews with prominent researchers. He just made unambigously clear what he thinks about scientific speculation which goes on and on and leads to an increasing heap of subsequent speculations and interpretations – being mathematical or not.

21. **Spiro Zafiratos**
October 29, 2007

It's funny that the topic of mathematics has come up at this time. I always believed since the beginning that String Theory was off. Peter and John are right it's not the math, we do need more of it. Maxwell won the Nobel Prize because he formulated the mathematical model of light, not Faraday.

I've always argued that current String Theory is at the same stage as astronomers were thousand of years ago when they created epicycles to describe the movement of the pkanets. Was the mathematics wrong? No, what was wrong was the model was built around the assumption that the earth was the center of the universe. The epicycle universe was a very complex mathematical model built on the philosophical view of the universe at the time. Shifting the sun to the center of the solar system created a much simpler, but still mathematical, model of the way the planets moved. It wasn't until Kepler finally changed the model from epicycles to ellipses that the model began to match observation. But, even though Kepler's model was simple it was still wrong. It wasn't until General Relativity that the observations and mathematical equations finally agreed. General Relativity not only agreed, but predicted the motion of all the planets.

Like the Ancient Greeks and Kepler, current String Theorists are basing their model on various assumptions. Like the ancients we can't make any direct observations to build a model around. Kepler had Brahe's detailed observations of Mars to help him formulate his theory. Will LHC help us? And, like the Greeks the more we try to make the string model reflect reality the more complex it becomes. For the Greeks the math wasn't wrong it was the original philosophical assumptions that were false.

So, is the math of String Theory wrong? No it's not. Is the fundamental model wrong? Only time will tell. Like relativity, we need a model that predicts nature not mimic it.

Now stop this and let that slacker Baez get back to work.

22. **Tim May**
October 29, 2007

"It's funny that the topic of mathematics has come up at this time. I always believed since the beginning that String Theory was off. Peter and John are right it's not the math, we do need more of it. Maxwell won the Nobel Prize because he formulated the mathematical model of light, not Faraday."

Maxwell died in 1879, more than twenty years before the first Nobel Prizes were awarded.

Look, I hope I'm not judged off-topic, but I just couldn't let this one pass.

I don't know if Lee Smolin and Peter Woit are right or not. I've been reading this blog for a couple of years now, read Smolin's "Three Roads
" in around 2002, read their more recent books in the past year, and am for various reasons fairly glad I decided not to further theoretical physics way back in 1974. (I instead entered industry, specifically, Intel, and did a kind of applied physics for a while, retiring in 1986 to pursue whatever interested me.)

Physics has been in a tough time for a long while. Feynman commented more that 35 years ago that physics was looking increasingly like smashing watches together at ever greater speeds and seeing more and more little pieces.

This is not too surprising. The energies available to build accelerators scale with technology, but at factors greater than the energies achieved, even as "interesting events" are probably falling off faster than the energies are increased.

So a lot of stuff was discovered in the 1 MeV to 100 MeV range, when basically a few thousand (up to hundreds of thousands, maybe) of bucks could equip a lab. And then a bunch of stuff was found in the BeV/GeV range, a la the Bevatron in the 1950s. A matter of tens of millions of bucks.

And so on, with the last 30 years seeing sparse discoveries in a couple of accelerators, each costing many billions of dollars. (I don't have the energy, no pun intended, to make up a graph of energy of accelerators in billions of electron-volts versus cost of accelerators in billions of dollars.

I hear the usual name for this is the "desert." Meaning, not nearly as many discoveries in the TeV range as in much cheaper, much lower energy accelerators. Which has implications for how much longer the politicians will fund bigger accelerators. (I'm too far out of things to know how likely supersymmetry/Technicolor findings are likely to be at the LHC. If there's some big surprise, maybe more generations will be funded. if not, maybe things slow down for a long while.)

I have a sneaking hunch one of the contributors here has it about right, namely, Greg Egan. Even though his "Diaspora" is science fiction, he anticipate that some of the accelerators needed to really answer some of the key questions–probing a dozen orders of magnitude closer to the Planck scale–won't happen for many centuries. I think he has it about right.

It just costs too damned much–and will cost civilization-sized amounts of money and energy in about 3 or 4 generations of accelerator energy regimes–to resolve niggling questions about the unification of the very large and the very small.

Put another way, there likely won't be funding beyond about 1.5 generations from now unless some new kind of bombs or some new kind of energy production seems likely…and neither of these seem at all likely.

Meanwhile, math research doesn't cost a lot and may yield some striking discoveries.

Cosmology, too. I'm all for building dozens of new and more powerful telescopes. I think new physics is much likelier to emerge from seeing what's out there than from hoping that a 300-km accelerator costing the GNP of Spain for 18 years reveals some new charmicle or coloron or whatever.

I enjoy this blog. I am saddened by what the debate has done to some of the partisans, though. And I think a certain Czech threw away his career in a misguided political frenzy. (I'm sort of sympathetic with his views, but physics is physics, not politics. I saw a department member get so wrapped up in fighting the war in Vietnam, through campus protests, that he was no longer doing any physics. This was in 1971-73. He left physics completely, as near as I can tell. Sad, as he had no effect on the war in Vietnam, and he threw away everything for it.)

Sorry for the length here. My first comment. Hopefully Dr. Woit will be tolerant.

–Tim May

23. **ScienceLover**
October 29, 2007

> Peter and John are right it's not the math, we do need more of it.

The question is whether you expect to get a sound theory out of the math or get the math into the theory. I don't think the latter has to be disputed at all. Physical theories which can't be expressed in a mathematical language shall not be considered as science. Without putting mathematics into the theory it's all just philosophy if not fraud.

What's left? I see following options:

a) Current theories don't have to be extended a lot conceptually but the math has to be "cleaned up" which requires obviously more math. This is the "normal science" viewpoint.

b) New concepts are primary mathematical inventions such as strings + extra dimensions that don't have any obvious physical purpose but can be interpreted as physical entities or background properties and they might help to patch the mathematical machinery. Despite violating Occams razor those inventions can often be justified when they are not too exaggerated and cause more problems than they solve. Otherwise they turn out to be phlogiston.

c) Some essential concepts, experimental links and observations are still missing and every attempt to make signifcant progress at the foundations without them is just a footnote in the history of illusions. Maybe we just have to be more patient with mother nature?

24. **Johan Couder**
October 29, 2007

John Baez said:

"But, in its day, it [Principia] was the peak of mathematical achievement."

hmm, or perhaps the pinnacle of obscurantism. Isn't Newton known to have said that he purposely made it difficult "to avoid being bated by little smatterers in mathematics"

Spiro Zafiratos
"Maxwell won the Nobel Prize because he formulated the mathematical model of light, not Faraday"

huh? the first Nobel prize was awarded in 1901. Faraday died in 1867, Maxwell in 1879. Posthumous nominations are not permitted. When did Maxwell win the Nobel prize ?

25. **John Horgan**
October 29, 2007

Good post on and responses to "Is Science Near Its Limits?", which as Peter says was a fascinating meeting. I just posted on it yesterday. http://www.stevens.edu/csw/cgi-bin/blogs/csw/?p=75 I focused on the suggestion of the eminent German neuroscientist Wolf Singer that researchers study parapsychology. Another speaker, Freeman Dyson, professed belief in psychic phenomena in a New York Review of Books Essay a few years ago. He reiterated this view to me in Lisbon. He said, however, that he doubts whether ESP can be scientifically validated, because it is usually only manifested in people under severe stress. Singer's suggestion about ESP seemed to be received with far more equanimity than my end-of-science schtick. My only regret is that, during my speech on the end of science, I didn't suggest that string theorists attempt to resolve their problems by postulating a new particle, the "psychon."

26. **Johan Couder**
October 29, 2007

still, Spiro Zafiratos has a point

all the essential elements of Newton's theory of gravitation appear in several of Newton's predecessors, and all of them appear in the work of Hooke [Hesse, Mary B. (1962): Forces and Fields The Concept of Action at a Distance in the History of Physics, Dover, p. 133]

Unfortunately, Hooke lacked the mathematical technique to represent the complete theory in all its mathematical inevitability, so Newton received all the credit.

27. **Spiro Zafiratos**

October 29, 2007

Sorry my error on Maxwell. Johan made my point. Hooke, Brahe, and Faraday did the work, but the mathematicians received the fame.

28. **Steve Myers**
October 29, 2007

On math & physics — a direct example from my work: I have a spreadsheet with over 65,000 data points for 8 devices. I can't make any sense out of that data without math — statistics, Fourier, etc. But before I gathered that data or placed those instruments, I had to understand what & why I was measuring. The concepts came first but without the math I just have a collection of numbers. A physicist trying to discover "the rules of the universe" is working at a deeper level but the basic method is similar. And in one case — involving airflow & pressure change — the math came first & suggested the key idea.

29. **Peter Woit**
October 29, 2007

I made a mistake in moderation here, allowing a comment from "Cool Hand Luke" = "Elliot McGucken", because I initially didn't realize who this was. It became clear after he posted many more comments to the thread, which I deleted. Leaving the initial one was a mistake, since it has led to a mostly off-topic and unenlightening discussion, and he keeps posting large numbers of comments here which I have to deal with.

Please, no more comments on the thread inspired by "Cool Hand Luke".

30. **Leonard Ornstein**
October 29, 2007

Peter:

You didn't address my main question; the seeming contradiction in the two following quotes:

"…to see what can be built solidly without reliance on validation by experiment."

"For such a conjecture to deserve to be called scientific, it must come with the standard sort of scientific evidence, or a plausible idea about how one might someday find such (empirical?) evidence."

You usually seem to believe Science requires "validation by experiment".

So what's the value your talking about in the first quote?

Only the pragmatic value that comes from building what appear to be self-consistent models…to be accepted or rejected AFTER empirical test?

Is that you definition of scientific radical Platonism?

That's fine, but it hardly fits Platonic ideology!

This may seem to be a straw man; it's just that many scientists DO believe that empirical testing…and testability…is what distinguishes science from math, logic, and all other 'purely tautological ideologies'. Blurring the definitional line between induction and deduction, isn't helpful, especially in discussions of strings and the future of science.

And when you label math as science, it also adds to the confusion; vive la difference.

I'm in no way trying to denigrate math or logic!

31. **Peter Woit**
October 29, 2007

Leonard,

In the end, any physical theory definitely needs validation by experiment, or it's not science. My comments were about what physicists should do along the way towards this ultimate goal. When I wrote about working "without reliance on validation by experiment", I was referring to the work done with the ultimate goal of coming up with something experimentally testable, but where that goal may still be far away. If you start investigating a very speculative idea, you often generally don't initially have experimental tests. It there is a lot of experimental data out there, you should be able to soon make contact with it. My point was that, if relevant experimental data is much harder to get than in the past, you often can't rely on it until much later, so need to be very careful about the consistency of what you are doing along the way.

32. **srp**
October 29, 2007

Given Peter's analysis of the prospects for accelerator progress, why isn't the community trying to direct substantial sums at wakefield research? That appears to be the only technology on the horizon that could give big jumps in performance/cost, but it seems like fairly small amounts of people/money are working on it. As a taxpayer, I'd rather spend a few hundred million dollars on basic R&D for a breakthrough accelerator technology, even though it might not pan out, than devote billions to a scaled-up version of existing tech (ILC, anyone?) that doesn't seem likely to do that much.

33. **Coin**
October 29, 2007

So I'm a little confused about one thing about this conference. The comments here seem to largely cover the question of whether *physics* is near its limits– reasonably, since this is a physics blog– but the conference title itself and the vague comments about "neuroscience" seem to imply that this was a conference about the limits of science *in general*.

I understand the "desert" problem people are worrying about with respect to physics– the fear that all the questions are turning out to be either trivially resolved or way out of reach– but it seems to me that this is in no way a worry which is applicable to all sciences at the present point in time. Science is larger than just physics and the crisis does not seem to be shared. The various biological sciences, for the first thing that comes to mind, seem to be in at a point where research is making measurable advances on a wide variety of fronts, with one entire promising *type* of research being seemingly held back primarily by U.S. laws concerning embryo disposal. I have not read John Horgan's book, so I don't know what his argument concerning the state of biology research was, but if the book was published in 1996 then it doesn't seem like it could have possibly taken into account the potential avenues of research opened up by stem cells– which to my understanding weren't even isolated in humans until 1998!

Meanwhile I'm not finding it too hard to list off growth areas off the top of my head even outside biology. Astronomy seems to have been having a really good decade, once the Hubble got fixed. Atmospheric science seems to have had a very productive last few decades, with its primary problem being to get anyone to listen to the results of its research… it seems that even if science stalls out on certain fundamental questions, there can still be niches where this doesn't stop one from being very very busy.

Meanwhile I'm not sure that we can even judge the progress of "physics" based on the troubles with *the sort of physics discussed on this particular blog*— which is to say, high-energy particle physics and fundamental theoretical physics. These are of course critically important areas, and with the LHC looming this is a good time to be focusing on those areas of physics. But they're not the only areas of physics, are they? Quantum computing, for example seems to be in the midst of a string of significant breakthroughs which shows no sign of stopping (though there are other commenters in this thread who would clearly know more about that than me…). For another example, I semifrequently hear Chad Orzel complain on his blog along the lines that lack of progress for HEP is judged to be lack of progress for "physics", while meanwhile potentially interesting advances in Orzel's own field, quantum optics, continue at a steady pace– but without much attention being paid to them, because they're not as dramatic.

Okay, so worst case scenario, the LHC finds one Higgs and nothing else, all the new physics looks to be at the planck scale and we still don't have any idea how to probe that. This is a serious crisis, to be sure, but all the people doing quantum optics and bioinformatics and climate modelling will just keep quietly chugging along anyway. Even in the worst case scenario, are we approaching the end of science, or just the end of "sexy" science?

Peter wrote:

> Yes, sometimes I describe my philosophy of mathematics as radical Platonism…

What's "radical" Platonism? There are many kinds of Platonism, and a *lot* of them are pretty radical if we take metaphysical naturalism as our standard of a boring ordinary worldview. I'm some sort of Platonist, but I want to know if I'm radical.

As for being "near the limits of science", does anyone here actually think we are? About the only scenario I can imagine where science ends anytime soon is one where our current civilization falls apart and is replaced by one much less interested in science.

35. **tytung**
October 29, 2007

Regarding the 'limit of science'…is this suppose to mean an intrinsic limit of our ability to understand nature? or does it mean the limit due to unavailable of suitable technology or some other practical reasons? or maybe it just reflects a limit of our imagination of how science should advance within the current paradigm?

36. **Thomas Larsson**
October 30, 2007

> As for being "near the limits of science", does anyone here actually think we are?

I always thought Horgan failed to make a distinction between several related notions: can sciences end, do all sciences end at the same time, and is this time now? The answers to these questions are obvious once you consider (terrestial) geography: it peaked around 1500 and was essentially over by 1900, well before the golden age of other sciences.

However, I do think that Horgan has a legitimate point when it comes to physics, but the extrapolation to other sciences is not valid. My opinion is colored by the fact that I started out in the statistical physics of critical phenomena in the early 1980s, and for various reasons I mainly worked with 2D models. A few years later, CFT came along and literally wiped out my chosen field of research. I was too young and unexperienced to jump onto this bandwagon (and I didn't notice the bandwagon until 1986), but it left me with the realization that physics, or at least subfields of physics, can end. Mine did.

Of course, 2D phase transitions is not a very important subfield, and physics as a whole can not come to an end before QM and gravity coexist happily. But the question is whether this unification requires new physics, or if all that is needed is to take the ideas from QM and gravity seriously. I vote for the latter.

37. **Peter Woit**
October 30, 2007

John,

I just made up the "radical" modifier to "Platonism" because I liked the sound of it, there's probably a more conventional terminology. What I mean by it is roughly the idea that not only is mathematics the investigation of certain fundamental objects that "exist" (not a study of formalisms freely created by the human mind), which is how I'd characterize "Platonism", but these objects are the same fundamental objects as the fundamental objects of physics (that's the "radical" part).

So, we want not just a grand unified theory of physics, but a grand unified theory of physics AND mathematics.

Max Tegmark goes on in a similar vein sometimes I think, although this leads him to something rather different (to me, he seems to treat math as kind of a black box).

38. **Andrei Kirilyuk**

John Baez wrote:

"About the only scenario I can imagine where science ends anytime soon is one where our current civilization falls apart and is replaced by one much less interested in science."

This has already happened, you've just missed the evolution. This is something typical of "science after the end of science": mainstream, very well supported scientists working and even living in a world of their own (a "Platonic universe"?) separated by the growing gap from the real world where the majority of other people, Earth civilisation as such, is actually living. Yes, they still allocate the necessary billions for your fruitless searches in purely abstract, over-simplified structures and technical tools, but already almost nobody except scientists themselves (and related interested bureaucracy) is really excited about the emerging or even expected advances. If you compare with the situation we had in the middle of the last century, you'll see the difference. And the change concerns not only fundamental physics. People are more directly interested in the ready-made practical results, in technology, but not in the "fascinating process of research" and related "promises" as it was all the time before (who knows, maybe indeed "one cannot fool all the people all the time" about "quantum computers" and other "nanotechnologies" that strangely fail to definitely demonstrate their real powers?). The shift is quite visible and ignoring it makes just another aspect of the real end of science. This is the "internal structure of death" of any system: it first becomes increasingly detached from any environment it used to intensely interact with during its life, which is the "first death" so to say, and then the actual, definite disappearance comes as the "second death". It remains to hope that another kind of knowledge can take the place of disappearing mechanistic science. If not, it can well be mere technology, or "applied science" (largely today's situation), but this one can hardly be "sustainable" beyond the very immediate future.

39. **a.k.**
October 30, 2007

..one could wonder at this point, if this dichotomy 'purely abstract' vs. 'technology/practical results' could be more likely interpreted being a growing 'cultural prejudice' than marking an inherent evolution that one could associate to 'the end of science', i.e. regarding the above discussions. In this sense, I do not see why a failure of string theory as a 'TOE' could exclude the possibility of very concrete links of some of its mathematical concepts to reality, the problem is probably to a less degree the lack of 'fruitfulness' of concepts involved but the growing prejudice to explore 'cross-cultural' communication, on both sides.

Quite recently, I discovered a not-so-recent paper by A. Pnueli linking the index theorem, notably the eta-invariant, to adiabatic charge transport and Hall conductance on surfaces with cylindrical ends, this application might be obvious, still there seems to be little research in that direction. I do not see why for instance mirror symmetry couldn't have long-term applications in, supposingly, material science, linking the 'symplectic/lagrangian' picture to purely algebraic concepts on the complex side, maybe one has to be courageous to cross (growing) 'cultural gaps', but this condition is not in any sense equivalent to the 'end of science'.

40. **Zathras**
October 30, 2007

Woit: *What I mean by [Radical Platonism] is roughly the idea that not only is mathematics the investigation of certain fundamental objects that "exist" (not a study of formalisms freely created by the human mind).*

This is a false dichotomy. The truth value of Mathematics can also be something in the middle, rather than purely ontological or purely "just in the head." Instead, mathematics can be seen as fundamental interactive, in that it deals with our apprehension of the world. From this viewpoint, Mathematics gives the Projection of reality that we can apprehend. It is fundamentally incomplete, since information is almost always lost in a projection, but it still contains truth value, and it says as much about the subject as the object. Such an idea has been present in the history of thought since at least Plato's Cave analogy, although its application to Mathematics is much newer.

41. **Coin**
October 30, 2007

Yes, they still allocate the necessary billions for your fruitless searches in purely abstract, over-simplified structures and technical tools, but already almost nobody except scientists themselves… is really excited about the emerging or even expected advances… People are more directly interested in the ready-made practical results, in technology, but not in the "fascinating process of research" and related "promises" as it was all the time before

Unless you're seriously suggesting that new practical results are indefinitely possible without ongoing fundamental research into the "abstract" problems, it seems like what you're describing here is really a problem of communication more than anything.

42. **Adud**
October 30, 2007

> physics as a whole can not come to an end before QM and gravity coexist happily.

I sort of disagree with this, for two reasons. First, most physicists are not involved with such unification, and most likely not even aware of it. People working in condensed matter, plasmas, classical and quantum chaos, etc., etc., etc., will keep making progress in their respective fields regardless of what goes on in QG, be it good or bad.

Second, even assuming that the unification of QM and GR is actually the holy grail of physics, which I do not believe, finally finding it need not be the end of physics, just like discovering and decoding DNA has not been the end of biology. Biologists found their TOE decades ago, yet biology keeps making progress and growing, and getting most of the research money everywhere.

43. **anon.**
October 30, 2007

'… but already almost nobody except scientists themselves… is really excited about the emerging or even expected advances…' – Andrei Kirilyuk

'… it seems like what you're describing here is really a *problem of communication* more than anything. …' – Coin

Coin, the lack of 'communication' (the political euphemism for 'spin and hype') which you perceive to be the problem is exactly what led string theorists into their mess. By trying to get media attention and massive funding ahead of any falsifiable theory let alone any experimental results (falsifiable theories are two a penny in physics), they ended up losing a grip on reality and ceasing to be skeptical (=scientific).

The problem is really a case of finding the simplest abstract theory that makes contact with physical reality, checking it experimentally, etc., not just generating more spin and hype (aka: communication).

44. **Thomas Larsson**
October 31, 2007

Adud, you misunderstood the direction of my implication. I did not claim that QG implies the end of physics, but that the end of physics implies QG.

45. **Leonard Ornstein**
October 31, 2007

Peter:

The models (or Zathras' "projections") of math and theoretical science differ mainly in their motivation. Scientific theories usually ATTEMPT to model external reality. Most of those of math and logic (refinements of conventional language), don't.

Establishing how much confidence scientific theories deserve, depends COMPLETELY on empirical realty checks, usually of experimental science. You usually appear to subscribe to this clear distinction.

Thus, your:

"What I mean by it is roughly the idea that not only is mathematics the investigation of certain fundamental objects that "exist" (not a study of formalisms freely created by the human mind), which is how I'd characterize "Platonism", but these objects are the same fundamental objects as the fundamental objects of physics (that's the "radical" part)."

fails to distinguish between many of the "formalisms freely created by the human mind" of math, from those supposedly designed specifically to model external reality. String theories belong in this second category. But separating the possible 'truth' of any physical theory from science fiction and pseudo science is at least, the line between purely deductive, "tautological" truth and inductive, empirical 'truth'.

Science, tries to model reality in a more formal way than 'straightforward' communication with conventional language. It seeks to help us understand and somewhat control our possible destinies. There will always be unsolved problems important to comfort and/or survival. The formality of science often generates more precision and utility.

I believe THIS is why it's hard to imagine an end to science…in rational societies.

46. **eiaboca**
November 1, 2007

We just need new kinds of science, revolutionary avenues of thought. It's happened many times before. Technology will advance, the set of all human knowledge will expand in some ways, perhaps contract in others, but from that set someone will be able to pull something out of the background noise that no one has ever noticed before.

Science is just finding empirical data about the universe and analysing it. If you think there is a lack of data in the universe to analyse, then I think you're kind of ridiculous.

There are certainly different "ways of knowing" about the world, and the crackpots might inadvertently hit upon some real theory about things, because the universe seems to be infinitely weirder than we've ever imagined.

47. **eiaboca**
November 1, 2007

You being the "royal" you, as it were, and not you specifically.

48. **Emil Lundh**
November 3, 2007

Coin and Adud, thanks for sobering remarks.
Finding out what's inside the quarks (so to speak) is surely just one of the goals of physics. There are lots of issues that are at least as fundamental. One of them is, how do we make sense of quantum theory? (HEP builds on quantum theory, but I don't see how it can actually advance the understanding of it the way that, e.g., experimental quantum optics does.) Another one is, how do we make sense of phase transitions? – that is, in the words of Laughlin, finding out the "principles of organization" for systems of particles, that seem to be quite independent of their microscopic laws of motion.
It is sad that the research programs that deal with these other kinds of fundamental question do not often get invited to conferences like the one we are discussing.

49. **mclaren**
November 7, 2007

One important point which it seems many folks have overlooked is Dr. Woit's focus on the fact that some of the biggest outstanding problems in current particle physics have little to do with larger accelerator energies.
Einstein's theory of gravitation remains a fundamentally classical geometrical model, whereas quantum theory is quite different. Einstein's tensors do not involve expectation values, there is no uncertainty principle involved, and above all GR is a continuous theory — quanta are discrete.
Arguably the biggest unresolved problem in modern physics involves finding a way to mathematically unify these radically incompatible mental models of reality. Every time someone has tried, the math has blown up.
This suggests several possibilities. First, we need a lot more and a lot better math than we currently have. Considering the immense sophistication of current mathematics, that's non-trivial. And we probably also need some radical new conceptual leap, something different in kind from current mental models of the universe, in order to successfully unify GR and quantum theory. One of the most powerful criticisms I've seen of string "theoy" is that it merely tacks on extra dimensions to current mental models. I.e., it takes pointlike particles and draws 'em out into circular strings in n dimensions. That's not a fundamental conceptual leap. Planck's conjecture that energy comes in packets did represent a wild leap beyond 19th century mathematical models of radiation, specifically, beyond Maxwell's equations.
John Baez asked:
"As for being "near the limits of science", does anyone here actually think we are?
The phrase "limits of sicence" was certainly poorly chosen for the conference. But yes, we are probably at or near the limits of terrestrial accelerator-based particle physics today. Future progress in particle physics is likely to come from astronomical sources. One advantage: such experiments will likely prove much less expensive than building accelerators, since they mostly involve dumping large amounts of ultrapure liquids of various kinds (cleaning fluid, mineral oil, et al.) into big underground tanks surrounded with photodetectors.
We have clearly not approaches the limits of science in other fields. Molecular biology, materials science, astronomy, etc. remain wide open.

50. **Michael Gogins**
November 7, 2007

I read "String Theory and the Crisis in Particle Physics" with great interest and appreciation. I am not sure that the cutting edge of physics already has raised the bar of intellectual difficulty over Newton and Einstein, but surely, it is not an unreasonable idea. At the very least, the difficulty of relating theory to experiment has obviously increased.

So, what kind of changes should be made in institutions, to support the "sit in an attic for 7 years and just think, like Wiles" kind of research that Woit is pointing to?

51. **Peter Woit**
November 7, 2007

Michael,

At various times I've suggested various ideas one might want to consider. It should be clear to anybody in the field of particle theory what the current incentive structure is: it is determined by how NSF and DOE grant proposals are evaluated, and by how hiring decisions are made. Everyone involved on both sides of these decisions knows how they are being made, and that the incentives are heavily on the side of not working on long-term ambitious projects that may not pan out.

If one wants to get serious about changing this, one has to

1. Make working on such projects more rewarding: announce that grant decisions will be made preferentially for such projects, have hiring committees tell candidates that they are looking for people to hire working on such projects.

2. Make routine work on research directions that have had huge investments but not worked less rewarding. Even a rumor that an NSF grant panel had decided to reject

grant proposals in active but failed subjects such as, say, string phenomenology, would have a huge effect.

As far as I can tell, the people with power to affect these decisions have reacted to the current crisis in particle physics not by discussing what can be done about it, but by getting defensive and attacking anyone who brings up the subject. Current thinking seems to be to just deny everything and hope that the LHC will solve all problems. Maybe it will, we'll see. At this point, maybe I'm wrong, but I see no hope of anything happening or any serious discussion taking place until a few years from now, after the LHC results are in.

I'd be happy to hear that I'm wrong about this, and that there are people out there taking this problem seriously and trying to do something about it.

52. **Thomas Love**
November 7, 2007

Researchers with ideas are going to pursue those ideas whether or not there is grant money available. People who follow the money should not be taken seriously as researchers

53. **Peter Woit**
November 7, 2007

Thomas,

This isn't about money, it's about jobs. For younger people, whether or not they can get a grant affects whether they can get a job or stay in one (get tenure). For people with tenure, a large part of their grant is used to pay students and postdocs. No grant, no job, if not for them, then for younger people they'd like to work with.

No one with a brain goes into this business to make money, but whether or not they can make get a full-time job that allows time for research is crucial.

54. **anon.**
November 8, 2007

'No one with a brain goes into this business to make money, but whether or not they can make get a full-time job that allows time for research is crucial.'

The predictable lame response of a string theorist would be:

'Wrong! Take Einstein, just a patent examiner in 1905, who had no problems despite having no faculty tenure at all.'

The Einstein claim is of course slightly misleading because the development of General relativity, 1915, which is really advanced mathematically, is another story and he would not have had the time and the helpful friends necessary to focus on the mathematics of tensor analysis without getting tenure:

'Up to this time [1911] Einstein had used only the simplest mathematical tools and had even been suspicious of the need for "higher mathematics", which he thought was often introduced to dumbfound the reader. However, to make progress on his problem he discussed it in Prague with a colleague, the mathematician Georg Pick, who called his attention to the mathematical theory of Ricci and Levi-Civita. In Zurich Einstein found a friend, Marcel Grossmann (1878-1936), who helped him learn the theory; and with this as a basis, he succeeded in formulating the general theory of relativity.'

– Professor Morris Kline, *Mathematical Thought from Ancient to Modern Times,* Oxford University Press, 1990, vol. 3, p. 1131.

55. **Jack**
December 8, 2007

Is Science near it's limits? Maybe, maybe not. Is Science near the limits of John Horgan's imagination? It would appear so.

56. **Gphillip**
December 14, 2007

I think it's clear that the "easy" discoveries have been made. Not to take anything away from the great minds of the past, but theirs was a simpler time in a world ripe for scientific exploration. Then monumental discoveries could be made in a small lab with a couple assistants. Now, we must invest hundreds of millions on apparatus like the LHC and employ hundreds of physicists and engineers for years to hope for a monumental discovery. This should come as no suprise. Science is nowhere near it's limits, but we are getting ever so close to ours.

In another century the scientific method will be so "picked over" it may take trillions of dollars of investment and thousands of scientists and engineers working for centuries to hope for a major discovery. Of course, all branches of science do not hit this wall of diminishing returns at the same time, but they all must pass their prime eventually. High Energy physics is just the most fundamental of sciences and will hit the wall first. All the other sciences will follow, eventually yielding fewer of natures secretes for ever more resources.

In the end, how much of all there is to be known can be illuminated by the scientific method? Perhaps one percent? Perhaps one thousandth of one percent? To know that, we would have to know how much isn't known, and that's probably something we can never know.

57. **Jack**
December 18, 2007

Part of it's about imagination, as I said before, but part of it's about patience. In Mathematics, mathematicians have learned that it is not unusual for a problem to be so hard that it will go unsolved for many hundreds of years. Some problems unsolved today are more than 2000 years old. Physicists have not experienced, over the generations, the experience of being unable to make any progress on a problem over such a timescale. Now they have been struggling with certain questions for 30 years or so, and it is making many people, journalists and physicists, uncomfortable.

Of course, in mathematics there are Lemmas. If you can't solve a problem, work on a related problem which you can solve. Progress can be made step by step in this way. Eventually, someday, you realise that the easier problems you kept working on have become Lemmas in the proof of the problem you couldn't solve before. It is not clear to me whether there is any analagous thing in physics. In mathematics you are spoilt for choice in terms of problems of all difficulties, easy, medium, hard, and incredibly hard, whereas in physics the main problems are more clearly mapped out and more easily summarized. This may seem like a good thing because things may seem simpler, but the downside might be that you have less leverage to make progress.

58. **Gphillip**
December 19, 2007

I generally separate math and science when discussing this issue. Math can always be abstracted to deeper levels. Some would say that the more abstract, the less it represents anything in the real world. Others would say the real world IS math (see "The Computational Universe" by Seth Lloyd). But I doubt that math will ever hit a wall where it takes ever larger number of people and huge expenditures to continue advancing. Math is after all just an abstraction of what we consider to be the real world. I believe that there is a subtle difference where science uses the scientific method to illuminate the secrets of nature, and math is just one of many tools employed in scientific pursuit. Math can also represent many things not associated with the scientific method, like accounting. In any case, all sciences will run their course in time. Either because they become almost completely defined with few meaningful questions left to answer, like Thermodynamics, or because the remaining questions would take unsustainable resources to pursue, like High Energy Physics. I'd guess Chemistry has probably just barley past it's peak, but lots more remains to be discovered. Biology doesn't seem to have quite reached it's peak yet, and we have probably just scratched the surface of computer science. But for math, I see no reason it can't toyed with until the end of time. That's just my own humble opinion based on my anecdotal observations though. I haven't seen any formal studies of the topic, though that would be an interesting.

Pressure Mounts to Tie String Theory to the Real World

October 30, 2007
Categories: This Week's Hype

Last week David Gross was in New Mexico, giving an "unclassified talk" at Los Alamos, and one on The State of String Theory at the Santa Fe Institute. There's a report on the Los Alamos talk from the Los Alamos Monitor, entitled Loose Strings: Pressure mounts to tie string theory to the real world. Unfortunately, pressure to tie string theory to the real world leads sometimes to reporters getting misled about such ties, since the article includes the information that:

> Located on the border of France and Switzerland, the LHC's headline tasks include the potential discovery of a Higgs boson, a relatively massive particle known as "the god particle," that would help explain how other particles have mass. Proof of its existence would tend to support string theory, according to the theorists.

Hermann Nicolai has an article in a recent issue of Nature entitled Back to Basics, on a more promising idea for tying string theory to the real world, one that has nothing to do with using string theory as an idea about unification. He reports on recent progress towards getting an exact solution of N=4 SSYM, allowing one to test whether it really is dual to a string theory.

According to a blog posting on Superstring Theory and the End of Man, we better hope that superstring theory doesn't connect to the real world, because if it does, a combination of the Anthropic Principle and the Doomsday Argument would show that humanity doesn't have much time left. The author expresses the opinion that mankind better hope that I am right about string theory, an opinion I endorse even if I disagree with his logic.

Finally, on a completely unrelated note, the latest issue of Symmetry magazine is out, featuring the results of a reader's contest to invent new particles. Third place goes to Jacobo Konigsberg, the spokesperson for CDF, who postulates the blogino, which he describes as

> Particles created by non-abelian Blog-Blog interactions. Bloginos typically are produced in a very excited state and with a high degree of spin. Even though all their properties have not yet been determined, it is commonly agreed that they exhibit considerable truthiness. They also have the annoying ability to propagate into extra dimensions, away from the blogosphere, and generate lots of phone calls.

Update: Lubos has a link to a Youtube video of a version of this talk by Gross that he gave in Berkeley on October 19, together with commentary. It appears to me essentially the same talk that Gross gave here in New York three and a half years ago, which I wrote about in my first real blog posting here. It is striking to note how little has changed in this field during this period.

Comments

1. **King Ray**
   October 31, 2007

   Well, perhaps string theorists should be tied to the real world before string theory can be tied to it.

   If string theorists had ever had a real job where they had to get actual results by some hard deadline, then they would realize that they are off on a wild goose chase. You wouldn't get away with this wandering in the wilderness for nearly 40 years in any other kind of job.

   I think theoretical physics needs leadership like Oppenheimer during the Manhattan project to set direction. At the least we need to cut off government funding for ideas that don't work.

   I have no problem however with people working on their own ideas on their own nickel. I do have a problem though with string theory monopolizing the market of ideas and funding and squeezing out all other things.

2. **Thomas Love**
   October 31, 2007

   Peter, The link to the Los Alamos Monitor article doesn't work for me. I went to the Los Alamos Monitor website and searched for David Gross. Got a blank screen in reply.

   I heard Gross speak in 2005 at a meeting honoring 100 years of relativity. It sounds like I heard the same speech you were talking about.

3. **Steve Myers**
   October 31, 2007

   Peter,
   The latest Scientific American on-line has an article called "The great Cosmic Roller-Coaster Ride" about string theory & inflation and branes & anti-branes. Aside from glossing over stuff it ends with: "In summary, string theory provides two general mechanisms for obtaining cosmic inflation: the collision of branes and the reshaing of extra-dimensional spacetime. For the first time, physicists have been able to derive concrete models of cosmic inflation rather than being forced to make uncontrolled ad hoc assumptions. The progress is very encouraging. String theory, born of efforts to explain phenomena at minuscule scales, may be writ large across the sky."

4. **Jimbo**
   October 31, 2007

   Yes, & its exactly the same talk (aka `sales pitch') with slides he showed at the U.of Oregon colloquium 8 mos ago. I suspect tho, that his Nobel spared him the admonishments any other academic speaker would have been subjected to, if they had included the word `bullshit' in their presentation.
   My respect for him has grown slightly, tho, knowing that he was arrested in one of the many anti-Vietnam war protests on the Bezerkely campus. He may have abdicated his scientific ethics of late, but at least he his political ethics were together back then.

5. **Peter Woit**
   October 31, 2007

   Steve,

   I wrote about this here:
   http://www.math.columbia.edu/~woit/wordpress/?p=609

6. **Peter Woit**
October 31, 2007

Thomas,

The link no longer works on the Los Alamos paper web-site, not clear is they automatically get rid of old content. If someone knows of another place that has this article with a working link, let me know and I'll fix it.

7. **chimpanzee (aka "joe")**
October 31, 2007

The Los Alamos article is in Google Cache here

Geezes. That article has some glaring errors:

"In 2004, Gross shared the Nobel Prize in Physics with Frank Wilczek his graduate student at Harvard [no..Princeton!], and with David Politzer, who was working on the problem separately at Princeton [no..Harvard!]"

"More recently, grousing among anti-string theorists has become louder, signified by such books as "The Trouble with Physics: The Rise of String Theory, the Fall of a Science, and What Comes Next," by Les Smollin [Lee Smolin]"

I can't trust anything in this article..looks like it is written by a dyslexic/illiterate.

There are a bunch of scientist quotes all out of context. To get the correct picture, you have to watch the COMPLETE 90 minute video (as per L. Motl's blog)…with a scientific background.

The above is an extreme example of why journalists have NO BUSINESS reporting on Science. John Horgan, Timothy Ferris, George Johnson, et al. THEY AREN'T SCIENTISTS..come on.

"Know your subject matter"
— maxim (Journalism, Science, Music, et al)

That's the purpose of a physicist blog ("citizen journalism")..scientists can do the reporting yourself.

"The authors are themselves amateurs [journalists], and when they venture into scientific topics their information is limited & sometimes outright wrong.."
— Harold Zirin/Caltech, solar astronomer
[applies to the recent PBS program by T. Ferris..it was 100% nonsense]

"Remember "journalists" are merely people who couldn't qualify for jobs
which require any sort of technical background."

"Yes, he did. I was a journalist myself, and I taught many young people. The first thing you learn is that you should be aware of what you are
doing before you put your foot-in-your-mouth."

"Nevertheless, the author [J. Horgan] of the stupidity from 1997, after those ten years that have demonstrated that his stupidity is among the greatest stupidities that have ever been pronounced by homo sapiens, has the stomach to come in front of a conference in Portugal and repeat the same stupidity.
— L. Motl, End of Science blog post

"Everyone who gave this book one star should realize that this book is
entertainment. Hancock [journalist] is not a scientist or an academic of any kind – he's a journalist! … Of course Hancock tailors the facts to fit his theories – he is not constrained by truth, science, or even ethics. He is a journalist.
…
This book, and all those like it that preach pseudo-science, appeal to the majority of people in this world who are scientifically challenged. Most Americans don't have enough scientific knowledge to understand the technology they face everyday, much less untangle the fact and fantasy in this book. It is entertainment, but it's dangerous – science interpreted by a journalist!"

November 1, 2007

Well today Frenkel and Witten have just posted a paper to the math arXiv about Langlands stuff http://arxiv.org/abs/0710.5939
Looks like Witten has put on hold his strings-related hep-th efforts. For how long is anybody's guess.

9. **IMHO**
November 1, 2007

Peter,

Feel free to erase this comment…

You are a public figure with a book deal. I wonder how smart it is for you to link to Lubos site. Have you seen his post about "…N-word zebrafish…"

Bigger men then you have lost more for doing less. Personally, I would never risk my success over principal…but that's just me.

10. **Peter Woit**
November 1, 2007

IMHO,

My linking to something in no way indicates approval of it or its author, often quite the opposite…

11. **Adud**
November 1, 2007

Well today Frenkel and Witten have just posted a paper to the math arXiv about Langlands stuff

"Geometric Endoscopy and Mirror Symmetry"

I had heard about "surgery" techniques in differential topology, and now there is "geometric endoscopy"…. I wonder how far mathematicians are willing to go with medical analogies. How about "categorical proctology" or "group gynecology"?

12. **IMHO**
    November 1, 2007

    Peter,

    I know that and I'm sure most of your readers know that.

    Your issue is that you aren't a just a blogger, you're also an investment, which means the rules are different for you.

    Just be pragmatic about things.

13. **King Ray**
    November 1, 2007

    For string theory, might I suggest "Rectocranial Sigmoidoscopy"?

14. **anon.**
    November 3, 2007

    'It is striking to note how little has changed in this field during this period.'

    Long live failure!

15. **Andr**
    November 9, 2007

    Really you have nothing to say about Lisi's paper? It seems you're one of the guys to be thanked for this "magnum opus"… 🙂

An Exceptionally Simple Theory of Everything?

November 9, 2007
Categories: Uncategorized

It's been unusually long since my last posting, with the main reasons being that

- Not much has been happening on the math/physics front…
- I've been busy learning more about geometric Langlands, which is a daunting subject. I keep intending to write something about recent work by Witten and others in this area, but saying anything both correct and intelligible seems a rather challenging task that I haven't been quite up for.

Garrett Lisi has a new paper on the arXiv, with the rather over-the-top title of An Exceptionally Simple Theory of Everything. Sabine Hossenfelder has a typically excellent posting about the paper, and Garrett has been discussing his work with people in the comment section there. Lubos Motl, has a typically, how shall I say, Lubosian posting on the topic.

I'm the first person thanked in the acknowledgment section of the paper, but at Sabine's blog Garrett explains that this is just because he is using reverse alphabetical order. I've corresponded with him in the past about his research in this area, without being able to provide any real help other than a certain amount of encouragement. Two of the ideas he is pursuing are general ones I'm also very fond of. One is well-known, and many people have also tried this, it's the idea of bringing together the internal gauge symmetry and the symmetry of local frame rotations. The problems with this are also well-known, and some have been brought up by the commenters at Sabine's blog. I don't think Garrett has found the answer to this, or that he claims to. I'm still hopeful that this line of thinking will lead somewhere, but think some dramatically different new idea about this is still needed. The other idea he likes is that of trying to interpret the fermionic degrees of freedom of the BRST method for handling gauge invariance as providing the fermions of the Standard Model. I suspect there is something to this, but to get anywhere with it, a much deeper understanding of BRST will be required. I've been spending a lot of time trying to understand some of the mathematics related to BRST in recent years, and am in the middle of writing some of this up. It seems to me that there is a lot that is not understood yet about this topic even in much simpler lower-dimensional contexts, so we're a long way from being able to really see whether something can be done with this idea in a realistic four-dimensional setting.

One idea Garrett is fond of that has generally left me cold is the idea of unification via a large simple Lie algebra like E_8. While there may be some sort of ultimate truth to this, the problem is that, just as for GUTs and for superstring models, all you're doing when you do this is changing the unification problem into the problem of what breaks the large symmetry. This change in the problem adds some new structure to it, but just doesn't seem to help very much, with the bottom line being that you get few if any testable predictions out of it (one exception is with the simplest GUTs, where you do get a prediction, proton decay, which turns out to be wrong, falsifying the models).

Anyway, I'm glad to see someone pursuing these ideas, even if they haven't come up with solutions to the underlying problems. Garrett is a serious and competent researcher who has pursued a non-traditional career path, and was recently awarded a grant to by the FQXI organization. You can read more about him in an article on their web-site.

Unfortunately, some of the reaction to Garrett's article has been depressing. A commenter who sounds well-informed but hides behind anonymity goes on about "this nonsense" (although Garrett's polite reaction to him/her did lead to a more sensible discussion). Early on in my experience with blogs I believed that no serious professional in particle physics would attack someone and try and carry on a scientific argument anonymously, so any such comments had to be coming from misguided students, or someone not in the profession. Unfortunately I've all too often seen evidence that I was wrong about this. Lubos Motl on his blog denounced the fact that Garrett's paper appeared in the hep-th section of the arXiv, then later wrote in to Sabine's blog to crow that it had been removed from hep-th. As always with the arXiv, how moderation occurs there is non-transparent, so I don't know how or why this happened. My own experience with the arXiv over trackbacks to hep-th has been a highly disturbing one. The current hep-th policy seems to be to allow any sort of nonsense to be posted there if it fits into the current string-theory-based ideology (see for example here), while suppressing any criticism of this. A paranoid person might be tempted to wonder whether hep-th is being moderated by someone so ideological and petty that criticism of string theory or including string theory critics in an acknowledgment section would be cause for having ones article removed from hep-th…

Update: I hear from Garrett that the story of this paper at the arXiv is that it was submitted to gr-qc, not hep-th. Before it was posted, it was re-classified as hep-th, and appeared there. Later on (after the appearance of Lubos's blog entry denouncing the arXiv for allowing the paper on hep-th I believe), it was re-classified again, this time as general physics (with cross-listing to hep-th).

Update: Latest news about this is that the paper has now been reclassified again, to the perfectly appropriate hep-th, cross-listed as gr-qc, although no one seems to know why this happened. Another continuing mystery is the trackback situation: there are four trackbacks to the paper, to postings by Lubos, Bee, and to Physics Forums, as well as to an old TWF from John Baez that doesn't even link to the paper. My postings still seem to be non-trackback worthy on hep-th, not that I can argue with this particular case, since the discussion elsewhere has been more substantive (except for Lubos's, which is valuable for the way it accurately represents the hysterical reaction to speculation that is not string theory speculation all too common in certain quarters).

Update: Garrett is making the news here. Whether this is a good thing is yet another question for debate on the next thread, I guess. A lot of the attraction for the media seems to be his personal story. Maybe it's a good thing for physics for people to see that one can be a theoretical physicist while surfing in Hawaii…

Update: Lisi-mania spreads. See stories in New Scientist, the Ottawa Citizen, Slashdot, and probably lots of other places I haven't noticed.

Update: Steinn Sigurdsson has an excellent posting summarizing the situation. As usual, blogs are the place to get the highest quality information about scientific issues…

Update: I've given up on keeping track of the media stories on this. For some discussion of the representation theory involved, see this posting by Jacques Distler, and comments from Garrett.

Update: The Angry Physicist examines the Distler critique in some detail.

Comments

1. **Garrett**
   November 9, 2007

   Hello Peter,
   This is a well thought out post, as usual. I did consider our short emails — and the very existence of you and this blog — encouraging enough to include you in the acknowledgments. Your concerns are all valid, and are some of the same concerns I discuss in the paper. Though I do think the way I've combined the gravitational frame-Higgs and used the MacDowell-Mansouri description of gravity is new. You are correct that I don't have a good reason or mechanism for what breaks the E8 symmetry, and this is needed. What I've done is break the symmetry by hand, including the few terms necessary to recover the action of the standard model and gravity. I am biased towards E8 because of its beauty, and similarly towards the general idea of unification. The success of electroweak symmetry breaking in the standard model is compelling evidence that symmetry breaking of this sort plays a very important role in nature, and I'm surprised you dislike the idea of applying this on a larger scale. Surely you acknowledge that successful predictions from electroweak symmetry breaking indicate it did more than just add new structure to the problem? In any case, I am very

much looking forward to reading your work on BRST, as it's a very complicated and fascinating subject, and it plays an important role in this E8 theory that I'd like to understand better.

2. **Kea**
November 9, 2007

There is a good chance that Garrett is on a watchlist. I have it on good authority that I'm on the hep-th watchlist, even without having tried to post anything there for years.

3. **Peter Woit**
November 9, 2007

Hi Garrett,

By "adding new structure" to the problem I meant to imply something not negative, but potentially positive. The new structure may be usable to constrain things and thus allow non-trivial predictions. If you are using a scalar field to do the breaking, then the question becomes how constrained this set-up is. In the electroweak theory, the Higgs sector on the one hand fits in well with the symmetries of the theory and has a limited number of free parameters, but it still has quite a few, and is the main source of the problems of the Standard model. Because of this situation, I've always been most interested in ideas about unification that tell you more about the Higgs, not so much in ideas that don't do that, but add other Higgs sectors.

That's my prejudice, but, sure, starting from other reasonable prejudices, like the desire for a single simple group to act on everything, may lead one somewhere. Maybe you'll have better luck than the GUT program, which hasn't been successful so far.

4. **Garrett**
November 9, 2007

OK, this makes sense. You must be looking forward to the LHC results even more than most, since it will provide some experimental insights into the Higgs sector.

Meanwhile, I'm sitting here with a bunch of old men, waiting for a proton to decay. 😉 But I'm not holding my breath.

These are interesting times.

5. **Coin**
November 9, 2007

This is kind of way over my head so I'm a bit afraid to comment, but what the heck.

In terms of just the pure *math* here– the one thing I'm at least superficially in a place to comment on– what Garrett's doing, with breaking down E_8 into the various gauge groups we'd need to describe reality, seems to make sense. Where I get lost is in trying to understand how you use this model to tell us something about the physical world (maybe Garrett's view of E_8 would be obviously useful or obviously unsuitable for this to someone with a good understanding of what the gauge group "does" in a gauge theory, but that person is not me). Can you help me understand what the physical significance of some of this stuff is or might be, assuming some understanding of what the groups themselves are doing?

I mean, so you've shown, it looks like, that E_8 can be decomposed into SU(3)xSU(2)xU(1)xSO(3,1)xHiggsxFermion. The mere fact that this is possible does seem suggestive of *something*. What do we gain, however, from describing all of these fields as the one big E_8 group– you know, rather than just leaving all those component groups separate with their own yang-mills theories and such (or perhaps just awkwardly x-ing them together like we do to hook up SU(3) to everything else in the Standard Model)? How does the unification of all these groups change things?

I'm meanwhile somewhat confused as to the physical significance we are meant to take from the various features of E_8's structure. I'm particularly baffled by what to make of the big root diagram which is shown in the video Bee links and in various ways in the paper. What does it mean for two roots in this diagram to have an edge between them? If I'm not mistaken (er, am I?) then from a mathematical perspective an edge between two roots in the E_8 root system polytope corresponds to the lie bracket between those two roots. But what does this mean physically, when we use E_8 as Garrett has here?

Also, what is the meaning of the "rotations" of the root system shown in the paper and the youtube video? Do these rotations correspond to anything physically meaningful, or are the rotations just showing the root system diagram in different ways to make the different groups the system breaks down into visually clear?

Meanwhile, if elementary particle fields correspond to roots in Garrett's gigantor gauge group, then what do products of those roots physically correspond to? The paper says "The interactions between all standard model and gravitational fields correspond to the Lie brackets between elements of the E8 Lie algebra, and thus to the addition of E8 roots." Hm, okay, so additions of E8 roots produce interactions between? What are those "interactions"? Or is this specified by the yang-mills action or something?

Also a little confused: so counting up all the fields we expect to see in nature we find they fit with 222 of the roots in your E_8 root system, leaving 18 "extra" roots whose properties as fields are described on page 22 of the paper. The paper seems to be saying that these 18 new fields each act kinda like the Higgs, and each one is identified with a specific one of three generations and a specific color or anti-color. If this reading is correct, what do these generation/color identifications refer to? Does this have to do with the color or anti-color of quark that the field is able to interact with, or is the idea that the field carries color charge, or…?

One more general, possibly dumb question, is there any potential form of correspondence which one could draw between how E_8 is used here, and string theories which use E_8 (or products of E_8) as a symmetry group? Or is the usage of a "symmetry group" simply too different in these different contexts?

Trying to understand, thanks!

6. **more questions**
November 9, 2007

As long as Coin is asking questions, I didn't understand (1) why this doesn't violate the Coleman-Mandula theorem, and, (2) what about the nonrenormalizability of GR?

7. **Coin**
November 9, 2007

MQ, Garrett does seem to offer an argument concerning your (1) in a reply to Moshe in the comments section of the Backreaction post:

> 1. Yes, the Coleman-Mandula theorem assumes a background spacetime with Poincare symmetry, but this theory doesn't have this background spacetime — with a cosmological constant, the vacuum spacetime is deSitter. So this theory avoids one of the necessary assumptions of the theorem, and is able to unify gravity with the other gauge fields. On small scales though, Poincare symmetry is a good approximation, and on those scales gravity and the other gauge feels are separate, in accordance with the theorem. (I'm not the first person to dodge C-M this way.)

Several more posts over the course of that thread drill down on this point further…

8. **Garrett**
November 9, 2007

more questions:

(1) The first person I know of to point out this loophole in Coleman-Mandula was Thomas Love (a visitor here) in his 1987 dissertation. There is also a discussion of this loophole in this recent paper by F. Nesti and R. Percacci: Graviweak Unification. Or you can go to the source and look at Coleman and Mandula's paper, in which their first condition for the theorem is "G contains a subgroup locally isomorphic to the Poincare group." The G = E8 I am using does not contain a subgroup locally isomorphic to the Poincare group, it contains the subgroup SO(4,1) — the symmetry group of de Sitter spacetime.

(2) I'm banking on the LQG community to crack this one. So multiply the odds of this E8 Theory being right times the odds of LQG finding the right answers for quantizing the theory… and I'm first to admit it's a long shot. But I think it's got a chance, which is why I work on it.

9. **Garrett**
November 9, 2007

Hi Coin,
Peter teaches classes in representation theory, so he can answer most of these questions better than I can, but I can at least help out with what's in this paper. You have a correct understanding of what's going on, so I'll just answer your specific questions.

"What do we gain, however, from describing all of these fields as the one big E_8 group– you know, rather than just leaving all those component groups separate with their own yang-mills theories and such (or perhaps just awkwardly x-ing them together like we do to hook up SU(3) to everything else in the Standard Model)? How does the unification of all these groups change things?"

Because all these fields are parts of E8, we can assemble an E8 principal bundle connection (technically a superconnection) which consists of 1-forms and Grassmann fields valued in this E8 Lie algebra, and use the curvature of this big connection to get the dynamics. The curvature, in the action, determines how E8 interacts with itself. And since everything is part of E8, this corresponds with how all the fields of the standard model and gravity interact with each other. This action is built by hand to match the standard model, which is an inadequacy of the theory, but it's very concise. And I think it's bloody amazing that this works at all.

"I'm meanwhile somewhat confused as to the physical significance we are meant to take from the various features of E_8's structure."

Physically, as this theory develops it should make definite predictions for the coupling constants, predict a handful of new particles and some non-standard interactions, and (if things go astoundingly well) have something to say about the particle masses. These predictions may end up being wrong, killing the theory, but so far things are looking good.

"I'm particularly baffled by what to make of the big root diagram"

The root diagrams correspond to the structure of the Lie algebra. If two E8 roots add to give a third (in eight dimensional Euclidean root space) then the Lie bracket of the corresponding two Lie algebra basis elements give the third. In the paper, I describe which roots correspond to which elementary particles. Also, since the projection used to plot the eight dimensional root system is linear, you can determine particle interactions by adding these roots together as two dimensional vectors, extending from the origin — it's fun, try it. This is standard representation theory, and it's very pretty. In my opinion, Peter doesn't push his own subject hard enough — I wish I had learned about this stuff earlier than I did, it's wonderful.

"are the rotations just showing the root system diagram in different ways to make the different groups the system breaks down into visually clear?"

Yes, precisely.

"Hm, okay, so additions of E8 roots produce interactions between? What are those "interactions"? Or is this specified by the yang-mills action or something?"

Yes, the addition of the roots corresponds to the Lie brackets between fields, which is in the curvature, which is in the action, and this gives the interactions between particles, appearing as Feynman vertices in QFT calculations.

"these 18 new fields each act kinda like the Higgs, and each one is identified with a specific one of three generations and a specific color or anti-color. If this reading is correct, what do these generation/color identifications refer to? Does this have to do with the color or anti-color of quark that the field is able to interact with, or is the idea that the field carries color charge, or…?"

Yes, exactly so. These new scalar fields have color quantum numbers, and so interact with the quarks and gluons.
In my dreams at night, these new Higgs fields give the CKM matrix, but I don't know how that works when the sun comes up.
They're also a potential dark matter candidate, but I don't say that in my paper because I think that's a cliche.

"is there any potential form of correspondence which one could draw between how E_8 is used here, and string theories which use E_8 (or products of E_8) as a symmetry group? Or is the usage of a "symmetry group" simply too different in these different contexts?"

They are completely different theories, which happen to use related Lie groups. I could list many specific differences:
non-compact E8 vs compact E8 x E8
gravity in E8 vs gravity via other
four dimensional spacetime vs 11 dimensional spacetime with Kaluza-Klein orbifold compactifications
principal bundle connection vs strings, branes, and who knows what
etc.

"Trying to understand, thanks!"

I consider it a testament to the simplicity of the theory that you seem to have understood most of it after a first reading. I should put that in among the differences list… 😉

10. **Coin**
November 9, 2007

I consider it a testament to the simplicity of the theory that you seem to have understood most of it after a first reading.

Hm, I think that would be an exaggeration to say I understand most of it. But thanks for the clarifications, this helps 🙂

11. **Thomas Love**
November 9, 2007

The Coleman-Mandula theorem applies to "All Possible Symmetries of the S-Matrix", the title of their paper. The S-matrix formalism is based on particle democracy, there are no fundamental particles. In "The Geometry of Elementary Particles", my 1987 dissertation which Garrett mentioned, there are truely elementary particles and the S-matrix formalism is not valid, hence the Coleman-Mandula theorem is not applicable. I use U(3,2) as the symmetry of a complex spacetime by passing the no-go theorems (which relate to the Poincare group).

12. **Tony Smith**
November 9, 2007

About Coleman-Mandula, Steven Weinberg said at pages 382-384 of his book The Quantum Theory of Fields, Vol. III (Cambridge 2000):

"… The proof of the Coleman-Mandula theorem … makes it clear that the list of possible bosonic symmetry generators is essentially the same in d greater than 2 spacetime dimensions as in four spacetime dimensions:
… there are only the momentum d-vector Pu, a Lorentz generator Juv = -Jvu (with u and v here running over the values 1, 2, … , d-1, 0), and various Lorentz scalar 'charges' …
the fermionic symmetry generators furnish a representation of the homogeneous Lorentz group … or, strictly speaking, of its covering group Spin(d-1,1). …
The anticommutators of the fermionic symmetry generators with each other are bosonic symmetry generators, and therefore must be a linear combination of the Pu, Juv, and various conserved scalars. …
the general fermionic symmetry generator must transform according to the fundamental spinor representations of the Lorentz group … and not in higher spinor representations, such as those obtained by adding vector indices to a spinor. …".

In short, since E8 is the sum of the adjoint representation and a half-spinor representation of Spin(16),
if Garrett builds his model with respect to Lorentz, spinor, etc representations based on Spin(16) consistently with Weinberg's work,
then
Garrett's model could well satisfy Coleman-Mandula.

Tony Smith

13. **Berlin**
November 10, 2007

Garrett: your remark at the end of section 3.2.1. Can this be translated into 'the theory is background independent', one of Smolins reasons to reject strings?

14. **Garrett**
November 10, 2007

Berlin: It implies that, yes.

15. **Garrett**
November 10, 2007

Berlin: I should clarify that this is not a complete quantum theory of everything, so in that sense it is incomplete. It will need to be successfully partnered with LQG and/or QFT — this is nontrivial, and time will tell whether it works or not. But the pieces are in place.

16. **Bee**
November 11, 2007

Hi Peter,

Thanks for the link. Anybody here knows how the arxiv makes decisions like this?

A paranoid person might be tempted to wonder whether hep-th is being moderated by someone so ideological and petty that criticism of string theory or including string theory critics in an acknowledgment section would be cause for having ones article removed from hep-th…

It might simply be insecurity. Whoever makes this decision they will try to make it such as to not upset the majority of users. And I doubt they do actually study the paper in great detail. Best,

B.

17. **Lucci**
November 11, 2007

Garrett: Your use of Clifford bundles, plus the fact that your theory allows the Standard Model to be extended, suggests a possible tie-in with ELKO spinor-fields, which have been proposed as an extension of the SM (and also – pardon the cliche! – as a dark matter candidate). For a very recent paper on ELKO, in which Clifford bundles are used explicitly, see: http://www.arxiv.org/abs/0711.1103
(Disclaimer: I am not in any way involved in research on ELKO myself.)

18. **D R Lunsford**
November 11, 2007

This seems a lot like Tony Smith's work. Mentioning Tony in your acknowledgments is guaranteed to get you watched. Calling him your "friend" gets you banned. There is neither integrity nor honor to be found there.

It's interesting work in a sense, but it's still phenomenology and doesn't improve the SM. The statements about gravity are much more doubtful. This approach has been tried again and again and always meets with the same problems.

-drl

19. **John Gonsowski**
November 12, 2007

Garrett references John Baez's Octonion paper and that paper also thanks Tony. Don't think they will be banning Baez any time soon. Funny, models with a great math basis get frowned on while philosophical ideas like the landscape get cheered. Yet they make it sound like it's those models with the great math that are too philosophical?

20. **Chris Oakley**
November 12, 2007

As happens more often than not, to the extent that I understand the issues (not very much here), I concur with DRL. I want something that simplifies. From that point of view E8 – in any context – is a non-starter.

21. **Marcus**
November 13, 2007

Garrett is giving the seminar talk at the ILQGS tomorrow.
His slides are online here
http://relativity.phys.lsu.edu/ilqgs/lisi111307.pdf

The audio will be available here
http://relativity.phys.lsu.edu/ilqgs

these International LQG Seminar discussions are often lively in part because they are conference calls where everybody has the slides to scroll through]
and you occasionally get questions and comment from Ashtekar, Rovelli, Freidel, unidentified Perimeter, Marseille, Penn State people.

Audio and slides from past seminars are available—same link.

I'll be interested to see how Garrett Lisi and Carlo Rovelli get along, to the extent that one can communicate usefully in that intercontinent telephone conference call setting.

22. **Shantanu**
November 13, 2007

Peter, currently I DO see 4 trackbacks (none of which refer to your blog, though)

23. **Peter Woit**
November 13, 2007

Shantanu,

Yes, the 4 trackbacks that are there now are the ones I was describing, sorry for the confusing way that was written.

24. **Marcus**
November 13, 2007

The ILQGS talk went very well. Abhay Ashtekar and Lee Smolin each had several questions/comments leading to discussion. An expanded set of slides is available.
slides are here
http://relativity.phys.lsu.edu/ilqgs/lisi111307_2.pdf
audio is here
http://relativity.phys.lsu.edu/ilqgs

Thanks to Jorge Pullin for organizing the seminar and making it available online!

25. **Bee**
November 13, 2007

Hi Peter,

Thanks for the update on the arXiv classification issue. Still I'd like to know, could anybody fill me in how decisions like that are made? Best,

B.

26. **Peter Woit**
November 13, 2007

Bee,

I don't know exactly how this works, and it's my impression that the process is rather non-transparent. The arXiv has a difficult problem on its hands of how to maintain a reasonable level of quality, and not get flooded by junk. There are moderators for each section of the arXiv who supposedly take a quick look at submissions and decide if they are correctly categorized and meet their standards. The places where they describe how this is supposed to work are

http://arxiv.org/help/moderation

and

http://arxiv.org/help/endorsement

I have no idea what happened with Garrett's paper (and I gather he doesn't either), but presumably decisions were made by gr-qc and hep-th moderators, and perhaps other people got involved later after questions were raised about the decision to classify as gen-ph.

27. **alex**
November 13, 2007

"Yes, exactly so. These new scalar fields have color quantum numbers, and so interact with the quarks and gluons.
In my dreams at night, these new Higgs fields give the CKM matrix, but I don't know how that works when the sun comes up.
They're also a potential dark matter candidate, but I don't say that in my paper because I think that's a cliche."

If your dark matter candidate has color quantum numbers it should interact strongly with ordinary matter. In MSSM the dark matter candidate is typically a neutralino. In

some models it's a sneutrino.
So, in either case it only couples gravitationally – that is why it is referred to as a dark matter candidate.
So, if some construction predicted, say, a gluino LSP (which is strongly interacting) that would be a disaster.

So if Garret Lisi thinks that a colored particle is a "potential dark matter candidate"… well, I'm, to say the least, puzzled.

28. **alex**
November 13, 2007

I said:"So, in either case it only couples gravitationally – that is why it is referred to as a dark matter candidate."
Correction: it's only true for the right-handed sneutrino, the neutralino is also weakly coupled, of course.

29. **Bee**
November 14, 2007

Thanks! Btw, I found someone for the conference I mentioned.

30. **Typo Guy**
November 14, 2007

The link to the Telegraph article is slightly defective.

31. **Peter Woit**
November 14, 2007

Typo Guy,

Thanks, fixed!!

32. **Hendrik**
November 15, 2007

NewScientist just published a review of Garrett Lisi's approach at http://www.newscientist.com/article/mg19626303.900

33. **berlin**
November 15, 2007

I am puzzled by (among others..) the gravitational part of tabel 9. Does the spin 2 graviton (still) exist in the theory?

berlin

34. **Marcus**
November 15, 2007

In response to "berlin"

> Does the spin 2 graviton (still) exist in the theory?

Loll recently put the business about gravitons succinctly:
The failure of the perturbative approach to quantum gravity in terms of linear fluctuations around a fixed background metric implies that the fundamental dynamical degrees of freedom of quantum gravity at the Planck scale are definitely not gravitons.

That is (from http://arxiv.org/abs/0711.0273) if a theory is fundamental, it should not have gravitons.

One should be able to set up certain fixed situations in which a graviton can be derived as an approximation. But the graviton should not exist in the theory as a fundamental descriptor. If it does exist, then the theory would not be fundamental–according to what Renate Loll says.

I would therefore be surprised if it turned out that the E8 theory being developed by Garrett Lisi (and possibly others lately) should turn out harbor the graviton as a fundamental component.

35. **Eric**
November 15, 2007

Actually, there isn't much to Lisi's work. It's mostly just hocus pocus and part of the Smolin et. al. public relations initiative to sell 'alternative' approaches to physics. Just read his book and you can see the blueprint, the romantic image of a lone maverick making breakthroughs in physics in between surfing and snowboarding. It's just marketing.

36. **Bee**
November 15, 2007

Given my rather boring lifestyle I think about becoming a ghost writer, and hire someone to market my papers with a better story! Anybody could please point me towards a 30something, white, male, single, good-looking US citizen, who has an interest in extreme sports of whatever kind, grew up under difficult circumstances (but doesn't suffer from an embarrassing accent), good socializing skills, likes to speak in front of people, does well on TV, preferably works in a patent office or likewise, speaks Spanish and French fluently, and, well, has maybe taken some physics classes in high school?

37. **Garrett**
November 15, 2007

Wow, apparently I'm an imaginary construct dreamed up by Lee Smolin!

Actually, this would explain quite a lot.

38. **Eric**
November 15, 2007

Hi Sabine,
Actually your place in the Smoliniverse is as the young, beautiful woman who happens to be a brilliant and creative physicist. It's very sly of Lee to choose you as part of his public relations campaign. 😉

39. **J. Barrett**
November 15, 2007

Is the title of the paper so much "over the top" as it is descriptive and a terrible maths pun, being that M8 is both an exceptional group and a simple group?

40. **Coin**
November 15, 2007

One should be able to set up certain fixed situations in which a graviton can be derived as an approximation. But the graviton should not exist in the theory as a fundamental descriptor. If it does exist, then the theory would not be fundamental–according to what Renate Loll says.

Hm, while I can see attractive aspects to that approach, that kind of sounds like a dramatic step to take. Do there already exist any other theories of quantum gravity, besides Loll's, which eschew the graviton or take the "graviton as approximation" approach you describe?*

Meanwhile I find Loll's argument in the paper you link against the graviton somewhat unconclusive. "Well, we've been trying to get useful answers out of this construct for decades and haven't succeeded, so it's a good bet we're doing something wrong" sounds like good *strategy* to me, but he doesn't seem to actually be putting forth an argument about reality there, only an argument about "how to proceed". I don't see any reason that just because we can't describe the graviton perturbatively, that would mean it doesn't exist– since, as far as I understand, perturbation theory is supposed to just be an approximation anyway. (And this is of course assuming that perturbatively modeling the graviton is impossible and not just too hard for anyone to manage right now). Am I missing something about Loll's argument?

* Does LQG, for example, have a graviton? Looking I am finding references to a "graviton propagator" in LQG but it is not immediately obvious whether that's the same thing.

41. **Peter Woit**
November 15, 2007

Please, Garrett's paper is a flimsy excuse for turning this into a quantum gravity discussion forum, which is something I don't want to run. Enough about this unless it directly has some relevance to the paper.

42. **Coin**
November 15, 2007

All right, sorry about that. I'll go harass Marcus on physicsforums 🙂

43. **Marcus**
November 15, 2007

J. Barrett

> Is the title of the paper so much "over the top" as it is descriptive and a terrible maths pun, being that E8 is both an exceptional group and a simple group?

Exactly!

Why do you seem to be the only person to get that? The funniest part was hearing the solemn preaching: "I think it would be better if you were not so over-the-top etc etc…"

I've been waiting for someone to point that out here at NEW. You have my gratitude and respect, J Barrett, whoever you are.

44. **Brian Mingus**
November 15, 2007

What sort of a minimum background would be needed to actually grok this paper?

45. **Aaron Bergman**
November 16, 2007

Believe me, nobody missed the pun.

46. **AGeek**
November 16, 2007

Coin, Renate Loll is a she (her name should be a clue). And assuming that "graviton" means what it's normally taken to mean, a perturbative free state propagating on some background a la DeWitt, then to say that gravity can not be described perturbatively is to say that gravitons do not exist.

47. **Dany**
November 16, 2007

P. Woit: "One idea Garrett is fond of that has generally left me cold is the idea of unification via a large simple Lie algebra like E8. While there may be some sort of ultimate truth to this, the problem is that, just as for GUTs and for superstring models, all you're doing when you do this is changing the unification problem into the problem of what breaks the large symmetry. This change in the problem adds some new structure to it, but just doesn't seem to help very much, with the bottom line being that you get few if any testable predictions out of it (one exception is with the simplest GUTs, where you do get a prediction, proton decay, which turns out to be wrong, falsifying the models)."

I admit that I didn't read the paper. However, in my view, all that PR tararam have very positive outcome: it again attract the attention to the Cayley numerical system which seems to be the natural candidate for QG and unification of all fundamental interactions. Since the connection with the GR and relativistic QM is the necessary constraint, one should define the real octonion valued self adjoint operators. My own experience with them is that it is exceptionally not simple problem (indeed, even the solution will be far from being theory of everything).

Regards, Dany.

48. **DB**
November 16, 2007

In the comments section to Lubos Motl's blog entry on Lisi's paper:

http://motls.blogspot.com/2007/11/theory-of-everything-triples-traffic.html

he reveals the apparent cause of his departure from Harvard as follows:

"The obvious and inevitable result is that those people with IQ below 100 not only control most of the general public but start to include ever increasing groups of people.

This physics-related pressure was at least as important for me to leave those circles as the purely political issues about the academic freedom because I became pretty much certain that all these things would be getting worse as time goes.

When I was first suggested by relatively powerful people that I should have been treating complete idiots such as Peter Woit as my peers if not more, it was just way too much for me. We may be ready that the society may misevaluate many things, nothing is perfect, but these things are just many orders of magnitude out of proportion.

What about next, I would be thinking. Would cranks with their 'theories of everything' who know less than 1% what I do and whose IQ is 45 below mine – literally an inferior species – would be placed upon us or even dictate what we can think about physics? Well, this epoch just here. It has become politically incorrect to say that what surfers like Garrett Lisi are doing are light years away from what theoretical physics is. The closer one is to the top of the real physics, the most impossible it is for him or her to declare any opinions. With a realistic idea about psychology and social science, where do you think that the society will be going if the relative influences are arranged in this way?"

Speaks for itself, doesn't it?

49. **wolfgang**
November 16, 2007

Garrett,

it seems that a central idea of your paper is the claim that BRST ghosts can become real fermions due to the special properties of E8 and your action. But you do not really explain this 'trick' in your paper (and you do not discuss quantization really).
Do you explain this somewhere else or do you have plans to elaborate on this point in a follow-up paper?

50. **Peter Woit**
November 16, 2007

Brian,

To understand the paper, at a minimum you need a graduate level education in particle physics, including a good understanding of the theory of Lie algebras.

On the whole, I think the hullabaloo in the press and on the internet isn't a good thing. There's a huge amount of nonsense being spread, of different sorts:

1. The press stories aren't awful, with reporters mostly trying to include some skeptical comments about how speculative this is, while at the same time as much as possible making an enthusiastic story about the latest "theory of everything". Unfortunately, for reasons I explain in the latest posting here, I think these kinds of stories don't really do much in terms of explaining what is really going on to people, often giving a misleading impression.

2. Comments on Slashdot and the blogs are all too much dominated by the huge number of people who think it is a good idea to write in about things they don't understand, happily spreading misinformation or irrelevancy, and burying serious comments under a mountain of junk. The noise to signal ratio on Slashdot is so high that very few people who actually know something about this subject are willing to waste their time reading the comments or trying to contribute to the discussion. Too many comments on this blog and on others come from people who don't actually know much about the topic at hand, but feel compelled to share whatever is on their mind anyway.

3. Some blogs and commenters try and fit this into the ongoing string theory/LQG warfare, which it isn't especially relevant to. As usual Lubos can be counted on to obscure whatever sensible criticism he might have with crazed rants about how people who aren't string theorists are lower life forms.

Blogs do sometimes manage to provide a place for some sensible discussion, even amidst a heavy helping of nonsense. In this case, the best I've seen is Sabine's blog, which has provided a forum for Garrett to discuss some of the issues raised by his paper in detail with her and others.

51. **Aaron Bergman**
November 16, 2007

As best I can tell, he uses the term BRST a few times, but there is no real BRST procedure in the paper. It's only used as a term to justify the formal addition of grassman and commuting variables in his "connection". But, of course, the BRST symmetry is a Grassman symmetry, not a commuting symmetry like E_{8+8}, so (like many other things in the paper) it doesn't really make sense to me.

52. **Peter Woit**
November 16, 2007

DB,

Still unclear to me whether Lubos jumped or was pushed from Harvard. But it is clear that one part of the story was his being driven over the edge by the fact that criticism of string theory has been taken much more seriously in recent years, both by the public and by the physics community.

53. **Mark Paris**
November 16, 2007

I agree with Garrett that this is a very exciting time. Congratulations to him on getting some very interesting and compeling work out. It's encouraging me to take a break from dynamical coulped-channel approach to meson production reactions to have another look at some issues of GR that I've thought about in the past.

Curiously, the question of renormalization doesn't appear to be getting too much play here. It seems that while the E8 unification proposed could solve some issues of organization, the fundamental issues of spacetime properties and particle properties still remain distinct. Garrett's bet that LQG will solve this issue is probably not all that much of a sucker's bet. It seems like background independence will be a key concept in the resolution — to me anyway.

But that's only "half" the problem. There seem to be two issues regarding renormalization. The non-renormalizability of GR has already been mentioned. But also, loop integrations will apparently still lead to divergences in the E8 unification — the theory enjoys no supersymmetry cancellations, for example. Then we're stuck with infinite renormalizations — fine, we're used to it. And physics can still be done. But the precision required to fix the couplings will make, I fear, accurate detailed predictions impossible. Spectroscopy make still be possible however.

Background independence seems to offer a way out of this aesthetically unpleasing situation.

54. **Aaron Bergman**
November 16, 2007

the question of renormalization doesn't appear to be getting too much play here.

Well, yes, because the theory has any number of barriers to being quantized. And even before that, the theory breaks the symmetry explicitly by the Lagrangian, so it's tough to say that things are really being unified here.

As for couplings, there are none as best I can tell. So, it's very unclear how one recovers the standard model from his structure.

55. **Michael Crowley**
November 16, 2007

Hi Peter,

Just wanted to let you know there is a very long and passionate discussion of this gentleman's theory on my favorite website, Democratic Underground. Naturally, we are not scientists, but I'm happily surprised by the passion aroused by this post. Just thought you might find it interesting.

http://www.democraticunderground.com/discuss/duboard.php?az=view_all&address=389×2281653

Hope that link works; I'm not sure how to post links here.

Take care, and thanks again for your marvelous book.

Mike

56. **Michael Crowley**
November 16, 2007

P.S.

I'm obviously "Mike03", making a fool of myself as usual and also referring people to your blog.

57. **Bee**
November 17, 2007

Regarding the pun: It might be perfectly obvious to everybody who works in theoretical physics, but I doubt many people of the broader public or even the journalists got it. Was it explained anywhere than here? I am constantly making terrible puns like this, which is always source of a broad confusion. But besides this, it's somewhat unfair to blame things on the title, there are other examples (testing quantum gravity! testing string theory!) that go the same way. It's probably a consequence of of people's sensitivity to news become lower and lower, because there's such an over flow of unbalanced hypes that needs to be filtered (not only in science). It's a very bad trend though. I mean, I do appreciate attention for theoretical physics, but things like this make the news, nothing comes out of it for the next some years, no revolution, no incredible insight, no change in world view etc, and people will start to wonder 'what ever happened to', do these theoretical physicists just make vacuous announcements that never come down to anything? All the while support dwindles for the less spectacular basics.

Let me give you an example. My husband is working for a scientific publisher in Germany. They publish a book series that contains literally every stupid fact about material sciences you need, and there's still data that's added since people are working in the field. It's an extremely boring read, it gets sold maybe to some thousand libraries worldwide for an horrendous price, since it takes a lot of time and effort editing. Nevertheless, it's an essential for anybody working in the field. Now it looks like the publisher will stop the series because it just doesn't pay off. I've suggested they apply for governmental, but not sure if they will do (its a rather large publisher having plenty of better fields to focus on). What I am trying to say is that not all we do is hip and cool and we're not all surfer dudes making E8 animations. Events like this raise in me the concern that support might go increasingly into media-suitable research.

Hi Garrett:

"Wow, apparently I'm an imaginary construct dreamed up by Lee Smolin!"

I neither said that, nor meant to say that. I am just as always surprised how much such stories about the alleged outsider (surfer dude! no university affiliation!) attract cheerful attention, whereas the 'inside of the ivory tower' is accused of ignorance and arrogance.

Hi Eric:

" Hi Sabine, Actually your place in the Smoliniverse is as the young, beautiful woman who happens to be a brilliant and creative physicist. It's very sly of Lee to choose you as part of his public relations campaign."

I know you didn't mean it to be insulting, but it is. I'm neither Lee's nor anybodies PR agent.

Best,

B.

58. **Bee**
November 17, 2007

"I've suggested they apply for governmental,"

should be

"I've suggested they apply for governmental support,"

59. **TE**
November 17, 2007

I would like to see the action expanded explicitly in component fields in a notation that particle physicists can understand.

Then, by inspection we should be able to check that:

1) All fields propagate with the correct signs in their kinetic terms
2) Higher derivative couplings are absent or suppressed by the Planck scale
3) All fields have the correct spin-statistics relation

or other obvious signs of inconsistency.

So far it is not clear to me that this theory is even consistent at low energies. I have not spent the any time decoding the notation to see if the above consistency constraints are satisfied. But I shouldn't have to… these issues are absolutely crucial and should be addressed prominently and explicitly in the paper.

Only after these basic hurdles are mounted, we can begin to discuss whether the model is useful or addresses any important problems.

60. **Garrett**
November 17, 2007

TE:
The action is written down in an efficient expression on page 25. I did use some fancy math tools, including Clifford algebra and the Hodge star, instead of using indices. However, over the following two pages I expanded the terms of this action in detail, including writing out the resulting Dirac action in curved spacetime, in indexed components. I did this because I share your desire for a complete and understandable exposition, in conventional notation.

You should be able to glance at the expanded, local coordinate form of these expressions and confirm they match those of the Standard Model, with all the correct signs, factors of 1/2, no higher derivative couplings, and the correct spin statistics. It is true that the original action was chosen by hand such that this comes out, but given the efficient expression used, I consider it non-trivial that this works.

61. **Eric**
November 17, 2007

Sabine,
I'm sorry that you found that insulting, but I was just making a joke and trying to complement you at the same time. The basic point is that if Smolin did want to use someone for PR, you would be a good choice. In any case, let's face it, this whole media thing with Lisi's paper is completely unwarranted. There's really no content there, just some big statements and nice pictures. It's really amazing that this work was funded by the Foundational Questions Institute, unless you consider that Smolin is on the scientific advisory panel. Even Smolin I'm sure knows that this work is wrong, but I believe he has an ulterior motive in supporting it.

62. **Bee**
November 17, 2007

Hi Eric,

I was just making a joke and trying to complement you at the same time.

Apology accepted.

if Smolin did want to use someone for PR, you would be a good choice

Definitely not. I'm a researcher, Eric. The attention my blog currently gets is about the maximum I am comfortable with. I am not writing it because I want to advertise PI, Lee's book or my papers, but because I like writing it. Since I am currently not teaching I find it a nice way to contribute my part to spreading knowledge, and to share the fascination my job brings – still, and still in new ways.

In any case, let's face it, this whole media thing with Lisi's paper is completely unwarranted. There's really no content there, just some big statements and nice pictures.

The paper has content, and I've explained in my post in great detail which. What it does not provide in my opinion is a Theory of Everything, so I agree that the media hype is unwarranted.

It's really amazing that this work was funded by the Foundational Questions Institute, unless you consider that Smolin is on the scientific advisory panel. Even Smolin I'm sure knows that this work is wrong, but I believe he has an ulterior motive in supporting it.

I don't want to comment on Lee's opinions, but it is quite astonishing to me how you can be 'sure' about what he thinks. Best,

B.

63. **Marcus**
November 17, 2007

When you see a new theory in formation it's legit to guess that the gaps will be filled, new things found to reconcile it with observation, and the theory will complete itself (if it looks to you like it will) and it's likewise kosher to guess that the gaps and imperfections won't be worked out and the theory won't complete.

Then if it is completed and firm predictions are derived it's anybody's guess whether experiments confirm or refute. Whether its right or wrong is a later issue. With the E8 theory we are seeing the outlines of something emerge and it seems to have both some problems and some nice features.

What's not acceptable is to hammer the theory relentlessly as if to punish it for the fact that it attracted general public interest. Whatever the public does or does not do, when you crit some new theory development it should be constructive—when you point out problems you should acknowledge how they might be resolved, at least in the first weeks and months when the whole thing, the only thing that matters, is whether or not the theory gets other researchers interested in working on it.

People in the public don't have to be protected from believing something might work. Plenty of them are smart and skeptical enough to know that proposed ideas often don't work, and they like to hear about new ideas anyway. It's common sense that new ideas can interbreed and morph and help start other ideas—that some will disappear forever and others you will hear about a few years down the road when they re-surface. I think the public knows that, or a substantial sector does.

In Garrett's case, what I read that he said sounded calm and forthright enough. He was constantly pointing to parts of the theory that he was dissatisfied with and looked to

improve. And he was repeatedly pointing out that it could turn out wrong—and might not agree with experiment.
I heard pride, but I did not hear hype.

The public reaction I saw was interest, but not whole-hog credulity. I don't think it was contrary to the longterm interests of science. Just normal reaction to some good news. It's good news that this new idea is out there trying to take shape, whether it's eventually shown right or wrong. And I really doubt anyone can confidently say at this point.

64. **Peter Woit**
November 17, 2007

Eric,

I'll delete any more comments insulting people, I don't want my blog used for this. You might want to note that this tactic hasn't worked for Lubos, I suspect one reason Garrett's paper got so much attention was that people read what Lubos had to say on the topic, and drew the conclusion that there must be something to it.

65. **Arun**
November 17, 2007

I'm now veering to the opinion that science should be created in privacy, like babies.

66. **King Ray**
November 17, 2007

Garrett,

I've only scanned through your paper briefly, but I can already say that your theory is 10^500 times better than string theory!

Does your theory shed any light on why the electro-weak group is U(2) and the electro-strong group is U(3), and the overall group is S(U(3)xU(2))? I've always wondered why the U(3) and U(2) determinants were related in that way, i.e., epsilon_abc*epsilon_AB is an invariant (lower case indices are electrostrong 1-3 indices, upper case are electroweak 1-2 indices). This has to do with the global structure of the gauge group of the standard model. If you assume that the global group is S(U(3)xU(2)), and that anomalies cancel in each family, then you get a unique solution for the hypercharges in a family (given the SU(3) and SU(2) reps of the quarks and leptons):

http://prola.aps.org/abstract/PRD/v43/i8/p2709_1

In your theory it is probably just due to the E8 structure. Have you looked at any possible anomalies and their cancellations?

Keep up the good work. I agree with Lee Smolin, it seems to be the most promising TOE for a while if everything works out. I never liked the plethora of gauge bosons that came with large gauge group GUTs.

BTW, I have surfed at Pt. Mugu. Very powerful waves there.

67. **Garrett**
November 17, 2007

It was. 😉

68. **Garrett**
November 17, 2007

(My last comment was to Arun)

69. **Garrett**
November 17, 2007

King Ray:

Almost all GUT's explain S(U(3)xU(2)) the same way, and this one is no different.

I haven't investigated anomalies yet, no.

70. **King Ray**
November 17, 2007

Garrett,

I can understand how larger gauge groups explain the global structure, for instance in SU(5) the U(3) and U(2) are block diagonal in the 5×5 SU(5) matrix and the total determinant must be 1, implying S(U(3)xU(2)) after breaking the SU(5), but can you elaborate a little on how it works in your theory? You don't have many extra gauge bosons like SU(5) or SO(16), do you?

71. **Garrett**
November 17, 2007

King Ray:

That's what the paper's for.

72. **King Ray**
November 17, 2007

Garrett, ok, thanks, and BTW I meant SO(10) not SO(16)! Brain cramp or senior moment…

73. **Kralizec**
November 17, 2007

Sabine Hossenfelder (Bee) said:

> I am just as always surprised how much such stories about the alleged outsider (surfer dude! no university affiliation!) attract cheerful attention, whereas the 'inside of the ivory tower' is accused of ignorance and arrogance.

The familiar sort of story you mention seems to be a product of the recurring antagonism between "the many" and "the few," or "the people" and "the great." Aristotle's *Politics* and Machiavelli's *Discourses on Livy* are both helpful regarding the properties and interactions of these recurring factions. Popular writers seem to have cast Garrett Lisi in the role of a man of the people who is challenging the great and proving again that the people are their equals in every way (including theoretical physics). I think Machiavelli discusses examples in which one of the great suspects that a man of the people is being supported covertly by another of the great. He appears to teach that the antagonism between people and great is reproduced among factions of the great.

In case you decide to read the works I named, I'll just make mention that Carnes Lord and Joe Sachs are good translators of Aristotle and that the best available translation of Machiavelli's *Discourses* is probably Harvey Mansfield's. Mansfield is also highly regarded in some circles as an interpreter of both Aristotle and Machiavelli.

74. **mitchell porter**
November 17, 2007

In the discussion at Sabine's, Garrett seems confident that "quantum E8 theory" is at least mathematically well-defined and therefore must be exploiting *some* loophole in Coleman-Mandula, even if he doesn't know what that loophole is. Whereas Aaron Bergman is very skeptical but asks whether he's missing something in the construction.

Surely this issue can be resolved. I am climbing a steep learning curve in order to participate here, but I have a few thoughts.

Let's start with the classical theory. Garrett has an E8-valued connection on 3+1 dimensions. He has an action (his equation 3.7) which explicitly breaks part of the E8 symmetry, including the part which notionally mixes fermions and bosons. I say "notionally" because those terms don't mean anything until we quantize.

Now compare this situation to the Standard Model coupled to gravity. A classical theory exists here too; then you get to the quantum theory by substituting operators for fields in the usual way.

This seems to be the crux of the debate with Aaron. You don't need a super-Lie algebra to quantize the Standard Model, because the fermions and bosons don't have to mix. Is it the same for Garrett's theory? If the action didn't already contain those symmetry-breaking terms, wouldn't Aaron be right? But given that it does, does that mean that Garrett's right? Section 3.2.3 must be the key here, because that's where the "fermionic" action is extracted.

75. **ScienceLover**
November 17, 2007

> Popular writers seem to have cast Garrett Lisi in the role of a man of the people who is challenging the great and proving again that the people are their equals in every way (including theoretical physics).

It hasn't gone that far right now. Lisi has not become a research politics factor – the common man challenging the establishment. Instead the media phenomenon shows all characteristics of a 15-minutes-of-fame story.

76. **Dany**
November 18, 2007

King Ray: "This has to do with the global structure of the gauge group of the standard model. If you assume that the global group is S(U(3)xU(2)), and that anomalies cancel in each family, then you get a unique solution for the hypercharges in a family (given the SU(3) and SU(2) reps of the quarks and leptons)".

Hi King Ray,

In case that you missed it, see also arXiv:hep-th/9801011v1

Regards, Dany.

77. **Arun**
November 18, 2007

Sorry for being disjointed here – why I'm thinking now that science should be developed in private, outside public gaze is that we've protested string hype – the public claims made by physicists that a theory will deliver what it cannot (yet?). We ought to be protesting Lisi E8 hype as well for exactly the same reason. No double standards in this matter, please.

78. **King Ray**
November 18, 2007

Dany, thanks, I have seen that reference as well as Saller's papers. The paper I cited above is referenced in Agricola's article that you cite and Saller's book (Vol. II) and papers. Was there a particular point in Agricola's paper that you were referring to?

79. **Marcus**
November 18, 2007

> we've protested string hype – the public claims made by physicists that a theory will deliver what it cannot (yet?). We ought to be protesting…

Arun,
impartiality and consistency are indeed essential but so is a sense of proportion.

80. **Garrett**
November 18, 2007

The hype is dying down. I've tried to make it very clear to every reporter I've talked with that no matter how beautiful and promising a theory looks, its validity is determined by predictions, and how those fare under experiment. And that with any new theory, including this one which is still developing, an attitude of healthy skepticism is appropriate.

The thing worrying me is… this E8 Theory was playing out very well in academia before the media hype. I gave four talks on it, in quick succession, and each one went better than the last, with a very good reception from physicists. And the paper generated a great deal of interest. Then what I thought would be a nice explanation for a lay audience in New Scientist spawned a media frenzy. I just hope the hype didn't obliterate serious consideration of the paper.

81. **King Ray**
November 18, 2007

Garrett,

I believe that you have handled yourself and the publicity as well as possible.

Last night I read all the posts on Bee's blog, and I think you handled all the attacks and criticisms that came your way in a manner that showed a great deal of class and dignity, always answering every question or challenge in a good natured way.

In everything I have read that you have said, I have detected no trace of your trying to overhype your work, as string theorists have been very guilty of doing with string theory. All I detect is the natural excitement and enthusiasm of a theoretical physicist for his work in trying to understand the laws of nature.

In every instance you are extremely honest and straightforward and always point out that the theory is in its early stages and could prove to be wrong, and that it will make predictions that will be testable. I find this quite refreshing and admirable. My hat is off to you for the way you have conducted yourself.

It might be useful for you to write a more expanded version of your paper, that is more in the notation familiar to particle physicists, where you carefully and redundantly explain your steps and methods, as if you were teaching a week or two long class on your theory. A review section on the key points of Lie algebras and group theory relevant to your work might also be useful, to bridge the gap, since the theory of exceptional groups may be an impediment to many. It is always good to show simple examples and then talk about the general case. I know it is hard to try to do something like that when you are in the middle of doing important work, but it could help your cause tremendously.

Keep up the good fight!

82. **Aaron Bergman**
November 18, 2007

A review section on the key points of Lie algebras and group theory relevant to your work might also be useful, to bridge the gap, since the theory of exceptional groups may be an impediment to many

This is not the problem. Everyone knows about E_8, Clifford algebras and BRST symmetries — they're standard material. What makes the paper difficult to read (for me, at least) is the lack of standard notation (all the tildes, underlines and dots, for example), and a number of missing steps in various derivations. I would like to see a detailed step-by-step derivation of the standard model using standard notation. I'd like to see the exact subgroup of E8 we're using and the decomposition of the adjoint rep of E8 under that subgroup with each rep labelled with respect to every factor in the subgroup.

The standard model has a well-known set of fields with a well-known set of quantum numbers and interactions. The paper presents a rather piecemeal approach of getting to the standard model stuff, and it didn't make much sense to me. I'd like to see the Lagrangian (3.7) expanded out in its full glory, so to speak.

Basically, right now it feels to me like reading the paper is a chore, and I have better things to do. It's not even clear to me at the moment what the resulting symmetries of the Lagrangian are, and the more things I have to figure out when I read the paper, the less urge I have to do so. Sounds selfish I know, but such things are true about papers in general — you should try to make things as easy as possible for your colleagues.

83. **Arun**
November 18, 2007

Sounds selfish I know, but such things are true about papers in general — you should try to make things as easy as possible for your colleagues.

A good reminder that to have one's ideas taken seriously by the scientific community is a hard-earned privilege, not a right.

84. **woit**
November 18, 2007

Arun,

I think there is a significant difference between the overhyping of Garrett's work and the overhyping of string theory. One has to do with a very speculative idea that just one person is working on, the other a very speculative research program that has dominated particle theory for a couple decades, involving thousands of people. I don't think we're anywhere near yet the situation where some of the smartest graduate students in the subject are leaving the field because they feel that only if they work on Garett's theory could they find an advisor and start a career for themselves at the best graduate programs.

There's a constant stream of overhyped articles in the press about specific speculative ideas in physics being promoted by one person or a small group. New Scientist has such an article almost every week. Commenting on all such articles would take a lot of time, and get them more attention than they deserve, so mostly I think it's best to just ignore them

The media Lisi-mania is a much more unusual phenomenon. It has gotten a much wider distribution than usual, so it's a good idea for physicists to put out some more realistic points of view. I think the blogs on the whole have done a good job of this. Anyone who reads the coverage here, at Sabine's blog, and at Sean Caroll's should get a pretty accurate view of what is going on. They could also read Lubos's blog, but he is likely to just convince them that Garrett has definitely accomplished something revolutionary that has driven string theorists insane.

85. **Dany**
November 18, 2007

King Ray:" I have seen that reference as well as Saller's papers. The paper I cited above is referenced in Agricola's article that you cite and Saller's book (Vol. II) and papers. Was there a particular point in Agricola's paper that you were referring to?"

King Ray,

I mentioned I.Agricola since you referred to 1991 paper by J.Hucks. My guess was that you know all of them, but just in case… I think the discussion of his results is off topic here. In addition, I consider it not adequate to the blog with the general title "Not even wrong".

Regards, Dany.

86. **King Ray**
November 18, 2007

Dany, no problem, I appreciate your pointing out the paper in any case, so thanks again.

87. **Arun**
November 18, 2007

Peter,

The current hype sounds to me like Pons-Fleischman cold fusion, or more charitably, Taleyerkhan's acoustic cavitation bubble fusion.

-Arun

88. **woit**
November 18, 2007

Arun,

I think we're still quite a ways away from the Pons-Fleischman level of media frenzy. And that was an experimental claim, which led to many groups doing experiments to try and replicate the results (as well as physicists selling platinum short, convinced that the way platinum had been bid up because it was the catalyst Pons-Fleischman used would soon collapse as the results weren't replicated). Claims from serious experimental physicists saying they have an inexhaustible source of free energy are rather more rare than claims from theorists that they have made progress towards a ToE.

89. **Kralizec**
November 18, 2007

> ScienceLover Says:
> November 17th, 2007 at 11:45 pm
> …
> It hasn't gone that far right now. Lisi has not become a research politics factor – the common man challenging the establishment. Instead the media phenomenon shows all characteristics of a 15-minutes-of-fame story.

Thanks; I understand, ScienceLover. I'm not, myself, suggesting that Mr. Lisi fits into a people/great frame of the sort I described. It just appears that some popular writers (and perhaps at least one fellow physicist) are trying to understand the physicists and Mr. Lisi in terms of that continually re-emergent sort of antagonism.

90. **amused**
November 19, 2007

The description of what has and hasn't been done in this paper should be made a lot clearer. E.g., I, and quite a few others it seems, got the impression that this was supposed to be a unified field theory with E8 gauge symmetry containing gravity and the SM. The e8 gauge connection and its curvature are discussed at length in a way that gives the impression that they are to be used to construct the action for the fields, presumably an e8 gauge-invariant one — otherwise, why go on about it? If this had really been the case then there would be an immediate issue with the Coleman-Mandula theorem. The remark in the paper about C-M not being relevant because the spacetime is deSitter is nonsense, since Poincare symmetry can be assumed for all practical purposes when applying the theory to particle scatterings in labs.

The real reason why C-M turns out not to be relevant here (as noted by Aaron B. over on Bee's blog) is that the action proposed for the fields is not e8 gauge invariant: Despite the impression the other parts of the paper give, the actual construction of the action is not based on the e8 connection and its curvature. Instead, it is pulled together from various parts of the e8 curvature in a way that breaks the e8 gauge symmetry; the action is not invariant under transformations that mix the gravitational and internal gauge parts of the e8 connection. This seems really ad hoc to me — there is no governing principle like gauge invariance for determining the action, it is just cooked up to reproduce the gravity and the SM. (This seems to be Bee's objection as well, if I understood her comments rightly.) In light of this I don't see any compelling reason for expecting that the new "color scalar fields" that arise have anything to do with nature. So at this point it seems that the paper is just one more not particularly well-motived proposal for what beyond the SM physics might look like. (String phenomenologists already have loads of these, apparently.) Well, it is not even that yet — first one would have to quantized the theory, determine the particle content, renormalizability etc. But a unified theory it certainly isn't — where is the unification?

As for the media hype, "surfer dude stuns physics" makes for a cool story but it wouldn't have happened without the backing of some big-name physicist. Smolin was most obliging in this role, but I'm sure it was for the purest of motives (let's not be getting cynical here ;)). I share very much Bee's concern about episodes like this leading to an atmosphere where people feel pressured to be working on media-appealing, hypeable topics rather than solid, conservative ones.

91. **Bee**
November 19, 2007

Hi amused:

This seems to be Bee's objection as well, if I understood her comments rightly.

You did. Best,

B.

92. **Harry**
November 19, 2007

Mr. Lisi is now making the headlines in France, in one of the most famous newspaper :

http://www.lemonde.fr/web/article/0,1-0@2-3244,36-979858@51-979860,0.html

(in french)

93. **H-I-G-G-S**
November 19, 2007

One does not have to examine the full E_8 structure to see the
"non-unification" unification aspects of the construction. Consider his
"unification" of the quarks and gluons of QCD using G_2. It is true that the 14-dimensional adjoint rep of G_2 decomposes as the 8 + 3 + \bar 3 of SU(3) under G_2 -> SU(3). And it is true that the gluons are in the 8 and the quarks and anti-quarks in the 3 + \bar 3. So what? What action does Dr. Lisi propose? I am very sure that if you wade through the obscure notation one will discover that either

1) It is the same action as that of QCD in which case G_2 plays absolutely no role in the contruction.

2) It is not the same action as that of QCD in which case the theory is ruled out by experiment.

It is a lazy author that can't be bothered to work out the simple consequences of his theory and explain them simply. And it is a lazy blogger (who is supposed to be an expert in representation theory after all) who blogs about a paper and adds to the hype without putting in a modest amount of effort to understand what is going on.

94. **Garrett**
November 19, 2007

amused:

This is a great improvement. It appears you are now understanding (if not actually liking) the paper, as your factual statements are mostly correct. Now please consider that matching the standard model fields and dynamics to parts of the E8 connection and its curvature, with only a handful of exotic fields, is non-trivial.

(You have passed through the first, second, and are now to the third stage of acceptance (described on Bee's blog).)

H-I-G-G-S:

I chose (1). And I've tried to make the paper as succinct as possible. On your last comment, I'll let Peter speak for himself.

95. **woit**
November 19, 2007

H-I-G-G-S,

This posting in no way purports to contain a technical examination of the paper and its problems. I have put a "modest amount" of effort into understanding what is going on, enough to see several problems with what Garrett is trying to do. The sort of general unification/non-unification problem you bring up is specifically addressed in the posting. I don't think there's anything at all in what I wrote that hypes the paper, quite the contrary. The links I provided to places where it is hyped were given in the context of noting that I don't think this kind of thing is a good idea at all.

I'll provide you with another link, to the discussion and my comments at Sabine's blog, about how unprofessional it is to attack people from behind the cover of anonymity, evading any responsibility for one's actions:

http://backreaction.blogspot.com/2007/11/anonymity.html

96. **Eric Weinstein**
November 19, 2007

Hi Garrett,

Sorry to wade in late to this thread…but as an outsider, I haven't yet learned to talk shop with the physics media circus at full tilt. You guys should get that thing fixed…

In helping us to understand the motivation for your beliefs, can you be at all specific about how you see the origins of E8 as a symmetry group? Is it effectively a black box to you or do you see a preferred set of objects (constructed without benefit of E8) on which E8 acts as natural symmetries? For example, do you have any insight into the Freudenthal/Tits magic square construction that is not already present?

As you are likely aware, many of us hold the prejudice that if nature uses exceptional algebra as you assert, a complete physical theory based on E8 should eventualy illuminate its 'purpose' through some kind of principle of emergent exceptional symmetry. As best as I can tell, at this stage your paper treats E8 as an unmotivated combinatorial anomaly from mathematics to be used by physics.

Lastly, there is a tremendous ammount of rich folk wisdom held by very respectable mathematicians about E8, most of which is unfortunately unpublished (as it is generally treated as a private hobby). If you would like to talk off line, I could recommend some folks to you who do not seem to be on your acknolwedgement list. This is pretty specialized theory even for Lie Group specialists.

Regards,

Eric

97. **amused**
November 19, 2007

Garrett,

"Now please consider that matching the standard model fields and dynamics to parts of the E8 connection and its curvature, with only a handful of exotic fields, is non-trivial."

To my mind this has the same status as various remarkable numerical relations and coincidences that people sometimes find among the fundamental constants of nature: interesting to some extent, but, on its own, not real physics.

98. **anon.**
November 19, 2007

Here's a link to Babelfish's English translation of the *Le Monde* article about Garrett's theory. (It's not much of a translation, but it's still helpful if your French is as rusty as mine.)

99. **Fabrizio Nesti**
November 19, 2007

HIGGS boson, Amused:

I also were quite surprised after understanding that Garrett's action was not E8 invariant. I think the paper is not so clear about this point. The question is then, which kind of unification is this? Of the three unification steps (find multiplets, give an invariant action and find a breaking mechanism) Garrett only carried out the first one.

Given that, the result of this first step is really nice and non trivial, since you should appreciate that some Higgs is contained in the E8 connection, as well as _three_ families. This is for the excitement. The rest just calls for much (exciting!) work in the future.

About Coleman-Mandula, I can clarify: the point is not desitter or noninvariance – because eventually one will look for an invariant theory. The point is that above the unification scale there is probably no metric, because the metric itself is inside the e8 connection. If at high energy there is no metric, there is no time, no standard scatterings and thus no Coleman-Mandula.

This point made Lubos go berserk even before Garrett's paper, so I suppose he was prepared – but more robust critics could have been raised than this one..

best,
Fabrizio

100. **Aaron Bergman**
November 19, 2007

Given that, the result of this first step is really nice and non trivial, since you should appreciate that some Higgs is contained in the E8 connection, as well as _three_ families.

But that's not true even if we accept the identifications made in the paper. The three families are not identical — they live in different representations and do not accord with the standard model.

The question about C-M is about the low energy effective theory, not so much about the high energy theory. But, given the lack of clarity about what the symmetries of the theory actually are, this may be irrelevant.

101. **Bee**
November 19, 2007

Gag, my visit count is going nuts again, thanks to

Stuff string theory – try E8 to explain the universe.

102. **Peter Woit**
November 19, 2007

Thanks Bee,

I've given up on trying to keep track of all the articles, thanks to my readers for posting here any they find that haven't been mentioned and are of interest. On the whole, about the science, many are overhyped and pretty misleading in various ways, a few include an appropriate amount of skepticism.

103. **H-I-G-G-S**
November 19, 2007

Dear Peter,

Thanks for the link. I suggest you read it. I am not anonymous, I have a pseudonym. As Bee points out, there is a difference. I've posted under H-I-G-G-S before and will do so again, unless you block my comments. My actions have consequences, at least in the blogosphere.

Anyway, let's get back to the physics. Garrett agrees that as far as the quarks and gluons are concerned G_2 is totally irrelevant. Since he does the same thing with E8, that is combines all the fields into one connection, but then writes down an action piecemeal to agree with the SM, I am tempted to say that the whole E8 is irrelevant. But I think this is not totally fair. After all the SM fields fit into E8 with some room left over, so the model "predicts" these extra particles. Of course I could just as easily invent a theory of everything based on a noncompact form of SU(248) or SO(196884) or an infinite number of other groups which would "unify" everything in the same way. And since the action is whatever he wants it to be and there is no dynamics to break the E8 symmetry, there is no prediction for the masses or couplings of these particles. If they are not found, he can just adjust the mass scale however he wants. I really would have to say that this model is a prime example of a theory that is "not even wrong." As the old joke goes, this paper contains new and correct results, but what is correct is not new, and what is new is not correct. What part of this do you find interesting and worthy of encouragement?

Sincerely,
Not the real P.W.H. FRS

104. **Peter Woit**
November 19, 2007

H-I-G-G-S,

I suggest you actually read my posting, where I explain precisely what I think about what Garrett is trying to do, and what parts of it I think are worthy of encouragement. You might also notice that I explictly make the point you're trying to make, explaining why I'm dubious about this kind of "unification" since it doesn't solve the problem of how to break the larger symmetry in a way that makes the setup predictive. In principle fitting SM symmetries together into a simple exceptional group like E8 could be constraining enough to be predictive, even after symmetry breaking, but lots of people have tried this kind of thing without success. He seems to be trying something different than a standard GUT set-up, one assuming a mixing of space-time and internal symmetries that won't work in the standard QFT formalism. Maybe he can get something out of this, I certainly encourage him to keep trying.

105. **amused**
November 20, 2007

Fabrizio,

"About Coleman-Mandula, I can clarify: the point is not desitter or noninvariance – because eventually one will look for an invariant theory. The point is that above the unification scale there is probably no metric, because the metric itself is inside the e8 connection. If at high energy there is no metric, there is no time, no standard scatterings and thus no Coleman-Mandula."

If at some point in the future someone comes up with an invariant high energy theory of the kind you describe, which has Lisi's model as a low energy effective theory, then we can discuss it. But at the moment there is no proposal for such a theory, and no compelling reason for expecting one to exist, so talking about it is just idle speculation.

106. **chris**

November 20, 2007

hi amused,

if it is only idle speculation, then why do you (and many others) keep poking at this point? is it just motl's evil spirit haunting 🙂

the lisi lagrangean does fulfill the C-M theorem. just plain simple like that. it does no nontrivial mixing. the hope (and it is just a hope) is, that maybe at higher scales a mechanism will ultimately provide… but he does not even speak about that.

107. **chris**
November 20, 2007

ps:

oh, and to anticipate the "then it's all vacous" argument: how much explicit dynamics did the original gell-mann eightfold way provide?

108. **Fabrizio Nesti**
November 20, 2007

Aaron:
The three families are not identical — they live in different representations and do not accord with the standard model.

Well, we do know triality. The point (I alrady raised in Bee's blog) is whether triality is inserted by hand or comes out of the theory itself. For this I think you'll need a high energy completion… again.

Peter,
I happened to re-read your posting and I have a comment that came to me also after reading your book. You wrote that as in GUT programs, you move the problem from symmetry to symmetry breaking, and for this reason you get no predictions, except maybe proton decay in simplest models, that we do not observe. I agree but I just want to point out that simplest models are anyway already ruled out by other aspects (by fermion masses, notably) so there is no point in ruling them out. Realistic nonminimal models, even SU(5), they do _not_ predict a fast proton decay, so they are not ruled out.

So the situation is probably even worse than how you put it. No new-physics idea can actually be ruled out, they are simply not predictive, alone. Not GUT – not certainly strings or extra dimensions – not even SUSY (if we'll not see it, one may still raise this and that to make it invisible). And not even these theories unifying Lorentz and internal symmetries.

Maybe the point is that mathematical ideas, geometry, unifications etc, are just nice frameworks… while one needs a complete detailed theory -scales- to make predictions. Btw this is what the standard model is – a complete theory up to 100GeV :).

ok, just free thinking,

best,
Fabrizio

109. **mitchell porter**
November 20, 2007

It would be funny if Garrett's theory turned out to be just another limit of string theory – perhaps of some "noncanonical" form of string theory (e.g. see Lubos's list under "Strong leadership of supersymmetry", here). There is actually a "single-E8" string theory, a heterotic tachyon. Only, that's a compact E8.

So far as I can see, the situation with respect to Coleman-Mandula is this. Garrett's action is consistent with the theorem because the full E8 symmetry is broken. However, the hope or presumption is that the symmetry-breaking terms come from somewhere and that the fundamental theory does have full E8 symmetry. At this point the CM problem returns. Fabrizio Nesti in his papers says that CM is evaded because the full symmetry only manifests in a high-temperature topological phase (no metric). If that doesn't make sense, we will be left with Aaron's suggestion to use supersymmetry after all – in which case we'd surely end up with some sort of supergravity, and my notion that this is just another superstring limit would look even more plausible.

What I want to understand now is the part about triality and the three generations. There is definitely handwaving on this point (page 28: "not presently understood well enough to write down").

110. **mitchell porter**
November 20, 2007

I'll risk really exposing my ignorance and voice one more thought. One of the basic ideas here is that E8 could provide a nonsupersymmetric way to unite fermions and bosons. Meanwhile, one corner of superstring theory has an E8xE8 symmetry; and the Monster group shows up in certain compactifications, e.g. a Leech lattice orbifold (I think). Now the Leech lattice is rather similar to a copy of *three* E8 root lattices. So I wonder if there's a third E8 lurking in string theory, that's responsible for the supersymmetry.

111. **amused**
November 20, 2007

hi chris,

It's hilarious to think that I might be possessed by Lubos' evil spirit 🙂 especially considering our previous history in the blogsphere (which includes, among other things, my successful goading of Jacques Distler into denouncing him…although I got the feeling that Jacques quite enjoyed the opportunity to do that). Perhaps Peter W. should be called on to perform an exorcism.

At any rate, my last two comments above were in reply to comments addressed to me by Garrett and Fabrizio, so I don't think they qualify as poking. And my first comment above was just a summary of my opinion on the paper after a bit of reflection and recovery from the mammoth discussion over at Bee's blog.

Your comment raises an interesting general question though: why were those of us who do physics for a job spending time on reading and discussing this paper? Is it really that interesting compared to all the other physics things we could have been doing? It's not as if Garrett is the only alternative physicist out there with his own theory. E.g. Tony Smith seems just as well qualified academically (he has a Ph.D. from Princeton), and, for all I know, his theories could be just as deserving (or undeserving) of attention as Garrett's. (Besides the media hype, it's kind of ironic that Garrett is getting blog postings devoted to his theory while Tony gets told to shut up every time he mentions his ones.) My own reasons for spending time on this were: (i) The reported opinions of various prominent physicists; e.g. Smolin apparently described it as “fabulous”. (ii) With all the media attention on this, Joe Public wants to know what the consensus opinion of professional physicists is, so probably we have some responsibility to assess the paper and make our opinions known.

But as far as “alternative theories” go, there are others that are much more worthy of attention than this one. Just to give an example, C. Wetterich has been developing an “alternative” proposal for explaining electroweak symmetry breaking based on chiral coupling of matter to massless antisymmetric tensor field in hep-ph/0607051, arXiv:0709.1102. This looks really interesting and elegant (without having studied it in detail), but seems to have been completely ignored so far. (However, the author is no doubt less colorful: he’s a full professor at one of Europe’s illustrious universities — how boring if progress in physics werre to come from someone like that!) I can’t help getting a feeling that something is fundamentally wrong somewhere when work like this is being ignored while Garrett’s paper is being debated on physics blogs and reported on Fox News. And it is a worry that with this and all the other hype they are subjected to, the public will be too jaded to pay attention and care in the future if and when there really is some major gravity/particle theory breakthrough worth telling them about.

In reply to the rest of your comments:

“the lisi lagrangean does fulfill the C-M theorem. just plain simple like that. it does no nontrivial mixing.”

Indeed. Which is why I wrote in first comment above that C-M is “not relevant” in this case.

“the hope (and it is just a hope) is, that maybe at higher scales a mechanism will ultimately provide… but he does not even speak about that.”

No, but Fabrizio did speak about it and my “idle speculation” remark was directed to him.

“oh, and to anticipate the “then it’s all vacous” argument: how much explicit dynamics did the original gell-mann eightfold way provide?”

One big difference is that Gell-Mann proposed SU(3) as a genuine (unbroken) symmetry of the strong interactions, so the properties (quantum numbers etc) of the new particles can be inferred from the fact that they are in the same multiplet as other known ones. There is no such information in Garrett’s model since the symmetry is broken. While we’re on this topic, a final poke: It is ridiculous how Garrett has been saying (in statements attributed to him in the press) that the LHC will determine whether his theory is right or not. How does he know whether or not the exotic particles in his theory should show up there? Maybe they should already have shown up in previous experiments, in which case their absence disproves the theory. Or maybe they show up at energies much beyond LHC? Does he have any idea at all at which energies they should show up?

112. **Fabrizio Nesti**
November 20, 2007

…“maybe at higher scales a mechanism will ultimately provide… but he does not even speak about that.”
No, but Fabrizio did speak about it and my “idle speculation” remark was directed to him.

Yes, Amused,
I did’nt reply to you because I agreed with Chris: Garrett does not speak of the full theory in the symmetric phase. (And in any case, he should speak for himself.)

As far as I am concerned, in our paper (Graviweak Unification) we _do_ provide both the action in the fully symmetric phase and its breaking: above the breaking scale CM does not apply, below it holds, of course. This is why I wrote that clarification.

In the E8 case, I can only hope that a similar breaking mechanism can be found, but it’s more difficult.

About the ghosts-as-fermions, I have no idea of how this could work, and if. Lubos says that this can not be done. It should be easy to work out a simple toy model using BRST. Maybe Peter has thought to it.

I think that blogs (let alone the media) are not the place to demonstrate something right or wrong, and the silence of most scientific community is a good sign. One should just close the browser for some time, sit down and try to see if ideas can be made to work. This is what serious physicists will do, anyway.

Fabrizio

113. **Aaron Bergman**
November 20, 2007

Well, we do know triality. The point (I alrady raised in Bee’s blog) is whether triality is inserted by hand or comes out of the theory itself. For this I think you’ll need a high energy completion… again.

Triality at the moment is just a bit of hand-waving hope. There’s no way that I can see that one could insert it by hand to recover the three generation structure of the standard model. Different representations remain different representations no matter how many automorphisms you do.

114. **chris**
November 20, 2007

hi amused,

thanks for your long, detailed reply. indeed i find it strange too, how the attention of the public and of the theoretical physicists is divided between different approaches and how they influence each other. i think it just serves to show how much our profession is affected by trends and hot topics, too. and also how little every one given individual can actually comprehend of the whole field or how much the judgment is not guided by any higher principle we like to appeal to (like truth or beauty), but just by trust in our or other peoples opinions.

well. one point i would like to make though is that i think it is not so far out to claim the unobserved particles in the spectrum not to be at too high energies. the natural reason i see is just plain simple again: these are particles that should show up in the effective theory at low energy. they explicitly populate the spots in the broken lagrangean. this is in stark contrast to e.g. the SU(5) X and Y bosons. so while it is still questionable to claim anything will be seen at the LHC it is no more of a misleading statement to me than the TeV scale bulk gravities or anything that tries to bring new particles within lhc reach.

and finally: you very well know that SU(3) is broken right from the start of the construction. weakly broken i concur, but nonetheless, there never was hope of an unbroken flavor SU(3). all there was were the SU(3) reps and particles of different mass that fitted them.

115. **amused**
November 20, 2007

Hi Fabrizio,

Thanks for your clarifying comment. I wasn't aware of your work, and it is interesting to hear that you have a high energy completion of this kind in your case.

116. **amused**
November 20, 2007

hi chris,

Yes, we are reliant a lot on the opinion of "authorities", which imo places a lot of responsibility on them to be careful about what they say and what they hype.

If the TEV scale gravity proponents, string phenomenologists etc make claims that their theories will be tested at the LHC then that is of course just as bad as if Garrett does it. But in the cases I've noticed those people always say maybe…

And yes, I meant of course approximately exact flavour SU(3) symmetry, not 100% exact.

117. **Tony Smith**
November 20, 2007

amused said "… I [amused] can't help getting a feeling that something is fundamentally wrong somewhere when work like …[that of]… C. Wetterich … hep-ph/0607051 … is being ignored while Garrett's paper is being debated on physics blogs and reported on Fox News. …".
Wetterich says in that paper:
"… Antisymmetric tensor fields with chiral couplings to quarks and leptons may induce spontaneous electroweak symmetry breaking in a model without a "fundamental" Higgs scalar. … Furthermore a scalar top-antitop condensate forms, giving mass to the weak gauge bosons and fermions. …".

Wetterich's idea of a physical antisymmetric tensor field is interesting both physically and historically, since similar structures were used by Einstein and Schroedinger in some of their models. Maybe Wetterich has found a physical use justifying the basic intuition of Einstein and Schroedinger ? Wouldn't that be something worthy of popular news commentary ?

Wetterich's idea of "a scalar top-antitop condensate" acting effectively as a Higgs mechanism, even if it may not be unique to him, is still a phase of his work that might be explored by experiments at the LHC. Wouldn't that be worth at least a little pro-LHC publicity ?

As amused said, Wetterich is "… a full professor at one of Europe's illustrious universities …", so lack of professional qualification cannot explain the fact that Wetterich's work is not as widely publicized and evaluated as that of Garrett Lisi,
and
that leads to amused's statement that
"… it wouldn't have happened [for Garrett Lisi] without the backing of some big-name physicist. Smolin was most obliging in this role …",
and
that leads to a question about whether or not approval by a prominent third party is a necessary condition for acceptance of new ideas.

For example,
only after Freeman Dyson's approval was QED of Feynman and Schwinger widely accepted,
and
only after Ben Lee's approval was 't Hooft's proof of electroweak renormalizability widely accepted,
and
without such approval-by-prominent-third-party, QED by E. C. G. Stueckelberg was ignored.

Tony Smith

PS -amused also said "… Tony Smith … has a Ph.D. from Princeton …".
Actually, my Princeton degree is an A.B. in math (1963),
and I do not have a Ph.D.,
so I am not "… as well qualified academically …" as Garrett Lisi,
but
I appreciate the other kind words from amused.

118. **Coin**
November 20, 2007

C. Wetterich has been developing an "alternative" proposal for explaining electroweak symmetry breaking based on chiral coupling of matter to massless antisymmetric tensor field… I can't help getting a feeling that something is fundamentally wrong somewhere when work like this is being ignored while Garrett's paper is being debated on physics blogs and reported on Fox News.

I don't think the "people shouldn't be blogging about X, because blogging about Y would be more important" argument is ever fruitful. If Y is important, okay, blog about that too. If someone wrote a blog post about the Wetterich guy's thing I'd read it. I'm not sure I'd completely understand it, but I'd try. In the meantime, the energy spent on covering Garrett Lisi is not energy that's being *taken away* from covering Prof. Wetterich. If Lisi's paper had not dropped this month I think the most likely alternative would have been that the physics blogs for the last couple of weeks would have just been quieter.

And it's certainly the case that if Lisi hadn't published this month, Fox News *still* wouldn't be talking about Wetterich's new approach to the EWSB problem– Fox News doesn't even know what the words "Electroweak Symmetry Breaking" mean. They do know what the words "unifies gravity with particle physics" mean, though, which is why they'll write stories about that but not Higgsless EWSB models. (If you want to identify something "fundamentally wrong" here, then focus on that– that some of the most objectively important problems in real physics are things that the general public doesn't even realize are problems that need to be solved! Never mind Wetterich's "interesting and elegant" new approach for a minute– if the EWSB problem were *solved* tomorrow, would you know how to express this in a way that a Fox News viewer would care, or clearly realize that something truly important had happened?)

119. **amused**
November 20, 2007

Good grief, I didn't mean that Wetterich's papers should be discussed in the popular media instead of Lisi's. That obviously wouldn't be appropriate. The point i was trying to make was that it might be interesting to consider how and why those of us who are trained physicists here ended up spending a fair bit of time discussing Lisi's paper when there are other papers out there that are arguably more deserving of attention but seem to be going unnoticed. The general question of what is it that determines which papers get attention from the physics community seems an interesting one, but perhaps that's getting off-topic here.

120. **Coin**
November 20, 2007

Amused: Well, alright, sorry I misunderstood you then.

121. **amused**
November 20, 2007

That's ok, I probably should have made it more clear.
And apologies to Tony for misremembering his degree.

122. **Nic**
November 22, 2007

Distler seems to have purely group-theoretical arguments to exclude the viability of the model:

http://golem.ph.utexas.edu/~distler/blog/archives/001505.html#more

123. **alex**
November 22, 2007

"Distler seems to have purely group-theoretical arguments to exclude the viability of the model:"

Good! At last someone put a stop to this absurdity.

Thanks Jacques!

124. **a.k.**
November 22, 2007

..I do not think Garrett claimed to have an 'embedding' of the direct product of the groups in question into E8 but to have any of these groups embedded as subgroups. As I already mentioned elsewhere, from my point of view, even at high energies, to get predictions, the E8-bundle should reduce to these subgroups which is by standard fibre bundle theory equivalent to having a global section in the bundle associated to E8/H, where H is the subgroup in question. Furthermore, the total connection should reduce to these subbundles, given they exist. Both facts might very well be true without having an embedding of a direct product as Distler discussed.

125. **Tony Smith**
November 23, 2007

According to a recent Telegraph article by Roger Highfield:

"… a representative of a Hollywood film production company has been in touch with the Telegraph saying that "I loved the article and think it has great potential for a feature film." And at least one major agent is scrambling to sell publishers a book that will tell the story of Garrett Lisi and his struggles to comprehend the cosmos.
…
he has become something of a celebrity and he admitted yesterday that he was finding the attention overwhelming – indeed he has refused to appear on television.
"I'm currently spending the bulk of my time corresponding with physicists, which I consider to be of prime importance. "…".

Garrett's preference for doing physics over TV etc seems to me to be a very responsible attitude,
and I hope that he is able to maintain it under the pressure of possibly exploitative offers from Hollywood, book agents, etc.

Tony Smith

126. **Dany**
November 23, 2007

Tony Smith:" I hope that he is able to maintain it under the pressure of possibly exploitative offers from Hollywood, book agents, etc."

Tony,

I guess it will be great fun to see Hollywood movie and read a book about "his struggles to comprehend the cosmos". But what about the former American common boy stereotype with the forelock? He is Ockham razor shaven.

Regards, Dany.

127. **Chris Oakley**
November 23, 2007

According to a friend at UCSD Garrett Lisi *already has* appeared on TV recently (dressed in once instance as a red indian). They obviously love the idea of him being the rebel who is rocking the foundations of physics.

Well – good luck to him.

But I wonder … if the string theory community had not started the trend of trumpeting speculative non-results to the press, would they have taken an interest?

128. **Tony Smith**
November 23, 2007

Chris Oakley said
"… According to a friend at UCSD Garrett Lisi already has appeared on TV recently (dressed in once instance as a red indian). …".

According to a Fox6 (San Diego TV Fox station) web article by Jim Patton:
"… Lisi is a San Diego native who received his Ph.D. in Physics from U.C.S.D.. He also appears to be a true San Diego son with an obsession for surfing and snow boarding that splits his time between Maui and Nevada.
My interview with Lisi took place via email. …".

In light of that, perhaps Garrett has been true to his "refus[al] to appear on television", and what appeared on San Diego TV may have been a news story by Jim Patton based on the email interview with background pictures from Garrett's web site. As to Garrett being "… dressed … as a red indian …", I suspect that may be a misinterpretation of the cover picture on Garrett's web site at sifter.org/~aglisi/ which picture shows Garrett at Burning Man standing in front of a colorful exhibit.

Tony Smith

129. **H-I-G-G-S**
November 23, 2007

Dear Peter,

While you did not hype the content of this paper, like it or not, once you have a science blog you become part of the science media. Science reporters will look to your blog and others (even though this is in general a dubious method of gathering reliable information) to find out what is new and interesting. Because of this I think you should take some care with the topics you cover, particularly when you say things like you are fond of the ideas he is pursuing or that you are hopeful this line of thinking will lead somewhere. In this case you contributed to the idea that this model has some credibility, which it does not. Sean at Cosmic Variance was an even more egregious example of this, so don't think I'm singling out your blog.

I'd also suggest that you be a mensch and replace your latest update concerning Distler's post on this with something more along the lines of "Distler has found an explicit error in Lisi's treatment of the representation theory of E8." You are supposed to be an expert on representation theory, so certainly you should be able to check whether Distler is right or not.

130. **Peter Woit**
November 23, 2007

H-I-G-G-S,

I see one of the main goals of this blog as being to provide a source of accurate information for anyone interested in the same topics as I am. I think that's what I've done in this posting, and that's what I'll continue to do.

The reference to Jacques's posting is perfectly accurate and I hope helpful to people. I see no need to editorialize in the way you suggest. For one thing, you might notice that the only comment in my posting about Garrett's E8 scheme is that it's the kind of thing that leaves me cold. As you might guess from that, I haven't worked through the details of the representation theory in Garrett's paper, nor the details in Jacques's posting, so I don't think it's a good idea for me to do anything other than to refer people to the actual discussion between them, where they can make up their minds for themselves.

As for the degree of my menschlichkeit, you might notice that I regularly link to and suggest that people look at many things that Jacques posts. In return, his policy towards me is one of absolute refusal to link to or acknowledge the existence of anything I ever write, as well as to make sure that no link appears in any internet source he controls, such as hep-th trackbacks and his Planet Musings blog aggregator.

131. **Arun**
November 24, 2007

The Economist gets Lisi-mania:

http://www.economist.com/science/displaystory.cfm?story_id=10170958

This hype is unjustified and IMO, is damaging to particle physics.

Quoting:

Yet the theory has several appealing facets. It is elegant. It is expected to make testable predictions. Unlike some of the more complicated efforts to devise a theory of everything, this one should either succeed relatively rapidly or fail spectacularly. And that is more than can be said for three decades of work by other physicists.

It hasn't occurred to them that it is not even a theory.

132. **How Can We Turn The Tide?**
November 24, 2007

It is now apparent that the Lisi affair was due largely to "String Theory Envy."

But two not even wrongs do not make a right.

It is understandable that Lee and Peter might have been swayed towards Lisi's paper by Lubos's rejection and dismissal of the paper, but it would have been better if Lee and Peter would have judged the paper based on its merits, which would have entailed reading it, and at least attempting to comprehend it, even if being comprehended was not Garrett's primary incentive for his media campaign, pictures of him surfing, and ultimately meaningless youtube video with the hot, english female voice.

At least Lubos read the paper, as did Distler.

Did Lee? And if so, how can he call it "fabulous?"

133. **Bee**
November 24, 2007

Can you turn the tide? : Garrett gave a seminar here at PI about his work in early October, he stayed two weeks during which we had several discussions. New Scientists asked Lee and me for comments on the paper before it was on the arxiv but then extended the deadline (I am not sure why but think Lee complained). I am glad they did, as I find it extremely inappropriate to ask people to comment on a paper they haven't even seen. If you ask me, they should leave at least several months to think about it. There is a reason why good peer review takes time. The only reason my blog post went out as soon as the paper was on the arxiv was that I had written it previously, since Garrett sent me a copy of the paper (plus it has been on his wiki anyhow). As far as I know NewScientist knew about Garrett's stuff from a talk he gave earlier during the summer this year. Nothing of that interest in Garrett's work had anything to do with Lee or Peter. I find it quite astonishing how you (and others above) manage to blame a single person using the word 'fabulous', ignoring all the hundreds of people who echoed the same initial articles over and over again, without adding one epsilon of content, gradually polarizing and distorting the little scientific content such an article can have at all. If anybody is to blame for that then its everybody not acting against such a decline of journalism down to cheap entertainment, with no other purpose than collecting links and visitors who click on the advertisement banner.

134. **TonyC**
November 24, 2007

"How Can We Turn The Tide" says "It is now apparent that the Lisi affair was due largely to 'String Theory Envy'":

Why is that? Have you found some fatal error in Lisi's E8 mapping? If so, share it with us. If not, what makes this claim "apparent"? If Lisi maps all known particles to E8 correctly, this puts constraints on possible interactions, and constraints on future discoveries. Why isn't that a "theory"? Even if he has to work out his symmetry breaks "by hand", we may gain insight by examining the results and looking for commonalities.

What evidence do you present that Lisi's primary incentive was anything other than being comprehended? It seems rather difficult to support your theory of "String Theory Envy" when Lisi's proposed mapping is at least falsifiable by the LHC and String Theory (also not a theory), to my knowledge, is not. If anything, I think the opposite is true, the string theory community envies Lisi getting any attention whatsoever, probably because the very concept of falsifiability threatens their funding and Lisi is emphasizing the value of that radical concept. As long as we are claiming things are "apparent" with zero evidence to support the claim, I claim my interpretation is even more "apparent" than yours.

135. **alex**
November 24, 2007

Bee, you forgot to add another Lee's quote: "It is one of the most compelling unification models I've seen in many, many years".
So, at least Lee has "seen" it and found it "the most compelling". To make such a conclusion one would presume the Lee must have taken some time (as Jacques did, for example) to check at least some of the details.

136. **H-I-G-G-S**
November 24, 2007

Bee,

I don't think you can blame this all on journalists gone bad. It's amazing that after a seminar and a few discussions neither you nor Lee could understand what Lisi was saying well enough to tell that it was total nonsense. If you had realized that I presume you would not have found it worth blogging about and the reporters would have had one less reason to get worked up over this.

TonyC,

Go read Distler's blog. If you know enough math to understand it you will see that all the elementary particles do not fit into E8. Period, no ifs ands or buts. And the "triality" he proposes as some kind of cure is equally meaningless. This "theory" won't be tested at the LHC. You can't make predictions if your starting point is bunch of jumbled up concepts that don't make sense, a hope and a prayer that someone else will make sense of it, and wrong math.

137. **TonyC**
November 24, 2007

H-I-G-G-S:

Distler proves you can't have 3 copies of R in E8. Lisi acknowledges this and anticipated the problem. Later Lisi admits to a mathematical misunderstanding. Distler has NOT proven all the elementary particles do not fit in E8, they just cannot fit in the way Distler thinks they must fit, so he dismisses the entire exercise as futile; while Lisi does not. This academic disagreement over whether Lisi's mapping has any merit or might lead to something useful seems to me pretty thin evidence for accusing Lisi of String Theory Envy or celebrity mongering.

138. **Arun**
November 24, 2007

H-I-G-G-S: I see nothing wrong in Bee's no-sharp-elbows approach – she reached the right conclusion.

139. **H-I-G-G-S**
November 24, 2007

TonyC:

Please tell me what you mean, in mathematical terms, by "Lisi maps all known particles to E8 correctly." Distler interpreted this in the obvious way and showed it was false. If you have some other mapping of this statement into mathematics please tell me and then we can check if it is true. If you can't tell me what you mean than I would politely suggest that you should withhold judgement until you learn more.

140. **Bee**
November 24, 2007

H-I-G-G-S: *I don't think you can blame this all on journalists gone bad. It's amazing that after a seminar and a few discussions neither you nor Lee could understand what Lisi was saying well enough to tell that it was total nonsense. If you had realized that I presume you would not have found it worth blogging about and the reporters would have had one less reason to get worked up over this.*

I don't blame it all on journalists, certainly not. I blame everybody who blames others, instead of taking responsibility. Journalists who say they just believed the scientists, scientists who say journalists just misrepresent them, bloggers who say it's all the media's fault. I blame myself since I possibly contributed to the hype, even though it was my intention to provide a balanced article with pros and cons. I had heard Garrett's talk, I had read the paper, and I told him (repeatedly) that I think he does not clearly state how much extra assumptions he has to make by hand. I told him that even before he gave the talk at PI. When I wrote my post, I knew the New Scientist article would come out soon, I knew they had asked Lee for his opinion, and I knew Lee's opinion. I know New Scientist enough to realize they would listen to him. I knew the title of the paper, and I know Lubos enough to predict he'd jump on it, especially thanks to the acknowledgement list. As somebody said so aptly in a comment somewhere (sorry, can't recall who or where), everybody did exactly what one could have expected.

How come things like this happen? Because it's a completely premature reporting on an unclarified issue, a paper that has just been out a couple of days, in a field where peer review takes months, and NO, I don't think peer review can be 'replaced' by discussions on blogs. I don't appreciate pressure on scientists to put forward opinions, especially when so completely unnecessarily as in this case. I mean, it's not like there was some phenomenon observed, and expert opinions were needed to explain it. If somebody says he doesn't want to comment or doesn't feel qualified one shouldn't criticise him for knowing what he doesn't know.
Regarding what I blogged about: I have repeatedly stated that there are many things about Garrett's stuff that I don't understand, and that I don't like. I have clearly written in my blog post what I find promising about it and what not. I have clearly stated that he does not quantize gravity, what problems he does not address, that he has to write down the action by hand to reproduce the standard model, and that I don't think it qualifies as a TOE. Neither do I think it is just nonsense. I just think it was, and still is, premature to decide whether it will eventually turn out to describe a part of how nature works.
If I would write the post today, I would have made the basic statements much clearer and more obvious, but I did not expect the audience I got. Also, I am not a journalist, I am a scientist, and my writing skills are limited. There are several points that only become clear in the comments, and I am afraid little people read more of my posting than the first sentences, and even less actually tried to understand it.
After all, I am really sorry for Garrett. Though I think he knew exactly what he was doing, the results might eventually not be as expected.

141. **Bee**
November 24, 2007

Hi Arun,
Thanks. Seems it took me an awfully long time to write the previous comment, so I only just read yours now. In fact, I said this already in the post, but maybe not clearly enough
"However, for me the question remains which problem he can address at this stage. He neither can say anything about the quantization of gravity, renormalizability, nor about the hierarchy problem. When it comes to the cosmological constant, it seems for his theory to work he needs it to be the size of about the Higgs vev, i.e. roughly 12 orders of magnitude too large. (And this is not the common problem with the too large quantum corrections, but actually the constant appearing in the Lagrangian.) To make predictions with this model, one first needs to find a mechanism for symmetry breaking which is likely to become very involved."

Have a nice evening.
Best,

B.

142. **Eric**
November 24, 2007

Just curious why noone has brought up the work of Jacob Bourjaily with geometric engineering three-family GUTs from E8? It seems to me to be somewhat higher quality work than that of Lisi.

143. **Arun**
November 24, 2007

Dear Bee,
Yes you did state it in the post; but then there was the comments thread, which might give the impression that some of your objections were being addressed; that is why the comment is important in my interpretation of the world – you were willing to listen (good!), and when nothing convincing was said, you said so (great!), and wound up the discussion (excellent!).
Best,
-Arun

144. **TonyC**
November 24, 2007

>> H-I-G-G-S: If you have some other mapping of this statement into mathematics please tell me and then we can check if it is true.

I can't, you are right, I was wrong to say so. I am basing that statement on what Lisi has said, presuming he isn't lying.

>> If you can't tell me what you mean than I would politely suggest that you should withhold judgement until you learn more.

Good advice. As I have politely suggested it is too soon to pass judgement on Lisi's mapping, based on Distler's proving the obvious approach won't work, when Lisi already anticipated that objection in his paper. I refer you to Lisi's response on Distler's blog. And it is also too soon to pass judgement on Lisi as some sort of fame whore, which seemed to be the suggestion of "How Can We Turn The Tide". Perhaps I am not the only one that needs to withhold judgement until they learn more.

145. **amused**
November 25, 2007

"It is now apparent that the Lisi affair was due largely to "String Theory Envy." "

It's quite funny how some string theorists (the less enlightened ones) think that any challenge to ST must be driven by "envy". Envy of what, exactly? Of all your PRL publications?

146. **alex**
November 25, 2007

Eric:"Just curious why noone has brought up the work of Jacob Bourjaily with geometric engineering three-family GUTs from E8? It seems to me to be somewhat higher quality work than that of Lisi."

Lubos blogged about it but the press did not pick up on that. Maybe that's because Jake is still a grad student and not a surfer with a Ph. D. :).

He does get exactly three families from a single E8 and his paper is much easier to read.

Curiously, he automatically gets three generations of Higgs doublets which is an interesting prediction. The symmetry breaking is geometric, described pretty explicitely by five complex parameters.

There is a very nice table on page 6 of his paper where the explicit spectrum is given. The title of Bourjaily's paper is more humble as he does not claim to have a "theory of everything", so maybe that's another reason why Bee and others decided not to blog about his work 🙂

147. **H-I-G-G-S**
November 25, 2007

Bee,

Thanks for the long and thoughtful response.

TonyC,

I read Lisi's response to Distler. I don't think Lisi is lying (and I said nothing about his being a fame whore). He has been very straightforward in his responses to Distler. I think the problem is more one of inexperience and a lack of critical judgement. It is not considered good form to make dramatic claims at the beginning of a paper (i.e. that all standard model particles fit into E8) and then only on page 22 point out that this is not really correct. You say Lisi "anticipated" this problem. I would say he was aware of it, and tried to solve it, but his solution (involving triality) didn't work. If you want to know why, please read Distler's blog.

It's probably time to drop this topic. No use beating a dead horse. Unless of course Lee decides to write in and tell us all why he thought this theory was so "fabulous."

That would be entertaining, to say the least.

148. **Eliza**
November 25, 2007

Watching the hostility and contempt heaped upon Garrett Lisi by the physics establishment has been an ugly spectacle, but hardly a shocking one. And he is right that his idea is a beautiful; I wish him every success in winning converts from among all the bright people futilely beavering away at string theory. But while his idea is beautiful he himself is also to be admired–an Overman of sorts. His battle with the string theorists–a herd of Last Men–reminds me of Nietzsche's Zarathustra:

Give us this Last Man, O Zarathustra," — they called out — "make us into these Last Men! Then will we make you a gift of the Overman!" And all the people exulted and smacked their lips. Zarathustra, however, turned sad, and said to his heart:

They do not understand me: I am not the mouth for these ears.

Perhaps I have lived too long in the mountains; I have hearkened too much to the brooks and trees: now I speak to them as to the goatherds.

My soul is calm and clear, like the mountains in the morning. But they think I am cold, and a mocker with terrible jests.

Now they look at me and laugh: and while they laugh they hate me too. There is ice in their laughter.

* * *

Long slept Zarathustra; and not only the rosy dawn passed over his head, but also the morning. At last, however, his eyes opened, and amazedly he gazed into the forest and the stillness, amazedly he gazed into himself. Then he arose quickly, like a seafarer who all at once sees the land; and he shouted for joy: for he saw a new truth. And he spoke thus to his heart:

A light has dawned upon me: I need companions — living ones; not dead companions and corpses, which I carry with me wherever I go.

But I need living companions, who will follow me because they want to follow themselves — and to the place where I will. A light has dawned upon me. Zarathustra is not to speak to the people, but to companions! Zarathustra will not be shepherd and hound of the herd!

To steal many from the herd — for that purpose I have come. The people and the herd will be angry with me: the shepherds shall call Zarathustra a robber.

Shepherds, I say, but they call themselves the good and just. Shepherds, I say, but they call themselves the believers in the orthodox faith.

Behold the good and just! Whom do they hate most? The man who breaks their tablets of values, the breaker, the lawbreaker: — yet he is the creator.

Behold the believers of all faiths! Whom do they hate most? The man who breaks up their tablets of values, the breaker, the law-breaker — yet he is the creator.

The creator seeks companions, not corpses — and not herds or believers either. The creator seeks fellow-creators — those who grave new values on new law-tablets.

The creator seeks companions and fellow-reapers: for everything is ripe for the harvest with him. But he lacks the hundred sickles: so he plucks the ears of corn and is vexed.

The creator seeks companions, and such as know how to whet their sickles. They will be called destroyers, and despisers of good and evil. But they are the reapers and rejoicers.

Zarathustra seeks fellow-creators, fellow-reapers and fellow-rejoicers: what are herds and shepherds and corpses to him! …

I will sing my song to the lonesome and to the twosome; and to whoever who still has ears for the unheard, I will make his heart heavy with my happiness.

I make for my goal, I follow my course; over the loitering and tardy I will leap. Thus let my on-going be their down-going!

149. **mitchell porter**
November 26, 2007

Eliza, the initial criticisms have been borne out. You are not doing the guy any favors with your cut-and-paste.

"Better to know nothing than to half-know many things! Better to be a fool on your own account than a wise man in someone else's eyes!"

150. **Eliza**
November 26, 2007

Mitchell, I don't think it's appropriate at this point to dismiss Lisi out of hand. Clearly his theory is in its infancy; there is a great deal of work to do; and as long as he is working toward falsifiability, sensible people should reserve judgment.

And my primary object is not to do favors for Garrett Lisi. What brought the passage to mind was the hysterical vituperation of people like Lubos Motl who have attacked Garrett with the zeal of religious fanatics.

And it's interesting that you cast yourself in the role of the trodden one. You must have a very narrow window on the world of knowledge, for the man goes on to expand and extend his remarks:

"That, however, of which I am master and knower, is the brain of the leech:- that is my world!

How long have I investigated this one thing, the brain of the leech, so that here the slippery truth might no longer slip from me! Here is my domain!…

For the sake of this did I cast everything else aside, for the sake of this did everything else become indifferent to me; and close beside my knowledge lies my black ignorance."

Moving on, anyone who thinks that Lisi's publicity is "bad for physics" is grasping the wrong end of the stick. I think we can all agree that if he is right, Lisi will be a celebrity, and money will be flung at researchers from all directions for many years to come. There'll be tearing up the county building particle accelerators.

If his theory fails? There will be very little mention of it in the popular press. "Surfer Dude's Theory of Everything Proven Wrong": That's a dog-bites-man story, not big news. But even if it is reported, the public is sophisticated enough to understand that falsified theories are still valuable: they tell us what the answer is not. Even a child can understand that.

Most absurdly, someone has suggested that if Lisi fails to deliver after all the positive press coverage, the public will then lose faith in physics research. Baloney. Decade after decade string theorists give us nothing but fodder for sci-fi novels; and yet, thirty years on, every time they pass around the begging bowl the taxpayers obligingly fill it up. And the beauty of it is that they make no falsifiable predictions that can be tested, so they can carry on the flimflam until someone like Lisi comes along and reminds everybody what the meaning of a genuine scientific theory is. That's the real threat he poses.

The truth is that people don't expect a whole lot of progress from the physics community. They don't even mind the somewhat parasitic nature of the relationship. What they do want for their money is evidence of activity, a sense that scientists are enthusiastically working as hard as they can to move the ball down the field. Whether Lisi's theory soars or flops, he's given people a sense that physics deserves to be funded. We should all be grateful for that, even you, master of leeches.

151. **mitchell porter**
November 26, 2007

If only I *was* a master of Leech-branes!

I am only self-half-educated in these matters. But after its trial by fire, it seems clear that Lisi's theory has two big holes, generation structure and quantization, which would have to be fixed before one could ever set about "calculating the masses". Lubos Motl was right about this and that should be respected.

152. **Chris Oakley**
November 26, 2007

Eliza,

You do not give me the impression that you have actually done research in theoretical particle physics. If you had, you would know that group theory is the easy bit. If it is a question of fitting all the known particles into representations of groups then it can be done in a much simpler way than Lisi's. SU(5), the simplest unifying scheme, accommodates all the known particles neatly, the only problems – at least in representation theory terms – being that it predicts extra unobserved gauge particles and does not include gravity. Lisi's model is not a GUT, but the classification of particles in representations of a gauge group would appear to proceed in much the same way. But this group symmetry can only be approximate – the particles in each group representation have widely different masses in the real world, meaning that the symmetry can only be approximate and it is in the – currently – arbitrary and ugly breaking of the symmetry that most HEP theorists will quail (or, at least, ought to). I would be much more interested in researches that address this more difficult, and yet more important issue.

153. **Bee**
November 26, 2007

Eliza: *"Moving on, anyone who thinks that Lisi's publicity is "bad for physics" is grasping the wrong end of the stick. […] Most absurdly, someone has suggested that if Lisi fails to deliver after all the positive press coverage, the public will then lose faith in physics research."*

It wouldn't have been my choice of words, so it probably wasn't me who you are referring to, but let me comment on that anyhow. Its not specifically about Lisi, but generally there are three problems with such reporting.

For one, such reports are simply inaccurate and cause confusion that was avoidable. The world is already confusing enough, why do we have to make people believe a giant Mandela explains the elementary particles, or we've found another universe, if we can't be sure of it. And if we are not, can't we at least expect it to be reported on with an appropriate amount of caution, clarifying the amount of speculation?

Second, as it is, the public opinion about our research matters. One aspect of this is what you dismiss, namely that if this happens more often they will start wondering what kind of science it is that we do anyhow. Is is good for something? Science or Religion? Fact or Fiction? I mean, look, theoretical physicists DO already have a hard time getting funding because it's not immediately apparent what our work might be good for. Prematurely spreading reports of fabolous successes that then end up in the category 'what ever happened to' won't help. What is maybe worse is that the way Garrett's story was sold it says hey, the surfer dude can do it, who needs all these overpaid professors? You should have seen the amount of 'Theories of Everything' that I got send since that thing hit the headlines.

Third, such reporting influences the discussions and the opinion making process in our community. If you deny that, you are hopelessly naive. It's the topic of the week, it's what people talk about on the corridor. How many grad studs are out there, who are now dreaming of pulling off a similar show?

I find these trends very worrisome.

154. **Dany**
November 26, 2007

Eliza:" anyone who thinks that Lisi's publicity is "bad for physics" is grasping the wrong end of the stick".

AGL et al did a great job; not in the theoretical physics but for the theoretical physics. I think he deserves a prize and I would be pleased to see him laughing all his way to the bank.

Regards, Dany.

155. **TonyC**
November 26, 2007

>>> BEE: How many grad studs are out there, who are now dreaming of pulling off a similar show?

Ha! I am a PhD candidate (not physics), I don't know any of us that can be characterized as "studs". But the story is certainly corridor-worthy, and who doesn't dream of having some revolutionary insight into the workings of our field? I know 99% of papers are incremental (or no) progress, but I actually think that "hero" stories like this are good for us grad students, no matter if Lisi turns out to be prince or goat. Chances are worth taking and original ideas really can revolutionize a field. My advisor revolutionized his field about 12 years ago. This kind of stuff is inspiring. If I thought my career would be a long series of incremental progress and survey papers, I'd leave for industry tomorrow. And, at the risk of being chastised by HIGGS, doesn't Lisi at least contribute a clever way of sidestepping Coleman-Mandula?

156. **Bee**
November 26, 2007

Hi Tony:

Sure, we all dream of having revolutionary insights. That's not the point I was trying to make. The question is what is more relevant: having revolutionary insights. Or making everybody believe you have revolutionary insights? Sorry about the 'studs', I must have picked it up somewhere, I didn't mean it in a dismissive way.

Best,

B.

157. **Peter Woit**
November 26, 2007

All,

The comment section on this blog is becoming something I mostly don't want to read anymore, and I'm assuming that may also be the case for many other people. Please stop submitting off-topic, irrelevant, mis-informed, poorly thought-out, etc. comments. This is not a place to write in with whatever comes into your head. From now on I'll be deleting many more comments that aren't substantive and informative.

158. **H-I-G-G-S**
November 26, 2007

TonyC,

I won't chastise you, but the answer to your question about whether Lisi has contributed a clever way of side-stepping Coleman-Mandula is "no."

Lisi himself does not make this claim. On his web site
http://deferentialgeometry.org/ you will find a set of slides from talks he has given. At the bottom are extra slides including one labelled Coleman-Mandula. On that slide he says
"E8 Theory does not allow a subgroup locally isomorphic to the Poincaré group. The S matrix exists as an approximation, in which the theorem is satisfied." What this means in plain english, and in terms of physics, is actually explained quite clearly on Lubos Motl's post on this if you can ignore the ranting. Briefly, in a theory with a cosmological constant there is no S-matrix. Coleman-Mandula is a theorem about symmetries of the S-matrix. So, no S-matrix, no theorem. But this fact is only relevant if you are doing scattering experiments on scales the size of the universe. At Fermilab, or the LHC or in any conceivable experiment you can treat space as flat to an extremely good precision. There is then an S-matrix that experimentalists measure. It obeys the Coleman-Mandula theorem. Lisi does not provide an exception.

Peter,

The above is on topic, but this comment is slightly off topic. I hope that pissed you off because your last "update" on this topic pissed me off. The link provides a "sociological" critique of Distler's analysis, not a mathematical or physical one. You might mention that, you know, just for clarity and fairness and to show you are such a mensch. Distler can be condescending and bristly, but he got the math and the physics right. You didn't, and neither did Lisi. And anyway, compared to Pauli, the author of the quote that provides the title of your blog, Distler is a pussycat. Maybe you should start criticizing Pauli for being such a jerk. Or maybe you see that criticizing Distler for being difficult while wanting to model your skepticism after that of Pauli's is exhibiting just a wee bit of hypocrisy.

159. **Peter Woit**
November 26, 2007

H-I-G-G-S:

First of all, I don't model myself in any way after Wolfgang Pauli. I'm just borrowing his phrase.

I linked to Distler's posting because, yes, he did have a worthwhile discussion of some of the group theory involved. The fact that Garrett responded to this intelligently and politely led to an exchange that was valuable for anyone to read who wanted to understand what is going on in Garrett's paper.

I also think though that the "sociological" discussion is highly relevant. There is absolutely no reason for Distler to behave in the juvenile way that he does. He's an adult, middle-aged man and should behave like a grown-up and like a professional. If he doesn't understand this, others need to point this out to him.

If you don't think this is a problem, that his behavior is acceptable, and mine is what you want to criticize from behind anonymity, that's your choice. I have no idea who you are: for all I know you're a high school student too young to understand what mature behavior is. If you're actually an adult professional though, and you are in the field of string theory/particle theory, you might want to consider what effect he and Lubos are having on the perception of people in that field by outsiders. Smolin got a lot of criticism for some of the comments in his book about the behavioral characteristics of some theorists (I avoided this topic in mine), but Jacques and Lubos make it look as if he was far too kind.

Go back and read carefully the posting I linked to. The person who wrote it I think does a good job of describing what this looks like to outsiders. They can't understand the group theory, but they can understand the significance of this kind of juvenile behavior.

160. **dr**
November 27, 2007

Peter,

"Detail"?!?

H-I-G-G-S,

People who have scientific arguments talk about science.
People who don't have scientific arguments talk about good manners.

You decide who between Distler and Woit/AngryPhys falls in which category.

161. **a.k.**
November 27, 2007

..I still have to correct my above remark concerning the 'non-product' structure of the embedding discussed, this of course applies only to the 'triality'-part of the embedding. From my point of view, at least by inspecting the triality-part of F4 and its specific Lie-Algebra-structure (see Baez' week 90) a given connection on E8 should reduce to any of the obvious 'subgroups' R in the triality part, given the E8-bundle reduces to them, but this should depend on the base manifold, imposing a condition (allowing sections in a E8/R-bundle). My hypothesis, of course, is that these facts are at least necessary to get 'predictions'.

162. **Chris W.**
November 30, 2007

Public Radio International's *The World* did a story tonight on Garrett Lisi's work. It includes an interview with Marcus du Sautoy (Oxford).

163. **Yousuf**
December 2, 2007

Hi Garrett, just wondering, was the fact that the E8 structure was just recently solved earlier this year by [mathematicians]() in any way related to the decision to use it as your model here? What I'm asking was if the E8 mathematics hadn't been solved earlier, would you still be able to come up with this physics theory?

164. **Peter Woit**
December 2, 2007

Yousuf,

The mathematical result earlier this year about E8 has nothing to do with the way Garrett is using it, they're two quite different things.

165. **Yousuf**
December 3, 2007

> The mathematical result earlier this year about E8 has nothing to do with the way Garrett is using it, they're two quite different things.

Hi Peter, thanks for clearing that up for me. I was a little curious, considering how coincidental the two announcements to do with E8 were with each other (i.e. well within a year of each other).

On another note, I was in the middle of reading your book *Not Even Wrong*, when this story broke. So I stopped reading the book to see what all the E8 hubbub was about. Ironically, when I got back to the bookmarked chapter, I found you were talking about some of the BRST and Coleman-Mandula theorems that are considered controversial about this theory. Just love these ironies and coincidences.

166. **mitchell porter**
December 7, 2007

Lee Smolin has a new paper ([arxiv:0712.0977]()) on Lisi-like theories in which he says:

"We close the introduction by noting that the well-known Coleman-Mandula no-go theorem is avoided because that only applies to an S-Matrix whose symmetries include global Poincare invariance. This theory, like general relativity, has no global symmetries, the Poincare symmetry acts only on the ground state not the action, and only in the limit in which the cosmological constant is zero. In fact, there is a nonzero cosmological constant, as it is related to parameters of the theory. By the time the S matrix in Minkowski spacetime could be defined in this theory one will be studying only small perturbations of a ground state in a certain limit and the symmetry will only apply in that limit and approximation. As we shall see below, the symmetry will already be broken by the time that approximation and limit are defined, in such a way that Coleman-Mandula theorem could be satisfied in its domain of applicability."

It has already been observed in a number of places that the Coleman-Mandula theorem has generalizations, and so one should not expect a slight deviation from Poincare symmetry to make much difference. It also seems to be true that the action actually advanced in Garrett's paper *can* be quantized without a problem, because most of the notional E8 symmetry is broken by hand, and the actual, residual symmetry is something far more mundane. This remark by Lee Smolin seems to segue between both of these 'reasons why Coleman-Mandula doesn't apply': we start out with the claim that global features make CM irrelevant, and then we are told that by the time we can actually calculate something, the symmetry will have been broken to harmlessness anyway. Call these the 'argument from global properties' and the 'argument from de facto symmetry breaking'.

My questions –

Is the argument from global properties (that CM is irrelevant to a certain class of theories, that a novel loophole exists) valid or not?

Is there any logical connection between that argument and the argument from de facto symmetry breaking?

I intend to go away and try to answer these questions for myself, but I know there are far more knowledgeable people reading.

167. **Thomas Larsson**
December 7, 2007

It will be interesting to see what Motl and Distler will make out of Smolin's paper. I bet they will be unimpressed.

Without being up to date about the fine print of the CM theorem, I am very suspicious of the idea that a bosonic operator can change a fermionic state into a bosonic one or vice versa. This seems to be the case with Lisi's paper, if he puts bosons and fermions into the same multiplet of a bosonic Lie group.

168. **Sara**
December 19, 2007

Can a theory of everything be "exceptionally simple"?

169. **mitchell porter**
December 19, 2007

The paper's title is a pun on the mathematical nomenclature; E8 is an "exceptional" "simple" group, *simple* meaning that it lacks a certain type of internal structure, and *exceptional* meaning that it's one of a handful of simple groups which fall outside the infinite families to which all the others belong. I suppose it's also a reference to the unified theories of recent decades; Lisi wants to do without unverified innovations like supersymmetry and extra dimensions.

A theory of everything can be simple, so long as its implications are sufficiently complex. Since most things that exist are regarded as already explained by existing physics, for most physicists the attempt to explain "everything" reduces to explaining, or at least completing, the existing fundamental theories. Everything else is just applied science and historical contingency.

170. **Sara**
December 19, 2007

Thank you Mitchell for your answer! It's a very clear explanation.

Popularizing Science

November 12, 2007
Categories: Uncategorized

While it's not one of my main goals in life, I'm all in favor of the idea of popularizing science and making it as accessible as possible to as many people as possible. But sometimes I do wonder about the kind of things scientists get involved with when they try and do this. Just this morning I ran into these stories about science that make me ask myself:

- Is it a good idea for physicists to appear on a radio show discussing what happened before the big bang, or does the lack of any evidence about this or of a convincing model mean that this is just inherently too speculative a topic to be sold as serious science to a wide audience? Should one perhaps leave this topic to the Bogdanovs?
- Is it a good idea for physicists to promote to the public their work on time travel? Or might this also give the public some misleading ideas about science? (via i postdoc, therefore I am, but there seems to be a whole genre of "time travel" books written by theoretical physicists).
- Is it a good idea for physicists to appear on a TV show explaining the forces involved in crushing beer cans, as part of a segment on whether women can crush beer cans with their breasts? Especially physicist bloggers known for attacking other physicist bloggers for their sexism and media-inflated nonsense? (via here and here)

Comments

1. **anon.**
   November 12, 2007

   'Is it a good idea for physicists to appear on a TV show explaining the forces involved in crushing beer cans, as part of a segment on whether women can crush beer cans with their breasts? Especially physicist bloggers known for attacking other physicist bloggers for their sexism and media-inflated nonsense? (via here and here).'

   The third link doesn't seem to work? It goes to a page with videos like 'How tiny can a G-String be before it becomes illegal?'

   This seems to be related to issues of string theory, seeing that the strings of string theory have zero width.

   Is the illegality of a G-string a metaphor for the illegality of string theory when promoted as being a scientific theory?

2. **Jonathan Vos Post**
   November 12, 2007

   You fool! You've given away the secret that women crushing beer cans with their breasts leads to time travel to before the Big Bang.

   Of course, that's because aluminum beer cans filled with virtual squids become gravity wave detectors, as the Joseph Weber/Bob Forward gravity-wave detection apparatus of 1969 was enhanced by SQUID detectors, as Hawking and Thorne deduced when Forward tunneled to an alternate universe where he was a best-selling Science Fiction author…

   The g-string hotlink had to be disabled, else your readers would Know Too Much about Bikini Atoll.

   Oh, wait a minute. So long as your audience is sure that we are joking, then we don't have to kill you. Which is good, because we think you can be useful in fighting the invaders from E8.

3. **Coin**
   November 12, 2007

   On points one and two, I would say that the answer is sure, as long as the physicists in question are unambiguous about exactly how speculative their responses are. People are always more interested in hearing about bleeding-edge speculative stuff than they are in hearing about stuff that already works– once something is understood it's no longer "news". Focusing on such speculations can even (if done carefully) advance "normal" science literacy, since once the "hook" of the speculative science is in place this can be used as an excuse to feed the listener some "normal" science to explain how the speculative science works. It's like getting the dog to swallow a pill by wrapping it in bacon.

   The case of Dr. Mallett in specific however maybe should count as an exception considering that there are so many basic unanswered criticisms of his work out there that I don't think he *could* accurately present the extent to which his work is speculative, short of actually saying "this is science fiction". Still I guess this too would be a matter of how it is presented. "If you can get me a naked singularity or a fiber-optic cable of infinite length, I can build you a time machine" would be a legitimate and interesting pop-science way of presenting this work, I guess, but leaving out those little details would seem to constitute dishonesty. I don't know what tack was taken in the article because no hablo alemán.

   I have no comment on point three.

4. **Peter Woit**
   November 12, 2007

   Coin,

   One problem is that I've never once seen a physicist discussing highly speculative work in the media accurately explain how speculative it was. Even if people do make disclaimers like this to reporters, that's the kind of thing that ends up getting cut in whatever appears.

   Sure, many people would rather hear about science fiction than science (no, not all people are this way, some actually like the real thing…). The problem with feeding them science wrapped in science fiction is that they ignore the science and pay attention only to the tasty science fiction morsel they are being encouraged to pay attention to. And they then end up unable to tell the difference between science and science fiction.

5. **dragon**
   November 12, 2007

   Comparing Carroll, Steinhardt, Khoury, and Brandenberger with the Bogdanovs doesn't really do a lot for your own credibility. In fact it looks very much like the kind of thing that Lubos Motl would say.

6. **a quantum diaries survivor**
   November 13, 2007

Hi Peter,

indeed, good question your #3. I think we can forgive Clifford for having been fooled a little by the soft porn business – his goals were commendable, and he does not seem to bother much if I read him correctly in his blog.

I think Clifford's will to appear on a TV show for guys way offset a critical assessment of the use they were likely to make of his good science explanations.

Cheers,
T.

7. **milkshake**
November 13, 2007

I am all for further elucidating the breast-crushing forces acting on a beer can. Unlike the two previous examples, it is all a healthy fun and no laymen are being blinded by science in the process.

8. **anon.**
November 13, 2007

'Comparing Carroll, Steinhardt, Khoury, and Brandenberger with the Bogdanovs doesn't really do a lot for your own credibility. In fact it looks very much like the kind of thing that Lubos Motl would say.' – dragon

Dragon, your comparison here of PW to LM doesn't really do very much for your credibility either! The Bogdanov's come into this for their book, *Before the Big bang*. BTW, Professor Ernest Sternglass of Uni. Pittsburgh has a similarly titled book, which is more exciting as it contains lengthy discussions of Sternglass' meetings with Albert Einstein who advised him to 'be stubborn' and with R. P. Feynman; who blew his top when Sternglass admitted he hadn't bothered to completely work out the consequences of his theory before trying to get interest in it.

9. **moron**
November 13, 2007

While it's not one of my main goals in life, I'm all in favor of the idea of popularizing science

That's good, because you've done nothing but accomplish the exact opposite: **un**popularizing science (and popularizing un-science.)

10. **anon.**
November 13, 2007

moron, you merely disagree with the following *definition* of science:

'Science is the organized skepticism in the reliability of expert opinion.' – Feynman.

(Smolin quotes that on p307 of the US edition of his latest book.)

Your attitude is very much in the Ptolemic mindset: that anyone asking being critical about mainstream so-called 'science' is doing a disservice to science, rather than the *exact opposite*. (Guess we'll just have to politely agree to disagree on this one … if you know how to behave.)

11. **Anders R**
November 13, 2007

un-science?

12. **Richard Feynman**
November 13, 2007

'Science is the organized skepticism in the reliability of expert opinion.' – Feynman.

Thank God someone, after all these years, **finally** interpreted my quote correctly!

Yes, indeed, "anon." is right (though Heaven knows why he would want to remain anonymous and forego having such brilliant insights attributed to him):

I meant to say, "Science is the organized credulity towards the reliability of fraud-and-crackpot opinion. The mark of a great scientific idea is a complete lack of any comprehensible relation to what many others have successfully done before." In fact, I would specifically have mentioned loop quantum gravity as the apotheosis of great scientific thinking, but I was too jealous to give them their rightful place in the sun. After all, when inventing quantum electrodynamics, I foolishly relied on the so-called "expert" opinion that said any new theory describing the interaction of charged matter with light would have to be tied down to the moribund ideas of such so-called "experts" as Einstein, Dirac, and Maxwell who claimed — **without any evidence or logic whatsoever** — that relativity, quantum mechanics, and classical electrodynamics would all have to be applicable in the appropriate regimes of validity.

If only I had been a true "seer" like Lee Smolin, who wisely dispensed with such garbage!
, and a stern refusal to ground one's work in the

13. **dagon**
November 13, 2007

"Comparing Carroll, Steinhardt, Khoury, and Brandenberger with the Bogdanovs doesn't really do a lot for your own credibility. In fact it looks very much like the kind of thing that Lubos Motl would say."

Anon, Dragon,

Indeed, it's quite misleading (and dishonest) to lump Carroll, Steinhardt, Khoury and Brandenberger in with the Bogdanovs. They are all serious and well-respected scientists and the post made no effort to distinguish between these kinds of scientists and the Bogdanovs. Anon, you may argue that the connection is simply the title of the book but I think that the innuendo of the post is quite clear and very insulting.

14. **Peter Woit**
November 13, 2007

dragon/dagon,

I'm well aware of the difference between Carroll, et al. and the Bogdanovs and was not saying that they are the same. But I'll stick to what I did say: until there is some relevant data or a convincing model for physics before the big bang, serious scientists should avoid going to the popular media to promote their extremely speculative work in this area. When they do this, I don't think they help the cause of science, but blur the distinction in people's minds between real science and its Bogdanovian varieties.

15. **Peter Woit**
November 13, 2007

moron/Richard Feynman,

Sorry to see that some of your anti-Lee Smolin rant got cut off by the blog software.

I don't think "science" is in any danger of being "unpopularized" by anything either Smolin or I have done. What is in danger of being "unpopularized" is a specific subfield of science. To the extent that is actually happening it's less due to me and Smolin than to the behavior of people like yourself, who from the most illustrious and respected research institutions in the world, post idiotic comments here using stupid pseudonyms to remain anonymous and avoid taking any responsibility for their own behavior. Between this kind of thing, Lubos Motl, Lenny Susskind and the widespread promotion of anthropic pseudo-science, yes, a previously respected sub-field of science is in real danger of being "unpopularized".

16. **fh**
November 13, 2007

It should exactly NOT be left to the Bogdanovs! To the laymen it is at first glance not obvious that the Bogdanovs are crackpot, if we say serious scientists shouldn't dabble in this speculative realms we leave them precisely to these people who are certainly not going to bother to infuse their presentations with caveats or down to earth science.

17. **Peter Woit**
November 13, 2007

fh,

Again, the problem I see is that serious scientists who go to the public with this kind of material just are not bothering to include appropriate caveats.

18. **moroner**
November 13, 2007

>un-science?<

maybe he means string theory?

19. **Anonymous**
November 13, 2007

Oh please make them stop! It makes one's job so much harder, obligating one to first unteach one's students the nonsense Kaku and his ilk spew on the media. I am disappointed in some of the new names who have joined that club.

I have a non-scientist friend who is truly interested in Physics. He reads popular articles and spends time trying to understand the ideas behind them. Every time I see him, he mentions some article he read about the latest in multiverses or whatnot, and I find myself in the unenviable position of having to declare his hard-earned insights illusory. For what they do to people like him, these pseudophysicists should share a special circle of hell with charlatan preachers and quacks.

20. **Bee**
November 13, 2007

I know I've said it before, but I want to repeat it again. This is not a problem that emerges in the scientific community, but just a reflection of a general sociological trend. If anything, it is surprising how long it took the popularity-drug to get into the ivory tower. It is worrisome though that even though dangers of these developments are immediately apparent, little people are able or willing to do something about it. Writing a blog post like this is better than nothing – at least it raises awareness for the issue – but on the long run it's not going to be sufficient.

21. **Bee**
November 13, 2007

oh, and if somebody could please let me know how one 'unpopularizes' things, I'd really like to hear. There's this immortal believe around that Einstein was wrong (with whatever), I'd really like to unpopularize that because my spam filter doesn't catch most of such crap and it's somewhat annoying. Thanks, B.

22. **Anonymous Person (AP)**
November 13, 2007

We should all grow up a little on all sides. If you are going to embarrass yourself on TV, then get paid for it! This idea that you are 'popularizing' science when you go on TV is naive. You are advertising science. That is what is happening.

Second, for those thinking that the public having an incorrect assumption about your silly little subject is somehow of paramount importance, it's really not. It has no practical importance really. The idea is to have people continuing to give money to support scientific causes. The reasons they might be doing this, whether it's because of extra universes or time machines or whatever is totally besides the point.

Please all of you who are advertising science, continue to expand the pool of money I have available to me! (Sing for my supper?)

23. **Peter Woit**
November 13, 2007

AP,

I agree that it probably is best to conceptualize what people are doing as "advertising" rather than "popularizing" their work, since the emphasis is typically more on selling the product than on explaining its features. My concern is that the sales tactics being used are ruining the brand, with possible future consumer backlash, or even intervention from the Federal Trade Commission…

24. **Kea**
November 13, 2007

Doesn't sound scientific to me. Heh, I'm muscular and buxom, but I don't believe I have such physical capabilities….

25. **Anonymnous**
November 13, 2007

"Second, for those thinking that the public having an incorrect assumption about your silly little subject is somehow of paramount importance, it's really not. It has no practical importance really. The idea is to have people continuing to give money to support scientific causes. The reasons they might be doing this, whether it's because of extra universes or time machines or whatever is totally besides the point." – AP

This kind of attitude might be expected from a politician or televangelist. My layman friend does care to know something fact-based about the way the universe works. If I understand you correctly, you are just too happy to reap personal profit, even if indirectly, from his being misled and lied to.

26. **dagon**
November 13, 2007

Peter,

"I'm well aware of the difference between Carroll, et al. and the Bogdanovs and was not saying that they are the same. "

That's a little like arguing that Bush never claimed that there was a connection between 9-11 and Iraq. Maybe you didn't explicitly say it but it's clear from the post that you intended to paint them all with the same brush. I was just trying to point out that doing so is extremely non-collegial. Moreover, I'm not sure it does a great deal of good for the lay-public to intentionally try to blur the lines between serious physicists like Carroll et al. and crackpots like the Bogdanovs.

27. **Peter Woit**
November 13, 2007

dagon,

You're intent on attacking me personally, based on things I did not write, do not think, and do not believe that any reasonable person would interpret my words as meaning. If you want to argue with what I actually did write, go ahead, but anonymous attacks based on accusations of insinuations that exist only in your mind are pretty sleazy behavior.

28. **zorba**
November 13, 2007

I think that a "reasonable person" would interpret

"this is just inherently too speculative a topic to be sold as serious science to a wide audience? Should one perhaps leave this topic to the Bogdanovs? "

as meaning [a] this is not "serious" science, and that [b] "this topic" is for crackpots. What other interpretation is possible? Did you really want to say , "when I say "sold as serious science", I don't mean that it isn't serious science, I just mean that, whatever it is, it should not be *sold* as serious science, even if it is serious science. Furthermore, when I say "this topic" I don't really mean work on early universe physics, what I really mean is…..umm…. something else….."
Oh. I see.

Your subsequent "When they do this, I don't think they help the cause of science, but blur the distinction in people's minds between real science and its Bogdanovian varieties."

doesn't really do much for me. Basically the show presented four competing views of the subject, which should tell any sensible layman that there is no consensus. There is not even a faint resemblance between the work of these gentlemen and bogdanovology, and the fact that you think that there is room for such a misunderstanding says more about your prejudices than about the subject.

In a word, I think an apology is called for. Do you really want to be a party to the descent of the blogosphere into a place where people's scientific work is exposed to this kind of unprovoked attack?

Even shorter: not one of your better posts.

29. **Tom Whicker**
November 13, 2007

Take Brian Greene's The Elegant Universe (video) as a prime example. It goes on for about two hours and never makes a single
coherent statement. The production is over the top, (do over saturated colors help young minds comprehend?)…
with Greene posing as a physicist of some type. No real content,
just the same meaningless analogies of Ants crawling around a
long steel cable;this to show the nature of compacted dimensions. And then Greene (Moulder) sits in the Quantum Cafe and keeps getting the wrong color Colada. This is supposed to mean something about quantum theory…..

And the voice-over just keeps re-introducing the opening premise "Could this be the Theory of Everything?!" I was reminded of the same technique used in the Von Daniken diatribes where the voice over uses the same technique of using a question to imply a non-substantiated premise, "Could this be the Work of
Ancient Aliens?!"

In the realm of Popularizing Science this was as big as it gets, and it delivered the equivalent of junk food to a starving world.

Maybe some of you actually know Greene and know what he thought of the final product. Maybe he's embarrassed. Maybe
PBS left all the real content on the cutting room floor. Where
was Scully when we needed her? So many questions…

30. **Tim May**
November 13, 2007

I think I'm older than most of you here (55, almost 56).

I grew up with a strong diet of popular science, from dubious sources in the 1950s and early 60s like "Popular Science," "Popular Mechanics," and even "Science News" (sort of the "New Scientist" of its day). And from a lot of science fiction and "Gee Whiz" science advocacy. Picture books on astronomy, the "All About" books on science, even "Topm Swift." And the classics of SF. Lunar bases, the drawings of Chesley Bonestell, the fantasies of Willy Ley, Heinlein, Clarke, Asimov, etc.

Yeah, science fiction played a big role in my life back then, but I clearly knew that things like the Moebius strip wall in one of Clarke's short stories was just SF, even as it helped motivate me to read Martin Gardner's articles on topology and Moebius strips. Cool stuff for a 13-year-old. (I'll bet most of you were similarly inspired, albeit in varying ways.) I'll bet that some 13-year-olds today are reading Lisa Randall's articles about colliding superbranes and getting interested in science….I just think that in the next 10-15 years they'll get past any initial biases and will become (some of them) full-fledged scientists. No harm done.

By the mid-60s, by the time I was about 12-14, I could separate the wishful thinking from the reality. Still, it was really, really cool (a technical word of our generation 🙂) to read about antimatter from Dirac's little mongraph on "Matter and Antimatter," which I spent my allowance on in 1966, even as "Star Trek" was beginning to air episodes where it figured in. And to read about such highly-speculative things as wormholes (via John Wheeler's articles, and recountings of his articles, circa 1968-69).

And who can forget the January 1970 cover of "Physics Today," with its famous depiction of a black hole bending spacetime? (I think that was the month….)

And so on, for Everett-Wheeler-Dewitt speculations about many worlds….

I think physicists learn to separate what is real or remotely possible from what is implausible. The "cool" stuff is a motivator–I think even for many of you folks here–but there's not too much danger that the pseudoscience will take over.

Or so I think. Believe me, there was a constant barrage of unproven or speculative or pseudoscientific cruft when I was a kid, from antigravity machines to time machines to Unified Field Theory. I don't think much harm was done to the public's interest in funding science. At least not back then.

(Maybe today's voters are less inclined to fund the next generation of atom smashers. Can't say as I blame them. But not because they got exposed to pseudoscience.)

Meanwhile, some of the speculative stuff probably is helping to draw in a whole new generation of young physicists, who will learn quickly enough the difference between pure fantasy, the speculative but possible, and the safe path of conformity.

I just don't think there's much risk that speculative science will actually mislead anyone capable of critical thought, at least not past their teenaged years.

Interesting topic.

–Tim May

31. **Peter Woit**
November 13, 2007

zorba,

Again, from behind the cover of anonymity, you're attacking me by making up things I never wrote or thought and that are not reasonable interpretations of what I did write. I'm not going to apologize for stupid things you or anyone else choose to make up. I'll stand behind what I did actually write.

Tom Whicker,

I'm not a big fan of "The Elegant Universe" TV show, for reasons that are much the same as my concern about radio programs on "Before the Big Bang". Highly speculative research with not a shred of experimental backing or other compelling evidence that it is correct just does not seem to me to be an appropriate topic for radio or TV shows aimed at very wide audiences.

And please just stop it with the hostility about things like the production values and other characteristics of Brian Greene's TV show. That's not relevant to the issue at hand. I don't question the dedication of Brian or the people on the CBC radio show to their science, their professionalism, or the sincerity of their desire to share with the public their enthusiasm for what they are working on. I just question whether such programs are really a good idea, for reasons that I have repeatedly explained.

32. **Peter Woit**
November 13, 2007

Tim,

Thanks for your comments. I think you're right that these things do play a role in inspiring some people, and that's the best argument for them. But that's only one side of the story and I think the other less positive side deserves some consideration.

33. **Tim May**
November 13, 2007

I agree Peter, and have been reading your blog for a couple of years now. (I only decided to start making a few comments when I felt I would not make a complete fool of myself in areas I know little of.)

I thought Brian Greene's 2-hour "Elegant Universe" special was pretty vague, with not much attention given to "But why do we think it's a plausible model?" sorts of considerations, but was not all that damaging.

It takes a fair amount of sophistication to understand the criticisms you and Lee Smolin make. (I really appreciated Lee Smolin's fairly even-handed treatment in "Three Roads to Quantum Gravity." His recent book was not so much to my liking, not because I'm a string theory proponent but for other reasons, too complicated to get into right here.)

You guys, and others, and the weight of a lot of non-evidence, have done a lot to shift the debate from "String theory must be right–it's just too beautiful to be wrong!" (my phrasing) to "Show me the money!" (someone else's phrasing).

Science is not a popularity contest, as many here have noted, but neither is it a "annointed by public acclaim" contest, which string theory was largely the benefit of during a certain period, roughly 1986-2003.

Me, I'm skeptical of any current theories. I expect a theory unifying gravity and the ultrasmall comes only when we can start to (experimentally, or observationally) probe scales a whole lot closer to the Planck scale than anything we'll see in our lifetimes or the lifetimes of our great-great-great-great-great-grandchildren.

I'd love to be wrong on this.

–Tim May

34. **Aaron Bergman**
November 13, 2007

Brian Greene's TV show is worth it if only for the best thing ever written about string theory.

More seriously, I understand the frustration one feels about the popularization of science. But what is the alternative? People are going to be excited about their work. Some of the best people are those who absolutely believe that what they're working on is the right thing to be working on. If we're going to be popularizing science, isn't that excitement what we should be showing. Caveats are great and all that, but who remembers those things in the end? Not only that, but should we start censoring those people who aren't sufficiently cautious in their public statements? Is Smolin OK but Greene not? Kaku but not Maguejio? You? There are going to be books. Many of them are going to make people like, say, me unhappy. But, really, if it gets people interested in science, it probably works out for the best in the end.

35. **Tom Whicker**
November 13, 2007

Peter,
Sorry if I sounded hostile to Brian Greene. Just my poor attempt at humor. The Elegant Universe is a bit personal for me, as I was
asked to host a showing of it to local science teachers. It is rare for such local people to show interest in Physics, and I was excited about the event (I hadn't seen the film at that point).
From their reactions and my lowly viewpoint, the film was just a
waste. I think it helped re-enforce some attitudes in group
along the lines of "why does our tax money go into this kind of stuff?"

36. **Tim May**
November 13, 2007

And I think the views of tax payers, about "why does our tax money go into this kind of stuff?" are valid concerns.

Fifty, or even 40, years ago the dollars spent on new accelerators like the Bevatron or the Brookhaven AGS, or even Fermilab, were not quite so huge as they are today.

And the money spent then, and especially in the decades earlier, had some practical consequences: figuring out how to build the A-bomb, to be blunt. So the public supported it, even if after the fact (secrecy and all).

Around the time of the Superconducting Supercollider, it could no longer be argued that building the world's largest accelerator was in and of itself justified. And so it was cancelled. Much talk about how a generation of theorist would wander in the desert (pun about the energy desert intented).

Look, I'm all for basic science. I would love to see the nature of the universe further explicated. But, let's face it, the cost of each 10x increase in energy (luminosity is another factor) is growing at rates that are unaffordable.

Unaffordable unless the new accelerator is likely to solve the problem of the Germans or the Japanese or the Russians (figuratively speaking, to go back to prior justifications).

No one is suggesting new understandings of energy sources, or of weapons, and there is every suggestion that basic understandings are now coming at, perhaps, 100-1000x increases in energy, not the 10x increases in energy (give or take) so common in the 1930s-1970s.

I sort of was opposed to the Hubble. But having seen what it has shown, along with several other comparably-priced telescopes, I'm now much more in support of these kinds of things.

I hope I'm wrong. I hope the LHC discovers one or more important particles. I fear I won't be wrong. Check back in several years.

And I doubt the taxpayers will authorize a 10 times more expensive generation after the LHC to keep on searching. At least not for a long while.

–Tim May

37. **Tom Whicker**
November 14, 2007

If we're talking about something in the current media/print world
that does popularize Science in a successful way to the average
person, I have to say Mythbusters is it. That show probably has
the right approach to interest some young kids in how science works (or used to work).

38. **Aaron Bergman**
November 14, 2007

I love Mythbusters. Explosions are cool. But there's a lot more to science, too. *The Elegant Universe* has apparently sold over a million copies, so people seem to have been interested.

39. **Tom Whicker**
November 14, 2007

They do get carried away with explosions. But they've done a wide variety of stuff like de-bunking free energy machines, etc. Often there is a nice lesson on thermodynamics, laws of motion, etc. If the general public could just get a tiny grip on basic conservation of energy concepts, it would be a good thing…

40. **zorba**
November 14, 2007

I said: " Do you really want to be a party to the descent of the blogosphere into a place where people's scientific work is exposed to this kind of unprovoked attack? "

I think I have my answer.

Alternatively, if you genuinely can't understand why "Should one perhaps leave this topic to the Bogdanovs? " is deeply insulting, then maybe you need to get away from the blogosphere for a while.

41. **Peter Woit**
November 14, 2007

zorba,

You continue to wilfully misinterpret what I wrote, which very clearly was not an "unprovoked attack" on anyone's scientific work. My only comment about the science was the uncontroversial one that there is no experimental evidence or convincing model for pre-big bang scenarios. My posting was not about science but about the advisability of media appearances by scientists.

42. **Peter Woit**
November 14, 2007

Aaron,

No one is suggesting censoring anyone. But I think it's worthwhile to raise this issue, and encourage people who go to the media to keep it in mind. Not every appearance by a physicist on a radio or TV show is a good thing for science.

43. **Jonathan Vos Post**
November 14, 2007

I basically agree with Tim May's first comment:

"… the drawings of Chesley Bonestell, the fantasies of Willy Ley, Heinlein, Clarke, Asimov, etc. Yeah, science fiction played a big role in my life back then, but I clearly knew that things like the Moebius strip wall in one of Clarke's short stories was just SF, even as it helped motivate me to read Martin Gardner's articles on topology and Moebius strips…"

Seeing the phosphorescent murals of Chesley Bonestell at New York's Hayden Planetarium and Museum of Natural History powerfully motivated me, as did climbing around on the Willammette meteorite.

I saw Willy Ley live, and he was an amazing speaker, as well as writer. Heinlein was a de facto Engineer, who did Defense research, although he always deferred to his 2nd wife Virginia as a better engineer. Sir Arthur C. Clarke did hands-on Electrical Engineering in developing radar for landing planes in foggy England during World War II (as described in his most autobiographical novel, Glide Path). Isaac Asimov was a Professor of Biochemistry.

These great men knew what Science, math, and Engineering were about. They intentionally, didactically, wrote on these subjects in fiction and nonfiction, explicitly to motivate people (especially youth) beyond the ability of most public schools. heinlein's "juveniles" (today called "young adult") made him less money than novels for adults, as his agent kept telling him. But Heinlein explicitly stated that he wanted to push enough young people into science and engineering and math that they would actually create the Space Program he longed for.

Half of all the astronauts and other technical people I worked with for 20 years in the Space program cited Asimov, Clarke, and Heinlein as early motivators. They also cited Bradbury, although they knew his work lacked science content as such.

It's sad that we've lost Asimov and Heinlein. They were, in many ways, irreplaceable. It's wonderful that Bradbury and Clarke are still alive and working. I'm honored to have been in contact, and sometimes coauthorship, coeditorship, cobroadcasting, with all of these.

But "the media" have never been clear on the fuzzy boundary between Science and Science Fiction. What got me on the NBC-TV Today Show, live to 10,000,000 people, was a pitch to contrast what Science and Science Fiction say about the Space Program. It was cool that they let me bring Isaac Asimov on as my "guest of guest."

I strongly agree with Peter Woit that "the media" seem increasingly unclear, increasingly distracted by coloful graphics, decreasingly interested in meaningful content.

Fortunately, we have the World Wide Web.

44. **Belizean**
November 14, 2007

Q. "Is it a good idea for physicists to appear on a radio show discussing what happened before the big bang…?"

A. Yes. As long the the physicists give the correct answer: "We have no idea what happened before the BB and aren't even sure that the question makes sense."

Q, "Is it a good idea for physicists to promote to the public their work on time travel?"

A. Yes. Whether physics permits time travel is a profound conceptual issue irrespective of the negligibly small number of physicists actively considering this question. A responsible popularizer should present the arguments in flavor of time travel (solutions to the Einstein equations featuring high angular momentum densities that result closed time-like curves), and arguments against (paradoxes, destructive feedback loop of virtual particles), AND point out that this question is generally ignored by the overwhelming majority of working theoretical physicists. [In the case of Ron Mallett, it's clear that what he's attempting is *in principle* probably not absurd (given van Stockum/Tipler). The questions is whether he can *in practice* achieve sufficiently high angular momentum densities using current technology.]

Q. "Is it a good idea for physicists to appear on a TV show explaining the forces involved in crushing beer cans, as part of a segment on whether women can crush beer cans with their breasts?"

A. No. Physicists should acquire sufficient media savvy to distinguish between producers genuinely interested in increasing public understanding of physics and those with other agendas.

45. **YBM**
November 14, 2007

Did you notice this ?

http://www4.fnac.com/Shelf/article.aspx?PRID=2062733&OrderInSession=1&Mn=1&SID=902a4926-8ace-0979-afa2-d9686866e4f3&TTL=091120070052&Origin=FnacAff&Ra=-1&To=0&Nu=1&UID=073768ffc-07a4-5f27-f209-6d31e8c5f43c&Fr=0

I didn't know Lubos was writing in french, or that he was about to support the worst cranks of all times (especially given that they are loud opponents of string theory) :

"L'équation Bogdanov"
Author: Lubos Motl
Forewords: Igor Bogdanoff, Grichka Bogdanoff
Publisher Presses De La Renaissance (a very cranky one !)
Date janvier 2008
ISBN 2750903866

46. **woit**
November 14, 2007

YBM,

Thanks for pointing that out. I'll be in Paris for a while in January, maybe can pick up a copy…

Lubos has often defended the Bogdanovs in the past, I suspect mainly on the grounds that John Baez and I were critical of them, so they must be all right. I wonder what the story of this book is, if Lubos even wrote much of it himself (I don't think he writes French, perhaps he had help from the writers of the foreword).

47. **anon.**
November 14, 2007

'Doesn't sound scientific to me. Heh, I'm muscular and buxom, but I don't believe I have such physical capabilities….' – Kea

Aluminium drinks cans are actually fairly easy to crush when empty, even when just using your hand or foot. Just make sure it really is an empty aluminium drinks can, not a filled steel one.

'I'll be in Paris for a while in January, maybe can pick up a copy…' – Peter Woit

Well, I just hope you will publish as fair and honest a review of Lubos' first book on Amazon, as he did of yours…

48. **Tom Whicker**
November 14, 2007

Jonathan,
Great post. Yes , Bonestell was somehow very powerful.
For me as a kid (, there was a series of articles in National Geographic from the Palomar 48 inch Schmidt

49. **King Ray**
November 14, 2007

Let's not forget Ben Bova. With his hard SF he is helping envision future missions to the moon and Mars. Heckuva nice guy too.

50. **Zathras**
November 14, 2007

Wow, 50 posts so far on popularizing science and not yet one word on Carl Sagan. His *Cosmos* was my first exposure to science beyond picture books. I think *Cosmos* has a good mix of proven and speculative science, just enough to inflame many an imagination, and every popular science book since has tried to reach the same balance, with some mixed results.

51. **milkshake**
November 14, 2007

LM position has been that Bogdanovs papers were a serious attempt but a mediocre contribution and that's why these papers went under the radar for some time – nobody was interested.

The Emperor's New Clothes: It's impossible to accept that his field could be ridiculed like this – hence the articles cannot be a gibberish.

52. **Aaron Bergman**
November 14, 2007

They do get carried away with explosions.

Not possible.

53. **vn**
November 14, 2007

Strugatsky brothers (see
wikipedia;
their slogan, Thinking is not entertainment but an obligation!)
are also worthy SF writers, e.g., their Ugly Swans/Rain Time;
this novel looks a bit like a kind of stylization on good old
Bulgarian spy novel (What could be better than the bad weather:).

54. **Steve Myers**
November 15, 2007

I don't know if there's any easy answer to whether pop science is good or not. Clearly it depends on the quality of the work (book, TV, etc.). Yes, I've known guys inspired by Asimov, and others — but I wasn't interested in that SF (for me math is real science fiction — the logical analysis of possibile functions, spaces, worlds.) But I have noticed that very often the interest in science is fed by a concerned adult — a teacher, father, uncles, so on. Feynmann traces his inspiration to his father; Einstein to his father's gift of a magnet. I showed by sons & their friends how to measure the mass of the earth with a pendulum. My 6 yearold granddaughter thinks photosynthesis is "awesome."

55. **LDM**
November 15, 2007

Feynman's enthusiasm for physics was infectious, and was based on a deep understanding of physical law. Transmitting that understanding so the non-scientist realized that they too could understand and appreciate the beauty of physical law is all that is really required.

People who attempt to popularize science by discussing speculative theories or use salacious examples have missed the point. Science is sufficiently interesting on its own to not need embellishment. IF somebody feels they must resort to such methods, then I would suggest it is because they don't really understand their topic deeply enough where they can present it in an interesting way. The solution is to get a deeper knowledge that can be conveyed to the audience, NOT to get more superficial by discussing speculative ideas.

56. **liverpool**
November 15, 2007

check this out: http://www.telegraph.co.uk/earth/main.jhtml?xml=/earth/2007/11/14/scisurf114.xml&CMP=ILC-mostviewedbox
looks like the British press didn't have the same objections to garret lisi's paper as some others…

57. **Mike**
November 16, 2007

In my country, in the way Russia numerous studies, but they spend in the USSR upbringing elderly who could not understand that young people are not very interested in science, such as physics. At this point, all the young people thought would earn as much money and maintain a business.

Sorry for my English

58. **anon.**
November 16, 2007

I agree with drukpa, but case of Dr Garrett Lisi is difficult because it is in a preliminary stage. The most fundamental things to popularise more are *empirical facts behind the models* used for electromagnetic, weak and strong interactions which are summarised in the standard model, and also the few facts empirically confirmed about gravity from successful tests of general relativity (cosmological dark matter and dark energy are not exactly successful predictions of general relativity, but more a case of epicycles which may indicate problems). Too many people think lump this experimentally confirmed stuff with stringy speculations, and can't see the distinction between facts and fantasies in physics.

If publicity gets Dr Lisi a research position, and he uses the opportunity to follow up physical facts and is prepared to abandon (or put on the back burner) ideas that fail, then it is fine.

What would perhaps be less good is if his ideas were to just *replace* mainstream string theory as the next groupthink hep-th subject, make no progress for the next 25 years – just like string – and end up creating a narcissistic pseudoscientific religion which can only defend itself by launching *ad hominem* attacks on the presumed low-IQs of those working on other ideas.

59. **Tom Whicker**
November 16, 2007

Funny how the mis-information about string theory slowly expands into the public relm. The November issue of National Geographic has a nice artice on Hubble images ("New Visions From Hubble"), but near the end of the text, the author is discussing so-called Dark Energy and he states: "….for all we know there are multitudes of as yet undetected particles, each with its own field, implying still more dimensions…….are these dimensions real or..just a handy way of calculating? Increasingly, physicists suspect they are real."

60. **Yatima**
November 16, 2007

"The case of Dr Garrett Lisi is difficult because it is in a preliminary stage."

I will say. It's a sad testament to my mental capabilities that I do not understand anything of it, so I shall keep an eye open for the appearance of "Lisi Bobbing Head" figurines at EntertainmentEarth. That should be a good criterium indicating that a successful new approach to ToE is indeed taking hold – even if it's only (Hegelian) phenomenology (isn't everything?). In 5 years or so.

61. **Assaf**
November 17, 2007

People will be people, and some will do anything to grab attention. The things you describe are of course completely irresponsible. What's even sadder is that there are so many genuinely interesting and well established physics notions and concepts that one has to wonder why some physicists choose to promote such pseudo science.

62. **Peter T. Brown**
November 17, 2007

I think its fine to use tricks to promote science. In this day and age you gotta grab them kids attention!

63. **Anders R**
November 18, 2007

the kids who have any potential are drawn into it anyway. i really think people are overestimating the use of this popularisation. you're probably not going to be able to come up with anything decent until you're 19-20 anyway so why shove half baked theories down the throats of teenagers and kids.

64. **Mathieu Bautista**
November 23, 2007

Hi Mr Woit,

I am a young french engineer passioned for mathematical and physical theories and I recently bought and read your book (in French, "Même pas fausse"). Unfortunately I am not able to do any work neither in string theory or any other physical or mathematical theory because I don't have the technical level to do so.

To use the same form you did, I have three points in response of your post "Popularizing science" :

– Pedagogy is unfortunately considered as the low degree of making science. Scientists don't want to make TV shows because people like you would later use this as an argument to bash their theory (chapter 15 of your book, about "the Bogdanov affair", this is the french sentence : "De nombreux détails croustillants émergèrent sur les frères Bogdanov et leur façon d'obtenir leur thèse. Ils étaient cinquantenaires, avaient été responsables d'une émission de science fiction à la télévision […] et présentaient actuellement une émission composée de courts fragments destinés à apporter des réponses à des questions scientifiques[…]". I will try to traduce it for non french speakers (sorry the this poor traduction) "Numerous crumbling details appeared about the Bogdanov […] they had presented a science fiction show […] and actually a show that tries to provide answers on scientific questions"…So the Bogdanov can only "try" to provide scientific answers…

– That's my second point ; why such a hatred about the Bogdanov, their TV shows and their theory ? In this chapter (the 15) you focus on the form and don't even try to present the content of this theory (you only give a short extract of their thesis deliberation). Have you read their books ? Have you attended just one of their TV shows ? The fact is that their theory IS undoubtedly a scientific theory (or else, it wouldn't be discussed whether it's true or false). I won't discuss this theory here, but after reading some string theory books for non specialists (like "Supercordes et autres ficelles", by Carlos Calle) and the book of the Bogdanov ("Avant le big bang") I can't tell whether the string theory is "more serious". The fact is that they are more people trusting and working on the string theory. But that doesn't prove anything, think about Albert Einstein : "If i was wrong, only one [scientist] would have made it" (sorry if this sentence is not exact, i only got the french version in mind)

– And the last point; you are a teacher in mathematics, specialized in quantum theory. But you say in your book that you are not an expert in quantic algebra (which i suppose involves the quantic groups theory) The problem is Grishka's thesis is based on these tools and it is the justification of the "Bogdanov theory" (I think about the 3.3.2 theorem). Of course, I don't have the pretention to understand this thesis better than you, but if you are so convinced this is all a fake, you should be able to demonstrate it, shouldn't you ? If that's not the case, then you shouldn't pretend that this theory is "laughable" ("risible" in french), this is not a scientific behaviour. Remember what happened to the "Big bang" of Fred Hoyle not sixty years ago ?

I have not read your book entirely yet, but i will very soon. I have a deep respect and admiration for people like you who popularize science. That's why I defended the Bogdanov a little, because they popularize science in France since 1980 (not only science fiction) and – like you – that doesn't mean they can't have great ideas and theories about cosmology or whatever.

November 23, 2007

Hi Mathieu,

About the discussion of the Bogdanov's TV show. What I actually wrote is that "they now have a new show of short segments in which they answer questions about science". No "try" there. I think you're reading something into the French translation which is not there. I had no intention of criticizing their TV show, partly because I hadn't seen it, just descriptions of it, and the descriptions I had seen were not critical of it.

In general I should warn people that I didn't see the French translation before it was published (and I'm actually slightly annoyed about this, since I do read French perfectly well and had asked for a chance to look over the translation). But as far as I know the translation is fine, I wouldn't have noticed anything remarkable about the part you quote.

As for the problems with the Bogdanov's research work, that topic has been rehashed many times by me and others. No, I am not an expert on quantum groups, although I know something about them. The technical mathematical material on these groups in Grishka's thesis is not the problem, the problem is the way this is used to claim to have a model of before the big bang based on topological quantum field theory, and topological quantum field theory is something I know quite a lot about.

To say something positive about the Bogdanovs, the nonsense level among mainstream theoretical physicists in this area has increased significantly in the 5 years since all this happened, so that the difference between their nonsense and the nonsense of other people is not as dramatic as it was back then. Maybe they were just ahead of their time….

Here is the "promotional" abstact of Motl's book :

L'EQUATION BOGDANOV, Le secret de l'origine de l'Univers ?
Un chercheur de Harvard, le Pr Lubos Motl, répond à cette question.
Est-ce que deux personnalités de la télévision peuvent prétendre résoudre l'une des questions les plus ardues de la physique moderne ? Est-il raisonnable de penser qu'elles puissent trouver des solutions aux problèmes effroyablement compliqués qui concernent l'origine de l'Univers et sur lesquels, depuis des décennies, échouent les savants du monde entier ?

Tel est le surprenant défi de cet ouvrage : montrer que la recherche et ses extraordinaires découvertes empruntent, parfois, les chemins les plus inattendus. Et surtout de nous apprendre qu'Igor et Grichka Bogdanov ont peut-être réussi, à force d'acharnement et de passion, à lever un coin du voile qui entoure l'une des questions les plus fascinantes de la cosmologie moderne :
celle du commencement du temps, de l'espace et de la matière. Tout le monde sait que les deux jumeaux sont des passionnés de l'espace et de l'Univers. Mais sait-on qu'en 2002 ils ont déclenché une tempête dans le monde de la recherche en publiant six articles sur l'origine de l'Univers ?
Des articles parus dans les meilleures revues de physique théorique, notamment la prestigieuse Annals of Physics dont les experts ont conclu que les Bogdanov avaient apporté des solutions nouvelles aux problèmes de l'origine du temps et de l'espace en dessous de l'échelle de Planck,
avant le big bang.

Dans les laboratoires, les discussions s'enflamment. Les Bogdanov sont-ils de véritables chercheurs ou bien s'agit-il d'un canular ? Pour la première fois un expert, ancien professeur à l'Université de Harvard, analyse en profondeur leurs travaux. Et il répond à cette question : Quel est le contenu des recherches des Bogdanov ? Après avoir lu attentivement leurs travaux, le Pr Motl a fini par conclure que les Bogdanov proposent rien de moins qu'une théorie alternative à la gravité quantique.

Google Translation :

THE EQUATION BOGDANOV, The secret of the origin of the universe?
Un chercheur de Harvard, le Pr Lubos Motl, répond à cette question. A researcher from Harvard, Professor Lubos Motl, responded to the question.
Est-ce que deux personnalités de la télévision peuvent prétendre résoudre l'une des questions les plus ardues de la physique moderne ? Are two television personalities can pretend to solve one of the toughest issues of modern physics? Est-il raisonnable de penser qu'elles puissent trouver des solutions aux problèmes effroyablement compliqués qui concernent l'origine de l'Univers et sur lesquels, depuis des décennies, échouent les savants du monde entier ? Is it reasonable to assume that they can find solutions to problems frighteningly complicated concerning the origin of the universe and where, for decades, scientists fail the world?

Tel est le surprenant défi de cet ouvrage : montrer que la recherche et ses extraordinaires découvertes empruntent, parfois, les chemins les plus inattendus. That is the surprising challenge of this book: to show that research and its extraordinary discoveries borrow, sometimes, the most unexpected ways. Et surtout de nous apprendre qu'Igor et Grichka Bogdanov ont peut-être réussi, à force d'acharnement et de passion, à lever un coin du voile qui entoure l'une des questions les plus fascinantes de la cosmologie moderne : And above all we learn qu'Igor and Grichka Bogdanov may have succeeded, by dint of hard work and passion, to raise a corner of the veil that surrounds one of the most fascinating questions of modern cosmology:
celle du commencement du temps, de l'espace et de la matière. As the beginning of time, space and matter. Tout le monde sait que les deux jumeaux sont des passionnés de l'espace et de l'Univers. Everyone knows that the twins have a passion for space and the universe. Mais sait-on qu'en 2002 ils ont déclenché une tempête dans le

monde de la recherche en publiant six articles sur l'origine de l'Univers ? But do we know that in 2002 they triggered a storm in the research world by publishing six articles on the origin of the universe?
Des articles parus dans les meilleures revues de physique théorique, notamment la prestigieuse Annals of Physics dont les experts ont conclu que les Bogdanov avaient apporté des solutions nouvelles aux problèmes de l'origine du temps et de l'espace en dessous de l'échelle de Planck, Articles published in the best journals of theoretical physics, especially the prestigious Annals of Physics, which the experts concluded that Bogdanov had provided new solutions to the problems of the origin of time and space below the level Planck,
avant le big bang. Before the big bang.

Dans les laboratoires, les discussions s'enflamment. In laboratories, ignite discussions. Les Bogdanov sont-ils de véritables chercheurs ou bien s'agit-il d'un canular ? Bogdanov The researchers are real or is it a hoax? Pour la première fois un expert, ancien professeur à l'Université de Harvard, analyse en profondeur leurs travaux. For the first time an expert, former professor at Harvard University, an in depth analysis of their work. Et il répond à cette question : Quel est le contenu des recherches des Bogdanov ? And he answered this question: What do the research Bogdanov? Après avoir lu attentivement leurs travaux, le Pr Motl a fini par conclure que les Bogdanov proposent rien de moins qu'une théorie alternative à la gravité quantique. After carefully read their work, Professor Motl eventually conclude that Bogdanov offer nothing less than alternative theory to quantum gravity.

67. **How Can We Turn The Tide?**
November 24, 2007

Peter,

Other than Garrett's non-theory receiving far more media coverage from the press, what is the difference between the Bogdonav affair and the Garrett Lisi affair?

Are not-even-wrong theories endorsed by Smolin et al what we have to look forward to for the next thirty years?

68. **Peter Woit**
November 24, 2007

How can we…

The Bogdanov's papers are gibberish, they don't make any sensible, comprehensible claims that can be accurately stated. Garrett's paper is straightforward, conventional theoretical work. His claims are clearly made, so clearly that some people have been able to identify specific problems with them, which Garrett has acknowledged.

69. **Tim May**
November 25, 2007

And even "New Scientist" could not find anything in the Bogdanov paper(s) to put on the cover. Which suggests the Bogdanov kind of gibberish was in a different league…

To defend "New Scientist" a little bit–since I've dumped on them as several others here have as well–I recollect other cover stories that were just about as "out there" as the recent examples. For example, I recollect at least several covers having to do with "the universe as a hologram."

Now I know that the hologram model (or conjecture) is not gibberish in the same way the Bogdanov papers appear to be, and that 't Hooft, Susskind, Maldecina, and the others are respected theorists. The hologram model probably sells magazines, too.

(And anything with a bizarre name, or a picture of a guy with a goofy grin on a bicycle or in a wheelchair or cracking safes at Los Alamos, this kind of "human interest" angle has been making cultural icons out of physicists for a long time. Snowboarding hippies just goes with the territory.)

So, cover stories for the holographic universe conjecture. Is it "not even wrong"? Does it have testable predictions? (My guess is no, at least not for things we'll be able to see in the next few centuries, but maybe I'm wrong.)

Is "New Scientist" wrong in putting these kinds of "wild conjectures" on the cover? (I could add a bunch of others, including theories of how all mathematical structures exist (Max Tegmark), how algorithmic information theory underlies all of physics (Greg Chaitin, though I'm oversimplifying his point here), how the universe may have just "fluctuated" into existence (too many names to list here), or even how vibrating strings and branes and whatnot may underly reality (!).

I think it's not so wrong for a popularly-oriented magazine to put things on the cover that hook some readers, even that generate some controversy. Provided the science is not truly bad, like the French brothers, or something like "New Support for Flat Earth Theory" or "Darwin Refuted!," which would be a whole different kettle of fish.

But stuff about possible imprints of other universes is, while very speculative, not actually misleading anyone. I recall having the same reaction to the idea that the microwave background map (WMAP) might have its bumpy structure determined by quantum-mechanical fluctuations in the first handful of Planck time periods to be pretty darned bizarre…but now it seems the accepted model. I don't know if NS ever had a cover story with a picture of the WMAP sky with a catchy title like "Did the Uncertainty Principle Shape our Universe?," but that would be unsurprising to me. Was it hype? Was it "Not Even Wrong"?

It seems to me that if people approach "New Scientist" and similar magazines (even "Scientific America" puts this kind of stuff into cover articles these days) with a certain amount of skepticism and views the conjectures as just speculative approaches, not too much harm is done. I even think kids (teens) who get exposed to this stuff may actually become interested in science, and will learn pretty quickly how to move beyond the hype and speculation….I know it worked for me in the 1960s, when I was able to get beyond reading about, as one example, tachyons (Feinberg, a popular cover story back in the 60s, in places like "Science Digest") and read what the underlying physics was about. (Feinberg, by the way, was no crackpot….but science journalists sure did hype up his work. Some foreshadowing of today, I think, but the faster speed of the Internet, blogs, SlashDot, etc., makes things move at _tachyonic_ speeds.

It might be nice if "New Scientist" were to have sidebars that suggest healthy skepticism, sort of like the guys who stood behind conquering Roman heroes and emperors and whispered to them that they are not gods.

But for now I guess I'm prepared to cut NS a lot of slack. We live in a time of a lot of hype, a lot of selling of stories, and way too many thousands of magazines.

Too long a comment here…sorry. But I think that what Peter Woit and Lee Smolin and others have been doing is to inject some healthy skepticism back into the mix. And part of this healthy skepticism may involve some wild speculations of other kinds, things which help to "deconstruct" the idea that string theory is the only game in town.

–Tim

Project X and Flavor Physics

November 18, 2007
Categories: Experimental HEP News

Last week Fermilab hosted two workshops on the so-called Project X proposal for building a linac designed to produce a high-intensity proton beam. The first workshop dealt with issues surrounding the proposed accelerator itself, the second with the physics that it might be able to investigate. Project X is being discussed in the context of an increasing realization that prospects for the ILC getting approved and built anytime soon are slim, so the US particle physics community in general, and Fermilab in particular, need to have a viable plan B for what they will be doing during the next decade. DOE secretary Ohrbach, in a recent talk at Fermilab made it clear that he thinks the ILC project is still at the stage of an R and D project, not yet near the point where a decision about it can be made and a full engineering design developed. For commentary about this from Barry Barish, director of the ILC project, see here.

One argument for Project X is that it would help develop some of the linac technology needed for the ILC, but the main arguments for the machine revolve around a striking change of direction for US particle physics, from the use of colliders to do experiments at the energy frontier to fixed-target physics at lower-energies. In some ways this would be a return to the older style of particle physics experiments that was the norm before the era of colliders. The point of Project X would be to produce a beam capable of being used to generate more intense beams of neutrinos that could contribute to neutrino physics, and to do what is now often called “flavor physics”. This is the study of phenomena involving heavy quarks and/or rare decays, with the hope of seeing beyond the standard model effects that occur not in lowest order approximation, but in higher order contributions to decay rates. There are quite a few decays that one can look for that either can’t occur at all in the standard model, or only can occur at unobservably small rates. An observation of such a decay and measurement of its rate would provide evidence of new physics. Many such studies already conducted provide strong bounds on quite a few possibilities, so one can imagine competing with colliders such as the LHC to either rule out or find new TeV-scale physics by doing this sort of experiment.

One interesting document to read about this is the account of a panel discussion on charm physics that occurred this past August. A participant emphasized how history has recently been running against the people working on flavor physics, telling the following story:

> … over lunch we were talking about the future of the field, and I was drifting off, and ended up in a fantasy world where things were done the right way. And in this world the LHC was in fact built and came on the air, and found the Higgs, and found many new events that we couldn’t explain with the Standard Model. And people had realised that in order to interpret these possible signals of new physics, we would also have to have flavour physics studies of rare phenomena, so that we could start to see patterns emerging… and working symbiotically together, the LHC and the flavor sector would get to the root of what was happening, something that would be very difficult if not impossible to do with the LHC alone.
>
> But then I woke up. And I thought about a colloquium I’d given recently, where one of the chief experimentalists there took me into his office and shut the door and said to my face, “Flavor physics is dead!” and apparently he’s not the only one who said it: some pretty important people have said it. And when something like that is said over and over it begins to have a truth of itself.

Deciding whether Project X makes sense will require figuring out exactly what kinds of experimental results it will make possible that would not be possible using existing or currently planned facilities. For more about this, see the introductory and wrap-up talks by Joe Lykken and a talk by Jon Bagger that summarizes the issues well. The workshop also featured an excellent talk by Michelangelo Mangano summarizing the current situation of particle physics, emphasizing what it might be possible to learn through other means than the LHC, which is what is getting almost all the attention these days. He pointed to the activities of the CERN Working Group on the Interplay Between Collider and Flavour Physics that are documented at this web-site.

Update: Alexey Petrov was at the Project X workshop, and has a very interesting posting about it.

Comments

1. **Flip**
   November 18, 2007

   Thanks for pointing us to the workshop PW!

   A quick note: streaming video of most of the talks are available at the Fermilab VMS site: http://www-visualmedia.fnal.gov/VMS_Site_2/

   Click on “streaming video archive” and search under series: “High Intensity Proton Source.”

   Cheers,
   F

2. **Peter Woit**
   November 18, 2007

   Thanks Flip!

   Personally I can’t stand watching videos on the computer, and only will do this if there are no slides available, or if I can’t figure out from the slides what the speaker was talking about. Maybe this is a generational difference, or maybe I just have the short attention span young people are always accused of having…

3. **Dave Miller**
   November 19, 2007

   Peter,

   In a time when hundreds of billions are going down the tube in Iraq, it’s easy for us physicists to think that of course we should be given a few billion (or is it a few dozen billion?) to build the next accelerator.

   But this is real money — it could be used to build a lot of libraries or hospitals (or pay for a lot of mathematicians or theoretical physicists or a few new football stadiums or…). Is there any credible case to spend it on a new accelerator?

   My Ph.D. is in particle theory from Stanford (SLAC), and I actually knew Barry Barish when I was an undergrad at Caltech, but I have since moved into other fields. Even from my perspective as a former insider, I am only mildly curious about the results that will be coming out of the LHC (curious enough to follow your blog, of course – thanks for all the effort you put in). Why should we expect our fellow taxpayers to fund a machine, the results from which do not interest most people and indeed which most people cannot even understand?

You have a rather unique view and position in the field of physics. Looked at objectively, can you think of any reason our fellow taxpayers should fund Project X – except of course to keep physicists employed?

All the best,

Dave

4. **chris**
November 19, 2007

hi dave,

"can you think of any reason our fellow taxpayers should fund Project X – except of course to keep physicists employed?"

when i hear this kind of argument, it always reminds me of that famous story about faraday. when asked by the king what good his novelty experiments on electricity were he responded by saying, that one day there will be taxes on it.

seemed pretty outlandish then, right? seems pretty outlandish now to hope for anything relevant to be discovered at a new accelerator.

5. **Roger**
November 19, 2007

Dave has a point. There is a feeling here that this is something just to keep people employed. The physics involved in project X is reasonably interesting but, in the absence of discoveries of non-Standard Model physics at the LHC, may just be more of the same fare we've been served over the past few decades.

This is an issue not only for Fermilab, but concerns the whole field of experimental particle physics. The most recent advances in fundamental physics have come from the astrophysics experiments – is this a trend for the future ?

If the LHC provides no surprises I can see good not not compelling arguments for further investment in large scale collider experiments.

6. **Roger**
November 19, 2007

7. **chris**
November 19, 2007

roger,

i think what we have seen over the past decades is the other fields catching up while hep-ex is – comparatively – starving. until basically the 80s politicians funded this field because of the perceived relevance for nuclear devices of whatever sort. now that it is clear that the results are not anymore directly relevant and biotech is the current cool technology, funds have decreased accordingly.

i am fully in favor of any alternative way to learn about fundamental physics and indeed the astrophysics results of the last decade are impressive. but ultimately, if you want to know the physics at a certain scale, you have to go there somehow. and that costs and therefore it is slow. but i do not see an alternative. except of course if we just decide that we don't care at all.

8. **Dave Miller**
November 19, 2007

Chris,

Of course, I've always loved that anecdote from Faraday (what physicist doesn't?).

But I'm skeptical that it is relevant any longer. Elementary particle/ high-energy physics has been around for a long time now. But no practical result has ever come from it, nor is there any on the horizon. And there seems to be an obvious reason for this — charmonium, the W/Z particles, the higher baryon resonances, the tau lepton, etc. are so massive and so unstable that it is hard to see what role they can ever be made to serve in everyday life.

Of course, it is always possible that when Lubos finds the complete solution to superstring theory that this will lead to countertop antigraivty and baryon non-conservation (which would provide an unlimited energy source).

But in all honesty, can you envision in your wildest dreams any practical result from particle physics in the next century? Faraday could (and did) accurately envision such results from his work, as the famous anecdote shows. I've been thinking about this (occasionally!) for more than thirty years since I was an undergrad — I still remember George Zweig's idea of using muons to catalyze fusion — and I cannot think of any plausible practical consequences.

Do you honestly think high-energy physics will ever "pay off" in practical economic terms (not counting as a physicists' full-employment program)? Practical results are not the only reason for science, of course, and we all have a perfect right to pursue our hobbies and interests on our own time and money. But is there any honest reason to urge our fellow taxpayers who lack our interests to spend tens of billions on this?

Dave

9. **Peter Orland**
November 19, 2007

Dave Miller (who I used to know a bit when I'd visit SLAC during the summers) raises an important issue. I think this is the central reason why physicists should popularize their work with as little dishonesty and hype as possible.

I think we can get the public interested in what we do thereby persuading them that funding experiments is valuable. It's important, though, that they not be lied to in the process, since they will not readily forgive us. NOTE: The space station and the space shuttle, devoid of scientific or technological value, can get away with such dishonesty – they have much larger budgets and a military connection.

10. **Dave Miller**
November 19, 2007

Peter Orland,

One of the main virtues of our host (Peter Woit) is that he does urge such honesty.

I remember when I was a grad student at SLAC that it was sort of a joke (openly discussed among faculty) that the only reason we were funded is that the feds were hopeful/afraid that we'd come up with another weapon like the nuclear bomb. Everyone laughed about it because we knew it was unlikely, but there was a consensus that no one should let the funding sources in on the joke.

Years later, a friend who had ties with the defense establishment told me that the feds weren't that dumb but that they did view the HEP program as a good technical training program for people who would end up working on nuclear weapons, SDI, and more conventional military programs (which happened to a lot of my classmates).

While I do endorse complete honesty, I do suspect that we may find that our fellow citizens care a great deal more about Monday Night Football and Paris Hilton than about science.

Dave

11. **Roger**
November 19, 2007

Chris – I totally agree. Progress will best be made with collisions at the energy scale one wishes to investigate. However, the problem will arise if the LHC does nothing other than confirm that the SM is a great low energy effective theorem. In this situation, there is no clear guidance as to which energy scale one would need to probe to make progress. Rare decays are of course sensitive to physics occuring at high mass scales but, with the exception of the tenuous g-2_muon result, there is so far little to suggest anything exciting so far. To carry on trying in this area is a good but not compelling argument for further large scale investment.

I'm a collider physicist so my career is tied up in all of this. However, should the LHC not do anything exciting I would be tempted to change fields and move in an astrophysics direction where one is more likely to make progress.

Accelerators are a comparatively recent technique and it may be that they've had their day. It may also be that in a few years time we'll be discussing some of the greatest discoveries mankind has ever made.

Slightly off-topic here and I hope Peter won't delete this but I'm a little gloomy that the latter possibility will happen given that the "compelling" argument for new physics at the LHC is the hierarchy problem. I've never been convinced by this, possibly because I don't appreciate it fully. Will someone explain to me why the hierarchy problem seems to have been elevated to "big problem" status and why it should be taken seriously ? I'm happy with the mathematics of it but it seems to rest of so many assumptions. To me, the strong CP problem or electric charge quantisation are "bigger" problems.

12. **DB**
November 19, 2007

This plan B sounds sensible. Whatever turns up at the LHC it is likely to be the Saturn V of our time. The LHC was sold on its ability to discover the Higgs, if it exists, whilst leveraging existing accelerator assets. Although it had a great case it was really touch and go on a number of occasions during the budget approval process. As things stands, neither the ILC nor CLIC can boast a similar clear-cut rationale and without it they will never see the light of day. Of course, the LHC may yet provide that rationale. However, even if the LHC astounds us, I don't believe politicians have the appetite for yet more mega-budget physics.
As we have seen in recent years with Kamiokande and Sudbury and now Auger, the detection – be it terrestrial or space-based – of astrophysical sources of HEP particles will continue to see lots of action whatever turns up at the LHC. Solid, low-hype, reasonable-cost physics which delivers in spades.
(Well it used to be low-hype, but recently some idiots have begun to refer to UHECR's (ultra high-energy cosmic rays) as "oh my God particles")

13. **woit**
November 19, 2007

Dave,

I believe one motivation for "Project X" is that it's a lot less expensive than something like the LHC/ILC, so can probably be built within the current level of US HEP funding. So, particle physicists don't need to ask the public for increased funding, just a continuation of the current level. I happen to think that's not hard to justify: it's a very small fraction of government spending, has spinoffs, a small chance of dramatic breakthroughs that are technologically useful, but, most importantly, I think the effort to understand nature in this fundamental way is a worthwhile thing for humanity to be putting some of its resources into. While most people are not well-informed about particle physics, my experience is that most of them put it in a category of interesting things they wish they knew more about, and have no problem with a few dollars/year of their taxes being devoted to this pursuit.

The question about "Project X" I think is not whether it's affordable, but whether the possible physics results it can achieve are worth it, in comparison with other ways of spending the money. That's the question this workshop was devoted to looking at.

14. **Adud**
November 19, 2007

PW:

> One argument for Project X is that it would help develop some of the linac technology needed for the LHC, but the

I guess this should be "ILC"? Great post!

DM:

> But no practical result has ever come from it, nor is there any on the horizon.

I guess one reason why many countries are funding this kind of experiments, such as the LHC, is that lots of practical results are coming out from them. Not in the form of making a cure for cancer from the Higgs boson, of course, but as related technology developments. This blog is one among many, and probably the least important, such developments.

Even more relevant, today low-energy particle accelerators are being used (and commercially built) for a myriad of important uses: as sources of synchrotron light and low-energy electron, nucleon and ion beams for research in materials science, nuclear physics, biophysics, biotechnology and medicine. One of the hospitals in the city where I live is seriously considering buying one for cancer treatments. I have no idea what kind of accelerator or what kind of treatments this is about.

Yet, current commercial and non-commercial low-energy accelerators where one day developed as the bleeding-edge laboratories of particle physics. In a few decades the LHC might well be considered a low-energy machine for applied science. I'm sure more concrete examples can be given, maybe someone else knows what DESY is going to be used for now that HERA has been decommissioned. Germans are certainly not going to just demolish it……..

15. **A quantum diaries survivor**
    November 19, 2007

    What's wrong with oh my god particles ? I find it quite funny, unconventional, witty, and pulling the leg of Higgs nicknames aficionados. I do not think we should be concerned with over- or under-hyping our experiments. Catch-words are useful in that they lower the barrier with non-scientists and give some humorous side to things. How are we going to take the public on our side of the funding battle if we show disdain for popularization and trivialization of science ? Science is not ours, it is everybody's.

    T.

16. **nn**
    November 19, 2007

    Chris,

    If your arguments about practical usefulness of science are correct where would that leave astronomy beyond the solar system? (I'm excluding the solar system because e.g. watching NEOs clearly
    has a practical purpose — just ask the dinosaurs)

    But it is arguably doubtful there will ever be any practical application
    of astronomy at a larger scale or cosmology.

    And some of the astronomy projects (like Hubble or Webb or the
    larger earth based telescopes) were/are also quite expensive in
    LHC scale.

    But I still find the results very interesting (not being an astronomer
    myself) and would be sad if it wasn't funded anymore.

    One advantage the astronomers have over the particle physicists
    is that their results are generally easier to understand for
    the layman. Perhaps that is something physicists need to work
    on.

17. **Markk**
    November 19, 2007

    Speaking as one of those taxpayers, not a professional academic, the reason to fund things like High energy physics are twofold.

    First and most important is that these are things should be done in a society in which I am proud to belong. As a society, curiosity about our universe and seeking of knowledge about it, are part of the definition of being healthy. When we lose that, and stop spending the pittance we do on things like HEP, we are sick and not long to remain as a coherent society. This is the classic point that everyone from Hardy to Lederman and who knows how many others have made. We are not spending NIH style money on high energy physics even if we would have built the SSC. You can make a point about funding levels, but that is a whole different administrative point, not an issue with goals.

    Secondly, as a practical matter, as an engineer, and person who used to hire engineers, I think that we need to keep a bank of knowledge of people who are doing research at the frontiers and can reproduce old research. Somebody who people can turn to for that little bit deeper knowledge and experience, when they have to.

    As an example, lets say a SM Higgs is found and nothing else and no signs of anything else at LHC. Do we turn off all the colliders then? If so, then why don't we stop teaching theoretical high energy physics – there is no point, we for sure then could never do anything with it and by the same reasoning it should go also. We lose the knowledge in peoples minds then. It might be in books, but that isn't online in heads. Now suppose some odd results come in from, say materials, that indicate long lived particles or other odd behavior. We'll have people from other areas that can jump in the research but there will be a gap, and people might not even notice it really, because there will be nobody with the theoretical background and nobody with the practical background to understand what is going on. I would say we'd end up spending a lot more money, and a lot more time at that point rebuilding the knowledge we would have had, if we even understand what we have in the first place.

18. **Peter Woit**
    November 19, 2007

    Adud,

    Thanks! Fixed.

19. **chris**
    November 19, 2007

    hi nn,

    also to that i can only answer by going into history. i think it was around 1850, when in a prominent textbook on astronomy the composition of distant stars was listed as one of the things that can never possibly be accessible to humans.

    my only answer is, who knows. how can you be so sure that what you find out there will not at one point in the future change our daily life.
    just to give a particularly bad and uninspired example, how do you know that watching supanovae going off in distant galaxies in the full spectrum will not be a main tourist attraction of the 54th century?

20. **chris**
    November 19, 2007

dear dave miller,

thanks for your long reply. i have only spend the last 1.5 decades in hep, so i grew up during the most boring of all times so to say. and yes, i do have similar doubts that results of any practical relevance in the mid-term future will come out of hep soon. and a third yes, i am also in it for the knowledge and not the technology, which is of course the motivation for almost every person doing hep i guess. but still. we are scratching at the frontier. per definition we don't know what comes next. there are people who claim that at 1 TeV you start leaving our brane and go into the bulk of the universe. and this is just the result of wild speculations while idling and waiting for nature to tell us what is there really.

i can't imagine any possible practical use of HEP within the next century except the spin-offs that i don't really want to count. but again, if i knew what to expect, i wouldn't do research. and after all, the periods in physics where everything seemd to be settled until now were followed by the most dramatic changes always. of course, one should not rely on this. but it still is possible i think.

21. **Low Math, Meekly Interacting**
November 19, 2007

I may be unusually interested compared to the average non-physicist, but this taxpayer, at least, is willing and driven to vote for politicians who promise (however obliquely) to give experimental HEP in the US a good financial boost.

If the theorists in the field are victims of the success of the S.M., they must at least be equally victims of having to wait about 20 years too long for TeV-scale accelerators.

That said, although I found Dr. Robert Wilson's eloquent statements in defense of mere discovery both inspiring and moving, nothing seems to persuade the legislator and executive quite like fear. It's hard to imagine the Apollo program without the Cold War. "We're losing our technological edge to Europe, including the FRENCH!", or the prospect of having to outsource nuclear research to China, might succeed where appeals to such frivolities as human curiosity may fail. The mere thought that China seeks to land a robot on the Moon seems to be enough to motivate our leaders to waste (in my opinion) $100 billion on human flights to Mars, so there's a lesson to be learned, however sordid and cynical it may be.

22. **nn**
November 19, 2007

chris,

I think you're misunderstanding me. I wasn't arguing against
funding astronomy. Just pointing out that if D.M.s efficiency/cost
metric would be strictly applied astronomy would likely suffer too.
And some other very interesting, but most likely also relatively
useless areas of science (although admittedly most are not
as costly as HEP or high-end astronomy). But it's not a pure HEP issue; more a general science problem.

Also there might be always uses for everything of course,
although they are hard to predict.

Standard example is number theory — which used to be considered
100% useless — makes public key cryptography and
the internet go around these days. But then the number
theorists also never needed any billion dollar toys to play
around with.

23. **srp**
November 19, 2007

I will once more shout down the well here.

The bottleneck is current accelerator technology. If a substantial fraction of the resources proposed for ILC or Project X were allocated to basic technology development of wakefield accelerators, could they be deployed in a reasonable time frame? If the likely answer is yes, then that strikes me as the no-brainer strategy, since it allows much higher energies at affordable prices (and device sizes). Experimental particle physics is rapidly being painted into a corner; it needs to innovate a way to smash through the walls.

As a taxpayer, I would be much happier paying for breakthrough accelerator research than for low-payoff conservative designs. If the physics community got behind this strategy they could appeal to a) the scientific superiority of ultra-high energy at affordable prices, b) the American love of invention, and c) the possibility of spinoff technology.

Of course, if there were a sound argument that wakefield technology is scientifically unsound or technologically too hard, then this strategy would be a poor one. Yet I have found no such statement, nor, curiously, much interest in assessing whether this technology is truly promising. It's like going for brain surgery before finding out if you can cure your headache by taking some aspirin. No commitments to any future accelerator proposals should be made until that wakefield assessment is made.

24. **Peter Woit**
November 19, 2007

srp,

It's my impression that the sort of acceleration technology you're talking about is nowhere near the development stage, but requires a lot more research to even see whether it is really feasible. There's a good argument for putting more resources into that research, but it's a very different thing, on a different scale in terms of money (less) and time (more) than the ILC or Project X. In those cases the technology is in place now, and the question is whether to spend the large sums needed to build a machine sometime soon (years, not decades).

25. **Dave Miller**
November 19, 2007

Peter,

Thanks for clarifying the cost issue on Project X.

Chris,

I think you're thinking of Auguste Comte, the philosopher and founder of positivism:

>We can never know what the stars are made of, Comte gloomily concluded in 1835:

>>On the subject of stars, all investigations which are not ultimately reducible to simple visual observations are…necessarily denied to us… We shall never be able by any means to study their chemical composition. (http://www.astrosociety.org/pubs/mercury/33_05/rainbows.html)

Markk,

Having moved from academic HEP to emgineering work in industry, I'm a bit skeptical of the "keep a bank of people with knowledge around argument." No one is suggesting that theorists be prevented from pursuing and publishing work in theory or that people like Peter Woit and I be liquidated because we still possess some knowledge of HEP. Assuming that we can continue to live in an affluent society with freedom of speech, etc., there will be people who continue to know and learn this stuff.

The issue is simply why our fellow taxpayers should pay big bucks for bleeding-edge experiments. And, on that issue, srp's point makes a good deal of sense to me. Do HEP experiments have to be this expensive? I understand the underlying physical reasons for the big accelerators, but do we also have a bit of a "NASA problem" here? Other countries (and now some private companies) have shown that you can put stuff in orbit a lot cheaper than NASA used to charge.

Is it possible that srp is right and that we have gone for the immediate gratification of the big colliders and had too little deferred gratification aimed at accelerator technology development?

Dave

———

26. **djm**
November 21, 2007

srp,

There are many other "high risk, high payoff" technologies in accelerator R&D than just wakefield, and even more low risk, lower payoff, some of which is being funded at a modest level through DOE, ILC, etc. It is a topic that could certainly be funded better. There is a distinct sense from ILC meetings I've attended that they don't want to talk about possible accelerator technology breakthroughs, because it could interfere with selling the current design. IOW, if a breakthrough may be 5 years out (which it always could be), why not wait for that and redesign?

Current technology is impressive but has a distinctly brute-force flavor, which does not appeal to those of us who have made clever technology work in other contexts (e.g. at lower energies).

27. **djm**
November 21, 2007

Dave Miller: "Other countries (and now some private companies) have shown that you can put stuff in orbit a lot cheaper than NASA used to charge."

Every successful orbit to date has been entirely or largely subsidized by a large government with enormous resources. Yes, it is cheaper to launch from Kazakhstan than Florida.

28. **srp**
November 21, 2007

djm: I just mentioned wakefield because I've heard of it. If other stuff looks like it might be better, then resources can be put into parallel projects. An intelligent research program in accelerator technology development obviously should allocate resources to multiple paths until one emerges as the best option.

The behavior you describe in ILC meetings, where people don't want the possiblility of breakthroughs to deter investments in the here and now is pretty common in all large organizations. It's even rational in many cases. The current situation is not one of those cases.

Given the current context–a dead end for conventional accelerator technology with marginal rationales being cooked up just to keep the game going after the LHC–it would make sense for the physics community to get behind advanced accelerator technology development the way it now gets behind conventional behemoths like the ILC or Project X. This is one of those rare situations where investing in the cool new cutting-edge stuff is more fiscally, politically, and scientifically responsible than sticking with the tried and true.

29. **wb**
November 21, 2007

srp,

The real promise of wakefield accelerators is in the range of 1 – 100 GeV where light sources can become university laboratory tools and where multi-spectral beams can be used to probe matter with femtosecond simultaneity. Once one is honest with oneself about building high energy colliders with such objects you do a calculation of the electrical power required for such devices. For all the charm about so-called compact size the power requirements come from very simple calculations of luminosity in terms of beam power. As a starting point note that at L=10^33 an ILC requires ~350 MW. Scaling to where a post LHC collider should really be (1.5 TeV in the c.m.), one see that a wall plug power of ~3 GW will be required. Be an optimist and imagine that lasers are 100% wall plug efficient and that wakefield accelerators will be as efficient as rf driven accelerators, and you may convince yourself that a post LHC linear collider will only require 1 GW of electrical power. There are many more practicalities that put TeV scale wakefield colliders far beyond what can be delivered in the next decade even if one can pay the power bill.

Laser driven accelerators have made great progress and they do have great promise for accelerator based science that can be delivered in the next decade if that R&D funded at 2 to 3 times the present rate. Unfortunately high energy physics is not one of those promises.

30. **srp**
November 23, 2007

wb: Thanks for your insights.

The advanced accelerator community does not appear to see things the same way; see for example

http://cerncourier.com/cws/article/cern/30148 where the author talks entirely in terms of high-energy physics applications and never discusses power issues (although he is worried about applying wakefield technology to positrons). This stance could be technological hubris or grantsmanship, of course–I think the tokamak fusion community has been accused of similar sins–but I need to explore the issue more thoroughly to know whether your dismissal is the end of the argument.

31. **srp**
November 23, 2007

And this guy is talking about 10TeV with 360MW wall-plug power:

http://www.bnl.gov/ATF/Meetings/AAC04/plenaryabstracts/Monday/GeraldDugan.pdf

Of course, there are some feats of beam compression involved to get the desired luminosity, and I have no way of telling whether these are plausible. But if it took spending $100 million to find out, I'd support that.

32. **wb**
November 23, 2007

srp,

Gerry Dugan is certainly an expert and not one pushing his own research program in this talk. Look at his CLIC example. This has 30 MW of beam power. At 10% wall plug efficiency and accounting for overhead power for the facility, CLIC will need at least 500 MW. (note that is completely consistent with ILC estimates at 1 TeV. At 3 TeV CLIC also needs other miracles to actual maintian nanometer beams in collision in space and time. No one has demonstrated that such control systems can close the loop or are stable. Nonetheless, I agree that search for such capability is worthwhile. It will tell us the limits of are capabilities with linear colliders.

His 10 TeV system at 1e36 luminosity assumes an efficiency that is rather incredible. Despite the fact, that the present state of laser efficiency from wall plug to ultra-short pulse lasers is ~1% and that the efficiency from that lase pulse to a beam is also of that order, the stated ifficentcy to two significant figures is 16%. The beams must be controlled to 1 Angstrom in the vertical plane. I'll have to think more about whether that last claim makes physical sense even.

The bottom line is that this technology will not be ready for 2025 even if R&D funding were increased many-fold. Fortunately the laser technology gets driven by commercial and defense interests. The only sure path forward to the 10 TeV mass scale is a very large hadron collider. Is that affordable? are we capable of managing a project of such large physical size? I'm not sure. I only advocate avoiding the hype and making sure that LHC and its upgrades give the very best possible physics output.

33. **Howard Walker**
December 13, 2007

Mr. Woit,

I have just finished "Not Even Wrong" and loved it. While it confirms my thoughts about String Theory, I was really quite pleased to see that professionals like yourself are coming out against it. I am quite angry though that so much money and time is being lost on this red herring and that it will not end any time soon as THEY are in charge.

If the TOE were to be announced tomorrow, THEY would say THAT is exactly what they have been saying all along and THAT IS what String theory really was all along. And THAT is what really bugs me to no end.

Please keep up the fight for real science.

Howard

Sidney Coleman 1937-2007

November 19, 2007
Categories: Obituaries

I just learned today the sad news of the death of Sidney Coleman, yesterday at the age of seventy. Coleman had been in quite poor health in recent years. I wrote about him here back in 2005, after attending a conference held at Harvard in his honor.

Update: More from Betsy Devine, Lubos Motl and Sean Carroll.

Comments

1. **A quantum diaries survivor**
   November 19, 2007

   Darn it. I am sick and tired of people dying! I know I sound silly, but I am serious. Today I learned Michael Schmidt, a colleague in CDF, also died – and he was quite young. May he rest in peace. And I want to remember here another friend who died only a couple of weeks ago, Riqie Arneberg, a non physicist with a bright mind who avidly read physics blogs. Sorry Peter for the off-topicness.

   Cheers,
   T.

2. **Roger**
   November 20, 2007

   Meaning absolutely no disrespect to his family, it sounds like it was a release from a lot of suffering. Parkinsons disease is a wretched illness.

3. **Betsy Devine**
   November 20, 2007

   Thanks for the link, though it goes to my 404 page. Anyway, the best part is the comments, which are a pile of Sidney Coleman stories:

   betsydevine.com/blog/2007/11/20/our-friend-sidney-coleman-has-left-the-planet/#comments

4. **Peter Woit**
   November 20, 2007

   Hi Betsy,

   Link should be working now. I second your recommendation to people that they should check out the comments!

5. **joe**
   November 20, 2007

   My Favorite Sydney Moment was his impression of an electron under various symmetry transformations – fisrt he walked across the room, then he walked across the room backwards, then he walked across the room backwards in the other direction.

   I was bad at QFT, but I loved Sydney's Lectures.

6. **Jimbo**
   November 21, 2007

   A lively Sidney Coleman invading a closed New Jersey county fair, to wax philosophical about the universe is a treat for all in the DVD, `Stephen Hawking's Universe, vol.3′.
   I think the lesson of Sidney's later years, is to treasure the masters who walk amongst us while we still have them. Soon, we will probably lose John A. Wheeler and other great spirits whose timeless contributions to physics were apparrent at the SidneyFest.
   A recent Godel-Fest article at the IAS by Dyson, mindbogglingly recounted how new post-docs were casusally told by Oppenheimer to "avoid Einstein" , as he was `totally out of touch with current physics'.
   Can anyone imagine avoiding asking Einstein out for lunch, so as to not have to hear about unified field theory ??

7. **D R Lunsford**
   November 21, 2007

   He was an excellent physicist. I hope he knows what breaks electro-weak symmetry now.

   -drl

8. **Jonathan Vos Post**
   November 21, 2007

   Note that Sidney Coleman is mourned by the professional Science Fiction establishment, because of his outreach to and partcipation in this speculative discipline.

   Locus magazine online, Tuesday 20 November 2007

   Physicist Sidney Coleman, a professor at Harvard University who was a co-founder of Advent:Publishers in the 1950s and who wrote several review columns for The Magazine of Fantasy and Science Fiction in the 1970s, died Sunday, November 18, 2007, at the age of 70.

9. **Garotte Lazy**
   November 21, 2007

   Sidney was a good man… a decent man… and in many ways a capable physicist.

But in the end, he was a **limited** man… sadly, sadly limited.

And his time had come and gone.

His scientific world was a world of crabbed, cramped limitations, so-called rules, and unimaginative, arbitrary restrictions like “unitarity”, “self-consistency”, “not adding complex numbers to grassman-valued numbers”, and so on.

He, like so many of his kind, had the soul of an accountant and the imagination of a Soviet bureaucrat.

The doctors may talk of Parkinson’s disease, but I think what truly dealt him the final blow was a sense of sorrow:

His crowning achievement — the Coleman-Mandula so-called “theorem” — had recently been falsified
(http://en.wikipedia.org/wiki/An_Exceptionally_Simple_Theory_of_Everything)
and his bigoted worldview of “consistent physics” had come crashing down around him, leaving his legacy in deep disgrace.

But why should I go on beating a dead horse?

Today, the Coleman era has passed.

Smolinian “seers” such as myself and the author of this blog are finally dealt our just rewards — FQXI grants, book deals, talk-show appearances, not to mention promotional T-shirts and coffee mugs with our revolutionary theories embossed on them — all the indicia of true scientific success.

Meanwhile Coleman and his degraded heirs — the soi-disant “string theorists” — stand on the brink of a vast obscurity.

Not a moment too soon, but let us be charitable —

De mortuis nil nisi bonum.

10. **Yatima**
November 21, 2007

> Garotte Lazy Says…

Very funny. You sadly fail at satire.

11. **Tony Smith**
November 21, 2007

Sidney Coleman lives on through the people he knew and taught, and through his brilliant works (his book of lectures Aspects of Symmetry, his Harvard lectures written up by R. Ticciati as the book Quantum Field Theory for Mathematicians, etc).

Unfortunately, in an attempted (failed IMO) satire “Garotte Lazy” referred to
“… Coleman and his … heirs … “string theorists” …”,
even though as Jacques Distler said on his blog on 18 March 2005
“… Sidney was not interested in string theory; he wasn’t even particularly interested in supersymmetry …”.

Since Sidney Coleman was Jacques Distler’s Ph.D. adviser, Jacques Distler’s assessment of Sidney Coleman’s attitude toward string theory is probably accurate.

If “Garotte Lazy” were to try to defend his statement by saying that since Jacques Distler is a string theorist and also a student of Sidney Coleman, a string theorist is in that sense an heir of Sidney Coleman, I believe that I would find such an argument to be specious.

Tony Smith

12. **woit**
November 21, 2007

“Garotte Lazy” = “moron” = “Richard Feynman”

I see that you appear to be affiliated with the physics department of the Institute for Advanced Study. For why I’m mentioning this, see
http://backreaction.blogspot.com/2007/11/anonymity.html#c219957437009240105

Posting stupid attacks on people from behind various juvenile pseudonyms is completely unprofessional. Dragging the reputation of a beloved and admirable person into this at a time that his corpse is not yet cold, with the claim to be his “heir”, is in addition morally repulsive.

13. **Mrs. Feynman**
November 21, 2007

“…Lazy” = “moron” = “Richard Feynman”

How can you insult my dead husband by calling him **“lazy”** and a **“moron”** ?? Don’t you **dare** speak ill of my poor, dead Richard, do you hear me?

How **could** you??

YOU MONSTER!!!

14. **Peter Woit**
November 21, 2007

“Mrs. Feynman”=“Garotte Lazy” = “moron” = “Richard Feynman”, and is a regular reader of this blog from a Linux machine at the IAS running an IAS customized browser. He posted the same thing at Lubos’s blog, where Lubos writes that he finds it inappropriate and wishes that he had deleted it before people started commenting on it.

15. **Bee**
November 21, 2007

This is sad, both Coleman's death and the inappropriately stupid comments you have to deal with. Best,

B.

16. **nontrad**
November 21, 2007

I was a student of a PhD student of Coleman's. I read 'Aspect of Symmetry' closely as a grad student and prior to that watched videos of Coleman's lectures (e.g. 'Quantum Mechanics in Your Face' about the Bell inequalities / EPR / hidden variables etc) and prior to that heard many stories. So, I was saddened to hear about this loss.

That said, I would like to *STRONGLY* second the idea that it is *EXTRAORDINARILY* inappropriate to use this loss as an opportunity to engage in polemics.

Regards,

nontrad.

17. **Observer**
November 21, 2007

Garotte Lazy Says: ……

No time, no place for those comments, not even in your wildest dreams you will get something similar to a a Sidney Fest to honor you. By the way with your last citation, De mortuis nil nisi bonum.
"No one can speak ill of the dead," embarrasingly you contradict your whole comment.

18. **T**
November 22, 2007

I still don't quite understand what *EXACTLY* Sidney Coleman contributed that merits such deep reverence for him after his demise; was he like Weinberg – i.e. a very intuitive and thoughtful field theorist – or Feynman – a highly creative and original thinker; or simply a good teacher who taught at (world-famous) Harvard – and hence his stature? Sidney Coleman's writings don't seem particularly any different from that of other well-cited physicists.

Regards.

19. **D R Lunsford**
November 22, 2007

Peter, couldn't have said it better, even though I tried.

-drl

20. **Steven H. Cullinane**
November 22, 2007

T: The following quotes may be of interest."Sidney Coleman comes as close as any active physicist to assuming the mantle of Wolfgang Pauli as a trenchant critic of research and as an expositor of ongoing developments in theoretical physics." —Book review of *Aspects of Symmetry*"He has… played the role of Wolfgang Pauli of his generation; he liked to disprove ideas, and he was also a genius in explaining things to others." —Lubos Motl

21. **Professor R**
November 23, 2007

hi Peter,
sad news that Sidney Coleman has died, just as his famous theorem is in the news again. (I'm enjoying all the recent comment on the recent Lisi paper on the physics blogs). Sidney will live on through his work and his students.

Re a historical point, did you know that the first proof of the 'impossiblity' of combining internal symmetries with the Poincare symmetry of space-time was furnished by the Irish physicist Lochlainn O' Raifeartaigh?(my late father). The 'O'Raifeartaigh no-go theorem' was a hugely controversial result at the time and brought quite a few PhD studies to an abrupt halt – see Dyson's book 'Symmetry Groups'. My understanding is that the debate was finally closed when Coleman and Mandula published a generalization of the theorem. Given the controversy, it seems a pity that the original theorem is never referred to now (although it is liberally cited in the Coleman-Mandula paper)…in other words Dad got all the flak but is now forgotten!
That said, I don't really understand the details of the difference, being an experimentalist.

Re Lisi E8 paper, as a rank outsider, I can't help thinking that it would be very surprising if the group theory specialists would have missed this, Dad and others were v familiar with this group….Cormac

22. **MathPhys**
November 23, 2007

Sidney Coleman was an extremely smart man who, in his prime, knew an incredible amount of Physics.

When he graduated from CalTech, Gell-mann wrote him a recommendation letter saying "Coleman knows more physics than anyone I know with the exception of Feynman".

He was also a very pleasant man. RIP, Sidney Coleman.

23. **Peter Woit**
November 23, 2007

Hi Cormac,

Thanks for writing. Your comment did encourage me to look at one of Coleman's papers on this that was in a book on my bookshelf ("Seven Types of U(6)", in "Mathematical Theory of Elementary Particles", edited by Roe Goodman and Irving Segal, proceedings of a 1965 conference).

The article is written with Coleman's typical clarity and humor, reading it reminds one of the reasons he is so highly admired. He begins with a quotation from the Marquis de Sade's "La Philosophie dans le boudoir":

"Let up put a little order in these revels: measure is required even in the depths of infamy and delirium"

which might also be an apt quote for the current state of particle theory…

Coleman mentions the O'Raifertaigh theorem in a note at the end of the article, characterizing it as saying that if you have an exact finite-dimensional symmetry group including both Poincare and internal symmetries, then all particles will have to have the same mass. He claims this is a weaker result than what he is after (the paper was written at a time that he suspected, but did not yet have an argument for what was to become the Coleman-Mandula theorem), since it allowed the possibility of constructing non-trivial theories combining internal and space-time symmetry, as long as the particles had the same mass. Recall that at the time, this was all about working with symmetries that were known to be only approximate anyway, e.g. flavor SU(3).

In the bibliography he includes, Coleman makes the following excuse to those authors not represented:

"This bibliography is representative, not exhaustive; it would require the talent of a Dunbar to compile an exhaustive one. Before omitted authors become indignant, they are advised to examine the text and see how I have represented included ones."

One of the main sources he lists is the proceedings of a conference held at Trieste in May-June 1965. I remember seeing this many years ago. There were a huge number of papers by people trying out all sorts of variants of large non-compact groups as possible symmetry groups including SU(3) and space-time symmetries. It was remarkable to see both how quickly people started working on this after the discovery of SU(3), and how quickly they stopped as the no-go arguments became apparent.

24. **Santo D'Agostino**
November 23, 2007

MathPhys,

I remember reading this story somewhere, as follows: Coleman got reference letters from both Gell-Mann and Feynman. Gell-Mann's said that, "Sidney Coleman knows more about field theory than anyone else, except for Feynman." Feynman's said that, "Sidney Coleman knows more about field theory than anyone else, except for me."

This Week’s Hype

November 23, 2007
Categories: This Week's Hype

This past week has seen a veritable bumper crop of media hype, involving claims coming from both string theorists and critics of string theory. Besides the overhyped claims and Lisi-mania that has made it into all sorts of media outlets, New Scientist has added a couple more examples:

- The cover story of this week’s issue is The void: imprint of another universe?, which features claims by Laura Mersini-Houghton about a feature observed in the WMAP data that vindicates string theory. According to her:

> It is the unmistakable imprint of another universe beyond the edge of our own.

and

> I think our evidence points to string theory being on the right track.

She also claims that string theory does make a prediction about what the LHC will see: no supersymmetry. Since many other string theorists are claiming that string theory could be vindicated by seeing supersymmetry at the LHC, I guess this logically shows that string theory has already been shown to be correct by the LHC results, since it predicts both that supersymmetry and no supersymmetry will be seen, and this is a prediction guaranteed to come out right.

- The same issue also contains an article entitled Has observing the universe hastened its end?, about this recent arXiv preprint of Lawrence Krauss and James Dent, where they, according to New Scientist

> …suggest that by making this observation in 1998 we may have caused the universe to revert to a state similar to early in its history, when it was more likely to end.

The Drudge Report today links to an article Mankind ‘shortening the universe’s life’ in the British newspaper The Telegraph.

A lot of this nonsense seems to be originating in Britain. Tomorrow at Cambridge University there will be a series of talks on God or Multiverse? that one can attend for the bargain price of 65 pounds. The talks are advertised with a quote from philosopher Neil Manson

> ~~The multiverse is the last resort for the desperate atheist.~~
> Note added 10/29/2014: Actually, that’s a misquotation and misrepresentation of what Manson wrote. For the true story, see here.

Perhaps the members of the clergy assembled for this event can lead those attending in a fervent prayer that we soon be liberated from this plague of hype and nonsense, whether it be inspired by string theory or not…

Update: The story mangling Krauss/Dent has made it to Slashdot. Seems to me that recent Slashdot stories on physics conclusively falsify one theory, that of the wisdom of crowds.

Update: Krauss has changed the last two sentences of the paper to avoid misunderstandings about what he is claiming such as the ones that appeared in the media, see his comment here.

Update: It appears that Krauss somehow got the notion that it would be a good idea to respond to Lubos’s posting about him in the comment section of the blog. He has now been banned there on the grounds that he is “unable to satisfy basic criteria of what I consider a rational debate.” Remarks from anyone supporting him have also been deleted, following the usual Lubosian practice of how to deal with dissent.

Update: The Telegraph article has been extensively edited, with the current version more accurately reflecting what was actually in the Krauss/Dent paper. The misleading headline remains. I also hear that Krauss has written a letter to New Scientist about the problems with their article. This also got picked up by Wired Science, where I seem to have acquired an affiliation with MIT I wasn’t aware of.

Update: Here’s an account of the “God or Multiverse” event, where prayers for deliverance from nonsense were not answered by the almighty:

> …given that multiverses are in favour in many physics departments these days, perhaps theology has something to contribute. Augustine and Nicolas of Cusa are just two theologians to have pondered the possibility way back, thinking it quite likely that the generous creativity of God would overflow into the formation of other universes…
>
> For theists, consciousness is ontologically prior to everything else. So in a sense the possibility of the multiverse makes perfect sense already. It would be every possible state of things that could exist, formed in the mind of God – who must be able to conceive of everything possible since that is implicit in the concept of divinity…
>
> …not all explanations of things are simpler than the things they are explaining (the multiverse as an explanation for the apparent fine-tuning of our universe being an obvious case in point…
>
> …In fact, maths looks rather like God – the former being necessary thinking, the latter necessary being…
>
> …However, if modern cosmology comes up with the multiverse as the fundamental, necessary proposition (at least in one version, it says that all possible worlds necessarily exist somewhere, we just happen to be in the one that we happen to be in), then Ward put it that the proposition of God as the fundamental necessity is actually a far simpler conjecture. In the theological case, all possible worlds would be said to exist in the mind of God, though quite possibly only a limited number of universes, and perhaps only one, actually exist. Occam would presumably have been much happier with that thought than heaped infinities of actually existing universes…
>
> God’s role in creation, then, is to allow only the universes that do exist, to exist.…
>
> …This would be a purposive explanation of the universe. Purposive explanations require knowledge of things, discrimination between things, an appreciation of goodness, and the power to chose good over evil. So to put it all another way, the big question in the cosmology debate is that of evaluation: how do you evaluate one theory over another?…

Update: John Baez explains what the Krauss/Dent paper is really about.

Update: The Krauss/Dent paper has now been refereed and accepted for publication in PRL.

   this plague of hype and nonsense

   It's just a matter of perspective. Think of it as science fiction. It's interesting, in a certain way. I read a lot scifi as a kid, and I've always found other universes and big mysterious voids interesting. I can understand that people like to read that stuff. I just think that in many cases the speculative character of ideas is not sufficiently well explained. And then there's of course the concern that under such circumstances it might eventually have an impact on science what people like to read about.

2. **Yatima**
   November 23, 2007

   I feared that Peter would not be able to resist the bait of the latest edition of New Scientist.

   The editors should move these speculative ideas to a different section than "Fundamentals", something like "Really Wacky Stuff" pronto.

   Something must be going wrong when arbitrary civilian (i.e. me) is presented with the daunting prospect of having to make sense of a text like:

   "Our measurement of the light from supernovae in 1998, which provided evidence of dark energy, may have reset the false vacuum's decay clock to zero" (thus hastening the day of vacuum decay)

   Only locally, one would hope. Additionally, reflect upon the fact that the blogosphere now observes the emergence of the idea that observing the universe may hasten its end. This might push the universe into a state in which this same idea is more likely to be true. We are doomed by a feedback loop created by a wrong interpretation of the verb "to observe".

   I will spare you %&+*#! bad puns about the truth emerging from large holes in the universe.

3. **wb**
   November 23, 2007

   The Krauss/Dent claim is rather amazing. The 1998 observations were no different qualitatively than those made earlier. What is different is the human concepts that emerged. So what did reset the universe in their concept? seeing a supernova? did seeing reset the universe a thousand years ago? or physicists thinking about it? If the later, those not accepting the dark energy theory would have had thoughts that did not reset the universe. Why did one set of thoughts win out? Suppose dark energy is false, does the universe revert to its former state. The observations themselves interrupted the flow of a less than 1 Joule of energy… an that resets the universe?

   Tis takes more suspension of disbelief than listening to presidential candidates.

4. **alex**
   November 23, 2007

   "She also claims that string theory does make a prediction about what the LHC will see: no supersymmetry."

   There is no such generic prediction. Her statement is obviously wrong. She is not a string theorist, nor a particle theorist so I would be suspicious of such claims.

5. **SnarkFest**
   November 24, 2007

   It's a good thing this slop has a lot less potential impact on our lives than the demented shenanigans that have occurred in the world of quantitative finance (and the investment strategies it enables) over the past few years. NSF and DOE will be lucky to have a budget by the end of the decade (not to mention the rest of us).

6. **PMembrane**
   November 24, 2007

   Does this mean we'll get to watch Krauss spear his hand with a pen-knife?

   Chaos is king! Magic is loose in the world!

7. **John Baez**
   November 24, 2007

   Bee wrote:

   > Think of it as science fiction. It's interesting, in a certain way. I read a lot scifi as a kid…

   I read a lot of sci fi as a kid too! Now that I'm grown up, I read a lot of SF. 🙂

   Whatever you call it — science fiction, sci fi, speculative fiction or SF — I think it's great stuff. By *labelling* it as fiction, we can let it inspire us without taking it too seriously. The problem comes when people try to pretend such stuff is real science, even when it's not precise and doesn't make any testable predictions. That's what Peter Woit is quite rightly complaining about.

   Let science be science; let SF be SF.

8. **PMembrane**
   November 24, 2007

   The silly phrasing of the coda to the Krauss/Dent preprint aside, I am curious as I have never seen a concise explanation of what the decay of a metastable ST vacuum means in concrete terms.

   I've seen it stated that the ground state of the ST vacuum is flat 10-d Minkowski spacetime—does this mean that the compactified dimensions suddenly "unroll", resulting in a supersymmetric 9-d universe?

9. **Bee**
November 24, 2007

Hi John: Yes, I totally agree with you. See the last two sentences of my first comment. Best, B.

10. **Arun**
November 24, 2007

IMO, particle physics is accelerating on its downwards trend: starting with the popularization of speculative, even if powerful, ideas in the public in the name of bringing science to the masses with now not-even-a-theory being heralded in blogs and publications like The Economist as the great new hope.

11. **Peter Shor**
November 24, 2007

I'm going to be agree with Bee, more or less.

Is this any worse than news reports of the quantum eraser experiment which make it sound like quantum mechanics means that we can change the past (and which are also totally baffling, especially to people who actually understand quantum mechanics)? There is real science behind the quantum eraser experiment, and there seems to be very little actual science behind the ones you report on this week, but I suspect that this distinction is completely invisible to the public. How can you tell the difference between botched reporting of good science and botched reporting of bogus science? They both get the public excited about science, which is a good thing.

Ideally, of course, the science writers would be clever enough to only report good science, and not botch their explanations of it. But we don't live in an ideal world.

I would like to believe that scientists who get themselves in the news with sci-fi stuff don't advance their careers. This would give incentives to scientists to come up with this sci-fi stuff, which isn't at all good for the field (as opposed to journalists coming up with the sci-fi stuff, which I can't see as being very harmful). Any thoughts on this? And how can we give scientists incentives to explain their work to the public honestly without giving them incentives to come up with this sci-fi nonsense?

12. **How Can We Turn The Tide?**
November 24, 2007

I had great hope last year with the publication of Peter's Not Even Wrong and Lee Smolin's The Trouble With Physics.

Finally someone put the Bogdonavs in perspective.

But their most recent actions, which helped fuel the media storm regarding Garret Lisi's non-theory, left me disappointed.

Garret mistitled a paper, spent hours preparing a pretty, but ultimately meaningless youtube video with a hot English female voice, which in fact does not unify gravity with the other forces, and succeeded in getting the non-physics video everywhere, along with Lee's "fabulous" appraisal.

The deeper I study the Lisi crisis, the darker it gets–there was a lot of pre-mediation on Lisi's behalf, aided by willing consultants and hype-master accomplices. Read Lisi's "gee whiz I'm a surfer and gee whiz I just figured out the universe and gee whiz it's a young theory and gee whiz I don't want to hype it and gee whiz it's the media's fault" posts at all the proper, pre-mediated points in the blogosphere–read his sycophantic posts throughout the forums, where he never quite answers anything, but only states that he is a poor hermit and surfer and snowboarder in Hawaii and Lake Tahoe. Does Woit think that this is any different from the Bogdonav Affair, other than that Lisi surfs and snowboards, which gives him a media advantage?

To the degree this media event succeeds, it devalues all the humble, hardworking, and generally underemployed physics Ph.D.'s; and it further encourages the public to distrust science.

I wish Garrett would have placed his physics first, which would mean first doing physics, I guess.

It would be so easy for Peter & Lee to speak out and to have spoken out, instead of calling Garrett's non-theory "fabulous."

It is time for Garrett to retract his paper from arxiv.org, retitle it with a more appropriate title, and resubmit it.

It would also be great if he were to contact all the media outlets and convey to them the simple facts and truth–his theory makes no predictions and cannot be tested, and it is replete with fundamental errors and handwaving that are now well-documented throughout the blogosphere, whose time he wasted.

If Lee and Peter ever meant anything by their books–if they are men of their words–the most important element in the advancement of science and all culture–they should call upon Lisi to set the record straight.

13. **Peter Shor**
November 24, 2007

To answer Pmembrane, I thought that Calabi-Yau manifolds were flat 10-d space-time (at least to the first-order approximation), so all these Calabi-Yau manifolds are ground states to a good approximation. This is probably what you heard stated. Higher order effects are what is believed to make one the true vacuum and the others false vacuums.

As for how you go from one Calabi-Yau manifold to another, I don't believe anybody understands this process in any degree of detail whatsoever. Please correct me if I don't know what I'm talking about (which is quite likely).

14. **AP**
November 24, 2007

Maybe I am missing something here … New Scientist is a magazine that they sell for money right? Would I want them to make less money to satisfy some irrelevant scientists? Not if they are the source of my pay check, right? (Here I am defining irrelevant as being less news worthy than which starlet got arrested for drunk driving last night). I can hear the 'but' coming already … 'but shouldn't they make money without hurting science?' One has to ask why? I don't let other people bully me about how to legally make money and I don't think New Scientist should let me, you or anybody bully them either.

That being said, what about the scientists involved in this debacle? Well what can one say? It seems to be working out for them right? No offense Pete, but you're one to talk. You use popularization for your own purposes too. But I'm sure you'll say you do it the right way and they do it the wrong way. Funny how life seems to work out like that …

15. **Tim May**
November 24, 2007

I'm not sure I should be commenting here, lest the future of the universe be further shortened. (We now have confirmation that blogging is killing the universe, something many of us had already felt was happening.)

Hey, I like science fiction as much as Bee, John Baez, etc., but what seems to be happening is the "tabloiding" of science, akin to "Entertainment Tonight!," "The National Inquirer/Enquirer," Paris Hilton, Brittny Spears, etc.

I think a certain amount of speculation is healthy. I vividly recall reading everything I could back around 1968-70 on Wheeler's ideas about black holes, wormholes, etc. (even before these became motifs in science fiction). I don't think the speculation was too way out, and it didn't cause much confusion….just a few bad SF movies.

This tabloidization isn't completely new. I remember "Science Digest" from the 1960s, a small magazine printed on pulpy-type paper, with lots of gee-whiz articles about time travel, flying cars, and our impending colonization of Mars. And "Science News" had its moments of silliness.

Then the 1980s hit, with the publisher of "Penthouse" producing "Omni." A glossy, glitzy magazine devoted to pop science, with lots of articles about living forever, uploading into computers, etc. Other mags, too. It eventually folded. (Along with a really excellent magazine called "High Technology," which had great articles about things like disk drives work, how chips work, etc.).

Even "Scientific American" moved away from its formerly staid, even formulaic, approach to articles in favor of shorter, more "with it" pieces. And cover stories designed to sell newstand copies. (I don't have any issues handy, as I no longer buy paper magazines, but I recall several breathless covers not too far removed from what "New Scientist" uses frequently.)

There's still "Nature." And "Science."

Oh well. Maybe someone will produce a paper saying that if _observing_ dark energy shortens the life of the universe, then _confusion_ and _errors_ about dark energy will REVERSE THESE EFFECTS!

(BTW, I looked at the PDF of the K & D preprint. The citations didn't seem to mention Nick Bostrom, who has written about Bayesian issues along the same lines. I don't think he would phrase things in terms of "the observation of blah _causes_ the universe to end sooner," but would express things in terms of what an observation means in terms of where in a thing's lifetime (civilization, environment, universe) we likely are. I'm not sure I agree with Bostrom, but at least he phrases the "Neo"-Bayesian points in a non-causal way.)

–Tim May

16. **Lawrence Krauss**
November 24, 2007

Hi.. I wanted to chime in with an apology of sorts regarding the confusion in the press regarding our work. Our paper was in fact about late-decaying false vacuum decay and its possible cosmological implications. Needless to say, the explosion of press interest, prompted by the final two sentences of the paper, misrepresented the work, which was not intended to imply causality, but rather to ask the question of whether by cosmological measurements we constrain the nature of the quantum state in which we find ourselves, inferring perhaps that we are not in the late-decaying tail. However, I do take responsibility in part for the flood, as I was undoubtedly glib in talking to the new scientist reporter who read the paper on the arxiv. I have learned that one must be extra careful in order not to cause such misrepresentations in the press, and I should know better. In any case, the last two sentences of the paper have been revised so that it should be clear to the press that causality will not be implied. mea culpa

17. **Peter Woit**
November 24, 2007

Pmembrane/Peter Shor,

10d flat space appears to be a stable solution to string theory, consistent if any solution is. A Calabi-Yau is a 6d space with certain properties, can be highly curved. String theory is believed to have solutions in which 4 dimensions are flat (space-time), 6 are a Calabi-Yau.

Saying that transitions between solutions are not understood in any detail is a huge understatement.

However, this discussion of the basics of string theory really is off-topic, if you want to pursue it, perhaps the blog of a string theorist would be a place to try.

18. **Peter Woit**
November 24, 2007

How can we…

I've not referred to Garrett's work as "fabulous", instead have tried on this blog to give an accurate description of it. Garrett, like any author, is entitled to a much more optimistic view of his own work than other people may hold. Taking this into account, I don't think his behavior has been unreasonable at all.

19. **J.F. Moore**
November 24, 2007

I would like to be sympathetic to science stories being "mangled" as our host Peter puts it, or "misrepresented" as L Krauss does. I certainly see many examples of this in pop science literature. But I'm having a hard time understanding how a science reporter, when given this quote (presumably via phone or email interview):

"The intriguing question is this," Prof Krauss told the Telegraph. "If we attempt to apply quantum mechanics to the universe as a whole, and if our present state is unstable, then what sets the clock that governs decay? Once we determine our current state by observations, have we reset the clock? If so, as incredible as it may seem, our detection of dark energy may have reduced the life expectancy of our universe."

is misrepresenting the science or the scientist if the reporter then prints that in the article he writes. Were there strong qualifiers that were omitted? I also don't think the pub crowd at Slashdot (which linked to the Telegraph article, not New Scientist) can be much blamed for taking such clear hints at causality and running with them.

I do respect the mea culpa here, but I would think it would do more good (maybe with some exposition) as a letter to the editor in New Scientist and the Telegraph, precisely the places where people who are easily mislead might then read it.

20. **Lawrence Krauss**
November 24, 2007

I have written to the New Scientist…btw…

and the quote was within the context of a wavefunction.. if our measurements constrain the wave function, and if the probability of decay depends upon the state we are in, then if we are averaging over probabilities the statement is true I believe.. what was glib was not being clearer on this than I was.

21. **Chris Oakley**
November 25, 2007

Lawrence,

It may be too late. Even by suggesting, or causing others to think that you suggested, that making astronomical observations could cause the universe to end prematurely you may have forced the universe into a quantum state where this could possibly happen.

Tim,

Why is it that none of you guys seem to be able to spell Britney Spears' name correctly? Peter and Lubos both have "Brittany" (see the Jan 22, 2006 NEW posting), which lends credence to my theory – admittedly on diminishing evidence – that Lubos is a fictitious adversary created by Peter to boost sales of his book.

22. **Nugae**
November 25, 2007

Every week New Scientist publishes a cover article that is either fallacious or nonsense. Don't be narrow-minded: try reading them when they're on some subject other than cosmology and you'll see it's true.

[Occasionally there is an exception, when in Du Sautoy style, the article is so vacuous that one can't even see whether it's nonsense or not].

A really forward-thinking university would organize a weekly New Scientist undergraduate seminar: a great interdisciplinary exercise for the enquiring mind. PhDs would be allowed in only if they had some residual ability to think outside their own field. A Britney test would be unfairly stringent, though: a Tolkien test might be easier.

23. **How Can We Turn The Tide?**
November 25, 2007

Peter,

What it all comes down to is that the public is entitled to the Truth.

I simply cannot comprehend how you can state in good conscience that Garrett's behavior has not been unreasonable. Your slipperieness is beocming more and more apparent, undermining the value of this blog and your book.

Garrett titled his paper "An exceptionally simple theory of everything," which the paper is not. Indeed, authors are entitled to optimism in their work, but that does not grant them the right to publish and perpertuate lies, with the aid of well-funded accomplices.

Smolin called the paper "fabulous," and look at the hundreds of pages which have resulted:
http://www.google.com/search?hl=en&safe=off&q=fabulous+smolin+lisi

Lisi claims that his theory can be tested, but this is also a lie. His theory offers no concrete predictions.

Lisi also went through an exorbitant amount of effort to make a youtube video with a hot women's voice and market his surfer image.

Again, all that we're asking for is the simple truth:

1) Woit and Smolin should acknowledge that the title of Lisi's paper is hype, and that his theory makes no predictions.
2) Lisi should withdraw his paper from arxiv.org, retitle and rework it to reflect it's true nature, and resubmit.
3) Woit/Smolin/Lisi should contact the dozens of major news outlets, and share the truth.

http://www.foxnews.com/story/0,2933,311952,00.html

And please, let's stop with the cutesy-irony, as Fox News reports, "For his part, Lisi self-mockingly calls his finding "An Exceptionally Simple Theory of Everything." in Laid-Back Surfer Dude May Be Next Einstein

http://www.foxnews.com/story/0,2933,311952,00.html

What it all comes down to is that the public is entitled to the Truth.

Anyone who disagrees with this can never contribute to science.

24. **piscator**
November 25, 2007

Dear Peter,

This statement

>Saying that transitions between solutions are not understood in >any detail is a huge understatement.

is plain wrong. Certain transitions – e.g conifold transitions – are understood very cleanly, and there is a beautiful story involving the presence of new light degrees of freedom (wrapped branes) at the singularity. This is really nice physics, the solutions are protected by lots of supersymmetry, and everything is under control.

This case represents a *great reason* to study string theory – the theory knows about topology change, and can describe it precisely and in a controlled fashion.

piscator

25. **Peter Woit**
November 25, 2007

piscator,

One can argue about how well this is understood in certain idealized models, but I think it is accurate to say that there is nothing remotely like a detailed understanding of such transitions in general, or most importantly, in the case relevant to physics, of transition between two string backgrounds complicated enough that one of them might have something to do with the real world.

26. **conifold**
November 25, 2007

Peter:"…the case relevant to physics, of transition between two string backgrounds complicated enough that one of them might have something to do with the real world."

Is the KKLT construction "complicated enough"? Recall that they compactify Type IIB on a CY which has a local structure of the Klebanov-Strassler deformed conifold.

27. **Peter Woit**
November 25, 2007

conifold,

Sorry, I just don't see how what is known about the conifold transition can be said to provide anything that can be called a "detailed understanding" of the transition from one realistic string background to another, including in the KKLT case.

28. **piscator**
November 25, 2007

Peter,

obviously I agree that the less supersymmetry you have the less control you have.

I very much hope that for backgrounds describing the real world, the theory of vacuum decay is not a question that is actually relevant to experimental physics 🙂

piscator

29. **Bad**
November 25, 2007

"Lawrence, It may be too late. Even by suggesting, or causing others to think that you suggested, that making astronomical observations could cause the universe to end prematurely you may have forced the universe into a quantum state where this could possibly happen."

Now kids, *that* there is some real wit. Bravo. 🙂

30. **nicky nichols**
November 26, 2007

hang on! surely new scientist is not that bad, the article does state that there is at least another explanation.

please do not criticise science journalists who have to assimilate a great deal of new information and understanding in a very short period of time. and besides, science articles are often written in a particular way, science magazines often exist for a particular reason beyond profit.

i could mention several examples of new scientist articles which when were immediately considered to be false, however wrongly so…

31. **Professor R**
November 27, 2007

hi Peter,

Re media hype discussed above:

I've only started reading New Scientist again in the last few months and am astonished how their articles undermine recent work in physics by both over-hyping and misrepresenting it. Here in Ireland and the UK, NS articles are then rewritten in the press, with further misunderstandings added.

I have huge concerns over this method of making science 'interesting'. Is it any wonder the public lack confidence in science, when the latest speculative ideas are portrayed as the new science? It also makes balanced discussion of the papers quite difficult afterwards, which is a pity for the authors.

For example, your own discusson of Lisi paper read as reasonably balanced and fair, but the NS article lacked any critical comment from specialsts. In fact, it pretty much made out that E8 was a new discovery in group representation. When I checked the only book on group theory I have on my shelf (, 'The Group Structure of Gauge Theories' O'Raifeartaigh, CUP) I was surprised to find a comprehensive discussion of the use (and limitations) of E8 in gauge theory as far back as 1986).

As for the NS article on Krauss's paper, its clear from his comments that the article misrepresented the central thesis …I think I'll stick with Physics World …. Cormac

Letter to the Editor

November 24, 2007
Categories: Uncategorized

To the Editor:

Paul Davies, in his Op-Ed piece Taking Science on Faith, uses recent untestable speculation about multiple universes motivated by string theory to claim that "the mood has now shifted considerably" among physicists. He characterizes physics as being, just like religion, "founded on faith", faith in the existence of intelligible laws describing nature and in a "huge ensemble of unseen universes", the so-called "multiverse".

The only real recent shift in mood among most physicists has been a loss of interest in string theory, precisely because its proponents have been forced to invoke the multiverse hypothesis in order to explain why string theory can't predict anything. The existence of mathematical "laws of physics", describing accurately and successfully the physical world in a testable way is not a "belief" but a fact.

Update: The Edge web-site is promoting both the Davies Op-Ed, and several critical responses to it.

Update: Lots of other bloggers weighing in, with the Science Blogs crowd (here, here, here, and here) uniformly Davies-hostile. The only positive blog entries I've seen about the Davies piece come from the IDers and Lubos Motl. Lubos seems to feel that the main issue here is that Steven Weinberg, Stephen Hawking, Lenny Susskind and Frank Wilczek may be unable to pursue their anthropic-principle-inspired research programs out of fear that I might criticize them. I would think they might be even more intimidated by P.Z. Myers, who reaches rhetorical heights I can not aspire to, referring to the Anthropic Principle as that *tiresome exercise in metaphysical masturbation that always flounders somewhere in the repellent ditch between narcissism and solipsism*.

Comments

1. **D R Lunsford**
   November 24, 2007

   Needless to say, someone should write a very hard-hitting Op-Ed rebuttal to this crap. This fiction that physics is somehow about *us*, is the ultimate expression of an absolutely pernicious narcissism.

   Davies, one notes, is British.

   -drl

2. **cyberfizzle**
   November 24, 2007

   I wrote a rebuttal, but I don't know if it's any good.

3. **gbp**
   November 24, 2007

   I think, we see just the beginning of this shift. I expect that all papers where nothing observable is computed with reasonable accuracy may be banned in some way (or labelled as junk). This is going to be the price the community will pay for the decades of superficial speculations.

4. **LDM**
   November 25, 2007

   Well, Davies is all wet.

   First, religious faith, where you are not allowed to challenge dogma, but must accept it even if it is contrary to reason, does not have a counterpart in science. *Everything* in science is fair game to be questioned, and any theory respected today could conceivably be overturned by a new fact discovered tomorrow. Not so in religion.

   Second, he accords the multiverse much more legitimacy than it merits.

   Third, his statement " *the very notion of physical law is a theological one in the first place, a fact that makes many scientists squirm*." is false. The notion of physical law in science, as already noted, is in fact the opposite of a theological notion. Any law is fair game, including the notion of physical law itself, and unlike religious dogma, science *needs* to have its ideas questioned to remain vital…Religion is the opposite, and cannot stand free inquiry and questioning.
   If, for example, I call Susskind a hack because I don't agree with his ideas in HEP, he probably could care less. If I draw a cartoon with him in it ridiculing his ideas… again, he could care less. But, if instead of Susskind I chose a certain religious figure, I could find a fatwa issued against me.

   Davies doesn't know what he is talking about.

5. **zorba**
   November 25, 2007

   Paul Davies said: "In other words, the laws should have an explanation from within the universe and not involve appealing to an external agency. "

   I fail to see what anyone [apart from religious people] could object to in that statement. Boltzmann *explained* the second law of thermodynamics [in terms of probability], Einstein *explained* the laws of gravitation, etc ; all PD is saying is that he wants to see this project furthered, and that people who deny that this is necessary are behaving in an irrational ["religious"] way. Lubos Motl regularly denies that certain things need to be thought about [for example, the smallness of the entropy at early times] and PD is just decrying this kind of head-in-the-sand attitude.

   By the way, the notion that multiverse ideas are *intrinsically* unverifiable is an error; to take just one example, see

   Anthony Aguirre, Matthew C Johnson, Assaf Shomer, Towards observable
   signatures of other bubble universes, arXiv:0704.3473

November 25, 2007

Davies' conclusion, that the' laws should have an explanation from within the universe and not involve appealing to an external agency. The specifics of that explanation are a matter for future research' seems reasonably sensible. And is the faith referred to in 'until science comes up with a testable theory of the laws of the universe, its claim to be free of faith is manifestly bogus' anything other than a belief in the efficacy of the scientific method? This is something all scientists have, I would have thought. Just by mentioning the multiverse, which he says is 'increasingly popular, but– doesn't so much explain the laws of physics as dodge the whole issue', and having a bit of 'history' in this area, Davies appears to become a target for unreasoned and ad hominem abuse (saying that the fellow is British, for example) of the type more usually associated with anonymous string polemicists.

7. **Coin**
November 25, 2007

Just in case you were wondering, by the way, [the "intelligent design" movement takes Davies' op-ed as vindicating what they've been saying all along].

8. **Constantine Tynyansky**
November 25, 2007

All mathematical axioms are religion. The mathematics are a sect of axiomatic religion. The mathematics nothing explains! For example, where an explanation, why is true (has the proof) any mathematical theorem? Physicists-theorists it the religious fanatics, which try to search for explanations with the help of mathematics. For example, theory of superstrings, multiverse etc.
Sample of religious fanaticism: "all mathematical structures exist" [Max Tegmark].

9. **nigel cook**
November 25, 2007

I read Paul Davies 1985 book *The Forces of Nature* as a kid, and it was helpful in explaining (without any mathematics) a little about the origins of fundamental forces from experiments in electromagnetism, beta radioactivity (weak force), and particle interactions (strong force and validation of the basic electroweak theory by the discovery of three massive weak gauge bosons in 1983). I think it did contain some speculative ideas like string at the end, but that wasn't hyped. The nice thing was the graphical explanation of how the idea of quarks arose from plotting known particles in geometric shapes with particles arranged at their points experimental data (arranging the known baryons and mesons by their charge and spin properties), which led to predictions like the omega minus (containing three strange quarks), which were experimentally confirmed. The book didn't explain everything very well, and the lack of presentation of any significant mathematics was unhelpful. But at least it showed that there was substance and scientific method in some modern physics. It's bad news that Davies has now moved on from explaining how science should be done, to seeking to replace it with religion. However, he clearly wants to be fashionable and he did receive a Templeton Prize for Religion a few years back. What do you seriously expect in this day and age? Science has reached a dead end.

10. **Leonard Ornstein**
November 25, 2007

The convention of accepting axioms and definitions, is an act of "faith". Thus all logic and deduction is rooted in faith.

Believing that observation of an incomplete sample of a class or process can be used to estimate properties of the class…or the future, is an act of faith. Therefore all inductive empirical reasoning depends, at least implicitly, on faith.

Yet Paul Davies is wrong, for the reason repeatedly cited above: Science, which MUST depend on these faiths, none the less, in contrast to theisms, insists that they all are provisional beliefs, scaled by some confidence intervals, and subject to possible refutation by future observation.

Science (as all rational disciplines) makes models of "reality" as perceived by imperfect minds in a noisy environment. No matter how beautiful, the relationship of a model to reality can only be judged by empirical "tests". Until multi-verses, string theory and even Higgs bosons are "tested", they are indistinguishable from good science fiction. And the longer it takes their proponents to at least "design" such tests, the greater our right to be skeptical!

There can be few absolute truths, even in purely logical systems, as Gödel demonstrated; the Platonic dreams of such absolutism by some mathematicians and physicists notwithstanding.

11. **Chris W.**
November 25, 2007

Davies' concluding paragraphs (already quoted in part):

> It seems to me there is no hope of ever explaining why the physical universe is as it is so long as we are fixated on immutable laws or meta-laws that exist reasonlessly or are imposed by divine providence. The alternative is to regard the laws of physics and the universe they govern as part and parcel of a unitary system, and to be incorporated together within a common explanatory scheme.
>
> *In other words, the laws should have an explanation from within the universe and not involve appealing to an external agency.* [emphasis added] The specifics of that explanation are a matter for future research. But until science comes up with a testable theory of the laws of the universe, its claim to be free of faith is manifestly bogus.

Some of the previous commenters (and Peter too) haven't read his essay very thoughtfully. It seems clear that he is *calling for* an explanation of physical laws from within the universe. This is hardly consistent with the viewpoint of intelligent design or earlier theological accounts, which call for an explanation *from outside*, ie, from a deity. He is hardly endorsing the notion of a multiverse as an adequate solution; on the contrary, he evidently regards it as deeply problematic and question-begging, if not altogether vacuous. **He is issuing a challenge, and I believe he hopes it can be met.**

12. **DB**
November 25, 2007

There is no belief system in science which is comparable to religion. What Davies claims to be science's belief system is in fact a set of expectations, based solely on the experience to date that the interplay between hypothesis and experimentation yields a progressively refined and more powerful grasp of the workings of our universe. This is a perfectly rational stance which requires no belief system to underpin it. As long as each iteration continues to deliver the goods, you stick with it.
Someday, this process could very well end in the conclusion that mankind had gone as far as its limited mental capacities allow. At which point the only rational position would be to acknowledge that we don't possess the ability to go further at this time. We are already at the stage that a thorough understanding of established QFT and GR demands exceptional mathematical ability and years of university level study and is therefore reserved to a tiny minority of humanity.
As Poincare explained so eloquently in his popular text Science and Hypothesis way back in 1905, our so called immutable laws are nothing more than a set of mathematical models of reality and are to be retained only in so far as they correctly predict the outcomes of experiments. To the best of our knowledge, they have no existence outside the human capacity to create and process the symbols which encode this information.

There is simply no overlap whatsoever between this position and the set of immutable fairytales for adults which serve as a psychological crutch for the ignorant, impoverished or weak-minded who have either been thoroughly brainwashed as children or, in their dotage, are terrified by the inevitability of death and personal extinction. Or indeed, with any of their modern reincarnations such as the anthropocentrism promoted by Davies.

13. **D R Lunsford**
November 25, 2007

What Davies fails to get is the difference between faith and intuition. Faith is a choice of free will – intuition is something ineffable and innate – either you have it or not. The nearest religious analogy is "grace".

When enough people share the same faith, they can then organize and block competing faiths. Thus faith is essentially negative because it leads automatically to dogma. There is no possibility of "enough people having the same intuition". Those come to a only a few, sometimes contemporary (e.g. Newton and Leibniz, Gauss, Bolyai, and Lobatchevsky etc.). Intuition leads on to physical law if properly interpreted. It can be mis-interpreted (Kepler) and so is not "perfect" in a religious sense. It can subsequently be re-interpreted (Kepler again) and that is the stuff of heroism.

What has happened is – religion and metaphysics have been systematically discredited by several generations of physicists (which however does not make them unnecessary and vital), and they have now spilled over into physics.

14. **lylebot**
November 25, 2007

> The convention of accepting axioms and definitions, is an act of "faith". Thus all logic and deduction is rooted in faith.

No, the axioms are just taken as antecedents at the very first step in a chain of modus ponens. We don't have to believe that they're true to use them to reason.

15. **ekzept**
November 25, 2007

With all the possible variations on even DNA-based life, and the contingent pruning happening along the way from LIPS and the occasional space rock, I think the words of Loren Eiseley might be remembered:

> Lights come and go in the night sky. Men, troubled at last by the things they build, may toss in their sleep and dream bad dreams, or lie awake while the meteors whisper greenly overhead. But nowhere in all space or on a thousand worlds will there be men to share our loneliness. There may be wisdom; there may be power; somewhere across space great instruments, handled by strange manipulative organs, may stare vainly at our floating cloud wrack, their owners yearning as we yearn. Nevertheless, in the nature of life and in the principles of evolution, we have had our answer. Of men elsewhere, and beyond, there will be none forever.

That's from Eiseley's essay "Little Men and Flying Saucers" in The Immense Journey.

16. **Bad**
November 25, 2007

Not until today have I been familiar with Lubos Motl. Can someone briefly explain what the heck is going on there?

17. **Peter Woit**
November 25, 2007

Bad,

That's rather off-topic, and I'd rather this thread not turn into a discussion about Lubos, no matter how entertaining the topic might be.

Short version is that Lubos is a string theorist, considered by some one of the leading young people in the field, and until recently a junior faculty member of the physics department at Harvard. He has done more to convince people that there is something really wrong with string theory and how it is being pursued than anyone else. Also a fervent climate change denialist. For more, read his blog.

Sorry folks, please don't go on about Lubos in this comment thread.

18. **Yatima**
November 25, 2007

I think this discussions should be put on ice until the moment Theological Engineering finally manages to disburse Mana from vending machines or until we have regressed to the Dark Ages, whatever comes first.

19. **Marty Tysanner**
November 25, 2007

My reading of the essay was similar to that of Chris W, and so after reading Davies' piece I was surprised how many others had a very different perspective on his words. This may be partly be a case of getting out of the essay what one brings into it. For example, I am especially sympathetic to Davies' statement:

> It seems to me there is no hope of ever explaining why the physical universe is as it is so long as we are fixated on immutable laws or meta-laws that exist reasonlessly or are imposed by divine providence. The alternative is to regard the laws of physics and the universe they govern as part and parcel of a unitary system, and to be incorporated together within a common explanatory scheme.

Relatively few people I have talked with share this perspective, so perhaps that partly accounts for the apparent majority who dislike his essay.

DB presents what seems to be a common perspective:

> There is no belief system in science which is comparable to religion. […] a set of expectations, based solely on the experience to date that the interplay between hypothesis and experimentation yields a progressively refined and more powerful grasp of the workings of our universe. This is a perfectly rational stance which requires no belief system to underpin it.

This is a very defensible viewpoint as far as it goes. However, it overlooks the "faith" component of the process, at least in theoretical physics and cosmology, by ignoring the crucial role of initial assumptions. To give two examples (many others could also be given):

1. Searches for quantum gravity, or even more restricted attempts to explain why the standard model has the form and parameters that it does, almost invariably seem to assume from the outset that quantization of some kind is fundamental. By "fundamental" I mean underived rather than emergent from some process or configuration of more primitive non-quantized objects. Most knowledgeable theorists don't seem to deny the *possibility* of emergence, but neither do they take it seriously. It doesn't fit in with their own beliefs about Nature.

2. Minkowski spacetime as the "ground state" in general relativity. An alternative to this viewpoint is to see Lorentz symmetry as emergent from more fundamental objects; if one does not assume fundamental quantization either, then this emergence would need to be be from more primitive, *continuous* objects. Almost no one I have talked with seems to take interest in this possibility, but again it seems to come to a matter of faith.

These examples are not trivial, in that they determine the scope and direction of major research programs, and more insidiously, help define what theoretic directions lie outside the mainstream (and hence define where a tenure-minded individual should tread carefully).

I don't see these two examples of faith among theorists as being equivalent to faith in religion, *as long as there is recourse to experiment to test whether a theoretical framework represents Nature*; empirical tests are the central distinction between science and religion. With concrete feedback from Nature, wrong assumptions should eventually be uncovered, or else out of desperation new generations of physicists will try a different set of initial assumptions that may prove more fruitful than those that led to dead ends. Nonetheless, I think it is hard to argue that faith (or "belief," if one prefers that as a "nicer" word) doesn't play an important role in science.

20. **Chris W.**
November 25, 2007

To follow up on what Marty said, in science as in life we make choices and commitments that we hope will be successful, while knowing that at least some of them will not be. To do this requires some faith that at the very least *we'll be able to learn something from our failures*. As Davies pointed out, the universe doesn't have to be constructed in a way that permits this. Nature could be just screwing with our heads in utterly inscrutable ways:

> Therefore, to be a scientist, you had to have faith that the universe is governed by dependable, immutable, absolute, universal, mathematical laws of an unspecified origin. You've got to believe that these laws won't fail, that we won't wake up tomorrow to find heat flowing from cold to hot, or the speed of light changing by the hour.

Many working scientists (and others) may consider it silly to worry about such a possibility. Such people do not understand what it means to confront a truly deep problem in the natural sciences.

21. **dark-matter**
November 25, 2007

Paul has a book out lately based on certain metaphysical thesis, which is not selling well, and he needs to kick up a fuss to help out on the marketing.

22. **Leonard Ornstein**
November 26, 2007

lylebot, Chris W., and Marty:

For language to work, there has to be at least some kind of explicit or implicit commitment, by its users, to an agreed upon set of "axioms", rules, and definitions. It follows that the same applies for ALL rational systems. Such discipline is distinguishable from a system of theistic faith, ONLY in the required absolute commitment of religions.

As I noted above, and as was established by Hume, empirical induction from the part to "the whole" also requires UNSUPPORTABLE faith.

The criticism that science depends on faith is therefore a straw man!

Degree of commitment in science, usually varies with the preponderance of the evidence. Since Jerzy Neyman introduced the concept of "confidence intervals" in 1937, this commitment has become somewhat quantifiable. But even when we're talking about a 99.999% confidence (e.g., that associated with the measured mean magnitude of the fine structure constant), it's not absolute, and new observation may prove that our confidence has been misplaced.

It's this recognition, WITHIN science, that distinguishes its practitioners from priests.

Unfortunately, some scientists(?) believe they ARE priestly prophets, and it's the RESPONSIBILITY of other scientists, at times, to disabuse the public on such matters.

23. **Hans**
November 26, 2007

what I think most disgusting these days, is that even nobel laureates join such an anti-physics campaign.
Here is a talk for laymans of condensed matter physicist R.B. Laughlin, who states, that high energy physics is like religion:

http://www.physik.uni-muenchen.de/aus_der_fakultaet/kolloquien/physik_kolloquium/laughlin/laughlin261107.pdf

(I have seen only the first 15 minutes of the talk, and then suddenly found out, that i must leave the room).
It is depressing, when someone, who apparently knows nothing about quantum field theory of gravity, and what the problems are in high energy physics, says, without any good foundation, that all high energy phycisists are doing religion
(And this in front of a full audience of laypeople!)

24. **Peter Woit**
November 26, 2007

Hans,

I'm no fan of Laughlin's, but his comment about medieval religion is not original, but something Glashow and some other particle theorists have been saying for years. Unfortunately Laughlin is not completely wrong: there are theorists promoting ideas that are little better than religion, and this has given encouragement to those like Davies who like their religion and science together. You may be justified in walking out on Laughlin, but I think it would be helpful if you would also walk out on some of the pseudo-science talks on things like the anthropic landscape.

25. **Hans**
November 26, 2007

What Laughlin wants to say is more!
He does not criticise specific attempts to build a quantum theory of gravity.

He wants to say, that you cannot build a theory of quantum gravity at all.

He has a book in press on this. For Layman, here:
http://www.amazon.de/Abschied-von-Weltformel-Robert-Laughlin/dp/3492047181

You can criticise theories like string theory or LQG. But it is simply wrong if you seemingly have no knowledge of high energy physics at all, you stand in front of laymans and say that it would be in principle impossible to find a quantum field theory of gravity (with no accurate scientific argument) and that all attempts are to be fruitless.

His wrong argument was, that for systems with a small number of particles, collective laws would break down. Therefore, he thought, you could not define any quantum field theory at small scales.

He seemingly did not know, for example, that high energy physicists would be very fine if they would have a quantum gravity that works at the scales where the standard model gives good results.

26. **Zathras**
November 26, 2007

As usual, there is a huge amount of inaccuracies in this discussion about what “faith” or “belief” is, and this misrepresentation completely skews the analysis.

Faith is most emphatically not a set of axioms held without evidence. Put crudely (there is no other way) faith is a feeling about things. It is synthetic, rather than analytic, in that it is based on some sort of continuum of how one feels about the world (notice you cannot really define faith without using words such as belief or feeling.

As Nietzsche observed, “philosophy allows us to rationalize what we already believe.” The axiomitization is the outcome of this rationalization process. The axioms of faith discussed here are just a by-product, not the core of what belief is.

At least part of what I think Davies is talking about here is the faith in progress. There is of course no single axiom that embodies this idea of progress for every single scientists, or probably even a majority of scientists. Scientists do what they do because they think that they can make or contribute to the progress of understanding the universe.

As DB says, “*What Davies claims to be science’s belief system is in fact a set of expectations, based solely on the experience to date that the interplay between hypothesis and experimentation yields a progressively refined and more powerful grasp of the workings of our universe*.” However, the scope of perceived past progress varies from scientist to scientist, and therefore so does the belief in
attainable future progress. No scientist has all the information of how science has progressed, or failed to progress, so far, so there is a different set of information which shapes each scientist’s faith in progress. A scientist from a subfield which has been stagnant for years will come to a very different conclusion than someone whose field has seen rapid advances.

27. **Peter Woit**
November 26, 2007

All,

Please, enough, I can’t stand it any more. Take the highly general discussion about science and belief etc. to one of the dozen or so other blogs featuring discussion of this topic.

28. **Leonard Ornstein**
November 26, 2007

Peter:

You started this “Letter to the Editor” topic with Davies’ title “Taking Science on Faith”.

Now you object to “the highly general discussion about science and belief etc.”!

A precise general discussion of the relationship between “Science” and “Faith” is just what’s needed to understand Paul Davies’ “mistake”. We may individually fail in our attempts to add to clarity. But you should be ready to put up with this kind of effort. Otherwise, why start the topic?

29. **Peter Woit**
November 26, 2007

Leonard,

I think the confusions of Davies on this issue have been dealt with more than sufficiently here and elsewhere. Further elaboration of this topic seems to me a waste of time and likely to convince anyone who comes to this blog looking for something worthwhile and interesting to read that they’re in the wrong place. So, please, enough about the Davies confusions.

30. **milkshake**
November 26, 2007

The salesmanship about far-off ideas in theoretical physics and cosmology can produce a wooly impression how the science normally works. Davies is trying to be provocative but he actualy sounds like a Jesuit seminary kid.

I think if the wheelchair luminaries were saying more frequently “we are trying to find out how this Universe works behind the scene” and “We don’t really know for sure, we postulate all kinds of ideas but in the end we take it the way it comes out” the public would get a lot less elevated view on natural laws and the fontiers of our understanding – and there would be less opportunity for this metaphysical gorp.

31. **D R Lunsford**
November 27, 2007

There’s a wonderful “Letter to the Editor” today, by Chance Reschke of Seattle, who states:

Condemning science for its failure to explain the divine makes as much sense as condemning Kant for failing to explain the aerodynamic properties of the Concorde, or Moses for failing to predict Google.

Beautiful!

-drl

32. **Belizean**
November 27, 2007

Getting back to physics, does anyone else have a problem with Davies use of the word "multiverse" in connection with the Anthropic Principle? While his usage is "correct" in that it's the one that has in the last few years come dominate particle physics, the word predates the current hyping of the Landscape.

Multiverse used to mean the ensemble of universes in the Many Worlds Interpretation of quantum mechanics. The AP and MWI multiverses are not the same. Unlike the AP multiverse, the multiverse of the MWI requires its constituent universes to interfere with each other, and the prevalence of any particular universe in the multiverse generally changes with time.

Yes, this is a bit OT, but a source of irritation nonetheless.

33. **manyoso**
November 29, 2007

I can imagine the smackdown Richard Feyman would give to Davies were he still alive…

Some quotes from Genius: The Life and Science of Richard Feynman:

"The scientist has a lot of experience with ignorance and doubt and uncertainty, … we take it for granted that it is perfectly consistent to be unsure–that it is possible to live and *not* know. But I don't know whether everyone realizes that this is true."

and…

"He believed in the primacy of doubt, not as a blemish upon our ability to know but as the essence of knowing. The alternative to uncertainty is authority, against which science had fought for centuries. "Great value of a satisfactory philosophy of ignorance, " he jotted on a sheet of notepaper one day. "… teach how doubt is not to be feared but welcomed."

and …

"You see, one thing is, I can live with doubt and uncertainty and not knowing. I think it's much more interesting to live not knowing than to have answers which might be wrong. I have approximate answers and possible beliefs and different degrees of certainty about different things, but I'm not absolutely sure of anything and there are many things I don't know anything about, such as whether it means anything to ask why we're here…

I don't have an answer. I don't feel frightened by not knowing things, by being lost in a mysterious universe without any purpose, which is the way it really is as far as I can tell. It doesn't frighten me."

34. **Kralizec**
December 4, 2007

> I would think they might be even more intimidated by P.Z. Myers, who reaches rhetorical heights I can not aspire to, referring to the Anthropic Principle as that *tiresome exercise in metaphysical masturbation that always flounders somewhere in the repellent ditch between narcissism and solipsism*.

Mr. Myers seems to have written as if his feelings are a proper standard for rejection or acceptance of opinions. I doubt we really think one's fatigue, boredom, hatred of idle pleasure, or repulsion from either self-loving or candidly lonely observers is grounds for rejecting or affirming an anthropic principle, or any other opinion. Most everyone writing here seems closer to thinking that an opinion is true or false irrespective of the way one feels about it or about the possible motives of anyone who may hold it.

Not Yet About Geometric Langlands…

November 26, 2007
Categories: Uncategorized

Tomorrow morning I'll head down to Princeton to attend the conference on Gauge Theory and Representation Theory at the IAS. Unfortunately I had to miss the first day of the conference (today), since I would have liked to have heard all the talks, most especially that of Dennis Gaitsgory on local geometric Langlands. Maybe someone who was there will explain to me what he talked about.

That might be even better than attending the lecture, since Gaitsgory's pedagogical style seems to be rather daunting. Here is an article about his experience teaching linear algebra, and the Harvard Crimson last year ran this frightening account of what it was like to take Math 55 from him. Math 55 is a legendary honors math class for the most fanatical first-year students, and I have fairly vivid memories of my own experience with it (that year it was taught by Konrad Osterwalder and John Hubbard). From what I remember, the first row of the class was occupied by a sizable proportion of the winners of the previous year's Math Olympiad, and being a rather average student in a math class was a new experience for me. The textbook for the course was a remarkable book by Loomis and Sternberg with the somewhat misleading title *Advanced Calculus*. It's now available on-line. Osterwalder made a valiant effort to follow the text during the first semester, while Hubbard more-or-less winged it the second semester, entertaining us by going over in class research papers on dynamical systems and assigning us Spivak's *Calculus on Manifolds* as something to work through during the reading period (about a week long) before final exams. Both Osterwalder and Hubbard seem to have been much mellower sorts than Gaitsgory though, since I remember working fairly hard on puzzling out problem sets, but also having a life with quite a lot of other things going on, nothing at all like the experience described in the Crimson article. Kids these days.

The first talk tomorrow morning is supposed to be Maldacena on integrability in N=4 SSYM. He really should be celebrating the day as the 10th anniversary of his amazing paper The Large N Limit of Superconformal Field Theories and Supergravity, which announced the AdS/CFT conjecture and was submitted to the arXiv on November 27, 1997. Work on this conjecture has dominated particle theory in a remarkable way over the last ten years. According to SPIRES, the paper has amassed 4897 citations, at a rate which has only accelerated in recent years, with 551 citations in 2006. It is now the third most heavily cited paper in particle physics, behind only those of Kobayashi-Maskawa and Weinberg. A simple extrapolation suggests that in another four years or so it should become the most heavily cited particle physics paper in the history of the multiverse. Several conferences are celebrating the anniversary, including one next month in Buenos Aires, and another in Fort Lauderdale. Davide Castelvecchi has a quite good popular article on the subject in Science News.

After it's over, I'll try and write something about the main topic of the conference, geometric Langlands. In the meantime, my ability to keep the comment section under control may be impaired. Behave.

Update: David Ben-Zvi is putting up his notes from the talks here.

Comments

1. **Charles**
   November 26, 2007

   He didn't talk about Local Geometric Langlands at all, and focused on localization of Kac-Moody algebras (I'm basing this largely on the fact that he said this at the beginning of his talk, I didn't follow very much of it).

2. **JC**
   November 26, 2007

   Peter,

   Not quite on-topic

   Just wondering. How many people finished math 55 in the year you took it?

   I didn't go to Harvard for undergrad, but in my freshman year I ended up doing sort of a mini-DIY version of "math 55" by taking the "honors" level real analysis and abstract algebra courses. (I finished most of the freshman + sophomore "non-proof heavy" math courses before I started university). The textbooks assigned were ones like Rudin and Royden for analysis, and Lang and Hungerford for algebra. The "honors" level courses also had a reputation for high drop rates.

   This was the first time I ever had to put a lot of time into any math courses, where I ended up almost completely burning out. This was also on top of also simultaneously taking the "weedout" freshman physics courses.

3. **Peter Woit**
   November 26, 2007

   Charles,

   Thanks. Here "localization" is the sort of geometric construction of representations I've always been interested in trying to connect to QFT, I'm sorry I didn't get to hear the talk (although I might have also got lost when he went into the derived category…). By the way, I just got what looks like an excellent book in the mail when I got home: D-modules, perverse sheaves, and representation theory, by Hotta et. al. Lots about D-modules, and it shows explicitly how they are used in representation theory. No Kac-Moody groups, just the finite-dim theory, but it looks quite readable, unlike almost everything else in this subject. Something to read on the train tomorrow…

   JC,

   From what I remember, there were about 40 the first semester, 20 the second. The first semester I think I was an above average student in the class, the second semester, not so clear….

4. **Chuck**
   November 26, 2007

   I just got that D-modules and perverse sheaves book too — looks good, I agree! I saw Gaitsgory give a talk at MIT a few weeks back and it was interesting, for the rather small percentage I understood . . . . He is a pretty good lecturer, although he moves rapidly (as one would expect).

   His work (with Frenkel) on localization of modules for Kac-Moody algebras connects somehow to their formulation of local Langlands in characteristic 0. Frenkel's book on the subject is not easy to read, although it seems as though if I could get through it I'd understand what they're trying to do.

5. **John**
November 26, 2007

Hi Peter,

I must stereotypically respond, “Wow!” It’s not an easy feat to take Math 55. Although I am not in Harvard, I have heard of Math 55’s status among college-level math courses.

I’m somewhat curious to know if the course is more a graduate-type abstract math course or a high school Math Olympiad-type course, or somewhere in between?

I’m quite interested in finding out as, since you are a graduate of the course, you (of any persons I know) would be able to provide some feedback to the following query – Does a course such as Math 55 help develop professional math skills from an early point onwards? i. e. would one be able to write one’s own research work (if albeit not completely professional) after completing the course?

Thanks,
John

Side-note: I have Sternberg’s and Rudin’s books, but somehow I found them too formalistic (and/or opaque) to learn from *and* understand the motivating reasons for the math simultaneously.

Can you suggest a more suitable option?

6. **Peter Woit**
November 26, 2007

Chuck,

I’ve been spending a lot of time reading the Frenkel book, slowly understanding the details of what they’re doing. I find him relatively easy to follow, although it took me a while to get a feel for what he is trying to do and to see how some of the ideas fit together (there’s still a lot I haven’t understood). He’s a good expositor, especially compared to some other people in this field… I guess a very specific form of my question about Gaitsgory’s talk would be: what did he talk about that’s not explained in Frenkel’s book?

7. **JC**
November 26, 2007

Peter,

What exactly made the 2nd semester slightly harder for you?

8. **Peter Woit**
November 26, 2007

JC,

The second semester wasn’t harder, actually I think Hubbard’s teaching style was such that you could get by with less work. But the twenty people who had dropped after the first semester were mostly not the best students in the class, so the twenty that remained were on the whole an impressive group. Luckily I’m not the competitive sort, otherwise I might have really not enjoyed that experience. But, in any case I was far more interested in my quantum mechanics class that semester, the beginning of a life-long love affair…

9. **JC**
November 27, 2007

Peter,

I didn’t know what my exact rank was in those honors level real analysis and abstract algebra courses I took in my freshman year. Through from I can recall anecdotally, I do remember there were at least two or three other folks who consistently performed better than me on assignments and exams, judging from a casual search of the piles of graded stuff. (The grader just left our graded assignments and exams on the front table for us to pick up ourselves, where it was easy to spot the ones with the better grades).

I was sort of a competitive type back in those days, which was one of the reasons I ended up not majoring in pure math. Another big reason was that I didn’t make it onto the Putnam exam team during my freshman year. It may sound silly now in hindsight, but it was a huge devastating blow to my ego at the time.

After my freshman year was over, I spent some idle time in the university library and came across several books on topics like engineering dynamics, particle physics, quantum mechanics, fluid dynamics, etc … which really grabbed my interest and attention. (I already had enough math background to be able to follow what these books were explaining at a basic rudimentary level). It took me awhile to mellow out from the hyper-competitive mentality, and eventually decided to change my major to physics. In hindsight, I’m glad that I found out early on as to what I was NOT interested in majoring in.

(This is getting off-topic, so I’ll stop here).

10. **odo**
November 27, 2007

John,

Math 55 is designed to prepare students to be professional mathematicians. It is not at all a math olimpiad problem solving course. It would normally cover the basics of real and complex analysis, some basic functional analysis (e.g. spectral theorem for compact operators), point set topology, introductory algebra, maybe some elementary Riemannian geometry (ala Spivak and do Carmo). The handful of students in it are usually exceptional; the year I was a freshman at Harvard the students in it included one who made full prof at Princeton before turning 30, one who is an associate prof at MIT, one who is at Stanford, etc. It’s full of the super fast thinkers who know a lot also.

In general it probably does not provide adequate background for doing research; no freshman course does. In normal circumstances even a very talented, hard-working kid would need several more years of courses before being able to do much of interest to researchers. Of course there are exceptional individuals who do research even in high school, someone like Drinfeld, but these people are anomalous, and their parents probably ought not to be emulated.

11. **Chuck**
November 27, 2007

Gaitsgory's talk (at least the part I kinda-sorta understood) started with the ind-scheme of opers on the formal punctured disc and its relation to representations of the corresponding Kac-Moody algebra (of the Langlands dual group) at the critical level. I think this stuff is in Frenkel's book. I had a hard time following what he did after that though. I think the issue for me is that all of these topics — opers, representations of Kac-Moody algebras (and the completed enveloping algebra) at the critical level, localization of modules on finite or affine flag varieties, hecke eigensheaves, moduli stacks, etc — are not too awful to get an intuition for individually; but I get very confused as to how they're all supposed to fit together to form a big-picture whole.

12. **Zathras**
November 27, 2007

From the piece on teaching linear algebra:

"I found the job annoying for two reasons. First, the students were primarily non-math majors."

This brings up one of my biggest bones to pick with mathematicians. Their insularity knows no bounds. While most fields have become more accepting of interdisciplinary work, mathematics has developed a significant population who are absolutely against any such work. Barbeckiism and abstraction are what is valued, not clarity, and certainly not application. For this reason, more and more engineering and science department are moving towards teaching their students calculus and other mathematics, just because mathematicians think it's their way or the highway.

13. **Peter Woit**
November 27, 2007

John,

I hope odo's comment helped answer your questions. The course is just an undergraduate course, although a fast-paced one, it's still a long ways from research-level math. One thing it does for students is to give them enough background so that they can start taking some of the basic grad courses during their undergraduate years, which does get them closer to the point of being able to get into research early in their graduate careers.

I thought it was an ideal course for bright, intellectually ambitious students, throwing at them at much as they can handle. The Crimson article may have been exaggerated, but I don't think it's a great idea for first-year undergrads to be spending almost all their time on a math course, no matter how good. A great university like Harvard offers students so many wonderful opportunities to learn many different kinds of things, and they should take advantage of this. As well as taking advantage of being young and irresponsible…

After Math 55, as an undergraduate I took mostly physics courses, only a few math classes, including one graduate course. Most of my math education came later in life, not through taking courses (sometimes through teaching them…). As for books, Loomis/Sternberg is quite a document, but not so great pedagogically. Among undergrad analysis textbooks I've seen, the recent series from Princeton looks good, although I haven't looked that closely at the books.

14. **jasper**
November 27, 2007

Zathras,

While one might aspire to be able a teach a top-rated course to people of all backgrounds, my (limited) experience has been that connecting with students who are interested in the topic that you're teaching is much easier than fighting the very uphill (but worthwhile, of course) battle with students who are forced to take your course as a requirement… This is very much in line with the tone of the rest of Gaitsgory's anecdote.

15. **Richard**
November 27, 2007

Peter,

I also thought that spending 30-50 hours per week on problem sets for a single class is a bit excessive, and wondered if they're learning anything else. On the other hand, I do like the idea of exposing the students to a lot of material early in their education so that they can see what's coming and appreciate better what they're learning in the context of the entire body of math. Perhaps this sort of thing is more suited to some kind of intensive summer program.

16. **David Ben-Zvi**
November 27, 2007

Hi — I'm posting notes to many of the talks
(in particular so far Gaitsgory, Beilinson, Ginzburg and Maldacena)
as we go along at
http://www.math.utexas.edu/users/benzvi/GRASP/lectures/IAS.html
(available off my GRASP lecture notes page also) — many of them are transparency talks and I don't even try with those, but
hopefully some of the transparencies will be posted later.

Gaitsgory's talk discussed two realizations of representations
of Kac-Moody algebras: as D-modules on affine flag manifolds
(localization) and as coherent sheaves on spaces of Langlands parameters. The equivalence between the two is an important
case of the local geometric Langlands conjecture.
I haven't checked carefully but I think the new results with Frenkel
(not covered in Frenkel's book) involve the localization
on affine flags (I think their earlier work was on affine Grassmannians) and were presented with a more derived-algebraic-geometry viewpoint.

17. **Peter Woit**
November 28, 2007

Thanks David. Congratulations on a fascinating talk today, I enjoyed it!

18. **surlygrad**
November 30, 2007

Was Hubbard eccentric back then? He was pretty off his rocker when I took the freshman honors class with him at Cornell.

19. **woit**
November 30, 2007

I wouldn’t say “off his rocker”, but definitely a bit eccentric, while highly enthusiastic. I found him rather entertaining, some of the more serious students in the class were a bit put off…

Geometric Langlands and QFT

November 30, 2007
Categories: Favorite Old Posts, Langlands

Wednesday's session at the IAS Conference on Gauge Theory and Representation Theory was mostly devoted to talks by Witten and his collaborators about their latest work on the approach to relating geometric Langlands and QFT that he has pioneered over the last couple years. The talks were quite understandable, giving a general overview rather than details of what are some very technical topics, about which the speakers have produced recently some very long papers. Before discussing the talks, I'll try and explain the background of this line of inquiry into the borderlands between mathematics and physics.

The history of this subject goes back thirty years, to a 1977 paper of Goddard, Nuyts and Olive entitled Gauge Theories and Magnetic Charge. In the GNO paper the authors noted that in a gauge theory with group G, while the electric charges take values in the weight lattice of G, the magnetic charges take values in the weight lattice of a "dual" group, which is now generally called the Langlands dual group ${}^LG$. This group was used by Langlands in a crucial way in conjectures about number theory that go back to a letter of his to André Weil in 1967. Also in 1977, Montonen and Olive, in Magnetic Monopoles as Gauge Particles?, conjectured the existence of a dual gauge theory interchanging electric and magnetic charges, and the gauge groups G and ${}^LG$. At the time Witten was a Harvard postdoc, and on a visit to England at the end of 1977 Atiyah told him about this conjecture and first suggested it might have something to do with the Langlands program. Witten met Olive, and they collaborated on the 1978 paper Supersymmetry Algebras That Include Topological Charges where they suggested that Montonen-Olive duality would be most naturally realized in a supersymmetric gauge theory. Later work showed that it is N=4 supersymmetric Yang-Mills that seems to have this duality property, now called S-duality and extended to not just a $\mathbf{Z}_2$ symmetry, but a much larger symmetry under the group SL(2,**Z**).

Warning: *What follows is an absurdly overly simplified discussion that will offend pretty much every mathematician who really knows the subject. Comments correcting anything that isn't at least in some vague sense more or less morally right are welcome.*

From the 1970s on, work on conjectures growing out of the Langlands program has come to be one of the dominant themes of number theory, achieving a fantastic success with the work of Wiles on one such conjecture, the so-called modularity conjecture, that led to the 1995 proof of Fermat's Last Theorem. Trying to explain the Langlands program in any detail is a huge task, but I'll try and give a few very vague indications here of what it is about. The field **Q** of rational numbers can be thought of as "rational functions", on a "space" called Spec (**Z**), whose "points" are the prime numbers and a special "point at infinity". Number fields are extensions of **Q**, and can be thought of as corresponding to covering spaces of Spec (**Z**), characterized by Galois groups, in particular the Galois group Gal(**Q**) of the algebraic closure of **Q**, which in some sense is the fundamental group of Spec(**Z**). Many questions in number theory can be expressed as questions about "Galois representations", representations of Gal(**Q**) in complex Lie groups such as G=GL(n,**C**). Thinking of Spec(**Z**) as a "space", representations of Gal(**Q**) correspond to local systems, i.e. flat vector bundles over Spec(**Z**).

The Langlands program has both a "local" and a "global" aspect. The "local" aspect restricts attention to the neighborhood of a "point" in Spec(**Z**), and the corresponding "local field" of functions. For the "point at infinity", the local field is the real number field **R**, for a "point" corresponding to a prime number p, it is the field called $\mathbf{Q}_p$. The local Langlands conjecture gives a correspondence between representations of Gal($\mathbf{Q}_p$) into a complex Lie group G and complex representations of the corresponding algebraic group ${}^LG$($\mathbf{Q}_p$) with $\mathbf{Q}_p$ coefficients. This correspondence matches up information on both sides that characterizes the representations, which can be expressed either in terms of L-functions, or in terms of the action of Hecke algebras. One can read this correspondence as possibly giving information in both directions: if you know the Galois representations, a so-called "arithmetic" problem, you get a parametrization of the irreducible representations of a Lie group, a so-called "analytic" problem. If you know about the Lie group representations, you get information about number theory.

In the global version of the Langlands correspondence, on the arithmetic side, the global group in question is just Gal(**Q**), and its representations in a Lie group G are central objects in number theory that one would like information about. On the analytic side, the global group is much trickier to describe. What one needs is something like a gauge group for bundles over Spec(**Z**), but remember that each "point" of this "space" has a different nature. One introduces an object called the "adeles" $\mathbf{A_Q}$ that puts all the local fields together, and then uses this as the coefficients in an "adelic" group ${}^LG(\mathbf{A_Q})$, that perhaps can be thought of as the gauge group of all changes in local trivializations about each "point" in Spec(**Z**). The representation theory on the analytic side is then harmonic analysis on this adelic group, with irreducible representations characterized by specific functions which are called automorphic forms (so this side of the correspondence is often called the "automorphic" side). Galois representations and automorphic forms are matched up by, equivalently, L-functions or the eigenvalues of the action of a Hecke algebra. For the case of 2d representations, the automorphic forms involved are very classical functions on the upper-half-plane, and readily computable information about the coefficients of their Fourier expansions gives deep information about number theory.

An important idea in number theory/algebraic geometry is that algebraic curves over a finite field $\mathbf{F}_p$ have many similar features to the "spaces" like Spec(**Z**) that characterize number fields. Functions on such curves give so-called "function fields", which behave very much like number fields, and one can transform number theory questions into analogous questions about these curves. For example, there is an analog of the Riemann hypothesis in the function field case, where it has been proven. One can translate the Langlands program conjectures into the function field setting, and there proofs have been found, for the global case by Drinfeld (rank 2 case) in 1974, and Lafforgue (higher rank) in 1999.

Given the Langlands correspondence for an algebraic curve over a finite field, a natural question is whether there is anything analogous if one replaces the finite field by the complex field, and works with complex algebraic curves, i.e. Riemann surfaces. In 1987 Witten wrote a beautiful paper entitled Quantum Field Theory, Grassmannians, And Algebraic Curves, where he explains how one can think of the holomorphic sector of a conformal field theory on a complex algebraic curve as giving something like an automorphic representation in this context, analogous to the ones studied using adeles for algebraic curves over finite fields. He mentions the Langlands program, but makes no attempt in this paper to describe what would be the analog of the Langlands correspondence.

Several years later, around 1995, Beilinson and Drinfeld formulated what is now known as the geometric Langland correspondence, giving a specific conjectural correspondence that is supposed to be an analog for a complex curve C of what happens in the function field case. On the analog of the arithmetic side, one just has a representation of the fundamental group of C in a Lie group G, i.e. a flat vector bundle. The automorphic side is much trickier, and they define "Hecke eigensheaves" on the moduli space of ${}^LG$ bundles that play the role of automorphic forms. In their massive (384 pages at last count), unpublished and still preliminary paper Quantization of Hitchin's integrable system and Hecke eigensheaves, they write

> We would like to mention that E. Witten independently found the main idea and conjectured . As far as we know he did not publish anything on the subject.

Since the mid-1990s, a lot of mathematical activity has grown up around these ideas, creating a new field that is now generally known as "Geometric Langlands theory", which connects to a wide range of different kinds of mathematics, and to physics via conformal field theory. With funding from the US Defense Department DARPA program, various workshops were organized that brought physicists and mathematicians together to discuss this subject. One such workshop was held at the IAS in March 2004, and there Witten gave a talk (see the end of these notes) about N=4 supersymmetric Yang-Mills and its dimensional reduction to a non-linear sigma model in two dimensions. He credits David Ben-Zvi with explaining to him crucial facts which made clear to him that what was needed to connect this to geometric Langlands was the introduction of boundary conditions in the sigma model, i.e. branes.

Witten first unveiled his version of geometric Langlands based on N=4 supersymmetric Yang-Mills in a talk at the beach at Stony Brook in August 2005; here are notes and audio from the talk. In April 2006 his 230 page paper with Kapustin, Electric-Magnetic Duality And The Geometric Langlands Program appeared, giving the details of a construction based on a topologically twisted (using the "GL twist") version of N=4 supersymmetric Yang-Mills, dimensionally reduced to give two topological sigma models with target space the Hitchin moduli space, for group G in one case, ^LG the other. These two models, known as the A and B model, are related by mirror symmetry. They involve boundary conditions and thus branes in two-dimensions, and as a result are related by what mathematicians now refer to as “homological mirror symmetry”. The fact that the Hitchin moduli spaces for G and ^LG could be thought of as mirror partners was shown earlier by my colleague Michael Thaddeus in work with Tamas Hausel.

Late last year Witten and Gukov’s 160 paper Gauge Theory, Ramification and the Geometric Langlands Program appeared, extending the QFT approach to geometric Langlands to the “ramified” case, which is that of a punctured Riemann surface, with non-trivial monodromy about the punctures. This was about the “tamely ramified” case, involving simple pole singularities at the punctures. Last month two new papers totalling 193 pages by Witten on this subject appeared, Gauge Theory And Wild Ramification, which deals with the case of higher order poles, and Geometric Endoscopy and Mirror Symmetry, written with mathematician Edward Frenkel.

The talks by Witten and Frenkel gave very general introductions to the two papers, notes taken by David Ben-Zvi are here and here. Witten mostly just explained the background for the wild ramification problem, not giving any details of how he solved it, so his talk mainly functioned as a good introduction to his recent paper. Frenkel also gave a talk which was more of an introduction to his recent joint paper with Witten. He explained that they were studying a special case of the question of what happens at singularities of the Hitchin fibration, for the simplest kind of singularity (orbifold), and simplest non-trivial case (G=SL(2), ^LG=SO(3), outlining the phenomena that appear. These phenomena are analogous to well-known phenomena in the number field case, where their study goes under the name of “endoscopy”. This part of the Langlands story has recently seen major progress, with the proof by Ngo of what is known in the subject as the fundamental lemma. Ngo is giving a series of talks at the IAS this semester on the subject, and Frenkel promised to give a talk next week about possible relations of what he and Witten have been doing to the work by Ngo.

For the story of a comment by Pierre Deligne during this talk, see this posting by Ben Webster.

To me the most interesting talk was Sergei Gukov’s on *D-branes and Representations*, in which he described what he is working on with Witten at the moment; no paper has yet appeared. Ben-Zvi’s notes are here, and Gukov gave much the same talk recently at Santa Barbara, notes here, audio here. I’ve been most interested in geometric Langlands because of its relations to 2d QFTs and representation theory, where the simplest story should be seen in the local version of the theory. Also, Gukov’s argument was based upon getting Chern-Simons theory out of the original 4d N=4 GL-twisted SYM theory using boundary conditions (something he didn’t explain other than saying what the boundary conditions are). I’ve always wondered whether it is possible to get Chern-Simons out of some sort of possibly supersymmetric twisted theory involving fermions. Someone in the audience asked if what he was doing gave such a theory, but he somewhat evaded the question, saying he preferred to think of things in 4d with boundary.

Getting down to two dimensions, he said that the Hilbert space of this Chern-Simons theory gave a representation associated to the punctured disk, and mentioned that this was related to local geometric Langlands. Someone asked “what happens on the boundary of the disk?”, and he answered that one only needed to impose boundary conditions at the puncture, not on the boundary. Greg Moore sputtered something like “really, on the boundary of the disk you don’t need boundary conditions??” (for the usual story about this, see this paper, which Greg co-authored), to which Gukov answered something about it being all right since they were only looking for supersymmetric BPS states. He went on, as one can read in the notes, to discuss a way of producing representations of a compact Lie group G (and its complexification and other real forms) that associates Harish-Chandra modules to A-branes on the cotangent space to the flag manifold, working out the details for SL(2, **R**). At the beginning of the talk, Gukov claimed that this was all leading up to a classification of the admissible representations of a real semi-simple Lie group in terms of D-branes, with the various geometrical constructions (e.g. D-modules) known to mathematicians just different faces of the same physical model. To me, the talk raised all sorts of interesting questions, so I’m looking forward to seeing the details when Gukov and Witten have a paper ready.

Comments

1. **Coin**
   November 30, 2007

   Hm, okay. So this is all really interesting from a mathematical perspective. What isn’t quite so clear to me is exactly what these things are expected to be used for in the context of physics. You say you see potential uses in geometric Langlands’ “relations to 2d QFTs and representation theory”; what is it that Witten et al hope to use geometric Langlands for? I’m particularly curious about this “ramification” thing; apparently Witten has something physical in mind when he works on those, since both of the papers on that subject which you cite him as being an author on have “Gauge Theory” in the title. Is there some particular set of physical problems which this punctured disk corresponds to, and Gukov and Witten hope to use the Langlands tools to analyze that problem? Or is this just a general set of tools they’re trying to develop? You say Gukov is using the punctured disk to get answers about “chern-simons” theories; is this the angle everyone is taking or just one of Gukov’s personal applications?

   Or I guess a clearer version of what I’m trying to ask might be this. The Witten and Gukov paper says in the introduction, just before it loses me completely, the following things:

   > The simplest version of the geometric Langlands correspondence involves, on one side, a flat connection on a Riemann surface C, and, on the other side, a more sophisticated structure known as a D-module…
   > The basic idea is that allowing ramification in the Langlands program corresponds, in gauge theory, to introducing surface operators, somewhat analogous to Wilson or ’t Hooft operators, but supported on a two-manifold rather than a one-manifold…
   > The gauge theory approach to geometric Langlands is based on N = 4 super Yang-Mills theory twisted and compactified on a Riemann surface.

   What I’m trying to figure out is exactly what it is the correspondence described here is applying to. As I understand all this so far the idea seems to be that you have a gauge theory that lives on a Riemann surface, and this surface has these thingies that you described as “punctures” and the paper describes as “surface operators”. The goal is to use the Langlands duality to convert this surface+(punctures/operators) to d-modules+ramification, where hopefully they’ll be easier to analyze. Okay, that makes sense, but as someone not very familiar with gauge theory what confuses me is, what exactly “are” the surface operators introduced on the gauge theory side? What physically are they supposed to be representing? Are they… particles, or what?

   One more question, you say “For example, there is an analog of the Riemann hypothesis in the function field case, where it has been proven.”. Given the known Langlands correspondence, why does this not give us a proof of Riemann in the number case? (Or is the Langlands correspondence just a conjecture or something?)

   Anyway thanks for this interesting writeup!

   PS, typo:

   In 1997 Witten wrote a beautiful paper…

   Should be 1987

2. **Peter Woit**
   November 30, 2007

   Coin,

   As far as I know, there’s no direct motivation from physics here at all. Gukov and Witten do mention the possible relevance of surface operators to problems in physics, but that's not why they are studying them. What they are doing is uncovering a relation between quantum gauge theory and some very deep ideas about mathematics. Whether what they learn this way will ultimately tell us something about physics is not known. That's not what they're aiming for right now, they're looking at the mathematics implications. Personally I think there's a lot more to come in this area. In the long run it may change how we think about quantum gauge theories, and the standard model is a quantum gauge theory. That's plenty of reason for people to work on this.

About the Riemann hypothesis. First of all, the Langlands correspondence is not really relevant to it. In the function field case the proof of the analog of the Riemann hypothesis doesn't involve the Langlands story. Secondly, I didn't try and discuss what is proved and what isn't within the Langlands program. On the whole, especially for number fields, this is still a subject where there are far more conjectures than proofs, which is why it is such a mathematically active subject. The things Drinfeld and Lafforgue proved for function fields remain still conjectures in the number field case.

3. **Coin**
November 30, 2007

   I see, thanks.

4. **Thomas Love**
November 30, 2007

   Peter, Thanks very much for the clear introduction to the ideas behind Witten's program. Now that I know that it is about the relation between electric and magnetic charges, I am interested. Whether my motivation will be enough to read the several hundred pages remains to be seen.

5. **milkshake**
November 30, 2007

   just curious: Was the current focus of Wittens work, on general math problems (that eventually might or might not connect to physics) brought about by the difficulties of ST?

6. **Michael**
November 30, 2007

   That's great that DARPA is funding relatively pure maths. Perhaps it has near-term cryptographic or physical applications?

7. **David Ben-Zvi**
November 30, 2007

   Peter,
   Nice summary! I wanted to add that the geometric Langlands program
   goes further back, at least to a paper of Laumon in Duke 54 (1987)
   where he explains the general program for GLn, inspired by Drinfeld's proof of the (not yet formulated) geometric Langlands conjecture
   for GL2 in 1983 (Amer.J. Math), inspired by Deligne's sheaf-theoretic proof of geometric class field theory in SGA. Interestingly the same
   Duke 54 volume (the Manin birthday volume) contains Hitchins paper defining the Hitchin system, which we now know is intimately related..
   Beilinson and Drinfeld then developed the complex version
   (in the language of D-modules rather than perverse sheaves and
   using many ideas of conformal field theory, which I believe they came at independently of Wittens wonderful paper that you mention – Manin, Beilinson, Drinfeld,
   Schechtman, and their collaborators were deeply involved in trying to understand the algebraic structures behind conformal field theory from the mid 80s.
   The other main necessary ingredient for geometric Langlands
   for general groups is the geometric Satake correspondence,
   with a complicated history starting from work of Lusztig in the 80s and involving Ginzburg, Drinfeld and finally Mirkovic and Vilonen.
   These days it has become quite an industry!

8. **David Ben-Zvi**
November 30, 2007

   Regarding DARPA, I dont know of any imminent applications
   to coding, defense, etc but I am very proud of finding the relation
   to antiterrorism, cf my Geometric Langlands page.

December 1, 2007

   Wow, thank you very much for the writeup, Peter. This is so far beyond my current level of knowledge, and so it's great to have a nice broad overview of the subject. It gives me something to shoot for, comprehension-wise. (I want to be a mathematical physicist "when I grow up," precisely because of these sorts of deep connections between physics and mathematics, and what they can tell us about how to solve the hard problems that have stymied physicists for the last n years.)

10. **Peter Woit**
December 1, 2007

    David,

    Thanks for filling in some of the history!

    One thing I didn't get around to adding to this posting was a list of references about where to read more. The best advice though is to go to David's geometric Langland's site, and take a look at his expository talks on the subject, together with the several long expository articles by Ed Frenkel.

11. **Peter Woit**
December 1, 2007

    milkshake,

    It's certainly my impression that if Witten had any ideas about how to make progress in string theory, he would be working on those. Unlike string theory, where people do seem to be stuck, the QFT/geometric Langlands field is one where there's a lot for someone with Witten's talents to do, and he seems to be enjoying working on this.

12. **M**
December 2, 2007

Peter,

Great post, but like most of this new number theory / physics esoterica I don't have a clue what's going on. But thanks for the post anyway.

December 3, 2007

    thank you. I think this is the best of your postings you ever made on this blog. I'll download all the articles you mentioned. What i've seen till now is very interesting content

Jumping the Shark

December 1, 2007
Categories: Uncategorized

Over at bloggingheads.tv today, John Horgan and George Johnson discuss the various excesses of recent physics news reporting covered here over the last week or so (Lisi-mania, evidence of other universes, observation of the CC causing ours to end, etc.), entitling their segment [Jumping the Shark](). I think this term came up in the comment section here at one point, but for a definition one can consult [Wikipedia](), where it is described as referring to an episode in the popular US TV series *Happy Days* in which Fonzie jumps over a shark while water-skiing:

> Since then the phrase has become a colloquialism used by U.S. TV critics and fans to denote the point at which the characters or plot of a TV series veer into a ridiculous, out-of-the-ordinary storyline. Such a show is typically deemed to have passed its peak. Once a show has "jumped the shark" fans sense a noticeable decline in quality or feel the show has undergone too many changes to retain its original charm.
>
> Jump-the-shark moments may be scenes like the one described above that finally convince viewers that the show has fundamentally and permanently strayed from its original premise. In those cases they are viewed as a desperate and futile attempt to keep a series fresh in the face of declining ratings.

Horgan and Johnson discuss the idea that, with the latest silliness, press coverage of fundamental physics has finally "jumped the shark", in response to a decline in substantive new results coming out of the subject.

I suspect that most physicists feel that, as a scientific idea, string theory conclusively jumped the shark with the advent of the anthropic landscape. The last year or so has seen an increasing amount of shark-jumping by string theorists desperate to find some way to address the problem of declining ratings. For the latest shark-jump, see this month's Physics Today, where the first article is entitled [String Theory in the Era of the Large Hadron Collider](). Much of the article has nothing to do with string theory, describing the standard model and its problems, and how they may be addressed by the LHC. Oddly enough, the abstract of the article doesn't mention string theory at all, whereas the subtitle ("The relationship between string theory and particle experiment is more complex than the caricature presented in the popular press and weblogs") makes explicit the goal of responding to claims made here and elsewhere that the anthropic string theory landscape is not really science since it can't predict anything.

The article heavily promotes the anthropic landscape and the idea that it "predicts" the right value of the CC, claiming that "The landscape and its explorations are exciting developments", but it really takes shark-jumping to new heights in the final paragraph:

> A few years ago, there seemed little hope that string theory could make definitive statements about the physics of the LHC. The development of the landscape has radically altered that situation. An optimist can hope that theorists will soon understand enough about the landscape and its statistics to say that supersymmetry or large extra dimensions or technicolor will emerge as a prediction and to specify some detailed features.

I've never before heard of anyone making this kind of claim that string theorists will soon be predicting detailed features of LHC physics. LHC results should start coming in 2-3 years from now. Dine and others have been trying to address the question of whether among the known string backgrounds there are more with high or low supersymmetry breaking for nearly 4 years already (see [here]()), and the answer so far seems to be that this is not possible. Even if it were possible, there is no reason to believe that all classes of string backgrounds are known. There is also no understanding of the cosmological mechanism producing our universe, and thus it remains unknown whether counting backgrounds is even relevant.

For a discussion by Dine of the issues involved here aimed not at the public but at his colleagues, see his talk last year at the Santa Barbara string phenomenology workshop, discussed [here]().

Update: Lubos [weighs in]() to praise the Dine article for what he sees as its message that the only good phenomenology is string phenomenology:

> Right now, it is extremely important for an idea about new physics to be reconciled with the solid cutting-edge picture of reality that is available, namely with string theory. In the absence of doable tests, this is pretty much the most important criterion that decides whether an otherwise conceivable idea is worth research or not.

Update: [Here]() is Chad Orzel's take on the Dine article in Physics Today. Chad characterizes my attitude towards this sort of thing as "snarky", while for him the situation is that

> You've got serious physicists running around jabbering about this sort of stoned dorm-room bull session material…

Oops, I fear that was a snarky comment…

Update: Cern Courier joins Physics Today this month with yet another [feature article promoting the multiverse](). I'm trying to think of a snarky comment, but I'm too depressed.

   Dear Peter,

   I remember the article on Lisi which appeared in The Economist. It was instructive reading because one could not avoid thinking that the author was the same person who gave a very good review to your book. I say so because, next to the hype (or Lisi-mania) you mention, he also argued that Lisi's ideas were somewhat more scientific than string theory, being at least testable. I don't know whether he meant to be ironic, but I am afraid he was serious. And it would not be surprising that he probably got this idea from your insisting on it.

   This brings me to the point that, undoubtedly, many scientists boldly exaggerate their claims, especially when they are writing research grant applications or books for the general public. But this may also be somehow the source of the problem. Why would physicists want, or need, to share their discussions with the general public? I don't think there are many civil engineers, to randomly name another group, who want to join any public discussion on the truth of the world. Not even many philosophers do that. Physicists may be good at doing science, but the jury is still out to decide whether thay are any good at properly shaping the opinions of the general public.

   This applies to string and anti-string partisans, to writers of books on the first minutes of the universe or to books that claim that the universe is a computer. As scientific claims, these ideas are fine and subject to open scientific discussion. But the scientific merit of putting them forward to the general public is more difficult to see. Apart from the sociologic value that the authors, as human beings, may be moved by the objective of extracting some professional/psychologic/economic benefit from them, of course.

2. **Michael Gogins**
   December 1, 2007

As a non-scientist, but one who is deeply interested in philosophy, philosophy of science, and fundamental science such as physics and biology, I must say I much prefer reading books and articles about science intended for the general public, or for scientists in other fields, that are written by the scientists themselves.

Furthermore, I see a number of writings that are evidently written by specialists for specialists, but in an accessible style, or with introductory or discussion sections that are accessible to non-specialists.

Finally, I note that a number of truly great scientists, including most notably Einstein, wrote accessible works about their research.

I think that leaving it up to science journalists and popularizers to do this is going to leave people like me much more in the dark…

December 1, 2007

> A few years ago, there seemed little hope that string theory could make definitive statements about the physics of the LHC. The development of the landscape has radically altered that situation…

I've never before heard of anyone making this kind of claim that string theorists will soon be predicting detailed features of LHC physics.

Maybe the idea is that the development of the landscape has taken us from "little hope" to "no hope"?

Ba dum ching

4. **a quantum diaries survivor**
December 1, 2007

Dear Alfonso,

you really did a random pick with civil engineering, but you could have picked medicine or biochemistry and your point could develop the same way. The thing is, it is mostly those who do pure research in physics who feel the responsibility to educate the general public on the need to push for answers to the very fundamental questions, as well as the urge to fight an anti-scientific revolution that is always on the verge of erupting – for a simple example read the latest encyclical by Pope Ratzinger, which warns against the horrors of marxism just as much against the dangers of illuminism.

You might perceive Ratzinger as a poor old chap with a hobby, but he ca reach several hundred million people. Unfortunately, I seldom see civil engineers take a stand for the need of scientific thinking and the advancement of science. Do you ?

Cheers,
T.

5. **Peter Woit**
December 1, 2007

Alfonso,

I doubt that writer got from me the idea that scientific ideas need to ultimately be testable. If he got from me the idea that string theory is not testable, that's accurate, and so much the better. As for Garett's theory, I certainly haven't claimed that is testable and I don't see how he could have gotten that from me.

6. **Chris W.**
December 1, 2007

Maybe researchers in the early stages of any kind of serious work at the frontiers of fundamental physics should all start treating the media the way they presumably treat telemarketers calling at dinner time. Perhaps quite a few already do, and we just don't hear about it.

(These days, when I answer the phone and detect the telltale delay suggesting that somone in a call center hasn't noticed that I've picked up yet, I just hang up.)

7. **Aaron Bergman**
December 1, 2007

Well, that (the Bloggingheads segment) was depressing. I mean, whatever you want to say about Lisi, it has next to nothing to do with loop quantum gravity. And Lisi's theory predicts new particles in the pretty much the exact same sense that string theory does. Why Lee finds it so interesting is probably best left as an exercise for the reader.

8. **milkshake**
December 2, 2007

Not quite in the exact same sense: Lisi was claiming his model had no fudge parameters. He came up with just one prediction. He was not saying "…and if the things turn out just the opposite way then I can fit that too."

9. **Aaron Bergman**
December 2, 2007

He came up with just one prediction.

And what prediction would that be? Just for reference, a prediction of a new particle should probably include the mass if you want to say that LHC will see it.

10. **dragon**
December 2, 2007

PW said: "the anthropic string theory landscape is not really science since it can't predict anything."

Well, all the people who want to make predictions are working on geometric langlands, right? Oh, not yet? How many years do you want? A lot less than twenty, presumably………

As for jumping the shark: that happened to this blog quite recently, when you started launching unprovoked attacks on the work of serious scientists like Robert Brandenberger, Sean Carroll, Laura Mersini-Houghton etc etc etc.

11. **?**
December 2, 2007

I also find it interesting that Dine writing an article for Physics Today is equated with advertising to the "general public". Last I checked, this was the journal of the American Physical Society, and Dine was most likely writing precisely for his colleagues, who are in a far better position to judge the merits or defects of his statements than "the general public".
Which includes most readers (and, from what I can tell, participants in commentary) of this blog.

12. **milkshake**
December 2, 2007

You know this better than I, how long it took for QCD to be developed to the point of calculating anything quantitative – such as the masses of the known particles (not mentioning the masses of newly predicted ones). The problem of "how to get the numbers out of the theory" continued long after it was generally agreed that it was most likely a good model – one that explained the known species of the particle zoo and predicted new ones.

13. **Aaron Bergman**
December 2, 2007

So you're agreeing that Lisi doesn't have a prediction, then?

After all, string theory predicts lots of new particles, too — I just can't tell you their mass at the moment.

14. **milkshake**
December 2, 2007

He made only one. ST cornered the entire prediction market.

15. **dave tweed**
December 2, 2007

Alfonso said "I don't think there are many civil engineers, to randomly name another group, who want to join any public discussion on the truth of the world." This is mixes up the fact that physics (along with philosophy) is "about the truth of the world" and that physicists are talking about their subjects. Most fields are judged more favourably when they can put forward folders of clippings or lists of radio interviews.

To my mind the biggest problem is that in the general media a story which says "here's a preliminary calculation that might lead to a more fully developed theory which might then be applicable to the world" is more likely to be unprinted/unread than one that confidently asserts one simple idea is groundbreaking.

16. **Peter Woit**
December 2, 2007

dragon,

I've been attacking media hype by serious scientists on this blog since the beginning, and getting nasty anonymous attacks from people like you since then. If I've jumped the shark, it was several years ago…

The work on geometric Langlands is producing interesting high-level mathematics. I've never complained about string theorists who are doing that. The meeting I was describing was a mathematics one, very few physicists were there.

17. **Douglas Natelson**
December 2, 2007

Alfonso – Isn't there some responsibility of scientists to try to explain to their work to the public since very often the public is *paying* for it?

18. **LDM**
December 2, 2007

dragon,

Regarding your statement "*As for jumping the shark: that happened to this blog quite recently, when you started launching unprovoked attacks on the work of serious scientists like Robert Brandenberger, Sean Carroll, Laura Mersini-Houghton etc etc etc*."

Not so fast. I have not read everything that Peter has written, but the impression I have from what I have read is that Peter's "attacks" are attacks on the merits of an individual's scientific ideas and work, and how these merits are being *oversold* to the public. This is normal scientific scrutiny and all scientists should be glad for it. Also, a scientist may be "serious", to use your word, but unfortunately still be wrong. Davies is a recent example. If on the other hand the work and ideas are correct, and are not being overstated, then they can more than withstand Peter's scrutiny.
I also hope Peter never tires of this rather thankless task, because I don't know who else would be willing to step up and do it.

19. **Peter Shor**
December 2, 2007

Reading the article, I also noticed that the pop-up box about supersymmetry claims fairly definitively that if the LHC doesn't find evidence for supersymmetry, then supersymmetry is dead. The opposite is implied by the main text of the article. Either Michael Dine has contradicted himself or, much more likely, somebody with different views wrote up the pop-up window about supersymmetry, and nobody proofread the whole thing very carefully.

20. **Peter Woit**
December 2, 2007

Peter Shor,

You're right that the wording of the pop-up box is inconsistent with the article, maybe Dine didn't write it. If supersymmetry is not seen at LHC energies, that will show it can't be the explanation for what stabilizes the electroweak breaking scale, solving what is called the "hierarchy problem". If supersymmetry is not seen at LHC energies, it could still be there, just broken at higher energies.

String theorists seem to recently be arguing that if supersymmetry is not seen at the LHC, that means that it doesn't solve the hierarchy problem, so the way to solve it is just like the CC: invoke the anthropic principle. Presumably once the LHC doesn't see supersymmetry, that's what we'll be hearing from the landscape people.

21. **Peter Shor**
December 2, 2007

You seem like you're betting that the LHC won't see supersymmetry. Is this just because there isn't any other evidence of it yet?

And apologies if this is drifting fairly far off-topic.

22. **Peter Woit**
December 2, 2007

Partly because nothing at all has shown up so far, partly because I just don't think that known supersymmetric extensions of the standard model really explain much, while making things a lot more complicated. The underlying idea of supersymmetry is in some ways mathematically attractive, but the specific models people are looking at here are not. Maybe there's a more interesting one we don't know about, maybe it's just not the right idea.

But this is kind of a large topic that can lead to a complicated and technical argument I'd rather not get into here. There is a chapter in my book where I go over some of this.

23. **?**
December 2, 2007

Actually, technicolor and/or warping are also widely viewed as non-anthropic solutions that are reasonable for the hierarchy problem, and that may well show up at LHC. This is true on hep-ph, and from what I know of the hep-th community, true there as well. So it is far from true that supersymmetry not being seen will immediately result in declarations that the weak scale is explained anthropically, from anyone.

24. **Peter Woit**
December 2, 2007

?

My comment was assuming that the LHC sees only a SM Higgs. If that happens I do think we'll hear from string theorists a lot about the "anthropic prediction" of the electroweak scale. If we see some other mechanism such as technicolor/warping, we'll hear about how this can be accomodated within string theory. I guess this was the point of Dine's article, as Lubos explicated it: all phenomenology is string phenomenology…

25. **John Campbell**
December 3, 2007

Links between the best scientific understanding and the general public are tenuous. Treatments of science in the media often range from indifference to 'jumping the shark'.

Although bringing scientific understanding to a wider audience is often flawed let's not forget its central potential importance to all people. As Einstein stated, in his view the most important function of science is 'to awaken this feeling (the cosmic religious experience) and to keep it alive in those who are receptive to it'.

Einstein saw the central function of science as its ability to provide us with a kind of cosmic religious worldview free of the supernatural and bonded to truth through empiricism.

The worldview provided by science is wondrous. Let's hope that the occasional straying from the path by New Scientist and others does not discourage those scientists who rob time from their research in order to communicate these wonders to the wider public.

26. **Jeff Moreland**
December 3, 2007

As someone with a lifelong interest in science, but who has not worked as a scientist for many years (I used to be a development metallurgist), I'd like to add a heartfelt endorsement to John Campbell's remarks. A big chunk would disappear from my life if I couldn't read serious (but non-professional) science and maths books and articles. The level that Scientific American published at about 40 years ago (yes, I'm that old) was perfect for me.

27. **Visitor**
December 4, 2007

The phrase "science as its ability to provide us with a kind of cosmic religious worldview free of the supernatural and bonded to truth through empiricism" is nothing but gibberish. I don't care if Einstein said it, it is foolish all the same. Science and religion are polar opposites and attempting to attempting to replace religion with science by attaching the word "religion" in any form to science is at best foolish and at worst dishonest.

And just as an aside, it is debatable that religion supplies or needs to supply people with a sense of wonder. What should be beyond debate, is that is supplies people with a sense of purpose.

For more of this same kind of foolishness, perpetrated by great scientists venturing, ill-advisedly, out of their fields of expertise and into the regions of social analysis, please read "The Sokal Hoax: At Whom Are We Laughing? – The philosophical pronouncements of Bohr, Born, Heisenberg and Pauli deserve some of the blame for the excesses of the postmodernist critique of science" by Mara Beller and available online at
http://www.mathematik.uni-muenchen.de/~bohmmech/BohmHome/sokalhoax.html

28. **milkshake**
December 4, 2007

"a kind of cosmic religious worldview free of the supernatural" means the mystery and awe, without the mysticism. The delight and the amazement that feeds the curiosity. The hope that we can figure out all kinds of things about this Universe, startng from few extremely-well hidden and indirect hints. I think this is a worldview which should replace the parochial men-centric religious views. It is also a pretty significant motivator for people who are active in far-out fields such as cosmology – and also for the public that takes delight in learning and thinking about these discoveries. I don't agree that the ol' Albert was turning into a New-Agey fool when he said these things.

29. **Changcho**
December 5, 2007

Visitor – the Mara Beller article (“The Sokal Hoax: At Whom are we Laughing?”) originally appeared on Physics Today, Sept. 1998 issue.

30. **Chris W.**
December 6, 2007

Visitor,

Einstein didn’t say it.

31. **anon.**
December 8, 2007

‘Update: Cern Courier joins Physics Today this month with yet another feature article promoting the multiverse. I’m trying to think of a snarky comment, but I’m too depressed.’

Look on the bright side: if anyone disproves the multiverse (which they can’t even in principle, because it’s not even wrong), Physics Today and New Scientist will just switch to promoting other non-falsifiable speculations. Maybe the physics of the resurrection, ESP, and miracles. So this continuing stringy multiverse hype isn’t completely your failure to communicate the scientific facts. It’s something that would go on even if every string theorist adopted scientific ethos today. The public just want to see sci fi hype supported by PhDs, and there are always some PhDs willing to give the public what it wants, especially when some funding is provided.

32. **Nikita Nikolaev**
December 10, 2007

I appologise to be getting perhaps even more off-topic, but I’ve seen some comments above concerning the supersymmetry breaking.

Suppose LHC doesn’t find any evidence of supersymmetry, but, at the same time, suppose supersymmetry still does exist. Is there any at all hint that comes from the theory as to why the supersymmetry breaking should occur at a higher energy than what LHC will have been aiming for?

33. **Eric**
December 10, 2007

Nikita,
There are really no fundamental reasons why supersymmetry breaking should occur at very high energies, unless you believe in fine-tuning or in some other mechanism (e.g. technicolor) to stabilize the electroweak scale. There are some string theorists, mostly at Stanford, who believe that the landscape and small cosmological constant point towards fine-tuning. These guys expect nothing but the Higgs to be found at LHC. This is called letting the tail wag the dog. On the other hand, there are many good reasons to expect TeV scale superpartners, namely 1) EW stabilization 2) gauge coupling unification 3) natural dark matter candidate 4) dynamical electroweak symmetry breaking.

34. **Nikita Nikolaev**
December 10, 2007

Eric,

Thank you so much for your answer.

News From All Over

December 4, 2007
Categories: Uncategorized

There's a long and interesting profile of Jim Simons on the Bloomberg web-site. It begins with him being told he has a call from Harvard string theorist Cumrun Vafa. Unclear whether Vafa was calling to talk about something related to science or something related to finance, since I've heard from several sources that Vafa recently has been working at least part of the time for Renaissance Technologies, the Simons hedge fund.

Director Ron Howard is making a movie based on the novel "Angels and Demons", part of which will be filmed at CERN. Here's a news report on his visit to CERN

Witten has posted two papers to the arXiv, one old, one new. The old one is Conformal Field Theory in Four and Six Dimensions, the write-up of his talk at the Oxford conference celebrating Graeme Segal's 60th birthday back in 2002. Until now this paper hasn't been available on the internet, you had to buy the book of the conference proceedings. It has acquired some new interest because of Witten's recent work on geometric Langlands, where Langlands duality comes from a duality symmetry that is part of a conjectured $SL(2,\mathbf{Z})$ symmetry of N=4 supersymmetric Yang-Mills in four dimensions. This $SL(2,\mathbf{Z})$ can be explained by the existence of a superconformal theory in 6d, which can then be reduced to 4d by taking it on the product of an elliptic curve and a 4-manifold. The modular symmetry then comes from the elliptic curve.

The new paper is with Alex Maloney and entitled Quantum Gravity Partition Functions in Three Dimensions. They calculate the partition function of pure gravity on an AdS3 space by summing the contributions from classical geometries, including quantum corrections, finding that "the result is not physically sensible". The paper includes a speculative discussion about what this might mean. It looks like 3d quantum gravity is still a subject that is far from completely understood.

Slides from talks at the recent HEPAP meeting are available. The FY2008 US budget for particle physics remains caught up in struggle between the White House and the Congress. They all agreed on a quite healthy budget number for particle physics, but haven't agreed on an overall budget. One possibility, a continuing resolution splitting the difference between the Congressional and White House total numbers, might possibly lead to a smaller particle physics budget than expected.

Physical Review Letters is publishing the latest paper by Chamseddine and Connes on their non-commutative geometry approach to the Standard Model. The PRL editor evidently forced them to change the name of the paper, from "A Dress for SM the Beggar" to Conceptual Explanation for the Algebra in the Noncommutative Approach to the Standard Model

Comments

1. **Lionel Hut**
   December 4, 2007

   There was an interesting news about Simons' otherwise quite secretive company a few months back.

   http://infoproc.blogspot.com/2007/07/algorithm-wars.html

2. **a quantum diaries survivor**
   December 4, 2007

   The PRL editor evidently forced them to change the name of the paper, from "A Dress for SM the Beggar" to Conceptual Explanation for the Algebra in the Noncommutative Approach to the Standard Model

   Tsk tsk, those poor souls at PRL lack any fantasy. We do take our papers a bit too seriously…

   Cheers,
   T.

3. **ali**
   December 5, 2007

   Hi Peter,
   It is very interesting that Cumrun Vafa calls Jim Simons. He is a quite senior person. How come he can work for a hedge fund company at that age, if the rumours are true? Do you have any other inside scoop on that?

4. **Peter Woit**
   December 5, 2007

   ali,

   I don't know what Vafa's arrangement with Renaissance is, other than that he was working with them at some point in the last year or so. While it's unusual for senior people to do this, I have heard of other cases of quite prominent senior mathematicians who have worked for Renaissance for a while, returning to academia afterwards.

5. **gs**
   December 6, 2007

   Speaking of senior people, George Zweig works for Renaissance.

6. **Chris W.**
   December 6, 2007

   Lately, I've been thinking that these associations are not particularly good for physics and mathematics, or the reputations of the people that study them—rather like nuclear weapons development in an earlier era.

7. **Maynard Handley**
   December 9, 2007

   "Angels and Demons"? By Dan Brown, author of the "Da Vinci Code".
   Yeah, that's going to make everyone at CERN proud.

I appreciate that they probably earn some money for this, but still, it's hardly something to boast about.

8. **Yatima**
   December 9, 2007

   Chris W. Says:

   "Lately, I've been thinking that these associations are not particularly good for physics and mathematics, or the reputations of the people that study them"

   I will say. I just came across this characterization, which I find myself unable to fully disagree with:

   Today's Wall Street fabricators of avant-garde financial instruments are actually called "financial engineers." They got their training in "labs," much like Dr. Frankenstein's, located at Wharton, Princeton, Harvard, and Berkeley. Each time one of their confections goes south, they scratch their heads in bewilderment — always making sure, of course, that they have financial life-rafts handy, while investors, employees, suppliers, and whole communities go down with the ship.

   I might be advisable to have plane tickets to small foreign countries without extradition agreements with the US handy if the economy worsens appreciably.

Latest Sci-Fi/Fantasy News

December 11, 2007
Categories: Uncategorized

Various particle physics-related science fiction and fantasy news:

Discover has an interview with Kip Thorne, who is working with Steven Spielberg on a science fiction film tentatively entitled *Interstellar* for release in 2009. The plot evidently involves the novel idea of a group of explorers who travel through a worm hole and into another dimension. Thorne expects that "nothing in the film will violate fundamental physical law." He also seems rather involved in fantasy as well as science fiction, believing that the LHC has a "good shot" at producing mini-black holes, and that "String theory is now beginning to make concrete, observational predictions which will be tested." (via Angry Physics).

Also on the fantasy front, I hear there's a new movie out called The Golden Compass, which supposedly has a plot based on multiple dimensions and particle physics. According to this review, the plot is not really fantasy, because:

> In the past thirty years or so, a majority of scientists have come to accept string theory as a so-called "Theory of Everything," one that helps to explain how everything in the universe works.

and string theory explains these extra dimensions.

One can follow the progress of the LHC project on the web, and unfortunately it's looking like the current official schedule, which plans on trying to circulate a beam next May and physics starting in July, is pretty much a fantasy. This schedule already was sticking to these dates in the face of delays that made them look unrealistic, but there have now been further delays. According to the schedule, sector 45 should be completely cooled down now and nearing the end of powering tests, with four others in the middle of cool-down. The actual state of affairs is that sector 45 is just finally getting fully cooled down to 1.9K, and the only other sector being cooled down is sector 56. A rough guess would be that they're three months or so behind the official schedule, so if nothing else goes wrong they might have a beam in late summer, physics sometime late in the fall. The CERN Council will be meeting later this week and get a status report on LHC progress, perhaps there will be an official update on the schedule at that time.

Michael Dine and collaborators have a new preprint about the Landscape, one that tells a rather different story than Dine's recent article in Physics Today. The authors discuss the question of the stability of Landscape states, given that there may be many nearby states, considering the possibility that this favors supersymmetric states. They also mention the problem of how to calculate transition probabilities into whatever the relevant metastable states are, which suffers from the well-known problem of how to pick a measure for eternal inflation, writing

> While we currently have little new to add to this discussion, we point out that the landscape is likely to be more complicated than assumed in many simple models of eternal inflation.

There's nothing in the paper that could possibly justify the Physics Today claims of hopes that landscape studies would soon be making "definitive statements about the physics of the LHC" and able to "specify some detailed features." Instead, there is a discussion of the possibility that landscape statistics are dominated by large volume, non-supersymmetric states, in which case:

> they are otherwise undistinguished, it is unclear how one might imagine developing a string phenomenology. Not only would we fail to make predictions, e.g. for LHC physics, but we would not know how to interpret LHC outcomes.

Update: For more sci-fi, tonight's arXiv postings include Warp Drive: A New Approach by string phenomenologist Gerald Cleaver and his graduate student Richard Obousy.

   December 11, 2007

   I seem to recall reading somewhere that Carl Sagan consulted with Kip Thorne while writing *Contact*, to tidy up some of the theory behind the alien contraption used for FTL interstellar travel. It was this collaboration, if memory serves, that got Thorne really active in the wormhole-as-time-machine business. I don't know if Thorne was also brought in for the movie.

4. **rob**
   December 11, 2007

   Yes, Kip was involved in Contact. The story as I remember hearing it is that Sagan originally wanted to use a black hole, and asked Kip how reasonable that would be. Kip of course told him that it wasn't a good idea, but that wormholes could more realistically serve the purpose Sagan really wanted. Kip later went on to write that series of wormhole papers investigating the issue in GR.

   And yes, I think he might have been involved to some extent in the movie, though I don't think he was credited. Also, Lynda Obst, one of the co-executive producers (with Kip and Spielberg) of Interstellar, was also a producer of the Contact movie.

5. **Low Math, Meekly Interacting**
   December 11, 2007

   Interesting to learn where some theorists may be getting their inspiration :).

I have to wonder if Thorne was misquoted somehow. I also seem to recall reading that this whole practice of serious academics doing reasearch into time machines was motivated by the very legitimate desire to push GR to its logical limits, so-to-speak. The upshot, if I understand correctly, is that if you can (with a dollop of exotic matter or some comparable unobtainium) actually construct a time machine without violating GR, thus producing something that could, in principle, violate causality, you've got yet another good indicator that maybe there's something seriously lacking in GR. Ergo, the fact you're not violating "fundamental physical law" means you surely need some better fundamental physical law. Then again, he appears to be saying ST fits that bill, so maybe the time-machine industry has evolved into something I'm not aware of.

6. **rob**
   December 11, 2007

   I was recently a student in Kip Thorne's group, and while I can't speak for him, and he certainly doesn't need me defending him, I will say that he always seemed to me to be basically noncommittal on the "string theory wars." The only time I heard him discuss quantum gravity in a public lecture, he did make a point of mentioning both string theory and loop quantum gravity.

   I'll also say that (as far as I've heard) he still hasn't conceded on his half of the bet with Hawking against Preskill on whether black hole evaporation is unitary. So he's certainly not a conventional string theory partisan.

   As for his "good shot" statement, I think he just really likes taking the side of underdogs, and in the public press these days, string theory seems to be the underdog.

7. **Bee**
   December 11, 2007

   Thanks for the update! Maybe we are witnessing the dawning of a new era in theoretical physics? If computer animations can do it in virtual, who cares about actual reality? Can we just compute another part of the multiverse and sell the fundamental laws to Dreamworks? Chances are we are just living in a computer simulation anyhow. Either way, seems like you missed out on Denzel Washington in Deja Vu, where a group of crime investigators together with some scientists watches the past through a wormhole. Memorable quote: "I asked you to explain it to me, not to talk science."

   (the movie is entertaining, but not really recommendable)

8. **rob**
   December 11, 2007

   Low Math Meekly Interacting:

   Well, this causality thing has a lot of ins and outs. The existence of closed timelike curves doesn't necessarily point to a problem in GR, or even necessarily a problem at all. I haven't really looked at this stuff, but I remember that Novikov was involved in some work showing that "consistent histories" (to borrow a phrase) can still arise even in the presence of closed timelike curves. He probably talks about this in his essay for the book "The Future of Spacetime."

9. **Peter Woit**
   December 11, 2007

   Bee,

   I'm afraid I was being snarky about the originality of the wormhole as plot device, having seen a rather large number of movies or TV shows where wormholes appear (including Deja Vu..). Presumably the Thorne/Spielberg wormhole will be a less cheesy and more authentic one than the usual, run-of-the-mill wormhole that normally puts in an appearance.

10. **Low Math, Meekly Interacting**
    December 11, 2007

    Thanks for the addition to my library list!

11. **Bee**
    December 11, 2007

    yeah, I read your remark as sarcasm, was just looking for an occasion to place that quote. I wish people would stop asking me about wormholes, time travel or the free will in quantum mechanics when they hear I'm a physicist.

12. **rob**
    December 11, 2007

    From what I've heard, the central motivation of the project, both for Kip and for Spielberg, is to make a "scientifically realistic" science fiction movie. Obviously they'll stretch the limits of practicality, but they at least intend that everything should be basically in line with published (though sometimes speculative) science. Hopefully it will remain that way after being filtered through screenwriters and special effects houses.

    For example, one very early idea that I heard (and I'll presage this with the disclaimer that I'm not at all privy to the developments) was that the wormhole would be discovered by LISA. Some would say that LISA taking measurements is no more realistic than finding a wormhole, but we relativists still like to think those people are wrong.

13. **Scott Aaronson**
    December 11, 2007

    "consistent histories" (to borrow a phrase) can still arise even in the presence of closed timelike curves

    Yes, it's possible to write down theories that have CTC's but no inconsistencies. One way is just to stipulate that, if S is the quantum operation acting around a CTC, then as the "input" to the CTC nature has to postselect a state &rho such that S(ϱ)=ϱ. (Such a ϱ always exists by linear algebra.) This idea goes back to a 1991 paper of Deutsch.

    However, these theories have an extremely interesting further problem. This is that, in order to *find* a consistent evolution around the CTC, nature has to solve an extremely hard computational problem! (In particular, it has to solve a PSPACE-complete problem, which is even worse than NP-complete.)

    So, to return to Peter's sci-fi theme: while physical theories with CTC's aren't necessarily inconsistent, they *do* necessarily lead to effects like in *Star Trek IV: The Voyage Home*. There the crew of the Enterprise goes back in time to the "present" (i.e. to 1986) and, needing a type of plexiglass that hasn't been invented yet, reveals the formula for the plexiglass to the company that's *going* to invent it, thereby causing it to be invented, etc. This is not a logical inconsistency but is nevertheless exceedingly strange.

14. **Dave Miller**
December 12, 2007

As an undergraduate at Caltech in '75-'76, I took a course on GR from Thorne, and I pointed out to him that you could build a time machine out of wormholes. I had in mind two separate wormholes moving in different reference frames – you don't need to invoke time dilation at only one end of one wormhole then: the Minkowski geometry is pretty obvious.

My point is not that I am the source of Kip's later work: it was a casual comment on my part, and I'd guess that he forgot it rather promptly. The point rather is that the idea of wormholes as time machines was pretty obvious to anyone, even an undergrad: wormholes obviously violate locality, and any particle theorist knows what that means. (Personally, I'm with Hawking on this: a wormhole time machine probably blows itself up for reasons Hawking has explained.)

And, Peter, the real news on "The Golden Compass" is that fundamentalist Christians are up in arms over it: I've heard this from personal contacts as well as seen it on the Web (NPR even ran a piece). Pullman is a self-announced atheist, and the theory is that the movie is really meant to seduce vulnerable Christian youth.

In fact, the movie is supposed to be pretty bland, and my own kids were actually given the trilogy by a Christian friend who had read through it all herself.

Of course, you can find fundamentalists on the Web who also denounce the "Chronicles of Narnia" on the grounds that Lewis, a famous Christian apologist, was really a secret pagan. (You see, he admired classical culture and enjoyed classical mythology…)

I am tempted to believe that critics of Christianity should just relax and allow the Christians to self-destruct.

Dave

15. **Alejandro**
December 12, 2007

Re *The Golden Compass*; in the books, at least, string theory is not mentioned at all, but the plot relies heavily on a fantasy take on many-worlds quantum mechanics and dark matter. Everett is mentioned by name, and a technology to communicate between parallel universes is said to rely on quantum entanglement. As for dark matter, well… (SPOILERS follow)…

…would you believe that dark matter is conscious particles that try to communicate with humans, that angels (including God, the oldest one of them) are complex structures made of these particles, and that human attachment to these particles, which signals sexual awakening, is what the Church calls original sin?

No, I am not making this up. Anyway, the books are awesome. Haven't seen the movie yet, but I expect to be disappointed.

16. **Bee**
December 12, 2007

Hi Alejandro,
I think I read the first volume of the trilogy because it showed up on my amazon recommendation list. I didn't bother to buy the other two. Maybe I've read too much Fantasy when I was a kid, but much like Harry Potter it didn't strike me neither as well written nor original. I didn't see the movies though. I like the part with the sexual awakening, maybe I should give it another try. To come back to the topic of Science Fantasies, since you mention dark matter it's kind of interesting in this regard what Rudy Rucker wrote in the book 'Dangerous Ideas' (among essays about multiverses, understanding GR and QM, or how capitalism will make the world a better place):

"On the one hand, it could be that the mind is some substance that accumulates near ordinary matter — dark matter or dark energy are good candidates. On the other hand, mind might simply be matter viewed in a special fashion: matter experienced from the inside. […]"

Best,
B.

17. **Bee**
December 12, 2007

Today's news: unparticle physics provides a mechanism for black hole formation.

18. **Alejandro**
December 12, 2007

Hi Bee. I didn't think too much of the first volume when I read it either -but in my case I think it was because I read it translated to Spanish; when I reread it in English I liked it much more. The other two are much more ambitious, both in a literary and a philosophical way; the whole trilogy is IMO a much "larger" thing than Harry Potter, which is a fairly conventional kind of story. Pullman's avowed goal is to provide a subversive retelling of Milton, celebrating rebellion against God and authority, and the loss of innocence related to maturity, self-consciousness, and yes, sexual awakening.

There are some problems in the third volume -the scope becomes so large that the plot becomes confusing, there are a couple of dei ex machina, and the anti-religious message is so explicit that it is grating at points- but overall I would recommend you to read the other two books to have an opinion; the central themes of the trilogy cannot be seen from the first volume alone.

19. **Alejandro**
December 12, 2007

Oh, and re the Rucker quote, it is rather similar to the premise of Pullman's fiction -but Rucker seems to be taking it *seriously*… :S

I have read only one book by Rucker, in my teens: *The Fourth Dimension*, basically a layman's explanation of 4-D concepts and their use in physics. He did get into some weird panpsychistic speculations by the final chapter, but it was all rather playful and he didn't seem to really believe it.

20. **Bee**
December 12, 2007

Hi Alejandro:

Yeah, sounds interesting indeed, I might give it a try. I yet have to make it through the last Harry Potter though, since I read the first six I think I will have to read the seventh as well. I know the 4D Rucker, though I didn't find it too illuminating, I had a couple of better books on higher dimensions that I liked better. I recall much better Rucker's book Master over Space and Time which I read probably being too young. I got seriously confused about what quarks are and so on. Maybe I would find it amusing now, but I think books like that better come with a manual or a warning. Best,

B.

21. **Moshe**
December 12, 2007

Scott says:"if S is the quantum operation acting around a CTC, then as the "input" to the CTC nature has to postselect a state &rho such that S(ϱ)=ϱ".

I am confused by that, I would say this is exactly what is *meant* by having CTC to start with. If you don't impose periodicity conditions the curve is not closed in any meaningful sense, am I missing something?

22. **John Baez**
December 12, 2007

I know Peter doesn't actually like talk about science fiction and fantasy here, despite the title of this blog entry… but can't resist telling Alejandro: I've read Pullman's *Dark Materials* trilogy and liked it a lot – and I found the movie adaptation of the first part to be *excellent!*.

Like the book, the movie doesn't mention string theory at all.

(It's fantasy, not science fiction: people should only watch it if they can deal with witches, daemons and talking polar bears.)

23. **Scott Aaronson**
December 12, 2007

Moshe: I agree with you — once you think about it clearly (which many people don't!), the requirement of causal consistency *is* pretty much inherent in the definition of CTC's. The slightly non-tautological observation in Deutsch's paper was that, while a consistent evolution doesn't always exist in deterministic theories (which is just a fancy way of stating the grandfather paradox), such an evolution *does* always exist in probabilistic or quantum theories. This is because every Markov chain has a stationary distribution, and likewise every superoperator has a stationary mixed state.

24. **Moshe**
December 13, 2007

Thanks Scott, I like your re-phrasing of the grandfather paradox, previously I thought about it as one of those linguistic pseudo-problems, but now I see at least one way of making a non-trivial statement.

25. **DB**
December 13, 2007

I think a lot of today's elder generation of physicist-speculators spent too much time as kids watching The Time Tunnel. The wormhole is easily the most hackneyed notion in filmed Sci-Fi, so it stands to reason that Hollywood will want to resurrect it for yet another outing.

26. **Alejandro**
December 13, 2007

Glad you liked the movie, John -it gives me raised hopes.

And by the way, I remember now that string theory *is* mentioned in the books! (albeit obliquely). In the third volume, when Mrs Coulter is approaching Asriel's fortress, she finds it similar to a model she saw once illustrating a "diabolical heresy" (quoting by memory, don't have the book here) according to which space had many extra dimensions curled up a tangled and tiny way .

In other words: the place from which Lord Asriel intends to overthrow God and build the Republic of Heaven resembles a Calabi-Yau manifold!

27. **Michael Bacon**
December 13, 2007

See http://www.edge.org/3rd_culture/serpentine07/Deutsch.html

At the above link is an equation from the paper by Deutsch that Scott mentions above: Quantum Mechanics near Closed Time-like Lines which appeared in Physical Review D44, 3197–3217 (1991).

According to Deutsch, it is the equation for the state of a quantum computer that is, by whatever means, provided with a method of sending its output back in time to interact with its input (I suppose he'd consider this "merely" an question of engineering.

He believes that the universality of quantum computation ensures that the results also apply to any time-travelling physical system, not just a computer.

I can't reproduce the equation (really don't know how to with my limited computer skills), but he claims that the self-consistency of this equation proves the self-consistency of time travel in quantum physics.

He says that analysis of the equation shows that if we had a time machine and tried to use it to enact 'paradoxes' (like going back in time to prevent our building the time machine), we would simply go back to a universe in which those events really happened.

Not being very well grounded in the math associated with this type of analysis, I settle for science fiction. It's fun and thought provoking — tautological or not.

I'd love to see a serious discussion between Deutsch, Scott and others who obvious know much more about this than me.

28. **Chris W.**
December 15, 2007

The above discussion of CTCs and causal consistency ties in rather closely with an interesting and lucid new review paper on the arXiv, **Causal Set Topology** (0712.1648).

(Thanks to Daniel Doro Ferrante for highlighting it.)

UK Pulls Out Of ILC

December 11, 2007
Categories: Experimental HEP News

The UK is planning on cutting the budget of its Science and Technologies Facilities Council over the next few years, ending British involvement in several large scale scientific projects, including the ILC. The STFC document laying out its plans through 2012 emphasizes CERN and the LHC, and has this to say about the ILC:

> We will cease investment in the International Linear Collider. We do not see a practicable path towards the realisation of this facility as currently conceived on a reasonable timescale.

In combination with recent remarks from the DOE, the current situation of the ILC proposal is not encouraging. Most likely it will require the discovery of new physics at the LHC of the sort that the ILC is the right tool to study in order to make the case for going ahead with it.

More about this here and here.

Update: More here, here, here and here. These budget cuts seem to be especially problematic for astronomy research, with particle physics not as badly affected as the UK retains its commitment to CERN and the LHC.

Update: More here. Best headline about this so far: Boffins slashed in big-science budget blunder bloodbath.

Comments

1. **Coin**
   December 11, 2007

   Let's say that the case is *not* successfully made that the ILC is the most appropriate followup to the LHC's findings, and the ILC ultimately gets scuttled (or at least suffers more dropouts like with the UK here). What happens then? Will this mean that that's money which simply won't get put into physics investment? Or will this just mean some other project gets attention diverted to it instead?

2. **Flip**
   December 11, 2007

   Thanks for the post, PW! Could you shed some light about what this means for the 10-20 year outlook of particle physics experiments? If the LHC's results end up making a compelling case for an ILC, would the STFC turn around and recommit to the linear collider?

   What is the significance of having national funding agencies committed at this [early] stage, especially if there is apparently no commitment to prevent them from walking away after a government spending review? Does this just mean that there's less R&D? If so, does this indirectly weaken Europe's bid to host the ILC (if it were to be built)?

   Cheers,
   F

3. **woit**
   December 11, 2007

   Flip,

   I don't know much about how UK budget decisions are made, so it's unclear to me whether and how this decision could get turned around at some point during the next few years. It seems to me that they have decided that the ILC project is too far off, likely to be in the US, and quite possibly will never get built, so R and D on it is a good target for cutting when they have a budget problem.

   One big problem for the ILC is that if it takes several more years before there's an LHC-based case for building it, at that point CERN's CLIC technology may have proved itself. CERN will have the money to start building it as LHC and LHC upgrade costs wind down 10 years from now. If CLIC is feasible and can be financed in Europe, there's not much of a case for the ILC.

   At this point, if I had to bet about what will be going on 20 years from now, it would be on a strong CERN program at the energy frontier involving CLIC and an upgraded LHC, with a weaker program in the US based on Project X at Fermilab and various neutrino experiments.

   But maybe the LHC will discover something that will change everything…

   Coin,

   Building the ILC would require a sizable part of the US HEP budget + new money. If it's not built, the new money wouldn't go to particle physics, might go elsewhere, or just might not increase the US fiscal deficit so much. There would be more money from the total particle physics budget available for other particle physics projects, e.g. things like Project X that Fermilab is considering.

4. **Coin**
   December 11, 2007

   There would be more money from the total particle physics budget available for other particle physics projects, e.g. things like Project X that Fermilab is considering.

   Well… something else I wonder about. If you look at the Project X web page they say: "The use of the Recycler reduces the required charge in the superconducting 8 GeV linac to match the charge per pulse of the ILC design; aligning Project X and ILC technologies." I'm not sure what this means– exactly what synergy does Project X get from its "alignment" with the ILC? Would the Project X project by itself be in some way less useful than Project X would be were it running contemporaneously with the ILC?

   Thanks!

5. **woit**
   December 11, 2007

Coin,

One selling point of the Project X proposal is that it would use some of the same linac technology as the ILC, and thus potentially help with the engineering needed for the ILC. One reason for highlighting this is just that Project X and the ILC are in some sense in competition for US HEP funds, so this is supposed to help sell the idea to ILC proponents worried that Project X means no ILC.

6. **Coin**
December 11, 2007

Oh, I see. So the idea is just to share engineering costs by reusing technology, not that like the similarities between the two accelerators would make it easier to do combined experiments or somesuch?

7. **Peter Woit**
December 11, 2007

Coin,

Right. I don't know of any plan to combine operation of the accelerators in any way, this is about the acceleration technology.

8. **Roger**
December 12, 2007

I'm a Brit working in Europe now. I think this should be understood in the context of the funding reorganisation last year which created the Science and Technologies Facilities Council. This replaced the PPARC agency which only handled particle physics and astronomy and is a kind of super research council including (amongst other things) particle physics, astronomy, laser and condensed matter physics. There are severe cost overruns on certain projects, including the "prestigious" (i.e. built in the UK) Diamond light source meaning that everyone else who shares the Diamond funding pot must take a cut. In the olden days of PPARC if there was a cost overrun for, for example, a particle physcics project the astronomers would take a cut on the understanding that this help would be reciprocated if astronomy was faced with a funding problem. This worked fairly well and none of the cost overruns were as severe as those faced at the moment. Overrun estimates for Diamond I've seen are for 160 million dollars. In effect, particle physics and astronomy are bailing out a wholly unrelated discipline, which through bad luck or bad contingency planning is in a crisis.

The ILC happened to be one of the superficially easiest items to chop. Its especially unfortunate in that the UK was one of the countries which jumped on the ILC very early, much to the surprise of physicists in many other countries. To invest so much, so early and now to pull out with inadequate consultation (very much unlike the way PPARC used to operate) is rather silly.

I know many people who are/were engaged on the ILC program. I know they put their heart and soul in the project and fully believed in it. They were also producing some cutting edge work on accelerators and detector technology. I really feel for them.

Most physicists I've spoken to seem to think that this is a result of incompetence rather than a deliberate, though underhand, attempt to cut back on particle physics which traditionally enjoys large budgets and therefore attracts much envy from other disciplines. I don't know what to think.

9. **lostsoul Ph. D.**
December 12, 2007

Money has been poured down the drain in the UK over the past 10 years or so, ostensibly, in the main, on 'good things' like health and education (and the odd war, of course), but in a way that has generated little of value for the taxpayer. Now the men in charge are embarking on a frantic and short-sighted cost-cutting/ face-saving exercise. When they pull out of the Olympics you will know that things are really bad; until then they will target anything whose decimation they think that they can get away with. And who amongst the electorate gives a monkey's about science of any persuasion these days?

10. **Arun**
December 12, 2007

The prospects in the US are even more bleak, if the dire warnings of requiring a taxpayer bailout of the banks are true (see my blog for details).

11. **young_physicist**
December 12, 2007

Arun:

The subprime mess is going to hit the uk pretty soon (I mean we will have our own borrowers defaulting) so I expect it is not just us banks that will have to be bailed out. If this causes a recession then the future for particle physics may become quite bleak indeed when goverment cuts spending due to reduced tax intake etc.

12. **Jon**
December 12, 2007

None of this is as a result of cuts in UK Government spending as implied at top of your article, in fact STFC funding is up 13% over next 2 years I understand, and science spending overall has doubled in real terms over last ~10 yrs. The current problems seem to be the result of over commitment mainly to new Diamond facility, as indicated by previous poster. Apparently capital spend for Diamond came in within contingency but operating costs appear to have been severely under estimated in the new Full Economic Costing model for staff recently introduced in UK. Previously separate Astronomy and PP funding is now having to bear the costs of this error following merger into wider STFC. Potentially head(s) should roll at STFC…?

13. **Big Vlad**
December 12, 2007

could someone who understands these matters please explain the implications for particle theory in the UK? Will theory be heavily affected by these cuts?

14. **Walt**
December 12, 2007

Arun, that article is wrong on a key point. Mortgage originators have to take back mortgages, but most of the subprime mortgages don't originate with banks, but with specialized mortgage originators — most of whom are likely going to go out of business. Defrauded investors, foreign or domestic, are going to get nothing, and no bank bailout will be required on that account.

15. **Peter Woit**
December 12, 2007

Arun and Walt,

I happen to find the whole mess in the banking system fascinating, but please, this blog is not the place to discuss it. Surely there are ones run by people who actually know a lot about this.

16. **DB**
December 13, 2007

This UK announcement doesn't really affect the prospects for the ILC which is essentially a US project with some modest international support tacked on. As a member country of the CERN consortium the UK remains very well placed to participate actively in HEP research.
If the core political will is absent in the US, as I believe is currently the case, then the ILC won't get built, period.
The UK may well prove to be useful fall-guy to blame, it has a long history of bureaucratic cock-ups associated with the funding of large science and engineering projects, but this shouldn't distract anyone from the core issue around the ILC: does the US have the stomach for this or not?
And I am sceptical about the continuing political will in Europe in support of large HEP projects. The LHC almost didn't make it past the politicians – CLIC – and I have confidence that the technical issues will be solved – will be many times more expensive and I just can't see it passing.
It would be a great pity if a misplaced confidence by the US in Europe's willingness to continue to do the heavy lifting in experimental HEP were to lead to the LHC being the last major collider to be built.

17. **Peter Shor**
December 13, 2007

Isn't the decision on whether to go ahead on the ILC entirely dependent on what is found by the LHC? If the LHC doesn't find any new physics that the ILC might shed some light on, it seems very difficult to imagine it getting funded no matter how gung-ho people are at this stage. On the other hand, if the LHC results require further study by an ILC or similar accelerator, then won't such an accelerator almost certainly be built eventually (at least in the absence of massive economic or geopolitical catastrophe)?

One question this brings up is: why is anybody doing any planning studies now? Wouldn't it be better to wait until after the LHC is built, and then start planning for the next accelerator? It seems to me that this would only delay the project marginally, and would save money if turns out that it's not worth building an ILC at all.

18. **Roger**
December 13, 2007

Peter Shor

One legitimate (though not great) argument is that much detector expertise would be lost if there isn't a continuous program of R+D at UK laboratories.

ILC research is not only accelerator-related, there is/was in the UK significant effort in developing an appropriate vertex detector and calorimeter.

On an unrelated note, the UK invested substantially in the ILC, with the encouragement of the then research council. Many of the same research council folk are present in the new body and they're now singing a totally different tune about how unrealistic the ILC is. Its true that the likelihood of an ILC has decreased recently but its construction was always uncertain. Heads really should roll for this planning debacle.

19. **Peter Woit**
December 13, 2007

Peter Shor,

The problem for US particle physicists is that the Tevatron will become more or less obsolete once the LHC is working well, and at that point the US will have no accelerator at the energy frontier. This may happen within a very few years from now. So US particle physicists need a plan for what to do next, and until recently the ILC seemed the best bet. The hope has been that getting the planning done and everything ready to build the machine would mean that, once LHC results came in, they would be ready to go. If they wait for LHC results to get started on planning, there will be a long period in the US with nothing even being built, and an even longer period without a high-energy machine.

The costs for the kind of planning they have been doing are relatively small, it's the construction costs that will be large, and most of this is for work trying to develop technology that ultimately will be useful, if not on the ILC, perhaps elsewhere.

20. **Roger**
December 13, 2007

Peter

The planning costs were very large for the UK both in terms of the R+D budget and the manpower which was devoted to this effort.

The ILC wasn't a relatively small back-office affair but a rather high profile activity.

21. **Peter Woit**
December 13, 2007

Roger,

Thanks for the clarification. My comment was about the amounts involved relative to the construction cost for the ILC, not the absolute amounts, which are significant. Actually, how much exactly has the UK been spending per/year on the ILC that will be eliminated by this decision?

22. **Peter Shor**
December 13, 2007

Thanks.

Training the next generation of physicists with detector expertise is useful, at least assuming that accelerators will continue to be built (which I assume depends on what the LHC sees). But the decision of whether to build the ILC still has to be years away.

23. **Peter Woit**
December 13, 2007

Peter Shor,

The people working on the ILC have been hoping for a construction decision in 2010. This is probably not realistic, unless the LHC very quickly comes up with results of just the right kind (e.g. a spectrum of new particles of mass low enough to be studied at the ILC).

24. **NEW Reader**
December 15, 2007

Hi Peter,

I get nearly all of my particle physics news from NEW. I have a simple question:

With the future going the way it is, (and as I had asked many – and *sigh* – many a times before), would it be a good life-long decision to study the subject?…

I love studying particle physics / mathematical physics, but am rather in a quandary as to its relevance – especially experiment-based particle physics – for the future, which seems increasingly being sqeezed into the marginal arena of academic / scientific pursuits; I fear within thirty years particle physics will cease to be of relevance unless there is a applicable defense and/or other high-profit-generating marketable involvement.

Do you share some of my concerns? Is the particle physics community losing some of its post-SM excitement in the early ’80’s?

Thanks for allowing me the post.

December 15, 2007

Postscript:

Also, I just happended to chance upon your “Holy Grail of Physics” post (post # 3) via Wikipedia. I read Mark Srednicki’s and your opposing views on the topic (actually, didn’t understand much… :)); but I’m wondering if you have notes from your QFT course of Steven Weinberg’s, and whether – with your permission (obviously) – you might like to send a copy to me.

[PPS: How do you make links? Don’t understand much webpage-technology stuff.]

26. **Peter Woit**
December 15, 2007

NEW reader,

The Weinberg course was on the quantization of gauge theories, and this material is in the second volume of his three volume series on QFT. The books are definitely more useful than my notes would be.

As for the future, mathematics is doing well, so anyone interested in the mathematical end of things should consider pursuing a math degree. For particle physics in general, a lot depends on what happens at the LHC….

27. **Roger**
December 16, 2007

New Reader,

The future of the “traditional” high energy collider physics program is uncertain and, as PW pointed out, much depends on the LHC. However, there is more to particle physics research than high energy colliders. A symbiosis between particle and astrophysics has been occuring in recent years and cosmic ray experiments may well, for example, become the principal tools for particle physicists in the future.

I can foresee a time when particle physics is less prominent than it is today but, since it is one of the few truly fundamental areas of science, I doubt if it will ever become a marginal activity. The best and most curious minds will always be attracted to the most important questions.

28. **NEW Reader**
December 16, 2007

Thanks to both of you for the respective responses.

29. **young_physicist**
December 20, 2007

British citizens and residents may wish to sign this petition in protest against the announced cuts to particle physics and astronomy (which do not just affect the ILC, but also many other less well known research programs):

Latest on ILC/CLIC/LHC

December 14, 2007
Categories: Experimental HEP News

Barry Barish, the director of the ILC project, has a statement here about the recent UK decision to stop funding R and D work on the ILC. He writes that "losing the UK's contributions to the ILC will have a significant negative impact on our R & D program." For more press stories about this, see here and here.

Barish also has an article here about CLIC, CERN's competing design for a linear collider, one that is in a much more preliminary state than the ILC design. He writes that the ILC project will now be exploring ways of collaborating with CERN as it investigates the feasibility of CLIC:

> When I visited CERN last month, I had the opportunity to have a meeting with the CLIC Extended Steering Committee, including CERN Global Design Effort members. I suggested that joint work between the ILC and CLIC could have benefits for both efforts. They responded positively, and a number of specific areas have been identified where both groups could benefit. It is clear that the timescale for a machine like CLIC, even if feasible, is much later than the ILC. So the reason to consider CLIC is for energy reach, if required.
>
> Following my visit to CERN, I discussed these joint efforts with the GDE Executive Committee, and we agreed to the general idea. As a result, the GDE Project Managers will explore specific areas of collaboration with CLIC. An exchange of ideas has begun by email, and a meeting is now planned at CERN for February 2008 to explore specific areas of cooperation.

Today the CERN Council officially ratified the choice of DESY's Rolf-Dieter Heuer to succeed Robert Aymar as Director General of CERN. At DESY Heuer was responsible for ILC R and D, so some people at CERN have been concerned that their new leader will be someone from the competition to CLIC, and thus might not be inclined to enthusiastically and aggressively now push the project and compete with his old colleagues from the ILC.

The Council also approved a budget designed to begin preparations for an LHC luminosity upgrade by 2016, and heard a report from the director on the status of the LHC project. Until recently the date for the LHC start-up was set at mid-May 2008, but the official word from Aymar now is just "early summer 2008", with no specific date to be set until spring:

> Today, we're on course for start-up in early summer 2008, but we won't be able to fix the date for certain before the whole machine is cold and magnet electrical tests are positive. We're expecting that in the spring.

The press release also notes that:

> Any difficulties encountered during this commissioning that require any sector of the machine to be warmed up would lead to a delay of two to three months.

The latest version of the official schedule is here, and news about progress here, with the news putting the project a month or so behind the schedule.

Update: Science has an article about Heuer's appointment, quoting him on the ILC/CLIC issue as saying "It's a mistake to back one horse. We need different horses". Also:

> Barry Barish, leader of the ILC's Global Design Effort, is happy to have Heuer on board. "Clearly, from the perspective of the ILC, the appointment of the new is a very, very positive thing," he says.

Comments

1. **Roger**
   December 14, 2007

   Rolf-Dieter Heuer is a first class physicist who understands CERN's core business of producing publications of experimental results from colliders. I've met him on several occasions and was impressed each time. He is ideal both for the LHC and CLIC programs – I don't buy the idea that he'll drag his feet on the CLIC issue out of misplaced allegiance to the ILC.

   With the UK funding agency debacle in mind CERN should be grateful they have a weighty, intelligent figure in the top post who knows what must be done on the ground floor to get the job done.

2. **Coin**
   December 14, 2007

   To what extent does CLIC function as a *replacement* for the ILC? That is to say, if we somehow wind up building the CLIC but not the ILC, would the CLIC be able to do everything the ILC would in addition to its better "energy reach" capabilities? Or would building just the CLIC force us to give up access to some block of data?

   When we say the CLIC is in a more preliminary stage than the ILC, or that its timescale is "much later"– vaguely how much later is "much later"? Two years? Five years? Ten years? If the ILC becomes delayed for some reason (say, because the LHC takes awhile in getting out the data needed to make a decision on the ILC, perhaps?) how long would it have to be delayed before we find the CLIC actually within striking range as an alternative?

3. **Peter Woit**
   December 14, 2007

   Coin,

   As far as I know CLIC would have similar capabilities to the ILC, but be able to get to higher energies (say 3 TeV vs. .5 TeV).

   I don't think anyone knows yet how long "much later" is, but it's definitely >2-5 years. The ILC people already have a detailed design and are not far from the point where you could start building a machine, CLIC is nowhere near that. My understanding is that the goal of the current research on CLIC is to be able to answer your question in 2010, so that when LHC results arrive, a sensible choice between the ILC and CLIC designs could be made.

4. **DB**
   December 17, 2007

   The debate between ILC vs. CLIC may be a red herring. What's increasingly clear is that the successor to the LHC will no longer be simply a US or European affair. Like the ISS, or ITER, it can only be successfully conceived and implemented as a truly international collaboration – because the financial commitment will be too great for

any one economy to justify. As currently formulated, the ILC is only half-hearted in its adherence to the spirit of international cooperation.
Similarly, CERN has conceived CLIC as a development of existing accelerator assets in Geneva.
When the time comes to make a decisions, I expect political and economic realities will force experimental HEP to mirror other mammoth civilian science and engineering projects by developing a truly global approach.
It may be that Barish and Hauer are already thinking along these lines.

A Passion for Discovery

December 16, 2007
Categories: Uncategorized

I've just finished reading a wonderful new book by theoretical physicist [Peter Freund](), entitled [A Passion for Discovery](). Freund grew up in Romania, and began his career as a physicist in Europe during the 1950s, emigrating to the US during the 1960s, finally ending up at the University of Chicago, where he is now an emeritus professor.

When I was writing my own book I tried to include amidst the expository material about physics and mathematics stories of some of the people and events that seemed to me illustrative in one way or another. Freund has had the excellent idea of writing a book that foregrounds such stories, interspersing in the background the actual physics and mathematics. A reader who doesn't know the science may not learn as much about it from this book as from others, but will get a feel for something perhaps more important, the "culture" of the field of theoretical physics. By this I mean the whole circle of knowledge that makes up the context in which theoretical physicists think and work. A reader who does know the science and some of the stories that Freund tells will deepen his or her knowledge by learning many more that he or she was probably unaware of.

When I moved from a physics environment to a mathematics one many years ago, one thing that struck me was that I had entered not just a field that studied somewhat different material, but a whole new cultural environment, very much like moving from the US to France. Different fields have different unspoken sets of values and beliefs, derived from their different environments and different histories. Shared stories about the history of the field and the quirks of leading figures of the subject make up a large part of this common culture. Freund does an excellent job of capturing the culture of twentieth-century theoretical physics, and one could learn much more about this from his book than from any textbook or most standard historical treatments.

It's tempting to repeat here some of the stories that I learned from Freund's book, but there really are too many to choose from, so I have to just recommend that you should read for yourself. Among the physicists you can learn about here are: Schrodinger, Heisenberg, Pauli, Dirac, Stueckleberg, Feynman, Salam, Chandrashekar, Zeldovich, Landau, Touschek, Thirring, Oppenheimer (who, unlike almost everyone else, comes off badly), Nambu, and many others. A significant number of mathematicians, including Emmy Noether and Andre Weil also put in an appearance.

Freund also does a masterful job of describing the story of how mathematics and physics operated under the totalitarian systems of the last century, including a description of how the Romanian dictator Ceausescu and his wife had the mathematics institute closed down and disbanded after their daughter, who was working there, spent the night in a resort motel with one of her colleagues. He tells the stories of some of the well-known German mathematicians and physicists who either collaborated with the Nazis or joined the Nazi party, and where this led their careers. There is also quite a bit about Russian physicists and mathematicians, illustrating their attempts to survive within the Stalinist system, and the institutionalized anti-Semitism that Pontryagin and others were responsible for supporting.

Freund describes particle theory research as generally having a single leading figure that the field follows. He sees 1905 to 1925 as the era of Einstein, 1926-1943 as that of Heisenberg, a transitional period led by Fermi, with Gell-Mann dominating from the fifties to the early seventies, at which point 't Hooft takes over, followed by Witten in the early eighties. Witten's long era of dominance now appears to him to be coming to an end, and Freund nominates Maldacena as the leader for the new era which I guess has already been underway for a while, as AdS/CFT has dominated research for the last ten years.

While Freund is very strong on conveying the culture of particle theory that dominated the fifties, sixties, seventies and eighties, unfortunately he has much less of the same sort of material to help explain what has been going on for the last twenty years or so, the age of Witten and now Maldacena. There aren't any stories he has to tell about Witten, 't Hooft, or any of the other researchers whose work has characterized this recent period. Perhaps part of the problem is that they're a less entertaining lot: while I've heard a lot about Witten over the years, I can't think of much in the way of really colorful stories.

Freund's take on the current state of the subject is blandly optimistic: everything's going just fine. He mentions the Landscape and suggests Susskind's book for further reading, but doesn't see a problem there other than that "we need time and perserverance", and maybe cosmology will save the day. He does promote a more realistic point of view on the prospects for string theory, seeing it as a set of ideas that may in the future be part of some quite different real advance. His analogy is with Lagrangian and Hamiltonian mechanics, which didn't really give anything you couldn't get from Newtonian mechanics, but were necessary foundations for the truly revolutionary quantum theory.

All in all, Freund has written a fascinating book, one which any person who wants to understand more about the culture of theoretical physics can learn quite a lot from, whether they're a novice to the field, or have spent much of their life in it.

   December 16, 2007

   Peter, you say "… Freund describes particle theory research as generally having a single leading figure that the field follows. He sees
   1905 to 1925 as the era of Einstein,
   1926-1943 as that of Heisenberg,
   a transitional period led by Fermi,
   with Gell-Mann dominating from the fifties to the early seventies,
   at which point 't Hooft takes over,
   followed by Witten in the early eighties.
   Witten's long era of dominance now appears to him to be coming to an end,
   and Freund nominates Maldacena as the leader for the new era …".

   As to 1926-1943, why not Pauli ? Wasn't he regarded as a leader with a strong personality who had a lot of influence through the Handbuch, not to mention being the origin of memorable phrases including the title of your blog ?
   As to Pauli v. Heisenberg, their relative leadership status should be indicated by their conflict (in the 1950s) over Heisenberg's urfield theory, in which Pauli's skepticism (expressed in terms of painting like Titian) clearly won the battle for the hearts and minds of the physics establishment.

   As to the "transitional period led by Fermi" of 1943 – 1950s, there are many reasons to consider Oppenheimer (whether he was a nice guy or a not-so-nice guy who "comes off badly") as the real leader of that period. For one example, it was Oppenheimer's eventual approval of Dyson's presentation of Feynman/Schwinger QED that may have been the pivotal point of wide acceptance of QED. For a not-so-nice example, it was Oppenheimer who pushed Bohm to leave the USA.

   As to 't Hooft being the leader from the early 1970s to the 1980s, it is certainly true that his work was the key to establishing the Standard Model, but I am not so sure that he acted as a socio/political leader. It seems to me that Glashow and Weinberg shared that role back then, and that Weinberg's approval of string theory in the early 1980s was pivotal in the widespread acceptance of string theory, and the ascent of Witten to leadership role.

   As to Maldacena being an heir to Witten's leadership position, that might happen in the future, but as of now it seems to me that Witten has a strong hold on the leadership position, being widely known to the public and also commanding huge audience attention whenever he speaks/writes anything.

It would not surprise me if a non-string theorist were to get the leadership role in the future, such as for example possibly Alain Connes if his Non-Commutative Geometry model is seen to be successful.

Peter also says "… Freund is very strong on conveying the culture of particle theory that dominated the fifties, sixties, seventies and eighties, unfortunately he has much less of the same sort of material to help explain what has been going on for the last twenty years or so, the age of Witten and now Maldacena …".
Maybe such stories might actually exist, but may not be widely circulated until after the leaders have been gone from leadership for a while.

Tony Smith

PS – As this comment is written, I have ordered Freund's book from Amazon, but not yet received it. Maybe when I read it some of the questions raised above might be answered.

2. **NEW Reader**
December 16, 2007

Hi Peter,

Do you know of similar works within the mathematical physics & mathematics establishments?

Would be curious to find out.

3. **steve bryson**
December 16, 2007

hi Peter – here's a very small bit of unexpected Witten color: In a former life I thought I was going to be a theoretical physicist, but now I work on the NASA Kepler mission, which will look for Earth-sized planets around Sun-like Stars. Last January I was at the AAS conference at which Witten was participating in a panel. I was in the Kepler booth, and up walks Witten, who starts playing with our displays showing strong interest!! I mention that I know his work and ask him what about Kepler caught his eye. He says he's really interested in extrasolar planets and stays for the better part of half and hour. He got deeply absorbed in a grade-school level educational program where you construct your own solar system by placing planets on a touch screen. It was fun to watch his delight.

steve

4. **D R Lunsford**
December 17, 2007

I am excited to read this book!

Does he mention Fermi's critical work in early QED (in the 30s)?

-drl

5. **milkshake**
December 17, 2007

There is lots of new material on Oppenheimer (and others) in the "Brotherhood of the Bomb" from Gregg Herken and I could recommend the book to people interested in the politics and personalities of the cold war.

Oppenheimer does not come off as the nicest person – but the blame for what happened to Bohm, Friedman and Lomanitz falls on their buddy Joe Weinberg who was caught on tape by FBI volunteering to spy on Manhattan Project for Soviets.

Oppenheimer did his best to protect his commie students and academic collegues (and his brother) but he found himself in terrible soup as he had hard time remebering the contradicting stories he told at different times to different security people. He used to be a CP member himself, until about 1942, and he lied about it vehemently

6. **Bee**
December 17, 2007

What comes into my mind showing a true 'Passion for Discovery' is this nice photo from Pauli and Bohr. It's hard to see on the scanned photo, but they are watching one of these tippy top gyroscopes.

7. **Peter Woit**
December 17, 2007

NEW Reader,

I don't know of a similar book in mathematics, although there are lots of books that have some stories about mathematicians.

drl,

There's actually not that much about Fermi in Freund's book, even though it is rather Chicago-centric.

8. **T.**
December 17, 2007

Hi Peter,

Thanks for the excellent review. I've been spending some time on Pontryagin's principle..did my master's thesis on the subject, back then. I had no idea he was antisemitic. What a shame.

What I knew from him was that he grew blind at a point, and his mother would help him in his research, by taking dictations. I thought this was such a beautiful story..now it's somehow stained !

9. **Tony Smith**
December 17, 2007

Bee, thanks for the Pauli-Bohr TippyTop picture.

After my high school senior class (1959 Cartersville High) got our class rings, with heavy stones on top, we spent a lot of time spinning them (heavy-end-down) on our desks and watching them turn heavy-end-up.

Tony Smith

10. **Haelfix**
    December 18, 2007

    I feel Dirac replaces Heisenberg somewhere in the early thirties as the dominant physicist. He was soft spoken and not a traditional leader, but everyone and their mother was going through his papers trying to figure him out b/c it was obvious that it was dee[and important.

    I agree with a previous commentator about Weinberg being the dominant physicist until Witten takes over.

11. **m**
    December 18, 2007

    Haelfix, do you think that Witten papers on strings are more important than the Weinberg papers on the anthropic cosmological constant?

12. **chimpanzee (aka "joe")**
    December 19, 2007

    Came upon a reference to P. Freund on L. Motls' blog:

    http://motls.blogspot.com/2004/10/frank-wilczek-thanks-and-poem.html

    F. Wilczek:

    > I also got a superb undergraduate education, at the University of Chicago. In this connection I'd especially like to mention the inspiring influence of Peter Freund, whose tremendous enthusiasm and clarity in teaching a course on group theory in physics was a major influence in nudging me from pure mathematics toward physics.

    I found a really good article on the influence of teaching, stimulated by T. Dorigo's post on Quantum Diaries (education/cheating):

    "Those who educate children well are more to be honored than parents, for these only gave life, those the art of living well."
    — Aristotle
    "American educators take this philosophy to heart – they view their jobs as preparing the citizens of the world's most influential society."

    I don't find it surprising P. Freund wrote a good book: he understands Physics ("Know your subject") & is a good teacher ("Communication is the key").

    S. Coleman was also mentioned as an influential teacher ("his reputation precedes him"). I did some research recently, & found out my instructor for grad level course on Group Theory (UIUC, Harvard PhD & Princeton post-doc) was Julian Schwinger's student!! As was a close family friend of ours: UIUC physics prof, whose wife Lillian H. co-edited "The Rise of the Standard Model: A History of Particle Physics from 1964 to 1970")

    [she is a Physics PhD (Columbia), double appt History/Physics. Like P. Freund, this is how Physics needs to be communicated: by people who UNDERSTAND physics. Not by some journalist (non-technical type) who writes articles for "entertainment value". M. Franklin/Harvard had the best quote, from her talk entitled "Why the NY Times doesn't get the right spin on our data"]

    "scholarly scrutiny" as my ex-classmate H. Rothman (UNLV History prof, dept head) puts it, is the key. He [his dad was a UIUC math prof, btw] & his colleagues had a good discussion on how TV/media can mess things up:

    "A film cannot show everything nor reach the depths of understanding found in a book or even an article, and filmmakers fall prey to the need to make it captivating for the viewer. A historically accurate
    film that bores and goes unwatched is worthless in this sense."
    — James Lewis, history prof

    This is a REALLY GOOD POINT. Film/TV/Print ("media") is designed to "entertain" (weave a story, sometimes w/"artistic license"), but History is designed to "tell" (boring facts, but can be presented in a stimulating way).

    "Facts tell [Science], but Stories [Entertainment] sells"
    — Auto Racing maxim (or any field, for that matter)

    "It failed because it was a Documentary ["facts"], instead of Telling a Story ["entertainment"]"
    — Michael xx (Emmy award producer of "Amazing Race")
    [Auto Racing (click on "chimpanzee") to see the niche-market I've been exploring. Just like Science, it's not well understood by the Public & has poor-funding]

    C. Johnson/Asymptotia had a rude awakening recently (his content was used in a sensationalistic "female breast" stunt, as humorously pointed out by P. Woit), & there is the Fox News article on G. Lisi. They focus on "Appearance", rather than "Substance".

    I noticed that journalists like J. Horgan, G. Johnson, T. Ferris are brought in to "transmit" Science to the Public. T. Ferris made a total farce with his recent PBS show (I happen to be an expert in the subject matter he was addressing), the avg viewer just doesn't know. L. Motl had some very harsh words for J. Horgan's recent foray into Science.

    Needs & Solutions

    The solution is that each scientist (& his/her respective dept) needs a *historian* (w/background in Science) to handle the "communication". P. Woit & S. Hossenfelder shouldn't have to deal with a New Scientist ("soft publication") for science news. Just have a Freund-like entity to write it up, & *distribute* it to any publications.

    The husband/wife combo @UIUC (physicist & historian), has counterparts at other universities. Caltech has physics prof D. Goodstein (who used to visit my group @JPL, for that Project Mathematics education initiative) & his wife Judith (university archivist & faculty assoc History Dept). S. Carroll/J. Oulette (English major), I guarantee SC will proofread JO's articles for science correctness.

    Moral of the Story:
    Teamwork. 2-man teams. Get one of your colleagues to handle the history/communication. Forget about external non-technical 3rd parties.

Vogan on the Orbit Method

December 17, 2007
Categories: Uncategorized

David Vogan was visiting Columbia last week, giving the Ritt Lectures, on the topic of Geometry and Representations of Reductive Groups. He has made available the slides from his lectures here.

Vogan's talks concentrated on describing the so-called "orbit method" or "orbit philosophy", which posits a bijection for Lie groups G between

- Irreducible unitary representations of G

and

- Orbits of G acting on (Lie G)*

This is described as a "method" or "philosophy" rather than a theorem because it doesn't always work, and remains poorly understood in some cases, while at the same time having shown itself to be a powerful source of inspiration in representation theory.

It is probably best understood as an expression of the deep relationship between quantum mechanics and representation theory, and the surprising power of the notion of "quantization" of a classical mechanical system. In the Hamiltonian formalism, a classical mechanical system with symmetry group G corresponds to what a mathematician would call a symplectic manifold with an action of the group G preserving the symplectic structure. "Geometric quantization" is supposed to associate in some natural way a quantum mechanical system with symmetry group G to this symplectic manifold with G-action, with the Hilbert space of the quantum system providing a unitary representation of the group G. The representation is expected to be irreducible just when the group G acts transitively on the symplectic manifold. One can show that symplectic manifolds with transitive G action correspond to orbits of G on (Lie G)*, the dual space to the Lie algebra of G, with G acting by the dual of the adjoint action. So it is these "co-adjoint orbits" that provide geometrical versions of classical mechanical systems with G symmetry, and the orbit philosophy says that we should be able to quantize them to get irreducible unitary representations, and any irreducible unitary representation should come from this construction.

That such a "quantization" exists is perhaps surprising. To a quantum system one expects to be able to associate a classical system by taking Planck's constant to zero, but there is no good reason to expect that there should be a natural way of "quantizing" a classical system and getting a unique quantum system. Remarkably, we are able to do this for many classes of symplectic manifolds. For nilpotent groups like the Heisenberg group, that the orbit method works is a theorem, and this can be extended to solvable groups. What remains to be understood is what happens for reductive groups.

Already for the simplest case here, compact Lie groups, the situation is very interesting. Here co-adjoint orbits are things like flag manifolds, and the Borel-Weil-Bott theorem says that if an integrality condition is satisfied one gets the expected irreducible representations, sometimes in higher cohomology spaces. One can take "geometric quantization" here to be essentially "integration in K-theory", realizing representations using solutions to the Dirac equation. Recently Freed-Hopkins-Teleman gave a beautiful construction that gives the inverse map, associating an orbit to a given representation.

For non-compact real forms of complex reductive groups, like SL(2,**R**), the situation is much trickier, with the unitary representations infinite dimensional. Vogan's lectures were designed to lead up to and explain the still poorly understood problem of how to associate representations to nilpotent orbits of such groups. At the end of his slides, he gives two references one can consult to find out more about this.

Finally, there is a good graduate level textbook about the orbit method, Kirillov's Lectures on the Orbit Method. For more about the orbit method philosophy, its history and current state, a good source to consult is Vogan's review of this book in the Bulletin of the AMS.

Comments

1. **Marius**
   December 18, 2007

   This orbit method of Kirillov-Kostant-Souriau is a very interesting tool
   discovered by mathematicians in the 70's. Should be read in conjunction with the work of Souriau (starting in the 60's).

   It is a typical examble of being shallow that only one author (Kirillov) of this method is mentioned, at the end of the message, moreover as
   an author of a graduate level introduction into the method.
   What about Souriau? Kostant? geometric quantization? second
   geometric quantization?
   See this, for example:

   http://books.google.com/books?id=PuhpI98ZkDgC&dq=%22geometric+quantization%22+Souriau&lr=

2. **Peter Woit**
   December 18, 2007

   Marius,

   I made no attempt in this post to discuss the history of any of this, which is why only Kirillov appeared, and only in a reference to his expository text. Geometric quantization of course has a long history. The book you mention by Woodhouse doesn't discuss at all the orbit method or the connection to representation theory.

3. **Marius**
   December 18, 2007

   Peter,

   Maybe this helps (Kirillov, A. A.
   Geometric quantization [MR0842909 (87k:58104)]. Dynamical
   systems, IV, 139–176, Encyclopaedia Math. Sci., 4, Springer,
   Berlin, 2001)

   http://books.google.com/books?hl=en&lr=&id=CCGCFCj-

QNsC&oi=fnd&pg=PA139&dq=%22orbit+method%22+Woodhouse+Kirillov&ots=o4YtWHGqQ1&sig=SUE7nUR3c_1U74GJZr4DGPm-MbI

especially section 1.3 "The statement of the quantization problem. The connection with the method of orbits in representation theory".

Indeed, maybe Woodhouse is not the best reference in order to quickly understand that all is about the fact that the "orbit method", "geometric quantization", and some topics in reprezentation theory are in fact one.

This has been discovered by Souriau, in fact. In his book (in french, then translated in english) he defines (elementary) particles as (some) coadjoint orbits of the Poincare group, after introducing what is now known as (first) geometric quantization. Each such orbit has some invariants associated with (and identifying it), like the charge, and so on. As far as I understand, Souriau ideea is just this: take all hamiltonian systems with symmetry group G, then you can classify (or decompose?) the dynamics into a family of dynamics of "particles", each "particle" being a canonical dynamical system on a coadjoint orbit of G. The "canonical" word is related to the "orbit method", which relates coadjoint orbits with "simplest" representations of G.

4. **John Baez**
   December 18, 2007

   I think Peter gave a very nice overview of a topic that's much too vast to really fit into a blog entry. One comment:

   > Already for the simplest case here, compact Lie groups, the situation is very interesting. Here co-adjoint orbits are things like flag manifolds, and the Borel-Weil-Bott theorem says that if an integrality condition is satisfied one gets the expected irreducible representations, sometimes in higher cohomology spaces.

   This is true, but it makes the situation sound a bit more "scary" or "bad" than it is. It's actually as beautiful as you could hope. Every finite-dimensional irrep of a compact simple group comes from geometrically quantizing an integral coadjoint orbit. And every integral coadjoint orbit gives you a finite-dimensional irrep of the compact simple group. There's a 1-1 correspondence!

   And, if you happen to know the other famous way to get your paws on these finite-dimensional irreps – namely, from integral weights in the Weyl chamber – you'll be pleased to know that an "integral weight in the Weyl chamber" is just what you get when intersect an integral coadjoint orbit with the Cartan, and look at the point that lies in the Weyl chamber.

   Well, I'm sure that sounds scary too to most people. But it's really great.

   On the other hand, I'm still terrified of the noncompact case, which is where Vogan comes into his own.

5. **Peter Woit**
   December 18, 2007

   Thanks John,

   Didn't mean to make the compact case sound scary (yes, the non-compact reductive one is…). It's an incredibly beautiful story, one that needs more like a few weeks of a graduate course than a blog posting to do justice to it.

   There is one subtlety that you don't mention which fascinates me: there are two possible choices of which orbit to associate to which representation (the "rho-shift"). Does the trivial representation get associated to the trivial orbit, or to the orbit of half the sum of the positive roots? Opinions differ. And half the sum of the positive roots is the highest weight of the spinor representation, for spinors on the flag manifold. The Dirac equation is everywhere…

6. **John Baez**
   December 19, 2007

   Peter writes:

   > There is one subtlety that you don't mention which fascinates me…

   You too, eh?

   > Does the trivial representation get associated to the trivial orbit, or to the orbit of half the sum of the positive roots?

   This happens to be something James Dolan has been obsessed with over the last month… and my guess as to the solution was confirmed in Dieudonne's book on Universal Enveloping Algebras. I don't want to give it all away, since I plan to write about this in This Week's Finds someday, but there are two different ways to get a representation of a complex simple Lie algebra G starting from a representation of its Borel B: induction, and coinduction. These are dual in some sense, as the names hint – but there's a kind of compromise halfway in between, which involves taking the induced representation and tensoring with a special representation whose highest weight is "half the sum of the positive roots".

   But here's what finally convinced me this stuff make sense. The line bundle on the flag manifold (G/B) whose sections give this special representation is just the bundle of *half-forms!*

   Strictly speaking I should say "a" bundle of half-forms, not "the". Given an oriented n-manifold, a bundle of half-forms is any line bundle whose square is the bundle of n-forms. An n-form is something you can integrate over your manifold, so a half-form is something whose *square* you can integrate. This is why "tensoring with a bundle of half-forms" is important in geometric quantization: it gives you a bundle whose sections naturally form a Hilbert space!

   There are typically lots of square roots of the bundle of n-forms. But in the case of a flag manifold G/B there's a god-given choice: the bundle induced from a certain special 1-dimensional representation of B, namely the one corresponding to "half the sum of positive roots"!

   So, it's all starting to make sense. It's sad how hard it's been to squeeze this explanation out of the literature. Lots of books on Lie algebras talk about "half the sum of positive roots". But few seem to give the geometrical explanation in terms of geometric quantization. I guess the authors are trying to stay pure, and hide the geometry behind a veil of algebra.

7. **John Baez**

December 19, 2007

By the way, my remark about something “seeming more scary than it really is” concerned the phrase “sometimes in higher cohomology spaces” in your description of the Bott-Borel-Weil theorem.

When you have a *positive* weight, it gives you a line bundle on the flag manifold G/B whose space of holomorphic sections form an irrep of G. Only when you want to terrify people who haven’t fallen in love with sheaves should you call this space of holomorphic sections the “0th cohomology” of the line bundle – or really, its corresponding sheaf of holomorphic sections.

The scary jargon becomes more forgivable when we consider *nonpositive* weights. These again give line bundles on G/B, which again give irreps – but only when we take some *higher* cohomology group.

However, even in this case, the jargon is a bit more scary than necessary. It came as a great relief when I discovered that a “higher cohomology group” of a holomorphic line bundle was just a fancy way of talking about the space of holomorphic sections of this bundle *tensored with another bundle* – I guess a bundle of p-forms.

Another digression:

The fact that I’m talking about half-forms when you’re talking about spinors suggests that I, at least, haven’t gotten to the very bottom of this “half the sum of positive roots” business. Both half-forms and spinors are “square roots” of something – but different somethings, and in different ways! And, they both show up as correction fudge factors in geometric quantization, but I don’t quite understand how they’re related.

I bet Eckhard Meinrenken does.

8. **Peter Woit**
December 19, 2007

John,

I’m looking forward to seeing your version of why the so-called “rho-shift”.

One indication that spinors are the right way to think about this comes from the following: Borel-Weil and Borel-Weil-Bott both crucially depend on the choice of invariant complex structure, which is the same as the choice of positive roots. Acting by the Weyl group changes the complex structure, makes dominant weights no longer dominant, and moves the representation from holomorphic sections to higher cohomology (or, OK, higher order differential forms). If you use the Dirac operator and spinors instead, none of this happens, the whole set up is completely Weyl-invariant.

9. **a.k.**
December 19, 2007

..at least as far as symplectic spinors are concerned the latter is possibly reflected by the fact that any compatible complex structure on a symplectic manifold (i.e. on a coadjoint orbit) gives rise to a reduction of the metaplectic structure of the manifold to a two-fold-covering of the unitary group, contained in the centralisator of the latter is a one-parameter-subgroup induced by the element in the Lie-algebra whose image under the exponential map projects to the canonical complex structure of R^{2n}. This subgroup factors to a familiy of representations of the circle over the eigenspaces of the harmonic oscillator, the corresponding splitting of the spinor bundle reveals as the ‘lowest eigenmode’ of the harmonic oscillator a line-subbundle, this is then a ‘canonical’ choice for a half-form on M (depending on the complex structure). Associated to a Lagrangian polarization is a O(n)-reduction of the spinor-bundle resp. of the above line-subbundle, this is the ‘half-form’ widely used in geometric quantization, as it seems.

10. **strangerep**
December 19, 2007

Hi Peter,

Good pedagogical explanations of the orbit method seem to be rare.
I looked at the brief section in your course notes (the section at
the end on the momentum map and the orbit method), but it was
a bit too brief for me to get a thorough understanding. I’ve tried
Kirillov’s course notes, but they require too much from (this) reader.

Is there any chance you could expand your course notes? E.g.,
talk in more detail about the H1 and SU(2) examples you mention,
and perhaps some others? There’s not quite enough detail on the
H1 case to follow it properly, and the SU(2) case is only couple
of paragraphs?

11. **Peter Woit**
December 20, 2007

strangerep,

I’ll be teaching that course this semester again, maybe I’ll get a chance to expand the notes, we’ll see.

I probably also discuss the SU(2) case when I discuss Borel-Weil theory, it’s really the same thing, which is one reason for not going on much about the orbit method in the compact group case. In the case of SU(2) orbits are just spheres, weights correspond to line bundles, for weights of the right sign quantization is just taking holomorphic sections of the line bundle. Quite concretely, such sections correspond to homogeneous polynomials of degree given by the weight.

The Heisenberg group case probably does deserve a lot more detail….

12. **Bruce Bartlett**
January 6, 2008

Hi Peter and John,

I’ve been trying to understand the basics, namely this geometric way of thinking about representations of compact Lie groups for a while now; various entries in this blog have helped me in many ways -thanks! However, can you point me to an explicit “equivalence of categories” statement?

For instance, my favourite way of conceptualizing it is the way of Guillemin and Sternberg in their book "Symplectic techniques in physics" (see the section on Kaehler manifolds). This is the approach which doesn't bother with coadjoint orbits in the dual of the lie algebra, but rather works directly with the representations themselves. The correspondence is roughly:

representations of a compact Lie group G complex G-equivariant line bundles having a finite number of orbits

Note I didn't say "irreducible representations"; I'm looking for an equivalence of categories here. A morphism between equivariant line bundles category on the right hand side is an *equivariant kernel* , i.e an equivariant collection of maps f_{x,y} : L_x –> L'_x.

From left to right, given a representation V of a compact Lie group G, one simply takes the G-orbits in the projective space of the representation which are complex submanifolds. (This is a slightly more intrinsic procedure than finding these orbits in the dual of the lie algebra). From right to left, one just takes holomorphic sections.

Does this make sense, and do you know of a precise statemen to this effect, so as to obtain an equivalence of categories?

I agree with Peter in that I am also fascinated by the spinor side of the story. Basically, my understanding (from the book "Heat kernels and Dirac operators" by Berline,Getzler and Vergne) is that under this geometric correspondence, the character of the representation computes in terms of the equivariant index of the Dirac operator living over these G-sets; in fact it localizes over the fixed points.

13. **Peter Woit**
January 6, 2008

Bruce,

In your way of associating a geometrical object to a representation, doesn't the orbit depend on which vector you pick?

I'm fond of the K-theoretic "quantization=integration" idea, but to turn this into a statement about categories (of equivariant vector bundles on one side, representations on the other) you need to "categorify" it, and I haven't thought about that. The people who seem to have precise equivalence of categories statements of this kind are those thinking in terms of D-modules. I think the Beilinson-Bernstein localization theorem is the kind of precise statement about equivalence of categories that you want. In the compact Lie group case, maybe it can be restated in various other ways.

14. **Bruce Bartlett**
January 6, 2008

Thanks for the reply! Peter wrote:

> In your way of associating a geometrical object to a representation, doesn't the orbit depend on which vector you pick?

No… that's what I learnt from Guillemin and Sternberg. I guess you are saying to me that it is the orbits of the maximal weight vector which are the orbits we need to pick out, and somehow this "maximal weight vector" requires a choice. But the more intrinsic way of looking at it is that, at least for irreducible representations (heh, I am out on a limb for reducible reps), there is only *one* orbit which is a *complex* submanifold of the projective space P(V).

In other words, from an intrinsic point of view, weight vectors don't come into it at all. One simply needs to "look for the complex orbits, Luke" (insert Obi-Wan voice here).

> but to turn this into a statement about categories… you need to "categorify" it…

Well, indeed I *am* in the "categorificaion" game; I work with "2-representations" and all that jazz. But here we're working with ordinary representations…. surely I'm not asking for a "categorification" of anything, I'm just asking for a nice elegant statement of the geometric correspondence between ordinary representations of Lie groups and "equivariant complex line bundles"… if there is such a statement, one would expect it to be phrased as an equivalence of categories.

> The people who seem to have precise equivalence of categories statements of this kind are those thinking in terms of D-modules.

Gulp! Sadly all that stuff is over my head. I'll crawl back under my bridge now.

15. **a.k.**
January 7, 2008

..if we are already that far: one should possibly not forget that the actual goal was to quantize classical *observables*, an observable in classical mechanics is nothing more than a function (for instance a 'symbol' on a coadjoint orbit), to these functions one aimed to associate more or less pseudodifferential operators on appropriate vectorbundles such that this correspondence is equivariant w.r.t. appropriate 'products' on both sides. I only want to point out that one advantage of the spinor view is that it makes it possible to associate to a certain class of functions (again, 'symbols') on a cotangent bundle *sections* in a (symplectic) spinor bundle, to do this, one needs a 'half-form', which is a subbundle of the symplectic spinor bundle, to compensate for an ambigous choice of (local) 'signs'. On the other hand one can localize functions on the zero-section of the cotangent-bundle and encode them as well as spinors, this is analogous to the 'micolocal lift' in deformation quantization. Using a Fouriertransform for spinors one can pair these two sections by the pointwise (spinor)-L^2-product over the manifold and gets the action of a pseudodifferential operator on smooth functions on the zero-section of the cotangent bundle which is exactly that one used in deformation quantization to define the *-product on symbols.

I never saw this spinor-quantization construction anywhere else than in my not-quite-recent diploma thesis, which is (funny enough) in german, but one should recall that a correspondence between orbits and sections of vectorbundles is only the very first step in quantization and unless somebody enlightens me and one is not conerned about varieties and algebraic groups, I do not see what <i<exactly the 'categorification'-theme aims at. The (symplectic) spinor-business seems for no clear reason to be a bit mystified and judged to be oversubtle or impenetrable, nevertheless it arises very naturally in the symplectic context, that is, in the context of quantization.

16. **Peter Woit**
January 7, 2008

Bruce,

I was just using the word "categorification" to show off, since one of the few things I know about it is that people use "decategorification" to mean taking K-theory….

Thinking more about it, what I was thinking about clearly can't work, but in more detail, the idea was that the index map
K_G(G/T) to K_G(pt.)=R(G) relates the K-theory of the category of G-equivariant vector bundles on the flag variety to the K-theory of the category of representations of G.

But, even at the level of K-theory, this isn't an isomorphism, since
K_G(G/T)=R(T) and R(G)=R(T)^W. The map is "Dirac induction", maybe there's some way of thinking about this though that does give an isomorphism.

As for D-modules, in this case Beilinson-Bernstein is just another way of restating Borel-Weil-Bott, but in a way that I guess gives an equivalence of categories. You need to just see what it is saying in this special case. I think the new book of Hotta et. al. explains this, also some expository papers of Schmid. Might or might not be in some lecture notes of David Ben-Zvi, who is someone who certainly understands this stuff.

Thanks, you've given me lots of leads to follow up here.

Disastrous FY 2008 DOE Budget

December 18, 2007
Categories: Experimental HEP News

The White House and the Congress, several months into the 2008 fiscal year, finally seem to have come to agreement on a budget, one that fully funds the Iraq war, but has a huge cut in the budget for DOE particle physics research. According to the AIP FYI bulletin, the DOE HEP budget for FY2007 was $751.8 million, and the White House had requested and Congressional committees agreed to $782.3 million for FY2008. The new budget agreement provides only $688.3 million, an 8.5 percent cut from last year. The cut eliminates funding for NOvA this year at Fermilab, and effectively shuts down R and D on the ILC, providing only 25% of the requested amount, much of which has already been spent.

Pier Oddone, the director of Fermilab writes in the December 18 Fermilab Today:

> This is a body blow to the future of the ILC, the U.S. role in it and Fermilab…. These proposed cuts, which come on top of the very limited particle physics budgets of the last few years, are destructive of our field and our laboratory. There is no way to sugar-coat this… If this bill becomes law I will be discussing consequences with you in more detail. Until then, I and many others who understand this disaster in the making are trying to inform Congress and the Administration of the dire consequences to the U.S. particle physics research program. These may be unintended consequences that were not considered in the pressure-cooker atmosphere that accompanies an omnibus budget bill.

It's not clear to me what the prospects are for doing anything about this at this late date in the budget process.

Update: More here, here, here and here.

Update: Also here, here, and here. A spokesperson for Fermilab says "This is the worst funding crisis in the history of the laboratory, no exaggeration" and that one option being considered is shutting down the lab for a few months. Lederman places the blame on spending for the Iraq war and says "I've been around this lab since it was all farmland, and I can't remember a crisis of this severity". Part of the problem may be the resignation of Dennis Hastert, who had been both the House Speaker and the representative for the district including Fermilab.

Update: JoAnne Hewett has more at Cosmic Variance.

Update: At an all-hands meeting at Fermilab, the director announced that the budget of the lab would be cut $52 million over what they had been expecting for the rest of the fiscal year. Dealing with this will require eliminating 200 full-time-equivalent positions, about 10% of the people working at the lab. They will immediately start shutting down ILC and NOvA, They will try and not shut-down the lab, focusing on keeping the Tevatron running, but will have a system of rolling 2 day/month furloughs, with not everyone furloughed at once. He said the first he heard about this was on Monday. It remains unclear who was responsible for this decision, which seems to have been taken in haste, with very few people involved. It also remains very unclear what this means for next year's budget, or for the future of the ILC and NOvA.

Part of the story here seems to have been that there was a Congressional decision to fund member's earmarks, while cutting scientific research that was not funded this way.

The APS has issued a press release about this which states:

> This action sends a strong message to the world: The U.S. is prepared to jettison support for one of our flagship areas of science that probes fundamental laws of the universe.

The press release also criticizes the Congressional decision to preserve and expand earmarks while cutting other programs:

> The APS notes with some dismay that had Congress applied the same discipline to earmarking as it did last year, the damage to the science and technology enterprise could have been avoided.

Update: One peculiar aspect of this story is how little attention it has gotten from the press (other than the local Illinois press) and from science blogs, where all I've seen is mention at Cosmic Variance and Tommaso Dorigo's blog.

The congressional representatives for the Fermilab district have put out a press release (on the Durbin and Biggert web-sites, looks like Obama couldn't be bothered to put it up) calling on the DOE Office of Science to "increase the funding request" for HEP in the proposed FY 2009 budget. The language used seems to me to be rather weak, since it doesn't mention either a size of increase or what base to use. See this comment that just came in for possible news about attempts to restore some of the Fermilab funding.

Update: The Obama web-site now has the press release. There's an article about this today in the New York Times.

   I recently heard some possible good news for our field. Someone said that the Germans had increased their particle physics expenditure. Can any Germans confirm this ?

   Peter, I hope you don't view this as off-topic. The UK and US decisions have been body blows to the whole community. It would be interesting to discuss worldwide particle physics funding here.

4. **Anti-insurgent**
   December 19, 2007

"The White House and the Congress, several months into the 2008 fiscal year, finally seem to have come to agreement on a budget, one that fully funds the Iraq war …"

War gets more media attention because it makes human interest stories: tens of thousands lose friends and relatives. This is what politicians really respond to. So if these particle accelerator physicists *really* want decent funding, they should produce military versions: massive particle ray guns to fight satellites, missiles and aircraft. It's a pity that modern physicists aren't so interested now in combining particle research and warfare. Back in the good old days when Feynman, Oppenheimer, Teller, Fermi, Lawrence et al. worked on the Manhattan Project, they got two billion for research (in 1945 dollars, uncorrected for inflation) just for delivering two small bombs.

I would not be too optimisitc. Some of it may be only du to needed phenomenological research with LHC data. In fact the increased budget with some projects in High energy physics came somewhat "accidentially".

In germany, research is founded by governments of each of the federal states and the federal government, with the states founding their universities, and the government founding the Max-Planck institutes and the DFG, a society similarly to NSF in US.

Recently there was an initiative, that the government will spend additional money to some of their universities, which have won in a competition after being evaluated by a DFG comission.

And accidentially, most of the physics projects that were positively evaluated, were High Energy Physics projects.
Obviously, this has something to do with the large experimental facillities at CERN and elsewhere, with which these projects collaborate.

That is: To fund high energy projects was not planned by german government at all. Unfortunately, most of it is experimental research (almost no theory project survived the competition at DFG), and even this experimental HEP research is funded only due to the fact that the politicians agreed to spend their money on exactly those projects, the people of DFG told them to do so. Funding HEP was not, what the politicians had in mind.

Instead, recently, german government decided, not to build ILC anywhere in germany. Unnamed officials in the ministry tell, that the future of HEP funding strongly depends on LHC, with government definitely not wanting to fund any large accelerator projects at a stage where one does not know what LHC will see.

December 19, 2007

Reg Germany, see e.g. The Terascale Alliance.

7. **woit**
December 19, 2007

John,

NOvA is Fermilab's main next-generation neutrino experiment, looking for muon to electron neutrino oscillations, trying to measure a non-zero value for the mixing angle theta_13. The project involves upgrading some of the Fermilab accelerator facilities, and constructing a near detector on-site, and a far detector in Minnesota.

Shutting this down and shutting down ILC R and D pretty much shuts down any investment in the future of Fermilab for the remainder of FY 2008.

8. **wb**
December 19, 2007

To make the ILC picture darker, the UK has stopped ILC related funding this year.

9. **Bee**
December 19, 2007

Hans: *That is: To fund high energy projects was not planned by german government at all. Funding HEP was not, what the politicians had in mind.*
They had in mind to fund the best and most promising research, for which they rely on expert's advice. That's the sensible thing to do. One can discuss whether it's good to do this via the DFG and what to think of their refereeing system, but I think it works pretty well. The problem with the German physicists is the dominace by not yet quite dead nuclear physicists for whom 'high energy' is somewhere around 10 GeV.

The US budget disaster just reflects the fact that this democracy is a farce. I'd like to see a poll on the question whether to blow up billions of dollars in funding actual or potential wars and loosing researchers to the North, East and West, or whether to assure technological and intellectual expertise in the own country does at least remain at last century's status (I won't even aim at improving it). If it goes on like this, I see the Europe -> US brain drain reversing. I can't avoid thinking of George Orwell's 1984 scenario with the country that engages in permanent war, things get constantly worse, but they report all the time great improvements. I'd recomment setting up the Ministry of Truth.

Best,

B.

I see it more that solid state physicists are a problem.
They often are making campaigns against allmost all ground based research. They can argue to the politicians that their science may lead into industrial products. And so, nanoscience, solid state physics and so on, receive a great more amount of money than mathematical physics or phaenomenology(at least in germany).

For example, Munich has, with its two universities and five Max-Planck Institutes one of the largest hep groups in the world.

And even there, the chancellor of the Ludwigs Maximillians University, Huber had circulated a document, in which High Energy physics was defined as an area to withdraw in future.

There had letters to be written from international persons to make Huber give up this plan.
It seems that there were a large amount of condensed matter physicists in the advisory board of the chancellor.

I know of another group where condensed matter physicists were even sucessfull in knocking down two professorships in the area of quantum gravity. The professorships of Heinz Dehnen, and Audretsch in Konstanz was a general relativity group. But the majority of condensed matter physicists decided, to cancel this professorships after the two men retired.

It seems that Germany has only 5 chairs devotet to relativistic physics (stringtheorists and particle theorists excluded, one at Jena, Kologne Freiburg, Tübingen and Munich).
It is known to the author that a majority of solid state physicists sometimes boycotted relativists, which wanted to hold conferences at the german physical society.

(and regarding your Quantum gravity group in Frankfurt: When a decision is made about a new research group at a university, DFG often has physicists of other areas in the decision comittes. When it is to decide about an area, where there are not many experts in Germany, those physicists from other areas have the majority. And then you might think what they decide……)

14. **wb**
December 19, 2007

SLAC gets hits moderately because it has had a fairly decent sized ILC program. Fortunately for the laboratory its prime program, LCLS, was fully funded. Besides citing Pelosi, Dick Durbin doesn't seem to have done much to defend Fermilab. So I'd call it a bi-partisan screwing – the cuts seem to have been deliberately placed not a mistake.

15. **JoAnne**
December 19, 2007

Peter,

I echo wb above, the language in the bill indicates that the cuts are deliberately placed. I have no idea why, except that the large international science projects ITER and ILC obviously didn't fare well.

As for SLAC, most of the lab itself is now supported by the Basic Energy Sciences division of the DOE. However, the particle physics and astrophysics division of SLAC is supported directly by the HEP division of DOE and will be severely hurt. We are (or should I say were) the major US player in the R&D effort for the ILC and there is no way we can now support that. In addition, we have (had) a sizeable effort on an ILC detector. Any ideas on saving money are very draconian. Just like Fermilab, folks are talking about shutting off the B-Factory or having "scrooge days or weeks" where people work without getting paid or layoffs. Little things like no travel money or new computer equipment for the rest of the year and a hiring freeze will be implemented, but will not be nearly enough.

16. **wb**
December 19, 2007

One theory I have heard about the reason for these targeted cuts was that ILC and ITER had received explicit White House backing. So these cuts would embarrass the Administration. That rationale does not explain zeroing Nova. Perhaps that choice was due to a staffer doing his/her homework and finding such physics as the lowest priority in EPP2010.

A difficulty that the lab directors face in trying to react is the money is not fungible and the cuts target people in specific organizations within the laboratory. It is hard to imagine that layoffs are not in order. If you expect this to be a one-time phenomenon, then you tighten the belt a lot and tough it out. But we have no reason to believe that science will fare better in the next budget – and as 2008 is an election year, the legislative season is shortened. Hence a continuing resolution or another Omnibus Bill is likely.

Perhaps a unified push by the presidents of major universities joined by CEOs from major hi-tech industries would help rescue the long range future of science in America.

17. **LDM**
December 19, 2007

In the US democracy one has the freedom to become politically active and change things if one is not happy with the government policies. One also has the freedom to openly express dissent.

Contrast this with Russia – also a democracy – where just this month the opposition leader, Gary Kasparov, was jailed for 5 days for attempting to hold a rally in opposition to Putin. Regarding the 'ministry of truth', there was no mention of the arrest on the Russian state controlled TV. And the Russian elections were totally falsified – which was made possible by the failure of Russia to grant international observers the needed visas so they could monitor the elections.
The US democracy, while not perfect, is still the best available, and taking 8.5 percent of the HEP budget to support our troops is a sacrifice we should be willing to make,

if indeed that is where the 8.5 percent is being allocated. I would suggest that such a sacrifice is nothing compared to that being made by our troops.
Being an excellent physicist (or mathematician as the case may be) does not imply one is also politically astute. Oppenheimer comes to mind as the canonical example.

18. **Peter Woit**
December 19, 2007

LDM and others,

If you have an intelligent comment about the HEP budget situation, please post it here. If you want to rant about the Russians, or otherwise engage in predictable political polemics, do this on one of the 1000 blogs out there devoted to this, not here.

19. **IMHO**
December 19, 2007

To inject a little clear-eyed realism into the conversation.

Why haven't you people been expecting this….I have. Why do you think HEP is first to the slaughter? It's because HEP has the lowest (cost to benefit-to-society) ratio of all the sciences. HEP has completely and utterly lost touch with the real world. These days it seems more and more like mental masturbation at it's finest.

Can we have hundreds of millions of dollars to study phenomenon with absolutely no societal or economic benefit what-so-ever…???

Welfare is never popular.

20. **Bee**
December 19, 2007

Hans: I agree, the nuclear guys aren't the only problem. In general I find Germany has been much too conservative. I think though the DFG is doing a good job, at least as good as they can, and from the little that I notice over here, things are slowly getting better in Germany. The biggest problem they face though is one that the DFG can't solve, the missing tenure process, the habilitation, and the 'Berufsbeamtentum' (I guess you're German so you know what I mean). A correction: There never was a QG group in Frankfurt, and unless a miracle happens I don't think there will be one in the soon future. There was, long time ago, a Quantum Gravity seminar, but that was ironically offered by the maths department. All we tried was physics beyond the standard model, and despite the large interest among the students and postdocs, and support from the faculty, we didn't get funding. Maybe we'd have better chances today. Best,

B.

21. **Tom**
December 19, 2007

IMHO,

Either you are a non-science oriented person or have lost touch with the fundamentals of technological progress. Society progresses technologically by first understanding nature, then understanding how to manipulate nature, and finally understanding how to do this in a way that everyone can benefit. Case in point Quantum Mechanics. At the time, nobody thought it would turn into anything of use. Niels Bohr himself thought it couldn't possibly be of benefit because nothing of use could come of something so small. 50 years later the transistor is invented, and 50 years after the computer is without a doubt one of the most essential parts of our existence. This process has been the same through our entire existence. Maxwell's equations into RF electronics, Kinematics/Static science into the design of anything mechanical. Thermodynamics and statistical mechanics into modern chemical engineering. We first understand nature, we then learn to manipulate it. Calling the first step unessential is claiming you don't need to mine gold to make a gold ring.

22. **Peter Woit**
December 19, 2007

Please, this is not a blog entry about whether particle physics is a worthwhile subject that deserves public support. If you want to argue about that, do it elsewhere.

23. **Tom**
December 19, 2007

Peter, it seems to me a blog entry on the HEP budget is the perfect place to argue whether the public should support or not support such efforts, but as it is your blog……

I will comment that I believe this is the very reason we are in trouble. We choose not to address those questions in a way that the public values the research.

24. **Peter Woit**
December 19, 2007

Tom,

Since this is a blog aimed at people with a serious interest in particle physics, the problem is that arguments about why it is a worthwhile subject will be preaching to the choir. If people want to put their energy into changing the minds of those who know nothing about this subject or are dubious of its value, that's great, but the right audience isn't here.

I don't actually think the problem is with the public not supporting this kind of research, which I think they support as much if not more than most scientific research, to the extent they care at all. The problem is that, at the last moment, some small number of people without any public discussion (or even private discussion with prominent scientists, as far as I know) made the decision to make US HEP research bear the brunt of this year's budget cuts. I'm curious to know why that happened, and what the implications are for the future.

25. **milkshake**
December 19, 2007

Hubble telescope was going to be "left for dead" by NASA at one point – and astronomy at least produces pretty pictures…

Arecibo was "de-funded" too, if I remeber correctly.

26. **wb**
December 19, 2007

Peter,

I think one should dissect the HEP cut even further. Almost all of the cut is in that portion of the HEP budget that was a foundation for Fermilab's future. Where can Project X go without superconducting rf development? How does Fermilab gain traction into a neutrino future with Nova zeroed? As for ILC, this cut seems to render that possibility comatose until either Japan or China steps up to the plate.

So I'd ask where was the Illinois delegation. Why did Sen. Durbin give a cold shoulder to pleas for help. So I'd like to understand why this shot directly amidships to the flagship of American high energy physics. Who had it in for Fermilab? There certainly was money that could have gone to HEP out of the $125 M of earmarks -pork – that was inserted into the Office of Science budget.

27. **Tom**
December 19, 2007

Peter,

The comment I was replying to is evidence that we are not "preaching to the choir". I think you underestimate the diversity of your audience. I also see great value in educating the lay with the correct arguments for basic science research. With this said, I really don't want to argue whether or not we should be discussing whether or not to fund basic science. So please continue to sleuth out the reasons the HEP budget took such a nasty hit. If you are able to derive the inner workings of how federal budget decisions are made, you should probably publish the work. Maybe even a book – you could recycle the same title as your last work.

28. **Sam**
December 20, 2007

wb:

Here's my take.

If the elected representatives of the American people want to decide not to do High Energy Physics, they clearly have the right to make that decision. If that is their intention, they should come out and say so. The budget as passed scraps the NOvA project (Fermilab's short-term upgrade project, to come online after the Tevatron is superceded by CERN's LHC.) NOvA is a stepping-stone on the way to Project X (the lab's medium-term upgrade plan, currently in the early planning stages). The budget also eliminates any further spending this fiscal year on the ILC (Fermilab's long-term plan). In short, it eliminates all spending on the future of accelerator physics in the US. The statement it makes looks rather like "carry on operating your current program, and go away and quietly die in 2010".

The reports talk about 200 people losing their jobs, but layoffs don't actually save you any money in the current fiscal year (as you have to pay termination and unemployment benefits). The only way to save significant amounts of money is to turn off the accelerators and send everyone home without pay for a month or so. You can do that.

Many of those people will find other jobs, rather than sitting around doing nothing for a month. The people who find it easiest to get interesting new work are going to be the employees that were most useful. They'll provide your 200 job cuts, but it'll be the 200 people you could least afford to lose. It might not quite be a death blow, but it'll be very close.

Does Congress really want to destroy the US High Energy Physics program to save $60 million? Maybe it does, and maybe it doesn't, but that's what it's done.

If that's really what Congress wants, it should come out and say "sorry, we're not going to be doing this any more" and then everyone knows where they stand. A few months ago (COMPETES etc.), they seemed quite keen on doing this kind of thing, so maybe it was more a case of a budget-crunch screwup that didn't understand the full implications of the cuts.

29. **Chris W.**
December 20, 2007

Arbitrary cuts with little regard for "functioning/crippled" thresholds is sort of business as usual for Congress and the current administration, isn't it? I think the attitude is basically "whatever; after a while they'll stop whining and figure it out." Even in the conduct of the Iraq War a lot of things have been approached as "throw 'em in the deep end of the pool and let 'em figure out how to swim."

You may also recall tax-cut activist Grover Norquist's declared ambition to reduce the size of the federal government (and its programs) to the point where "they can be drowned in a bathtub".

Then again, I suppose one should remember the old saying, "never ascribe to malevolence that which can be explained by incompetence"—passing 3,000 page bills that nobody has actually read.

(The late hour must be exacerbating my cynicism—sorry.)

30. **wb**
December 20, 2007

Sam,

I completely agree with your comments. COMPETES was passed and signed into law; the mark-ups in the Energy and Water Appropriations bill were very supportive. So what changed? In the Omnibus Bill HEP gets to compete with rural hospitals for money, but other Office of Science programs have the same competition. Yes, it is the perogative of Congress to decide what to fund and what not to fund. It is our right to ask why. I just don't buy the inadvertent "screw-up" theory. As you say, "hey should come out and say so."

31. **Chris Austin**
December 20, 2007

As a British physicist who might be indirectly affected by these cuts, (via reduced likelihood of another US visit), I would like to suggest that these cuts might be because the US government has identified that the ILC isn't expected to make fundamental discoveries in the same way as the LHC is. In other words, this might be a wake-up call, with the government saying, "You've got to do better." I understand that the financial situation will be difficult for everyone, but since the appropriate direction for HEP to make further fundamental discoveries after the LHC depends so completely on what is found at the LHC, perhaps it would be good for the next three or four years to focus on maximizing the return from the LHC and drawing the implications from its results, which is sure to be quite difficult.

Best regards,
Chris

32. **Steve Demuth**
December 20, 2007

I will respect Peter's request that we not use this as a forum to debate the value of HEP funding, but I do want to say that I disagree with that judgment. I am not a professional physicist, but I do follow physics closely, and I doubt I am the only such person who reads this blog. I would welcome a discussion about the cuts that focused on why they are justified or not.

And … depending on the case made, the results of such a debate could well be a letter from me to my representatives opposing – or endorsing – the cuts.

33. **Peter Woit**
December 20, 2007

Steve (and others whose comments I've deleted and will continue to delete),

What I write here about experimental particle physics and its funding is intended to provide useful and accurate information to people interested in what is happening in this area. I attempt to do so with a minimum of editorializing. This particular event is an extreme case, in the size and timing of the budget cut, and the lack of transparency in how it was arrived at. I hope that you'll take advantage of what this blog does provide, accurate information, in reaching your own decisions about what you think the federal government's spending priorities should be. I hope you'll also realize that there is some advantage to not having to wade through large numbers of comments from people discussing their feelings about government spending, swamping actual information about what has just happened.

On this blog I'd like as much as possible to make this deal with my readers: I'll do my best to spare you my blathering about political issues, please spare me yours. If you want to find a blog where political debate on scientific issues is encouraged, there are other places to go, Cosmic Variance is a pretty good one.

34. **Michael Bacon**
December 20, 2007

"The press release also criticizes the Congressional decision to preserve and expand earmarks while cutting other programs."

Actually, earmarks declined from the prior budget somewhere between 25% and 43%, depending on who you want to believe. Obviously, still too high, although it's hard to imagine members of Congress completely eliminating this type of special funding for their districts.

The real problem is lack of understanding and leadership in Congress and the White House and a broad swath of the population that not only doesn't understand what's at stake, but that doesn't even think about it.

35. **Peter Woit**
December 20, 2007

Michael,

I'd be curious to know a source for solid numbers about this. A little research on the net turns up the claim that there were essentially no earmarks in the FY 2007 DOE budget, but that this year's final budget language includes

"Funding under this heading in the amended bill includes $125,633,000 for Congressionally Directed Projects."

At the FNAL all-hands meeting, someone who was not very happy about it brought up the claims by Illinois senator Durbin from his web-site that he was responsible for $448 million in earmarks for Illinois projects. I think the implication was that his focus on bringing in earmarks, in an environment where more earmarks meant bigger budget cuts for labs like FNAL, was part of the problem.

36. **MathPhys**
December 21, 2007

Best wishes on the festive season, Peter, and thank you very much for a very informative blog.

37. **Michael Bacon**
December 21, 2007

Peter,

Yesterday evening on The News Hour with Jim Lehrer on PBS they had an in-depth piece on the new budget. The numbers I quoted came from the two non-partisan analysts who were interviewed at length and who agreed that earmarks had declined, but disagreed about how much. I believe that I remembered them correctly. The analysts were, however, talking about the overall budget and not the DOE budget. I agree that earmarks always reduce the amounts available for other projects and I certainly wasn't trying to say that it isn't a problem, only that the number and total dollar amount declined over the prior overall federal budget. I still think that's the case, but since I'm relying on others on this point, I could certainly be wrong.

38. **Michael Bacon**
December 21, 2007

Peter,

Here is a link to the transcript of the program.

http://www.pbs.org/newshour/bb/politics/july-dec07/earmarks_12-20.html

My memory was slightly off on the percentages. According to the two analysts, the decline was either 25% or 40%. It isn't clear what accounts for the difference, but it may be whether you're looking at the total dollar amount of the number or earmarks.

39. **wb**
December 21, 2007

The ILC detector collaboration just sent around the following message:

"Chip Zukoski, UIUC's Vice Chancellor for Research, just got very good news from April Burke, of Lewis-Burke Associates. (They do federal relations consulting for UIUC and are active in HEP advocacy.) As I understand it, Senator Durbin now appreciates the enormity of the spending bill's negative impact and has instructed Fermilab to cancel the layoffs that were being discussed, Senator Durbin will work to restore (some of the?) funding to HEP once Congress begins its next session after

the New Year."
… "Senator Durbin has responded to concerns regarding the cuts to High Energy Physics funding by contacting Secretary Bodman. Senator Durbin made a commitment to work to prevent layoffs at Fermilab. At this time there are no details as to whether complete funding will be restored, including the project funding for NoVA and ILC. However, efforts are underway by Senator Durbin look for a solution to funding shortfalls at Fermilab and for HEP."

So let's hold our breath and watch for the next episode.

40. **wb**
December 21, 2007

Further news on this front:

DURBIN, OBAMA, BIGGERT CALL ON BUSH ADMINISTRATION TO INCREASE FUNDING AT FERMILAB

In light of recent funding cuts, Illinois members will meet to discuss strategy

WASHINGTON, D.C. – U.S. Senators Dick Durbin (D-IL) and Barack Obama (D-IL) and Representative Judy Biggert (R-IL) today sent the following letter to Jim Nussle, Director of the Office of Management and Budget (OMB), calling on him to increase next year's funding for the High Energy Physics (HEP) program, which supports research at Fermilab in Illinois, and at several other laboratories and universities across the nation that are doing vital, cutting edge research.

Durbin, Obama, and Biggert are in discussions with Congressional appropriations and authorization committees and the Department of Energy to address the current funding situation and avoid potential layoffs during fiscal year 2008. They also plan to call for an Illinois delegation meeting in January with representatives from Illinois labs and organizations to discuss a strategy to avoid potential job loss at Fermilab. The spending bill, approved by Congress this week, provided the HEP program with $88 million less than was requested. This challenges Fermilab's ability to remain one of the world's preeminent research facilities after it has achieved outstanding success in research on neutrinos, the high energy frontier, and particle astrophysics.

Adequate funding for the labs is critical to ensure that our country maintains its technological edge and that we continue to add to our high-tech manufacturing base. Fermilab is the nation's premier high-energy physics laboratory. The laboratory leads U.S. research into the fundamental nature of matter and energy, and in 2007, Fermilab's researchers and facilities achieved results judged by the American Institute of Physics as among the Ten Top Physics Stories from around the world.

[text of the letter is below]

Dear Director Nussle:

We are writing to you concerning a matter of critical importance to our country, to science in America, and to our global competitiveness. As you continue to develop the President's Budget for Fiscal Year 2009, we respectfully request that you increase funding for the High Energy Physics (HEP) program in the Office of Science at the Department of Energy.

As you know, the budget approved this week by Congress dealt a severe blow to HEP, which received $88 million less than requested. This budget rejected funding for the NOvA neutrino experiment at Fermilab, and drastically cut funding for research and development on the International Linear Collider. These cuts could cripple Fermilab's ability to remain one of the world's preeminent research facilities. And this is at a time when Fermilab has achieved outstanding success, with significant results in each of its central areas of research: neutrinos, the high energy frontier, and particle astrophysics.

The facilities at Fermilab are essential for the basic scientific research that nurtures technological and scientific advances, and that fuels American innovation. Fermilab is one of a handful of our nation's premier training sites for scientists, and a centerpiece of the system of DOE National Laboratories. Disruptive funding shortfalls have ripple effects throughout the American scientific community, displacing today's scientists and discouraging tomorrow's. We must work together to restore funding in basic physics research to maintain America's role as the innovator in technology, to retain our leading scientific institutions and their skilled workforces, and to provide opportunities for future scientists.

While we recognize the formidable challenges you face regarding the demands on the federal budget, we respectfully encourage you to increase the funding request for the Office of Science, particularly for the HEP program, in the President's FY2009 Budget.

Sincerely,
Barack Obama
Richard J. Durbin
Judy Biggert

41. **Peter Woit**
December 21, 2007

Thanks wb,

I had just seen the press release and was adding a link to it. Looks to me like Durbin and Biggert have realized they screwed up and may lose votes from their constituents over this. Obama presumably is planning on no longer being a senator representing the Fermilab area after the next election.

The fact that the press release mentions neither an amount of increase nor which base seems rather peculiar.

The ILC detector collaboration message is also unclear. That Durbin "has instructed Fermilab to cancel the layoffs" makes no sense since he has no power to do this. Unless he plans to pay 200 salaries out of his pocket, he has to first find a way to get new funding for Fermilab from somewhere, or find a way for the DOE to get around the language in the bill he just signed.

42. **Peter Woit**
December 21, 2007

By the way all US readers who would like to see something done about this, in case this isn't obvious, now (or after you finish your holiday shopping…) might be a really good time to write to your congressional representatives. Obama might also be someone to write to even if you don't live in Illinois, since he's looking for your vote too.

43. **Peter Woit**
December 21, 2007

Michael,

Here are some numbers from the AAAS about earmarking in R and D spending. Looks like it had gotten really bad in FY2006, was eliminated in FY 2007, is now back, at pre FY2006 levels.

http://www.aaas.org/spp/rd/earm08cf1.pdf

The rest of the AAAS budget analysis is here

http://www.aaas.org/spp/rd/upd1207.htm

It describes the decisions about cuts as being made "in a frenzy of weekend work" last weekend, with the results only known on Monday morning, passed into law 72 hours later. Not exactly a carefully deliberated process…

44. **Michael Bacon**
December 21, 2007

"Not exactly a carefully deliberated process…"

What do they say? You don't want to watch either sausage and law being made.

I hope the general trend will be for lower levels of earmarks for the next several years — they really climbed over the past decade or so.

45. **wb**
December 21, 2007

Peter,

What is disturbing and unfortunately not surprising is how unsymapathetic the Illinois delegation was before Director Oddone put a number on the impact in term politicians understand 200 hundred layoffs + ~10% salary reductions in a Republican district that the Democrats have a chance of taking with Fermilab the largest (or at least one of the largest employers). But once a voter impact is revealed the response was swift.

Had the cut to the HEP budget been much more diffuse would we have gotten the same response? Anyone for a little cynicism here?

Let's wait to see if "concern" can be transformed into cash.

46. **Coin**
December 22, 2007

looks like Obama couldn't be bothered to put it up

As of right now I'm finding it on his Senate site as the third entry on his press releases list, and a link to a Chicago Sun-Times article on the subject is currently the top entry in his "News" section, both clearly visible from the site's front page even if they're not the very most prominent thing on the page.

(That is, of course, just his Senate site. He does *not* mention anything on his Presidential campaign site that I can find, so perhaps one could levy the criticism that he's not using the full extent of his ability to public awareness here.)

47. **Roger**
December 22, 2007

Slightly off topic.

If any Brits (including expats) wish to protest the UK governments recent cuts and urge a restoration of the lost money then there is an online 10 Downing Street petition they can sign.

http://petitions.pm.gov.uk/Physics-Funding/

So far its attracted more than 8000 signatures.

48. **J.F. Moore**
December 22, 2007

@wb:*Had the cut to the HEP budget been much more diffuse would we have gotten the same response? Anyone for a little cynicism here?*

The cynicism is warranted, and experimentally verified, as such cuts frequently occur across the rest of DOE, and generally the complaining stays within the community. The funding trend with BES at least is to concentrate dollars in large, visible user facilities because they find these easier to pitch to DOE, congress, and review committees consisting mainly of university scholars. The money for facilities comes largely by defunding smaller programs. The endpoint of this is that the BES culture will become much more like that of HEP, with large, facility-driven science and a diaspora of participants.

On a different subject I'll note that neither Durbin or Biggert are in remote danger of losing their seat next year. Sometimes politicians just won't push for something if they don't know how to make the argument, or that they need to step up and do it. That normally would have been Hastert's job, and they just got blindsided. Hopefully it can be fixed with a supplemental.

49. **Alexey Petrov**
December 22, 2007

Peter,

I can't believe you said that it got little press or mention in the blogs! I think the situation is quite the opposite. Even NY Times got the article about that…

BTW, we were told during DOE site visit last week that that the situation at DOE is so bad that they are even considering shutting down either BaBar or Tevatron next year… hope that does not happen…

50. **Peter Woit**
December 22, 2007

Alexey,

Sorry, I forgot the posting on your blog. The NY Times article came out today, quite a while after I wrote what you quote. Until that story, I know of nothing at all in the national press, just local Ilinois stories.

Was the DOE site visit after they had the bad news about the FY 2008 budget?

I thought a plan to shut down BaBar after the current run had been made long ago, is that not true? Shutting down the Tevatron next year would be pretty crazy. Between that, the situation at SLAC, and the congressional language shutting down the ILC, Project X and NOvA, that would pretty much be the end of experimental HEP in the US.

51. **Alexey Petrov**
December 22, 2007

Peter,

> "Was the DOE site visit after they had the bad news about the FY 2008 budget?"

No, but they anticipated the results — and told us that the bill will likely be passed by the Congress and signed by the President (it appears that they could judge the behaviour of the Congress on the short-time-scale reasonably well). So they planned 2% cuts across the board for most University groups. We were told that LHC-related programs would be less affected (which is probably why we only got a 2% cut). It is interesting that at this point the Continouous Resolution would be a much better path for the US HEP program.

Also, on Friday, there was a Science Friday on NPR where at one point they did talk about funding cuts to US science programs, but did not mention the cuts in the Omnibus bill in particular. Actually, it was a very dissappointing SF program — it sounded to me that the panel had no idea what they were talking about.

52. **Constantine Tynyansky**
December 26, 2007

The theory of superstrings does not require experiments!

53. **Zathras**
December 26, 2007

I have some contacts in Congressional science staff, and I can tell you that the perception is out there that particle physics has the least benefit to society, and this perception is unquestionably why particle is getting the biggest part of the ax.

So the question is how can this perception be countered? Arguments about the benefits of experiments done long ago, or about the importance of science in general were tried when the SSC was axed, and they did not work then. TPTB want to know what particle physics has done recently. So is there anything the particle physicists have done in the last, say, 20 years to which society can claim a concrete benefit? I ask this not to have a general debate on the worth of particle physics, but to see what kind of coherent argument can be made in a letter to Congressmen.

54. **Peter Woit**
December 26, 2007

Zathras,

The argument that all of a sudden the US Congress has decided that particle physics needs to be axed since it is not of benefit to society doesn't explain "Why Now?". The general arguments about whether the US should or should not be spending 2-3 hundredths of a percent of the federal budget on fundamental research of this kind are exactly the same as they were 20 years ago, when this number was significantly larger. A huge effort has been made over the last few years to sell the importance of particle physics to the public (see the materials available at the SLAC, FNAL, ILC, symmetry magazine, US-LHC, etc. web-sites).

Last year, the White House put out a proposed budget making physical science research (including HEP research) one of the government's highest priorities, and the Congress debated this and signed off on it. Then, with no debate, and, to this day, not the slightest explanation of what happened, a huge budget cut for HEP was put in the budget at the absolute last moment. Maybe it was because of generalized private hostility to HEP as not useful, maybe it was because the one or two congressional staffers who decided this don't like HEP, or maybe it was because they didn't know what they were doing. Maybe it is because the way things work, the only people responsible for making sure Fermilab gets funded are three members of the Illinois Congressional delegation, and one is incompetent, one was only paying attention to earmarks, and the other was busy campaigning for President.

The other program that got whacked in the budget was ITER, and it's hard to think of anything of potentially more practical importance than that. So, while the effort to convince people of the value of continuing to invest a small amount in HEP research is an important one to continue, I think hand-wringing about how HEP is being cut because it is not useful and attempts to put more effort into that argument may not be what is needed. What is needed is to figure out exactly what happened here and make sure it doesn't happen again next year.

55. **Zathras**
December 26, 2007

PW,

1) As for "why now," there is a confluence of factors that has led to an attempt to cut a lot of things across the board. Chief among the factors is the general belief that we are about to head into an economic downturn, so things should be cut sooner rather than later. Many projects have been cut outside of the sciences, and the science cuts are just part of the plan.

2) Particle physics is the choice among the sciences because a lack of prestige, not just for particle physics, but for physics in general. People can look at biology and chemistry research and perceive concrete good for society. People look at physics and find it wanting.

3) ITER was also targeted because of the delays and cost overruns it has had which are both enormous, even by the standards of big science. The perception is that the project had high goals but has no chance of meeting them.

4) Also, the pork barrel spending issue goes back to the SSC. The SSC in the early and mid 90s was repeatedly cited as the biggest pork barrel project ever. Memories of that have made any big particle physics project appear to many to be pork barrel spending.

5) The efforts to publicize particle physics have done very little to do so. However, even if it did, it would not address the problem that there are (I believe) no full time lobbyists for big science. If you want to keep the funding, that's what particle physics need, regardless of any distaste for that sort of politicking.

56. **Peter Woit**
December 26, 2007

Zathras,

I'm still not convinced by your argument that the problem is that people don't want to fund HEP research because it is not useful, just pork. One of the problems with the DOE budget this year seems to have been the return of an emphasis on pork (e.g. earmarks) this year after last year, when earmarks were eliminated. The only thing that seems to have gotten the Illinois congressional delegation interested in the problems of Fermilab was when they realized that they had just voted for a budget that eliminated lots of jobs in their district. The problem this year seems to have been a Congress mainly interested in pork, but ill-informed about the size of this particular piece of pork.

I was under the impression that there are lobbyists working in Washington lobbying for science funding, funded by the APS, AAAS, and even Fermilab. At the all-hands meeting, there was a hostile question to Oddone about the people Fermilab has hired to represent them in Washington. I don't know who those people are, and whether they can engage in lobbying, maybe not if they're funded by taxpayer money. Perhaps this was all due to not having the right kind of lobbyist, or some lobbyist not doing their job. Maybe instead of getting Jim Simons to fund an accelerator run, he could fund hiring a high-priced lobbying firm, and political donations to the relevant people. I fear that in the present political environment, that sounds to me like a more promising plan than making high-minded arguments about benefits to society…

57. **Zathras**
December 26, 2007

I'm not sure what the applicable lobbying funding rules would be.

It is interesting to compare the relative advantage biology and chemistry have in regard to lobbying. They have big Pharma which helps them do the lobbying for them. Physics has nothing like such a developed institutional tie to industry. Individual physics groups may have such ties, but such ties are too inconsequential to generate the needed lobbying. For a long time many physicists have eschewed such ties (MGM's comments about "squalid state physics" are but one early example), and now the physics community is reaping the damage. Fifty years ago such ties were present and were strong. They are now too weak, and this is shown in the lack of an effective lobby.

December 26, 2007

Zathras,

I tend to agree with Peter for a couple of reasons. 1) HEP was not targeted until the last minute and then cuts were precisely targeted at Fermilab rather than at the field as a whole. 2) The Fermilab had an advantage of no congressional staffers "minding the store." 3) There was strong industrialist backing for a large physical sciences boost (including HEP). 4) Antipathy to HEP is generally ascribed to one powerful member from IN. 5) Rather than only looking to how well our HEP community projects benefits to society, one also needs to ask did DOE/SC overlook potentially troublesome members through either neglect or ignorance.

It is hard to see how one can call SSC pork given that it was thoroughly peer-reviewed in the HEP community and especially in retrospect a far better option than the LHC.

ITER was a strong technical preference of the US fusion community and was vetted through FESAC. As for zeroing ITER, that was very clearly a slap at the White House which had publicly signed on to ITER support.

I am not saying that we could not make a better case for HEP and other physical sciences. I am saying that the damage to HEP seems more related to petty politics and the fact that a big cut could be made while affecting primarily one congressional district.

59. **SLACer**
January 11, 2008

As an engineer at one of those S.F. Bay Area physics labs (the one near Palo Alto), I clearly remember the big boost in financial support that various federal pollliticians touted was coming our way. Speeches by the Secretary of Engergy, University big-wigs; a dog-and-pony show it was!

As a Democrat, I firmly hold the Democratic Congress largely responsible for this funding disaster and I will NOT be granting my Democratic Congressional members from California the honor of my vote. They were too busy funding their earmarks (PORK: oink-oink) and the war(s) to to the right thing. As a result, important projects are being terminated early, postponed, or not getting off of the ground at all. The Babar experiment, strongly supported by the international community, is being terminated seven months early. What message does that send to the international physics community about U.S. support and integrity as a research partner? I will try to bring this issue to light in the coming Presidential primaries and I hope others will do likewise. Let's see if any of the canditates can give an honest and meaningful reply instead of the usual sound-bite.

Unfortunately, most of the leading Presidential wanna-bees are in Congress and therefor part of the problem. What's a voter to do?

To quote the director of one of the S.F. Bay Area labs:

"It pains me greatly that at a time when particle physics needs to be ever more international, the political process in the U.S. has resulted in real damage to the relationships with our international partners."

Complete text at:

http://today.slac.stanford.edu/feature/2008/All-Hands-010708.asp

Our U.S. Federal government has its priorities so messed up that it is just mind-blowing. I just wish enough voters could see this do something about it.

Money, Money, Money

Categories: Uncategorized

Theoretical physics and mathematics are much cheaper to fund than experimental particle physics. I don't know yet what the implications of the FY 2008 budget are for these fields, but it appears that they are not facing large cuts like Fermilab. In other funding-related news:

DARPA, a Defense Department division responsible for funding research that might lead to new technology with military applications, is soliciting applications for grants to fund pure mathematical research. In the past they have funded work on the geometric Langlands program, now they have put out a list of 23 Mathematical Challenges, illustrating what they would like to fund. These include some conventional Clay Millennium Prize problems like the Riemann Hypothesis and Hodge Conjecture, and some less conventional ones like

> **Biological Quantum Field Theory**
> Quantum and statistical methods have had great success modeling virus evolution. Can such techniques be used to model more complex systems such as bacteria? Can these techniques be used to control pathogen evolution?

There's even one I find extremely tempting:

> **Geometric Langlands and Quantum Physics**
> How does the Langlands program, which originated in number theory and representation theory, explain the fundamental symmetries of physics? And vice versa?

Benjamin Mann, the program officer, explains the rationale here.

On the question of grants, there are some interesting comments by Tom Banks in the comment section of this posting at Cosmic Variance. The posting quotes Harvard president Faust as warning lesser schools that they should get out of the business of scientific research, since Harvard is going to be vigorously and successfully competing for increasingly scarce government funding for such research. Banks describes how when he and others were trying to build up the string theory group at Rutgers

> …we never got the kind of government funding that the elite institutions have (I'm counting dollars per person). This was at a time when certain elite institutions were at a low ebb and were getting scandalously large amounts per person in return for mediocre research. And of course, in the end, two of our most successful researchers got stolen away by elite institutions.

I guess he's referring to Seiberg, who went to the IAS, and Shenker, who went to Stanford. I don't know which are the "certain elite institutions" that were doing "mediocre research" that he is referring to.

The Rutgers string theory group was originally built up when the university spent large amounts of money to bring in several prominent string theorists. One version of this story that I heard was that a Rutgers official called up Dan Friedan one day in his office, and asked him what it would take to get him and several other well-known string theorists to move there. Friedan had no interest in going to Rutgers, so made up what he considered an absurd list of demands (huge salaries, lots of postdocs, new building, little or no teaching, etc., etc…). The official thanked him and then hung up, with Friedan convinced he'd never hear any more about this. A couple hours later though, the phone rang again. It was the same official, telling Friedan that they would be more than happy to meet all his demands.

Another institution that I hear is trying to compete with the elite by starting up a new, well-funded institute for research in math and physics is Stony Brook. The money is coming from Jim Simons, as part of a donation announced last year. Some other information about donations from Simons to other institutions is available at the Simons Foundation website. This foundation is largely devoted to funding research on autism, but also describes donations to the Math for America program to recruit math teachers, as well as to Brookhaven, Stony Brook, the IAS, IHES and MSRI. Simons has been funding summer workshops at Stony Brook for several years that are largely devoted to string theory. The math department has an NSF-funded RTG program in geometry and physics, and the web-site there includes links to write-ups of some of the expository talks that are part of the program.

   January 25, 2008

   Meanwhile, British science continues to take a beating. I just received an email from the Canadian Astronomical Society (CASCA) letting us know that Britain is dropping out of the Gemini telescope.

   Details of the announcement can be found here:
   http://www.scitech.ac.uk/PMC/PRel/STFC/Gemini-Update.aspx

This Week's Hype

December 27, 2007
Categories: This Week's Hype

Over the past year or so, as public awareness has grown that string theory is a failed idea about unification due to its inherent untestability, I've been surprised by the way in which many in the string theory community have chosen to deal with this. Instead of just honestly admitting what the problems are and describing the sensible reasons to keep working on string theory despite them, some have decided instead that the thing to do is to go to the press with misleading and dishonest claims that string theory really is testable.

The endless examples of this in New Scientist are probably best ignored, but this week's example is being promoted in the highly respectable journal Nature. It's all based on this letter to Nature from a group of condensed matter physicists at Lancaster University, now prominently highlighted as an "Advance Online Publication" at the Nature Physics web-site. The authors describe an experiment in which they manipulate the boundary between phases in a superfluid, showing that when such boundaries come together, one gets left-over in the remaining phase the well-known topological defects that one would expect.

The Nature letter itself makes rather ridiculous claims that this kind of otherwise unremarkable phenomenon is somehow closely related to brane cosmology and string theory. The authors do note that

> The precise correspondence between the ^{3}He phase interface and a cosmological brane is still a matter of discussion, the closest correspondence probably being to the D-brane. For the present purposes we may note that the correspondences are as much topological as specific.

While the letter makes no explicit claims about "testing" string theory, the press release issued by Lancaster is the usual sort of dishonest nonsense:

> Low-temperature physicists at Lancaster University may have found a laboratory test of the 'untestable' string theory.
>
> The test – which uses two distinct phases of liquid helium – is reported online this week in Nature Physics (published 23 December). Their paper will also be published as the cover article in the paper edition of Nature Physics in January.
>
> String theory is a multidimensional theory based on vibrating strings, as opposed to the point particles described in the Standard Model.
>
> Within string theory, a brane is a large surface embedded in higher dimensional space — our Universe could occupy such a brane.
>
> A collision between a brane and an antibrane can leave behind topological defects, including perhaps the Big Bang itself. But however elegant this theory, it makes no falsifiable predictions, or at least none using current technology.
>
> Richard Haley and the ULT Group have taken a lateral step to address this barrier….

Similar wording is used in a press release put out by Nature about this.

Nature has a relatively reasonable news story by Geoff Brumfiel about this, but also an article by string theorist Cliff Burgess hyping string cosmology ("The subject of string cosmology is a hot one these days, with theoretical advances in understanding string dynamics riffing with recent precise observations of the cosmic microwave background") and the relevance of the Lancaster group's work to it. He mostly sticks to hype in its pure form, just devoting one paragraph to the actual scientific result. There he ends up acknowledging that this actually has nothing to do with string theory in the following rather ludicrous way:

> The quality of the details of the comparison between ^{3}He and cosmology is not really the point. Like a tap-dancing snake, what is amazing is not that it is done well, but that it is done at all.

After this he shifts gears to start hyping AdS/CFT, without mentioning that this has nothing to do with the Lancaster group's claims that he is writing about.

The whole point of this kind of exercise is to generate misleading articles in the press that will convince some people that string theory really is testable. This seems to be working well, there's already one entitled "Test tube universe" hints at underlying theory in the Telegraph, which tells the public that:

> A "universe in a test tube" that could be used to assess theories of everything has been created by physicists…
>
> The Holy Grail of physics is to establish an overarching explanation to unite all the particles and forces of the cosmos. But one of the complaints commonly levelled at a leading contender for a "theory of everything", called string theory, is that it is impossible to test.
>
> But now, according to the study in the journal Nature Physics, it may be possible using the universe in a test tube. "It was a serendipitous discovery," says Haley…
>
> For the past three decades it has been known that strings are one member of a bigger class of objects called branes, which exist in higher dimensional space, that could be extended in more than one dimension – from strings of one dimension, to membranes of two dimensions, to those of p dimensions, dubbed p-branes. Moreover string theories and p-branes are facets of one underlying 11-dimensional M theory, which suggests that we live in a brane world: a four-dimensional surface, or brane, in a higher dimensional mixture of space and time.
>
> People and most particles move in the brane, while the higher dimensions provide a framework to unify all forces, from gravity to those that act between atomic particles. While experiments have begun to highlight cracks in the current best theory, called "the standard model", there is evidence that M theory's extra hidden dimensions could be revealed next year when a Geneva atom smasher – the £4.4 billion Large Hadron Collider – begins experiments. But the Lancaster team offers another route to address this impasse.

Update: Wired Science has an article about this entitled A Test for String Theory After All? Or Just PR?, which shows excellent judgment by linking to this posting…

On the scientific front, it's worse than I thought. There a conference in London at the Royal Society next month on Cosmology Meets Condensed Matter, where the head of the Lancaster group will speak, and the idea that "coherent phase boundaries mimic branes" is listed as one of the four justifications for the conference. I guess this emerging new field might best be called "Squalid-State Cosmology".

Update: David Appell has a posting about this, which includes a quote from Witten:

> There is definitely no test of string theory here.

Unlike me, Witten goes on to try and find something positive to say about this.

Update: Physics World has an article about this entitled Cosmic strings in a test tube? In the short article, one of the physicists working on this Richard Haley, is twice described as denying that this is a test of string theory, and Grisha Volovik is "adamant that the work is neither a test of sting theory…". Despite these firm denials, the press release from Lancaster about a test of the "untestable" string theory is still up.

Comments

   December 27, 2007

   I've just deleted comments by "Elmer Fudd" (and responses to them), a string theory partisan who turns out to only be interested in posting insulting anonymous comments here, admitting he actually doesn't know anything about the issues involved.

   Please, comments insulting people anonymously are never welcome here. If you understand the physics issues involved and want to tell me I'm wrong anonymously in an insulting manner, I suppose I'll allow that. But if you don't understand the issues, best not to do this.

2. **Florian Walchak**
   December 27, 2007

   Peter –

   I haven't seen any comments about Kenneth Lang, the noted solar/astro physicist and astronomer, on your site. I refer you to his recent book Parting the Cosmic Veil, a popular but serious treatment of astronomy and cosmology. He gives a response to the Elmers of the string world in the last chapter (6) of the book. One notable quote is:

   "Now, a vocal minority of cosmologists [string threorists??] has pushed into the domains of myth and religion, at the boundary between what is known and the mystery of creation. Mathematical equations and computer simulations are employed to construct their own epics, using the language of science rather than mythology. They have attempted to show how everthing – mass, energy, space and time – might have originated in the Big Bang that set the Universe in flight, and then moved on to speculate about what happened before the beginning. They have become today's shamans, hiding their magical pronouncements behind equations or even books that almost no one can read or understand. With an amazing arrogance, presumption, hubris and lack of humility, they even claim authority because of it, asserting that they alone can percieve the true beginnings of the Universe. But that does not make their explanations true." [pages 192-193]

   And another: "If we probe further back into time, before the hypothetical inflation that created our personal Universe, the energies become higher and higher, perhaps entering the domain of the tiny, invisible vibrating strings that occupy unseen places and extra dimensions, spring out of nothing and accounting for everuthing…Yet despite a quarter century of investigation, the string experts still do now [sic – I presume a typo for not] know how to test their theory or even how to solve the equations in the extreme conditions at time zero." [page 196]

   And finally: "Many astronomers, who like to observe the real world, are becoming fed up with all the hype, the persistent appeal to the unobservable and unverifiable, created from complex mathematics and esoteric theory that almost no one can understand. As the the American writer Mark Twain quipped: "There is something fascinating about science.One gets such wholesale returns of conjecture out of such a trifiling investment of fact."" [page 196]

   There's more. It's an enjoyable read. I recommend it.

   Florian Walchak

3. **Coin**
   December 27, 2007

   The quality of the details of the comparison between 3He and cosmology is not really the point. Like a tap-dancing snake, what is amazing is not that it is done well, but that it is done at all.

   "String Theory: Like a Tap-Dancing Snake". Now there's a fantastic endorsement.

   So, I'd like to at least *try* to be charitable about this He3 thing, but I cannot access the Nature article so I'm not sure what it is they're saying. Could someone perhaps clarify exactly *how* it is that they think this He3 thing links to string theory? The press release and the Independent article on the subject seem to vaguely be saying that the Lancaster people have shown similarities between helium superfluid and the large-scale structure of the cosmos. Okay, but what does this have to do with String Theory?

   1. Is the idea supposed to be that string theory predicts that helium superfluid and the large-scale cosmos will share structural similarities, so if those similarities bear out it will be a successful prediction for string theory?

   2. Or is the idea that string theory predicts things about the behavior of superfluids, and they can test those predictions by analyzing He3? (If so that sounds dreadfully useful, but why bring in cosmology?)

   3. Or are they seriously saying "string theory can maybe predict things about the structure of the cosmos, helium superfluid looks kind of like the cosmos, so we'll make some predictions about the structure of the cosmos and then instead of testing them against the cosmos we'll compare it to the structure of a helium superfluid"?

4. **Oswald Spengler**
   December 27, 2007

   Peter, there are no legitimate reasons to continue working on string theory, and such work doesn't warrant to be called "research." String theory has turned theoretical HEP departments into a work place where everybody is aware that the work of most/all people there is funded and performed under the false pretense that according to current understanding a *competent* researcher or observer *actually believes*—as opposed to *with intend to mislead conveys the false impression to believe*—that this work is advancing scientific understanding in the field of fundamental physics *in the strict, narrow, literal, original, old fashioned meaning of this term*. People's entire careers are based on this kind of work which *has no genuine scientific merit at all*, and, even though it is taboo to say so, *everybody is, **of course**, keenly and painfully aware of this, as well as of the even more painful contrast to the generation of, say, Feynman and Gell-Mann*.
   Everybody knows that all these people have ever done and all they do is to defile the tradition of generations of honest physicists from Copernicus, Galilei, Kepler and Newton to the fathers of the Standard Model. They are infecting new graduate students with this disease—and they have never known anything else. It creates the nauseating atmosphere of the Middle Ages *where everybody is aware that their time and all their efforts are a joke in comparison to the days when science was still real and actual insight into the nature of the real world was made*.

   It makes you sick in the soul when you know that everything people around you do falls somewhere between dishonesty and incompetence—because that is all they can think of, or all they can get funding for. You can feel nothing but pity and contempt for them. Now you know what it feels like **to watch the sun set on a Civilization.**

5. **Peter Woit**
   December 27, 2007

Coin,

There is no real connection to string theory, and Burgess admits as much. What I don't understand here is why the Nature referee allowed this paper to be published, and Burgess thought it was a good idea to use it to hype string theory.

Oswald,

Please, try and stick to the topic of the posting. I don't think the "everything is equally awful" attitude is helpful. People are working on hundreds of different things under the name "string theory" and some are more worthwhile than others. It's not exactly unusual in science for people to be working on not very good ideas that aren't going anywhere. It is unusual to see this level of dishonest hype being promoted in Nature.

6. **Oswald Spengler**
December 27, 2007

Peter, it's not that I disagree with you there. For me the point is to be evocative. You may think of my post as in-between quotation marks. A soliloquy created specifically for this stage. A polemic addressing a situation so dire that the characteristics of polemics are melting away like butter in a frying pan.

7. **wb**
December 27, 2007

If the Lancaster group were correct and were Nature not just hyping a non-test of string theory, then perhaps why Congress had it right. Why would we need a $10 – 20 B ILC when a small condensed matter lab would serve just as well to reveal the unifying theory of the universe.

8. **Tim May**
December 28, 2007

With apologies to Dr. Hook and the Medicine Show and "On the Cover of the Rolling Stone":

Well we are string theory slingers, we've got golden fingers
And we're loved everywhere we rant
(but testing is something we can't)
We write about beauty and we write about truth
At ten million dollars a grant
We got all kind of brains to figure out the branes
But the thrill we've never known
Is the thrill that'll get you when you get your paper
On the cover of the New Scientist

{Refrain}
New Scientist
Wanna see my theory on the cover
New Scientist
Wanna buy five copies for my mother
New Scientist
Wanna see my smilin' face
On the cover of the New Scientist

9. **Bee**
December 28, 2007

Hi Peter:

"but also an article by string theorist Cliff Burgess hyping string cosmology "

This actually caused me to read the article, it doesn't sound like Cliff at all. I don't think you are being fair on him, I find the article very reasonable and balanced. He is careful with his wording (*"requires knowledge of the laws of physics at very short distances that string theory claims to have"*), and he expresses his scepticism pretty clearly (*"The underlying hope is that this 3He dynamics, which also produces a stringy residue, might capture something universal about a cosmic brane cataclysm. Although this hope may be faint […] and the dynamics may differ […], the comparison may nonetheless be instructive."*) And he even points out that this kind of 'string' effect doesn't actually say something about THE string theory as a TOE *"Even if future experiments should prove that nature spurns string theory as the description of quantum gravity…"*. Yes he is optimistic and finds the developments interesting *"the great irony may be that it yet lives on as part of the core curriculum taught to future generations of nuclear and condensed-matter physicists."*, but this is very far from being *"hype in its pure form"* as you call it. (No idea though how the AdS/CFT paragraph belongs there.)

Best,

B.

10. **Peter Woit**
December 28, 2007

Bee,

I think the Burgess piece carefully avoids making completely untrue statements, but the whole thing is fundamentally a piece of dishonesty. This experiment has as much to do with string cosmology as my jumping in a swimming pool has to do with how heavy quarks lose energy in a heavy-ion collision. Burgess is aware of this, and if you read carefully what he says, that's clear. The sentence that I quoted about string cosmology is pure hype, and the tacking on of AdS/CFT hype without mentioning that it has nothing to do with this is intentionally misleading.

Burgess's contact information is on the Nature press release describing this as a "laboratory test of the "untestable" string theory".

Sorry, but I think this kind of thing is really disgraceful, and not honest, no matter how carefully worded the article is.

11. **Bee**
December 28, 2007

Hi Peter:

"Burgess is aware of this, and if you read carefully what he says, that's clear" I think this was the intention of his article? He makes clear what it is and what it isn't about, I don't see how you find it 'clear' while at the same time calling it 'a piece of dishonesty' because you would probably have been more blunt. Is your criticism that one has to read it carefully because the headline doesn't explicitly state it's not a test of quantum gravity? The only "hype" I could see in your quotation is the word "hot" (I am not actually sure what 'riffing' means I have to admit, something like 'goes along with'?). I fail to see what's disgraceful about him finding a field interesting that you apparently don't find interesting, and calling something an 'irony' doesn't actually sound overly enthusiastic either. I said above I agree that the AdS/CFT reference doesn't quite belong there, but whether or not he knew his name would appear with something about a lab test of ST his article is clearly far off other 'hypes' you've pointed to, and I find calling it 'hype in its pure form' an exaggeration.

Best,

B.

12. **Peter Woit**
December 28, 2007

Bee,

The use of the musical term "riffing with" to describe the relationship between "theoretical advances in understanding string dynamics" and "precise observations of the cosmic microwave background" is just pure hype and obfuscation. The actual relationship is that Burgess and others would like to use the first to predict the second but have so far failed to do so.

It's not a question of whether the claims of this paper are "interesting", it's a question of whether they are nonsense. Looking at boundaries between phases in a superfluid is not a test of brane cosmology models and Burgess knows this. If the editor of Nature calls you up, and says "we are publishing a letter claiming to test string cosmology models by looking at phase boundaries in a superfluid, will you write an article explaining the significance of this?", what would you do?

1. Tell them the truth, that this is nonsense and they shouldn't be publishing it.

2. Agree to write the article, spend most of it promoting string theory, only very indirectly indicating that the claims in the letter aren't true.

Don't you think one of these is honest, and one isn't?

The headline of his article "A surprising and fascinating interplay may be emerging between string theory and condensed-matter physics" which is outrageous hype about this experimental result, and his name is on a press release about how the experiment shows testability of string theory in the lab. Maybe this is none of his doing. It will be interesting to see if Nature publishes a letter to the editor from him saying he has a problem with this.

13. **Peter Shor**
December 28, 2007

I assume that Cliff Burgess' article was solicited. Nature editors often solicit commentary on especially exciting research results, and even ignoring all the dubious connections to strings, this sounds like a fairly exciting and ground-breaking experiment; correct me if I'm wrong, but I assume this is the first demonstration of topological defects introduced by phase boundaries.

Unfortunately, it seemed as if the Nature editor made the mistake of assuming that there was a much more solid connection to string theory than existed, and furthermore asked the wrong string theorist for commentary. Even if he did then realize the article was mainly PR, he may not have had the guts to reject a solicited submission.

14. **Peter Woit**
December 28, 2007

Peter Shor,

Independent of the claims about string cosmology, I don't see any evidence that this is a ground-breaking experiment in terms of what it demonstrates about either topological defects or phase boundaries in a superfluid. The authors claim nothing like that in their abstract, and I suspect that if they did have such a result, they wouldn't be going on about cosmology. If there's an expert on this subject, I'd be interested in hearing what they have to say about the significance of this other than as a "test of string theory".

15. **Gabe**
December 28, 2007

I really don't have any knowledge of this, but: What exactly are they trying to say about liquid helium phases and extra dimensions?

16. **Bee**
December 28, 2007

Hi Peter:

If the editor of Nature calls you up, and says "we are publishing a letter claiming to test string cosmology models by looking at phase boundaries in a superfluid, will you write an article explaining the significance of this?", what would you do?

I'd assume he dialed the wrong number.

1. Tell them the truth, that this is nonsense and they shouldn't be publishing it.

2. Agree to write the article, spend most of it promoting string theory, only very indirectly indicating that the claims in the letter aren't true.

Don't you think one of these is honest, and one isn't?

Well, what I'd try to do if I find the field interesting is explaining why I generally think it is interesting, while trying to make clear that the claims in the paper are somewhat far fetched. That's what Cliff did, at least the way I read it. It doesn't seem like a place to tell the editor what to publish and what not, it's not a referee report? True, one could interpret the article as he just used the opportunity to talk about what he knows and likes, true, maybe he should (could?) have insisted on toning it down, but I find it far from being an 'outrageous hype'.

Best,

B.

17. **Peter Woit**
December 28, 2007

Bee,

Again, “interesting” isn’t the point. The claims about testing string cosmology in this article are nonsense, and Burgess should have just said so, whether he’s the referee or not, instead of going on about how it “stands out like a sequoia in the Sahara” and is “Like a tap-dancing snake”.

18. **Peter Woit**
December 28, 2007

Or, to make the point more clearly using Burgess’s analogy:

Finding a sequoia in the Sahara would be interesting. But if the fact of the matter is that there is no sequoia at all, the only interesting thing is why a reputable science journal is publishing a bogus claim that there is one.

19. **Peter Woit**
December 28, 2007

Gabe,

There is no relation at all between liquid helium phases and higher dimensions. The authors are claiming that the two dimensional interface between two phases is in some way vaguely analogous to the idea that our three-dimensional space is a brane in higher dimensions. There is nothing here other than an extremely vague analogy between two very different things.

20. **Stugots**
December 28, 2007

Peter,
You really need to get a life. Who cares if they try to connect their work to string theory? To me, this is not string theory hype, but rather some condensed matter physicists trying to sex up their own work by mentioning it in the same breath as string theory. So much for your thesis that string theory is losing favor in the scientific community…

21. **Peter Woit**
December 28, 2007

“Stugots” (my you string theorists have classy nicknames…)

Sure, you’re right that what is going on is condensed matter physicists trying to sex up their work by connecting it to string cosmology (I think the cosmology is the sexy part though, as many string theorists have noticed, they’ve given up on particle physics and moved into the “hot” area of cosmology).

What’s pretty funny though is that Burgess is clearly trying to sex up his work in string cosmology by connecting it to rather obscure behavior of phase interfaces in low temperature condensed matter physics.

22. **Tim May**
December 28, 2007

Mathematical structures, models, and theories are not necessarily the way the world actually is put together, the physics of it. There’s the “unreasonable effectiveness of mathematics” issue, which makes the point that often things found in mathematics are found somewhere in the natural word, whether in seashells or curved space-time or (yet to be determined) Calabi-Yau manifolds. (And some of the best stuff to come out of the last half-century of work in HEP is the new mathematics, a point many of you make. But this doesn’t mean, of course, that the real world is actually like some of this math. Experiments will provide answers, someday.)

So it’s interesting that certain results in topological defects may show up in superfluid work. (I’m far from from an expert on this, but isn’t this close to a lot of the “anyon” work that Freeman and others are working on, a la fractional quantum Hall effects?) So maybe there’s a mapping from math to these states….wouldn’t be the first such mapping, that’s for sure! But taking something from condensed matter physics and saying it provides support for M-theory seems way too big a speculative reach.

And _maybe_ there’s also a mapping between the math and the actual structure of the universe a la string theory and branes.

But finding the one mapping doesn’t imply the other mapping. (No functor between these mappings is guaranteed, loosely speaking.)

What matters is taking some of the “unreasonable effectiveness” of the math and predicting some particular particle not yet seen, or something not yet seen in the larger universe. As with the Eightfold Way, which said that if the real world actually matched the group theory analysis, there ought to be a previously-undiscovered particle with these properties…and there was. Pretty impressive stuff.

But if the “predictions” stay at the metaphorical level, whether about how the universe is a foam, or a turbulent sea, or a test tube filled with liquid helium, then not much is gained. (The rubber sheet view of curved spacetime is an intuitive, easily-explained mode of gravity, but had it just stayed at the level of a metaphor and not made certain numerical predictions which could be checked, not much would’ve been gained. String theory is still seemingly at the metaphor level–bundles of vibrating strings, with way too many adjustable parameters, and with even more exotic stuff, like colliding brane-worlds, with absolutely no predictive behavior, at least not at energies obtainable by Earth-level economies.)

I hope this changes, either by concrete predictions testable within the next few decades, or with new theories that are so testable. This whole situation has a lot do to with why HEP funding is getting cut, I think.

Partly it’s the “desert” in energy, and the logarithmic increases in energy and budget to find the next range of interesting experiments. It didn’t cost much in real dollars to find the particles that past theories predicted. A detailed analysis of budgets in real dollars for the Bevatron, AGS, SLAC, Fermilab, and CERN would be interesting to see, but we can get a Feynman-like estimate of the real costs just by looking at the physical _sizes_ and _staffs_ of these labs….by any economic measure, the Bevatron was very inexpensive, SLAC was a whole lot smaller in footprint, building costs, and staffing costs, than the LHC will be. If the LHC doesn’t find something crucial, say goodbye to the generations after that for a long time.

And it’s also what a couple of astute posters here have mentioned: by now there is no longer any hope or expectation that any new kind of weapons-suitable or industry-suitable physics will come out of HEP.

So the main theme of Peter's blog, "Not Even Wrong," is also related in a deep way to the funding situation in HEP. And the hype of the PR campaigns for string theory is clearly part of this whole mess.

But, hey, I'm working on a theory that our universe is just one bubble in a giant bathtub of soap bubbles. I think I've found evidence for this in some experiments I'm doing in my kitchen sink….Now if I can just get this on the cover of the New Scientist.

–Tim

23. **milkshake**
December 29, 2007

When I came to US in early 90s I joined a tiny startup biotech technology company. Our finances were precarious (we stood 3 months from folding at one point) and I understood the need for our research boss impressing the investors. There was a steady stream of press releases and gee-whiz publications (typically communications without any detailed experimental supplementary) coming out of our little company – and it bothered me great deal to see how oversold everything was: Half-baked or tentative stuff was presented as a "core technology", experiments were carefully staged to produce impressive results to demonstrate the usefulness of our proprietary methodology. This was done all at the time when there was growing doubt within the company whether *any* of it was actually useful.

I am not very proud of taking part in it (at least my papers were not a baloney) and I gather this is a quite usual PR coming out of a struggling startup company. It bothers me to learn this kind of lack of integrity is now common in theoretical physics also

24. **Roger**
December 29, 2007

To those with long memories, has it always been this way ? Renormalising away the effects of the rapid internet communication we have available today, were, for example, the GUT models hyped in a similar way ?

25. **Peter Woit**
December 29, 2007

Roger,

My memories of particle physics coverage in the press go back to the seventies and I don't remember anything at all like this going on 20-30 years ago. GUTs got attention in the media mainly in the context of proton decay experiments that were testing them, not in a context of pure hype.

I don't think think what's going on now has much to do with the internet. Several years ago the internet was there and there was string theory hype, but you didn't see the kind of dishonest claims about "We've found a way to test string theory!!" that you see in recent years. This only started once it started to become obvious that string theory couldn't be tested, and its partisans started feeling they had to deal with this public perception somehow.

26. **Bee**
December 29, 2007

ah, Buffy, what I actually meant to say is don't waste those silver bullets, not everybody is a vampire. Have a nice weekend and a happy New Year,

B.

27. **Tim May**
December 29, 2007

My memories of physics hype go back to the 1960s. I certainly remember a lot of coverage of tachyons, black holes, wormholes, white holes, etc. The difference then was that most of this coverage was in "Science Digest," sort of the "New Scientist" of its day, and even in "Popular Science" (which was more about gadgets and tools, more akin to "Popular Mechanics," than about science per se).

I also remember the wild speculations about "baby universes" shortly after Guth's work, especially around 1982. (I vividly remember a party where this was debated for an hour…I think "Science" had even run a one-page piece on this possible implication of rapid inflation, but I may be misremembering events from 25 years ago.)

And of course there's been a lot of coverage, even hype, about black holes for at least the past 37 years (I remember it escalating dramatically after "Physics Today" did a famous cover story on black holes, circa 1970).

At least back then "Scientific American" could be counted on to do their articles in a certain, even prosaic, way, with little hype. They later went more Madison Avenue, abandoning the old article format, jazzing up the graphics, and putting pure speculation on the covers. I no longer even read it.

As I've already opined, I don't think _some_ of this speculation is harmful. It may even get the kids interested in physics (though whether we need more kids interested in physics right now is itself an interesting question). Where there's real risk is when the hype is used to "sell" a very expensive public project. If that hype is seen as hype, or if the "God Particle" (for example) turns out to be not quite so important in the scheme of things, the backlash may be huge. I suspect this is what killed the SSC (before it even had a chance to find the God Particle).

Finally, I'll give my memories of the "funding climate" back in the late 60s, early 70s. The story of the day was this: "Physicists are driving taxi cabs." That was the scare story, circa 1970. Indeed, some physicists were unemployed in their profession. A lot of staffing-up in physics after Sputnik had filled physics departments with tenured professors…some of these tenured physicists lasted until just the past decade or so. I think Lee Smolin makes this point in his book.

There had also been huge layoffs in the aerospace business, dumping a lot of engineers into the unemployment lines. Some physics grads, too.

Some went into finance (the rising "quants," even before the term was used). Some went into semiconductors.

Hype, Unified Field Theories, Theories of Everything, and God Particles are not something new.

–Tim

28. **Peter Woit**
December 29, 2007

Bee,

Thanks for the advice, and best wishes for the New Year.

Maybe 2008 will see the end of the living dead stalking the land with their “tests of string theory”. Already, New Scientist seems to be ignoring this one, causing it to die a quick death. Hopefully Nature won’t take its place as Zombie-central…

29. **Brett**
December 29, 2007

GUTs were hyped too. I can remember numerous TV programs and popular articles about particles physics that claimed that we would see X particles soon. People were excited about the discovery of the first intermediate vector bosons and expected to see more of them soon (at the SSC, I guess). But that stuff disappeared when the proton decay experiments came back empty handed. The SU(5) GUT was wrong. The X particles weren’t there where people had hoped, and people stopped hyping them (although the failure wasn’t conveyed to the public very well).

However, I think the hype was pretty forgivable. The SU(5) GUT really seemed too good not to be true, and I don’t think people were being intellectually dishonest. (A few years back, a friend told me that it was really unfair that Georgi wouldn’t win the Nobel prize. The GUT theory was wonderful, and it wasn’t his fault that it happened to be wrong!) And when the theory’s predictions were wrong, people accepted it and either stopped working on the GUTs or tried to come up with a reasonable generalization that wasn’t ruled out.

30. **Roger**
December 29, 2007

The whole business of hype and its influence on public perceptions and funding would be a very interesting topic for a science communication Ph.D. .

Is anyone aware of any research on this issue ? It would be useful to know what policy makers and the public make of particle physics these days. We could learn an awful lot of lessons in making our case for continued funding.

31. **nc**
December 30, 2007

Roger, the hype in particle physics is unique: in other sciences you get controversy, not pure unadulterated hype. Journalists don’t believe everything they’re told in other areas, they get counter arguments from other experts and publish those in the article to give some sense of balance. There’s endless research by Professor Brian Martin into controversies in other sciences, but these people don’t take any interest in stringy hype even if they are relatively well qualified to investigate it. (Martin is now Professor of Social Sciences in the School of Social Sciences, Media and Communication at the University of Wollongong, but his PhD was in theoretical physics.)

32. **Oswald Spengler**
December 30, 2007

Brett, but then the plausibility of GUTs evaporated. More and more it became an *old* and *artificial* idea—but the community never adapted to this. In fact, nobody’s argument shows the natural evolution of an intellectually honest and competent observer. Instead, their positions evolve like those of ideologues or those of lawyers. It is then inevitable that one adjusts one’s view of them accordingly.

Every year around this time the Edge web-site posts responses from a large number of scientists to some particular question. This year the question is "What have you changed your mind about? Why?", and the results should be posted tomorrow. John Baez has posted his answer here. He writes that he changed his mind about the question of whether he should be thinking about quantum gravity after he realized "the more work we did, the more I realized I didn't know what questions we should be asking!", and compares the effort to "throwing darts in a darkened room and hoping to hit the bull's-eye." Since changing his mind he has been working on other things, and feels that as a result "I'm making more real progress understanding the universe than I ever did before."

I think I share John's point of view on this in many ways, even though I've never actively worked on a quantum gravity research project. The problem with quantum gravity research has always seemed to me that, since you can't measure quantum gravitational effects, you're in great danger of coming up with lots and lots of "quantum gravities", but unable to ever know which if any of them has anything to do with the real world. This is kind of what has happened with string theory in recent years. One hope has always been that one will find a mathematically uniquely compelling model, but that has yet to happen. To me the best bet has always been that one might understand quantum gravity by unifying it with the standard model, in a compelling way such that the unified theory explains some of the things the standard model leaves unresolved. This hope was also behind much of the original interest in string theory: it wasn't just a quantum theory of gravity, but also a theory of particle physics that could be tested.

Like John, I think we still have a long ways to go towards understanding at a deep enough level how quantum field theories really work, and how the internal symmetries of particle physics and the space-time symmetries of gravity can be unified into a more fundamental structure. Progress towards this goal may even require new mathematics, and this means there are all sorts of things to think about and work on.

One person who hasn't changed his mind about some things is Lubos Motl. According to his latest posting, I'm

> …a typical incompetent, power-thirsty, active moron of the kind who often destroy whole countries if they get a chance to do it.

The arXiv puts out charts each year showing the number of submissions by category, the ones for 2007 are now available here. Commentary about this here and here. The general trend is that quite a few years ago the number of HEP papers leveled off, as just about all of them were posted on the arXiv. The number of math papers is still growing quickly, it is only recently that posting math preprints to the arXiv has become a widespread practice. While mathematicians probably write papers at a slower rate than physicists, there are a lot more mathematicians than particle physicists.

The end of 2007 has brought one undesirable change. Recently I was down in Princeton, and found out that the University Store, traditionally one of the best places in the world to buy math and physics books, has now gone out of the book-selling business, turning it over the Labyrinth Books. The new Labyrinth store has some math and physics books, but far, far fewer. Maybe they just are getting started, and 2008 will bring better news about this.

This past summer Terry Tomboulis posted a preprint claiming to have a proof of confinement. Recently there has been a note posted on the arXiv by Ito and Seiler claiming to have found a problem with his proof, and a response from him claiming there is no problem. I'd love to hear from an expert who has taken the time to follow these arguments carefully and can explain what is going on here.

For a recent article by Arthur Jaffe surveying the history of rigorous studies of quantum field theory, see here.

Heading off late tomorrow for a 9 day vacation in Paris. Blogging will probably be light to non-existent and it will take me longer to get around to deleting comments. Please don't feed the trolls.

Best wishes to all for the new year….

Comments

   December 30, 2007

   Hi Peter,

   Thanks for the link. I wish though you had not mentioned that writing of Lubos, it spoiled my day which was so far very nice. I see no point in leaving a comment at his place, so I'll leave it here. Lubos frequently makes statements where he claims to speak for *"everyone in the field"*. Being in the field, and knowing a lot of people in the field, I can assure you if Lubos Motl says *"everyone in the field"* thinks this or that, it is most definitely not the case. Best,

   B.

2. **Hans**
   December 30, 2007

   When you are in Paris, don't forget to buy Lubos recent book
   http://www4.fnac.com/shelf/article.aspx?PRID=2062733

   L'équation Bogdanov
   * Lubos Motl
   * Essai (broché)

   Article en pré-commande, livraison prévue à partir du 17 janvier 2008

3. **Hans**
   December 30, 2007

   Seems one can order it from Amazon france, too:

4. **Shantanu**
   December 30, 2007

Peter, did you see the slides of the Cambridge workshop on inflationary cosmology
at here did you find anything interesting there? Some of the talks did touch upon string theory.

5. **Daniel de França MTd2**
   December 31, 2007

   Hello Peter!

   Happy new year! 🙂

   Unfortunantely links from your website were banned from LM blog. You must read an annoying message to get into his post.

   Best wishes.

6. **Peter Woit**
   December 31, 2007

   Bee,

   Don't worry, I think that people are no more likely to believe Lubos when he says that he speaks for "everyone in the field" than when he claims that I have the ability to "destroy whole countries". Unfortunately he's not the only delusional string theorist around, but few of them are as far gone as he is.

   Hans,

   Thanks for reminding me of that. Maybe I'll even meet up with the Bogdanovs and find out the story behind that book…

   Shantanu,

   Unfortunately I don't really have the time now to look at many of those talks. There appear to be some useful summaries of the history and state of the idea of inflation. As for "string cosmology", I still don't see how it can possibly lead to a testable prediction, and the few talks about this I looked at there don't appear to give any promising ideas about how such a prediction might arise.

7. **Andy T-S**
   December 31, 2007

   Regarding Motl, I have, in my work, observed a researcher who exhibited paranoiac symptoms similar to those of Motl. Ths self-righteous psychopathic "bad apple" wasted enormous amounts of my co-workers' time and energy and, eventually induced clinical depression in two individuals.

   I have read both your and Lee Smolin's books, and have followed your blog for about a year. I have also attended several of Dr. Smolin's talks and audited part of his course on quantum gravity at the Perimeter Institute. My impression is that you both are generally fair and diplomatic critics. (As an example of skilful diplomacy, I observed Dr. Smolin at others' presentations cloak his criticisms by phrasing them as questions that, taken at face value, imply his own, not the presenter's, ignorance. This is quite the opposite of Richard Feynman's supercilious caustic sarcasms, hurled from the front row, that left some presenters in tears.)

   Neither you nor Smolin have ever said that research in string theory is totally useless and should therefore be dropped entirely. Unfortunately, this gets drowned out by irrational attacks from some unthinking researchers who feel threatened, and by misinformation in the media.

   Hans Selye (the discoverer of how stress induces disease) ascribed his success partly to the fact that he worked well with most of his colleagues without, at the same time, squandering his resources trying to befriend those he called "mad dogs".

   For what it's worth, my advice is to ignore Motl's shenanigans in future blogs. I would also remove your link to his site: he doesn't need your help to prove himself a "mad dog".

8. **King Ray**
   December 31, 2007

   Peter, and everyone,

   Happy New Year!

   Peter, I hope you have a great time in Paris!

   I think John Baez is right, it is hard to make progress in quantum gravity. It is difficult to know where to start. A new paradigm is probably needed, as Kuhn has said. Sometimes it is better to work on something where you can gain some traction for a while, rather than spinning your wheels going nowhere for years.

   I think Einstein's practical experience working in the patent office helped sharpen his mind. String and other theorists could probably also benefit by doing some practical work in physics and engineering for a while. It helps build your physical intuition. Einstein said his patent office work helped him to see quickly to the heart of the problem.

9. **Hedge Fund Physics**
   December 31, 2007

   Happy New Year!

   On Betting Against Physics Hype in 2008

   We're expecting the LHC to find approximately nothing new, but it could be a lot of fun watching a lot of people claiming that they have the new TOE which the LHC will prove right or wrong.

   And we're upping the ante, and hedging against postmodern groupthink and tenured hypesters by calling them out, and betting them $137 that their claims are false. That would be $137 per claim.

   Let's start with claims made by the esteemed Dr. Kip Thorne who in a recent interview stated, (continued at
   http://hedgefundphysics.blogspot.com/)

10. **mitchell porter**
December 31, 2007

Have the readers of this blog ever suggested conditions under which they think *string theorists* would stop working on string theory?

In looking through Jacques Distler's blog in recent weeks, the most important thing I've learned is just that there is no known string vacuum which *exactly* reproduces the Standard Model (below 1 TeV, or whatever; and I suppose one should throw in the new "cosmological Standard Model" too) – there are just a few large classes of qualitatively realistic vacua. Jacques recently completed his proof that you can't fit the Standard Model into E8; one can imagine a similar, case-by-case proof for string theory (though it would have to be considerably more complicated). But so long as there are several potentially viable approaches, of course they'll keep at it.

11. **layman**
December 31, 2007

wow, princeton bookstore now sucks. I visited it around 20 yrs ago and i couldnt leave. Too bad. I was gearing up 2 go there again.

12. **Roger**
January 1, 2008

With respect to the question of what scientists have changed their mind about this year my answers would be the ILC and science communication.

I've come to see the ILC (at this point) as the experimentalists' string theory. Far too much effort has been sunk into it and too many reports have been published based on detector and Monte Carlo simulations, which are themselves largely based on speculative theories of beyond-the-standard model physics and expectations of what we may see at an, as yet, uncommissioned accelerator. The recent funding cuts are, to an extend, our political masters seeing the emperor has no new clothes (or possibly no new particles). Over the past few years whilst effort has been thrown into the ILC we've had a number of excellent facilities online which could have more profitably exploited much of the ILC's funding- Babar, HERA etc. Having worked on HERA I found the gradual loss of manpower to be very regrettable, especially since there are still many useful measurements to be made, which may now never take place. I'm not against the ILC but, in the UK at least, the rush to sink so much money into the project was IMO ill-advised, especially in light of the recent decision to throw that investment away and pull out.

On a related theme, I used to think that particle physicists were good at communicating the results of their research and the need for support for their field to the power brokers and the general public. It appears that we need something of a rethink in this area (in some countries at least), especially if results from the LHC are further delayed or turn out to be simply unexciting.

13. **Fabien Besnard**
January 1, 2008

I guess that not knowing the right questions to ask is precisely what makes quantum gravity attractive to some people, and discouraging to others. I'm pretty sure JB was fascinated by this aspect of the subject in the first place, and will change his mind again in some future (I hope so).
In my opinion, there might be another difficulty in quantum gravity, which is related to but distinct from the good questions to ask, this is the good time to start. It is quite possible that some pieces of the puzzle are still lacking, and it is just too early to start thinking about quantum gravity. In my opinion, one of these pieces might lurk in the quantum mechanics corner.
Anyway, there is no reason to feel depressed about this, since the work done so far in QG already led to considerable progress. After all, mathematics benefited immensely from the work of many people who started to think too early about Fermat's last theorem…

14. **milkshake**
January 1, 2008

One thing that this site could possibly achieve (and did, partially) is to puncture the orthodoxy bubble that "ST is a very powerful and beautiful framework and the only game in town".

The other one is to point at the general problem of salesmanship in presenting the research results – I have seen this in biology and chemistry (including some outright faked work) and I think it is a rather more insidious problem than particular fads and orthodoxy. In chemistry it can still take few years to uncover baloney or lay the hype to rest – and the experiments there are much easier, cheaper so the interesting results could be re-checked by a number of groups.
It is quite easy to fool yourself and from then on it is even easier to start fooling others.

15. **Arun**
January 1, 2008

Recently I was down in Princeton, and found out that the University Store, traditionally one of the best places in the world to buy math and physics books, has now gone out of the book-selling business, turning it over the Labyrinth Books.

That spoiled my day. Motl-Wotl is piffle.

16. **TomD**
January 1, 2008

I hate to hear of the "demise" of the U-Store. I spent a lot of my disposable income there as a grad student at Princeton, and have returned there several times since and had a great time browsing and buying.

It's getting tough to find good technical bookstores. Even with the existence of Amazon, we still need a place to actually see books before buying them. Last summer I had the pleasure of going to the Cambridge University Press bookstore in Cambridge, England, as well as Heffer's Bookstore, and those were wonderful….

17. **Andrew**
January 1, 2008

Peter, I think your New Year's resolution should be to ignore Motl. He appears to be a paranoid crank. Don't give him the oxygen of attention that he craves…

18. **dark-matter**
January 1, 2008

Lubos Motl and Britney Spears are identical in every way.
Does that help settle the matter? Let's move on.

19. **Paul Jackson**
January 3, 2008

Just as it's always darkest just before dawn, your report that a sophisticate like John Baez is finally giving up on quantum gravity may be a portent that a new way forward is about to emerge.

Nil desperandum, Peter Woit!

The work of the Brazilian theorists Aldrovandi and Pereira (on de Sitter relativity) looks to me suspiciously like the breaking up of a logjam on a big river of sterile theory. And that's my pennyworth.

20. **Kochemasov Gennady,RFNC VNIIEF,Sarov**
January 5, 2008

Pushkinean Quantum Gravity (1983-1986)

Dear colleagues!
It is clear that the big turmoil exist inside theoretical physicist's community. And main controversial problems are the status of quantum gravity and superstring theory (sorry for my English). In such situation I think that for some scientists will be interesting and may be useful to know about QG version which was developed twenty years ago by bright but mostly unknown physicist Alexander Vasilyevich Pushkin (1947-2004) who had worked in Russian Federal Nuclear Center VNIIEF located in Sarov. Unfortunately, A.V. Pushkin's results in fundamental physics have been published not in full measure, while those published are sometimes of fragmentary nature and mostly in Russian. Below I try to explain his ideas very shortly. Partly they were developed in collaboration with Dr. Gorbatenko M.V. I start by quotation from the book [A.V.Pushkin, "Geometrodynamics" which was written in 1997 and was published in 2005 in Russian by RFNC VNIIEF].
"As a result of a research (January 1983 through April 1986) the author managed to solve the problem of construction of the consistent (divergence-free) quantum gravity theory. Moreover, it was possible not only to prove finiteness of the theory, but also to constructively express its properties in a closed form – in the form of a system of nonlinear partial differential equations, whose solution set includes all the four-dimensional manifolds consistent with the causality principle <>. As it turned out, the construction of a consistent quantum gravity is equivalent to that of unified theory of material fields with unbroken local scale invariance. In the physical language this means that the theory satisfies the fundamental experimental fact, viz. the absence of absolute dimensional scales in the nature.
In the algebraic language the mathematical content of the theory reduces to a unique object, viz. commutative nonassociative algebra discovered by Griess, and a group of automorphisms of the algebra, viz. "Monster", or "Griess-Fisher Friendly Giant".
The geometric properties of the theory are expressed in terms of four-dimensional manifolds, whose structure is exhausted by that of two-dimensional surfaces globally embedded in them.
The connection between the two descriptions is established by the theory of representations of the Monster group, which is a theory of representations of some infinite affine Lie algebra of <>. In its turn this means that the quantum gravity theory can be expressed in terms of a system of completely integrable nonlinear partial differential equations, i.e. in that closed form which has been spoken about above. In what follows we will refer to this system of equations as geometrodynamics equations, or simply geometrodynamics.
Eventually, the complete integrability property provides a tool for comparison of one physical process with another by means of representation of invariants of one solution to the equations in terms of invariants of other solution(-s).
The author's research series (December 1986 through 1992) was devoted to solution of the inverse problem: A system of 10 geometrodynamics equations is given; the structure of mater and objects has to be constructed in the form of relations between their invariant characteristics.
That is, first, it was necessary to determine as consequences from the equations the principal laws, relations and set of basic constants that have been discovered in the nature and formalized in the set of phenomenological approximations (such as Newton and Coulomb laws, Dirac equation for electron, …, many-body coherent systems of quantum continuums, …, and, finally, nonlinear motions of ordinary continuums and up to cosmological-scale astronomical phenomena).
