The best bits were the sequences showing the lab hardware, especially Thorsten Schmidt's X-Ray beam apparatus to split an electron into orbitrons and spinons (quasiparticles).

7. **BJM**
September 6, 2012

@Mike Mathison
In your transcript of the program:
"For now, string theory remains a theory, with no experimental evidence for any of its mind-boggling predictions…"

Are you sure the comma after "theory" belongs there? It makes a big difference in the meaning. With the comma, the entire concept of the term theory is demeaned as something without evidence (a widely held popular perception).

8. **Cormac McGuinness**
September 6, 2012

Damn! Only watched it for three minutes and then switched away – would have enjoyed seeing the Swiss Light Source and my colleague Thorsten at a beamline that I have worked at. Could not have expected that the programmers would juxtapose orbitons observed via RIXS (resonant inelastic x-ray scattering) and the non-predictions of the string theory landscape.

9. **jg**
September 6, 2012

Yes, the programme was a bit of a mishmash, along with some cool hardware they had Michael Green going on about how the tiniest particle could also be the whole universe (I guess he was referrring to dualities), and a rock-music sequence with Dr Giovanni Amelino-Camelia riding a moped through Rome and then talking gibberish about space-time (*"what is space-time, you know? [etc]…, you see what I'm trying to say? It is very tricky."*)

Schmidt's experiment is shown from ~22:00 onwards (I mistakenly wrote 'orbitrons' above it, it should be 'orbiton' as Cormac wrote)

10. **Peter Woit**
September 6, 2012

I did get to watch the program, and just added something to the blog about it. The first half was very good, and I would have loved to hear more about the experiment Cormac mentions, instead of the "trip down the rabbit hole" that followed.

As Shantanu mentions, the Lorentz symmetry violations MAGIC is looking for are something some string theorists (e.g. Nanopoulos) claim as evidence for string theory, others claim string theory predicts no such violations. Same with pretty much everything else (another good example is variation of fundamental constants). Since the program featured string theory and MAGIC, it would have been a good idea to address this issue.

11. **Mike Mathison**
September 6, 2012

@BMJ – I put in the comma to try to reflect the delivery of the spoken commentary – and listening to it again I'd also say there's some pronounced emphasis on the second occurrence of theory: "*[…] but for now [slight pause] string theory remains a *theory* [slight pause] with no experimental evidence for any of its mind-boggling predictions […]*." Obviously I can't speak for the intended meaning of the writers of the commentary, or for the person who delivered it. The sentence in question begins around 40 minutes and 7 seconds.

12. **Cormac McGuinness**
September 6, 2012

Peter: If you are interested in the experiments on spin-orbital separation mentioned above (and in the program), concerning the fractionalisation of the electron into distinct quasiparticles, then the relevant paper was published in Nature in April. The observation of orbitons in Sr_2CuO_3 was obtained via RIXS measurements by Schlappa et al (i.e. Thorsten Schmitt and co-workers).
See the nature article, and even the supplementary data which has some of the more interesting information for the specialist.

For those not in the field then the BBC news report can be read instead.

September 6, 2012

Is the Wang particle part of the hype?

14. **Peter Woit**
September 6, 2012

lun,

Looks suspiciously like the “Wang particle” is its very own form of hype, but I know nothing about it.

15. **lun**
September 20, 2012

In related news, apparently the multiverse killed god

Langlands and Twistors?

September 6, 2012
Categories: Langlands

I just heard about this from George Sparling, who is giving a talk this afternoon with the title “From Roger Penrose to Robert Langlands and back” at a symposium in Pittsburgh. I don’t at all know what this is about, but am posting this quickly because he tells me there may be a live stream of his talk at 5pm today, available at

http://live.twistor.org

Evidently yesterday and today at Pittsburgh there’s a symposium on “Towards the Unification of Mathematics and Physics”, with the following schedule:

4pm Wednesday: Mellon Professor Thomas Hales, “The present status of the Langlands Conjecture”.
5pm Wednesday: Jonathan Holland, “Parabolic geometry”.

4pm Thursday: Tim Adamo, University of Oxford, “Twistor-String theory and gravity”
5pm Thursday: George Sparling, “From Roger Penrose to Robert Langlands and back.”

Last week there was a workshop at Banff on The Geometry of Scattering Amplitudes, with videos now available. I’ll try soon to take a look at some of them, Sparling’s may give an idea of what he is up to.

And, for something completely different, see this interview with Edward Frenkel about the Langlands Program at the Fields Institute blog for this fall’s Fields Medal symposium.

Update: There’s a video of the Sparling talk available here.

Comments

1. **Richard Cerezo**
   September 6, 2012

   Thanks for the mention! I hope to interview a number of other mathematicians regarding the Langlands program. If you have any ideas or are willing to do a phone interview with me, that would be great! Please shoot me an email.

   Sincerely,
   Richard

2. **Peter Woit**
   September 6, 2012

   Hi Richard,

   You’ve got a long list of distinguished speakers for the symposium (I’m hoping to come up to Toronto to hear some of them), I’ll send you by e-mail some suggestions about interviewees, many of them would be great choices. As for me, anyone interested in my opinions can get far too much of them already at this site….

3. **Jack**
   September 6, 2012

   Do you know if this conference will be posted on other websites as well? I have a slower internet connection and the stream on Twistor in loading for more then 10 minutes and nothing happens.

   Thanks,
   Jack

4. **Peter Woit**
   September 6, 2012

   Jack,
   It doesn’t look so far (5:02 pm) like there will be video of the talk. I don’t have any other information about the talks at this symposium. One reason for the posting was that I’d like to hear from anyone else who does.

5. **Peter Woit**
   September 6, 2012

   As of 5:15, video of Sparling’s talk is streaming, a bit shakily…

European Strategy Group Meeting

September 10, 2012
Categories: Experimental HEP News

CERN has a new version of the European Strategy Group (last convened in 2005/6), tasked with updating medium to long-term plans for future accelerators and particle physics in general. This week they're running an Open Symposium (live webcast here), with presentations covering a wide array of topics from the state of speculative ideas about BSM physics to possible new accelerator technologies.

While the presentations themselves often focus on the really interesting question of how to learn more about the Higgs and electroweak symmetry breaking, media articles based on reporting from the conference have started to appear, often featuring the usual nonsense. See for example this piece, from the Sunday Times, which tells us that:

> Such a machine might help resolve some of the questions raised by Albert Einstein, who could not reconcile the forces operating at the level of atoms with the force of gravity, which governs the movement of stars and planets.

which then gets picked up by the Daily Mail and turned into a story about how CERN reveals plans for new experiments measuring 50 miles in length to solve the mystery of how gravity works, which explains:

> The collider will be used to solve a new batch of mysteries of the universe, such as how gravity interacts on a molecular level.

Maybe the European Strategy Group could as part of its deliberations develop a strategy for stopping physicists from going to the press with nonsense about quantum gravity….

Comments

1. **Bee**
   September 10, 2012

   Interesting that one needs a 50 mile collider to study the behavior of molecules.

2. **fuzzy**
   September 10, 2012

   I note that the Chair of SPC is a respected theorist. I see from INSPIRE that he obtained a lot of results on supersymmetry, supergravity, strings and such. I am not sure we can call this physics, but I guess that if he is the Chair, many people will be lead to consider extra dimensions, supersymmetry, etc, as part of high energy physics. So I am not surprised that a journalist will not express a critical view about that, rather, he reflects the views of the community.

3. **Mattias Dahl**
   September 10, 2012

   http://www.youtube.com/watch?v=3wHKBavY_h8

4. **Peter Woit**
   September 10, 2012

   Mattias,

   That's pretty funny, hadn't seen it.

5. **Hamish**
   September 12, 2012

   Bee, a few generations ago one would be forgiven for asking why a large circular accelerator would be needed to study molecules — now we build them just for that purpose! Big toys arn't just for particle physicists anymore!

6. **paddy**
   September 12, 2012

   I shan't say anything about the provincialism implied by the name "European Strategy Group Meeting". Oops..I did.

7. **Bobito**
   September 13, 2012

   Whatever the merits of a particular kind of science, the last thing any of us needs is some "European Strategy Group" stopping it from being published.

8. **Jeff Moreland**
   September 13, 2012

   Paddy & Bobito,
   All 20 member states of CERN are European, and virtually all the people they employ and the money they spend is European. I don't think they are trying to control or censor the rest of the world!

9. **epp2010**
   September 13, 2012

   Does anybody remember the EPP2010 report from a few years ago? (Jonathan Bagger chairman.) PW probably has a post about it smoewhere. (More than one?) The official purpose was to set a strategy for the USHEP experimental program for the next decade (or more). The whole report, when it came out, was explicitly to "restore US leadership in particle physics". Provincialism? The report was so outrageous it caused a public outcry, even within the US. It was promptly hushed up.

10. **Claude Leblanc**
    September 16, 2012

Peter,

the slides are now online. Did you have a look at the ones by Alvarez-Gaumé or the ones of the last section, which summarize the various working groups? This must have been one of the most unproductive strategy meeting in the last 100 years. The theory strategy is particularly disappointing. Basically, they say: "we have no clue what to do, we need more young people to join us".

I have often experienced how managers who did not know what to do changed the situation: they organized a strategy workshop, structured it well, asked the right questions in the right sequence, and then forged a coherent strategy supported by everyone. But this meeting obviously failed completely.

The theory people have not yet digested the failure of supersymmetry. Instead of looking for alternatives in a systematic manner, they still seem to be depressed. After the leadership they provided for decades, when they successfully induced experimentalists to build the LEP, the Tevatron, the LHC, they are now lost. The main statement is: let's wait for the LHC 2013-14 results. Wow. What a great strategy!

What we need here, above all, is a theory strategy. A theory strategy were theorists sit down, evaluate all possible options, and then explore the most promising ones. Instead, the last slide of the theorists says: "The TH community is useful and healthy, we should keep it that way" Given that it is a community of thousands of well-educated and well-funded researchers but that this community did not produce almost any correct idea in the last 40 years, there is some humor in the statement.

"Useful and healthy"? No, it's "useless and depressed."

11. **M**
September 16, 2012

From a mathematical point of view High Energy Physics is a ordered field. There is only one direction: towards higher energy.
So these strategy groups mostly have a political purpose

12. **Bobito**
September 16, 2012

@Jeff: I don't think you caught the sense of my comment. In any case, I live and work in one of the 20 member states.

13. **leadersheep**
September 16, 2012

"After the leadership they provided for decades, when they successfully induced experimentalists to build the LEP, the Tevatron, the LHC, they are now lost."

The HEP expt side will doubtless offer a very different point of view about this. In the 1950-60s the accelerators were producing copious new physics, all of which cried out for an explanation. It was the plentiful and unexplained data which drove the theoretical innovation. Many of the new particles being discovered fitted into patterns (mesons and baryons, octets and decuplets), the theorists came up with SU(3) and the Eight-fold way, and later with quarks. (The peculiar decay of the phi meson? It led Zweig to his model of aces.) At the same time there was data on the weak interactions. This led to ideas of weak neutral currents. And of course to W and Z bosons. And also of symmetry breaking. The absence of flavor-changing neutral currents led to a suggestion of charm. And CP violation was totally unexpected.

"… successfully induced experimentalists to build the LEP, the Tevatron, the LHC, they are now lost." All of these machines (and others SPEAR, CESR, DORIS, PEP, PETRA, TRISTAN, VEPP-2, VEPP-4, SPS, ADONE … others … HERA?) were all e+e- colliders or hadron colliders/fixed target rings, all pushing the energy frontier in their own way (or serving as spectroscopes for quarkonium resonances).

But since the Standard Model was put together circa 1974-75, all new particles which have been found have all fitted into the SM (b-quark, top quark, Higgs). For forty years or so, particle accelerators have NOT produced copious new particles which lack a new theoretical explanation = BSM physics. The new frontier seems to be dark matter and dark energy, and there is no clear way how to detect or quantify that.

"The theory people have not yet digested the failure of supersymmetry. Instead of looking for alternatives in a systematic manner …" How would the HEP theorists propose to modify the design of the ILC/muon collider/super-B/super-LHC/you name it/ to look for alternatives in a systematic manner? All of LEP, Tevatron, LHC, etc were all e+e- or hadron colliders. The HEP theory community did not provide any technical ideas for new accelerator technology.

There simply has to be new data = new particles, or new symmtery violations (super-CP-violation, whatever that might mean…). For example, perhaps the Higgs does not decay as expected and the branching ratios disagree significantly with SM predictions. Or it decays via some channel which should be forbidden. New resonances appear = "bump hunting" of the 1950s, which do not fit the SM. Then all of that will give the HEP theorists something concrete to work on, to suggest hypotheses to test at proposed new machines. But the new machnes will almost certainly still be e+e- or mu+mu- or hadron colliders.

14. **Claude Leblanc**
September 16, 2012

To leadersheep

It might well be that you are right, and theoreticians have not provided any leadership at all.

But then the situation is even worse now. Because there is no reason at all for a larger machine; as long as there is no effect beyond the standard model, there is no reason to build a larger machine.

Maybe one has to harsher and say that nobody knows what to do. A really bad situation in a time where there are more particle physicists than at any previous time in history. So many smart men, and still they have no clue…

15. **leadersheep**
September 16, 2012

What leadership could the HEP theory community offer? Let's consider LEP. It is widely acknowledged that LEP was extremely successful. But LEP produced no BSM physics. What leadership or guidance could the HEP theorists offer to do things differently? LEP was an e+e- collider (lepton). LHC is a pp collider (hadron) in the same tunnel. What else to do? Maybe p-pbar. Is that really an innovative way to search for alternatives to supersymmetry?

After the b quark was discovered at Fermilab in 1977 (in a fixed target expt, not the Tevatron, which was not operational in 1977), that is to say, after the discovered Upsilon particle was realized to be a bound state of a new species of quark with charge -1/3, then the theorists immediately said there is a partner t-quark, with a charge of +2/3. So there was a theoretical impetus to build machines to find the t quark. PEP, PETRA and TRISTAN were all built to find the top quark, and they all failed to do so. Was it wise to build them? PETRA discovered gluons via 3-jet events, also PETRA observed QCD deviations from Bjorken scaling, one of the earliest validations of QCD. But that is not why PETRA was built. Since the beginning of QM, the theorists have never had any good idea at what ebergy scale the next "new physics" will appear. Most "new physics" has been a surprise.

One can always stop building machines because the theorists have no ideas for what comes next (BSM n the case of HEP). By that logic Kammerlingh Onnes should not have measured electrical resistance at liquid He temperatures. Kammerlingh Onnes was actually trying to verify Ohm's law at low temperatures. That's as boring as boring can be. Which theorist would propose building a cryostat to do that? Would you jump at the opportunity to do a PhD thesis to validate Ohm's Law to (almost) absolute zero?

16. **no clue**
September 16, 2012

"Maybe one has to harsher and say that nobody knows what to do. … So many smart men, and still they have no clue…"

I suppose Helen Quinn and/or Lisa Randall might object to that, but never mind. When Dirac discovered the Dirac equation, he had no clue about antimatter. Carl Anderson discovered the positron completely independently of Dirac. When Yukawa proposed the meson (U particle) and a particle of the approximate mass was found by Anderson and Nedermeyer, nobody recognized it as a lepton not a meson. After WW2, cosmic ray expts produced strange V particles. Accelerators could produce such particles more copiously and reliably, and that was a big reason to build accelerators after WW2. But nobody expected the huge number of resonances which appeared. When the AGS strong focusing proton synchrotron was built in 1960, there was no theorist who said it would discover CP violation. Nor did anyone say the AGS would produce the J half of the J/psi. Indeed in 1960 no one even spoke of quarks. The AGS and the CERN PS were built because the strong focusing principle was a new idea which allowed accelerators to reach much higher energies, and yet have a reasonable size. But in all cases, there was plenty of unexplained physics lying around, and good reasons to build accelerators of higher energy.

Most of the famous accelerators became famous for discovering physics completely different from the reasons why they were proposed. Bevatron, SPEAR, AGS … The SPS at CERN was built as a fixed target synchrotron. It was never intended to operate as a p-bar collider. No HEP theorist said that one should build a p-pbar collider. Carlo Rubbia said that (actually, to convert an existing fixed target proton synchrotron into a p-pbar collider).

17. **Peter Woit**
September 16, 2012

epp2010,

I did write about EPP2010, see for instance
http://www.math.columbia.edu/~woit/wordpress/?p=382
where I wrote

"The committee did a very good job of recognizing the difficult situation of US HEP, and coming up with a plausible strategy for how to make the best of it. I have my doubts about whether it's really a good idea to sell this as "Revealing the Hidden Nature of Space and Time", since it's not especially likely that that is what is going to happen. There's no particularly good reason to believe that extra dimensions will show up at the LHC or ILC energy scales, so over-selling this is dangerous."

In retrospect, I think emphasizing the ILC was a mistake. One of the main arguments for the ILC was always "we think the LHC may see lots of superpartners below 1 TeV, the ILC would be then the best way to study them, so we should have a design ready to go when LHC results come in". The problem is that the superpartners were always very unlikely, so even back then you knew that the most likely situation you would be in once LHC results came in was the one we're in now: no BSM physics at ILC scales. The ILC thus shouldn't have played such a prominent role in the EPP2010 proposals. Other than that though, US HEP then (and now) is in a difficult situation, with no obvious great options, and I think those working on this played as well as they could the bad hand they were dealt by nature and fiscal reality.

Claude Leblanc,

I did look at the slides. It's not surprising that Alvarez-Gaume thought this was not the time or place to admit failures, but tried to make the case for future support. I note that the words "string theory" don't appear in his slides: the decision seemed to be that it was best to not bring that up in this venue. I hope the theory community is finally getting around to thinking through the implications of the failure of string theory unification (which has been clear for a long time), as well as the failure of SUSY extensions of the SM (which is becoming definitive as LHC results come in). Any useful debates about this though are likely to take place just among theorists, not when they're facing the outside world to ask for future financial support.

18. **chris**
September 17, 2012

well, let's face it: classical, accelerator based particle physics is coming to an end. the LHC will be productive for at least another decade after which some next gen collider will clean up the few remaining pieces and that will be about it.

time for theorists to reorient themselves or concentrate on teaching if they prefer that.

19. **David Nataf**
September 17, 2012

Chris,

What is the basis for your claim that accelerator physics is over?

It's not even clear that the Higgs cross sections match SM-predictions.

20. **fuzzy**
September 20, 2012

Hi David, just wanted to try to formulate my reaction to your question in words. I think that if it some brilliant theorist had predicted a big deviation of the Higgs branching ratio into 2 photons, the experimental hint to which you allude could have been interesting. Now as now, if we want to act as scientists, we should just say that the search conducted using the standard model as a guide was successful. Of course all of us is interested to see the next data, but I would dare to say that extra dimensions, quantum gravity, Lorentz violation etc, seem to be more in the pages of Nature, than in the Nature.

PPAP Community Meeting

September 18, 2012
Categories: Uncategorized

Following up on last week's European Strategy Group Meeting in Krakow, this week UK particle physicists are doing something similar, with a Particle Physics Advisory Panel community meeting in Birmingham.

The talks on the experimental side tell much the same story as the Krakow talks. On the theory side, the UK meeting has more, with a phenomenology talk which discusses prospects for "Saving SUSY" while noting that:

> It's ironic that the solution to the absence of SUSY is to add even more stuff: composite 3rd generation or Higgs, R-parity violating couplings, scalar gluons, or new singlets.

There's extensive discussion of UK particle theory funding here. I don't understand very well how particle theory is funded in the UK, but was interested to note that the slide on page 5 has string theory's piece of the pie stable at 27% last year (also 27% in 2008, 28% in 2005). Mike Duff (see commentary here) wrote a piece for the forthcoming *40 Years of String Theory* volume arguing that the 2006 books by Lee Smolin and me were responsible for destroying funding of string theory in the UK, but the numbers in this new talk don't seem to bear this out. I gather there's a separate story about the EPSRC and mathematical physics, and curious to hear from anyone who knows more about that. But if the state of affairs is that the mathematical end of string theory is being defunded while the phenomenological end is going strong, that can't be because someone in authority read my book…

Update: The US has its own version of this planned to take place over the next year, Snowmass 2013, starting with a meeting next month at Fermilab. It looks like this will be purely about planning on the experimental side, with the problems of particle theory not on the agenda.

Comments

1. **Shantanu**
   September 18, 2012

   Peter, OT to this thread.
   if you attend this talk
   http://www.columbia.edu/cu/physics/pdf-files/Colloquium2012Anderson.pdf
   at Columbia,
   could you provide a report?
   Thanks
   shantanu

2. **Peter Woit**
   September 18, 2012

   Shantanu,
   I was planning on attending that talk and writing about it. Unfortunately I just heard the disappointing news from Anderson himself that he's likely to not be able to make the trip here next Monday because of health reasons. Hopefully he'll make it here for a talk sooner or later. If so I'll be sure to attend and report on it.

3. **piscator**
   September 19, 2012

   Note that the combinations of `Strings' and `QFT' though has gone from 43% to 32%. This is probably a better reading of the figures given that many quantum field theorists may now be labelled as string theorists due to working on AdS/CFT and related topics.

4. **Peter Woit**
   September 19, 2012

   piscator,

   That may be true. Probably the most remarkable thing about that pie chart was "QFT" going form 15% to 5%. If your interpretation is right, it reflects a collapse in non-AdS/CFT research into QFT, with AdS/CFT now the only approach to formal QFT research that can get any support.

5. **P**
   September 19, 2012

   Peter and piscator,

   Agreed that it's strange to see QFT taking a hit, and maybe it's a labeling issue where people doing research on AdS/CFT and related topics are lumped into strings rather than QFT.

   But with a few hot new QFT subfields in the last few years, shouldn't we expect it to go up? e.g. amplitudes, Gaiotto (2,0) theories, AGT, 3d-3d correspondences, others, etc etc . . . Though certainly motivated by stringy ideas, these ideas really are in QFT proper. Maybe the decline in QFT funding is a reflection of the fact that not quite as much of this new work has been done by Brits?

   Cheers,
   P

6. **Mitchell Porter**
   September 20, 2012

   "Since the discovery of gauge/gravity duality and other developments, it has become clear that QFT and string theory/M-theory are NOT distinct subjects. String theory and M-theory can be viewed as important components of the logical completion of quantum field theory… String theory grew out of the S-matrix theory program, which was popular in the 1960s. For many years string theory appeared to be a radical alternative to quantum field theory. It is now clear that string theory and M-theory are not radical at all. In fact, they are the most conservative and inevitable ways in which to formulate quantum theories of gravity." — John Schwarz, Strings 2012

7. **P**
   September 20, 2012

   Mitchell,

   Thanks for the quote, I hadn't heard that one! He definitely has good perspective, and is one of the people best qualified to comment on the progress of string theory over the last 40 years. Strings and QFT do go hand in hand, but I'm curious about the use of the word "inevitable" in relation to strings and quantum gravity. It seems to imply QG –> string, rather than the other way around.

   Cheers,
   P

8. **Peter Woit**
   September 20, 2012

   Mitchell Porter and P.,

   Can we please stick to informed discussion about the topic of the posting, and what is going on in the UK? I don't see how anyone here can conceivably learn anything of any interest from discussing this particular piece of string theory hype.

9. **P**
   September 20, 2012

   Peter,

   The part that was hype I effectively labeled as such. The rest is not.

   Besides, it followed from a thread of discussion brought up by Piscator and followed up by you about AdS/CFT research being groupable into either QFT or Strings. Mitchell then brought up a quote along those lines from a renowned physicist, which was also relevant to the thread of discussion, and then I made a comment on said quote and also a criticism. Not sure when the discussion you yourself were a part of went too far afield . . .

   Not to mention, I did comment directly on the British QFT situation and the labelling issue, and it went unanswered.

   Cheers,
   P

10. **Peter Woit**
    September 20, 2012

    P,

    I don't know the answer to your question about British QFT, and would love to hear from someone who does. I'm pretty sure though that allowing this comment thread to degenerate into yet another discussion of string theory hype (e.g. string theory as "the logical completion of quantum field theory") will ensure this doesn't happen. Enough.

11. **P**
    September 21, 2012

    Peter,

    Just take note that I did not say that, and even criticized that sentiment.

    It seems that this thread has died. But since you'd like to hear a statement about British QFT and no one else has said anything, I'll just add the comment that I can only think of a handful of people who have works on the formal things I've mentioned – Hanany and collaborators, Bullimore and collaborators (when he was in Britain), and maybe a few other people at Oxford. Much of the action has come from North America and a handful of very good people in Japan, and this observation might be in correspondence with the data in the pie chart.

    Cheers,
    P

12. **piscator**
    September 21, 2012

    Some quick comments about how UK research is funded. The main grant system (which the slides refer to) are group grants often called Rolling Grants. They are awarded to particle theory groups as a whole and provide some number of postdocs to the group as a whole. So this means that each group – who may cover a spectrum from QCD to formal string theory – submits a single application, and gets a single award.

    Individual groups then use these grants to hire postdocs, normally collectively. The piechart describes the slicing of postdocs by subject area. There are probably O(30) STFC-supported postdocs at any one time so there is some element of noise.

    As far as I am aware this is NOT like the US system where faculty members apply for individual grants which fund their individual postdocs. Some of these exist – e.g. ERC grants – but the slides are about STFC and so do not refer to those.

    The main areas of `pure QFT' research in the UK I would say have tended to relate to integrability, strong coupling, solitons. Many of these areas are now either subsumed into or closely linked to AdS/CFT or D-brane physics. As P points out, there is not much UK work on e.g. Gaiotto-esque stuff.

    The 5% figure doesn't strike me as obviously low, QFT that could not be classified as either pheno or strings or lattice isn't that big an area.

13. **John**
    September 21, 2012

    Peter,

Check out this nifty-looking website:

http://whystringtheory.com/

14. **Peter Woit**
September 21, 2012

John,

One of the students responsible for that site wrote to tell me about it a while back. Was going to mention it here at some point, but I don't have much to say about it. It just repeats the same promotional case for string theory that has been endlessly made for nearly 30 years now, ignoring why the ideas being promoted don't work. It's very similar to the superstringtheory.com site that Patricia Schwarz set up way back when, but has been abandoned for about 10 years. Like that site, the material about string theory pretty much stops about 15 years ago, with AdS/CFT.

It's interesting that people at Oxford thought this was something that the world needs. Maybe one motivation for its creation was concerns about future funding for string theory in the UK. I have no idea whether this sort of things makes a positive impression on whoever is making those funding decisions.

15. **Peter Orland**
September 21, 2012

piscator says:
The 5% figure doesn't strike me as obviously low, QFT that could not be classified as either pheno or strings or lattice isn't that big an area.

In terms of the number of people working on it, absolutely true. Maybe this is good for those of us in the 5% (not much competition) or sad (not much interest of colleagues).

16. **Joseph Conlon**
September 21, 2012

Peter: the motivation for its creation was the belief that the general public – who fund scientific research – are entitled to accurate and accessible information on why their money is spent on string theory, what string theory is, what it has achieved and what it hopes to achieve.

I have tried to ensure that all statements on the site are accurate and fair – identifications of erroneous claims are welcome and they will be corrected.

17. **Peter Woit**
September 22, 2012

Joe,

With this kind of site, you're not providing people a product for their money, you're providing advertising to encourage them to give you more money, which is something rather different.

18. **chris**
September 24, 2012

It is not true that Snowmass is purely experimental. It just so happens, that theory is not a separate "frontier" but rather part of some of them. I find this rather more convincing than the European approach where theory is split off from the major developments and seems to exist more as an appendix to the true direction the field is going.

19. **jg**
September 24, 2012

Peter,

Slightly off-topic, but you might like to know that in the recently published 2012 Review of Particle Physics, the chapter on 'Experimental Tests of Gravitational Theory' has an interesting edit. In the introductory section the reference to a the theoretical spin-2 field origin of gravity has been removed as have the following sentences at the end of the introduction:

Quantizing the gravitational field itself poses a very difficult challenge because of the perturbative non-renormalizability of Einstein's Lagrangian. Superstring theory offers a promising avenue toward solving this challenge.

The 2010 version is available here and the 2012 version here

(The "promising" superstring reference has been there at least since the 2000 version (where supergravity was also described as promising, not sure how much earlier)

20. **Peter Woit**
September 24, 2012

Thanks jg,

I guess there is some time limit on how long you can be "promising"…

21. **Anonyrat**
September 24, 2012

If SuperString Theory was a person, it would no longer qualify (too old) for the Fields Medal….

22. **A.**
September 25, 2012

I left the UK shortly after STFC lost the huge lump of cash which was the catalyst for much of the current problems. In the following years the word from the (rather sheepish) funding bodies was "there is very little money, and there won't be for a long time".

The approach they then took was consolidation, which meant that any money they did manage to scrape together was given to Cambridge, Oxford, and Durham. Hence the collapse of so many physics departments in the UK. There is a firmly entrenched attitude, at least in England, that if a university isn't hightly ranked for education, then it's research departments are automatically rubbish. (Someone high up in the Durham IPP once had a fit of hysterics when I suggested that some of the smaller UK groups were going interesting work. He said, and I paraphrase, that they should all be put down.)

If you want to see where UK theory is headed, then the research going on at Oxbridge and Durham is basically it.

Wide World of Links

September 26, 2012
Categories: Uncategorized

Some short items of a wide variety of kinds:

- Witten has posted to the arXiv a long paper about the work on superstring perturbation theory that he has been doing. Superstring Perturbation Theory Revisited, together with two papers of background material (see here and here) weighs in at 400 pages. For an explanation of the main points, you might want to start with one of Witten's recent talks on the subject, for instance this one at Strings 2012.
Witten doesn't make much in the way of claims for the significance of this work, portraying it more as a project of going through the foundations of the subject of how you define higher loop superstring amplitudes in a much more careful way than was common during the mid-late 80s when this was a hot topic of research. The technicalities here are ferocious, well beyond my expertise. It will be interesting to see if this project revives interest in the subject and others start working on it again.
- Also on the arXiv is a new paper from Paul Frampton, with affiliation now including the Centro Universitario Devoto, part of the prison where he is unfortunately still incarcerated in Argentina. He argues here that he is still able to fulfill his duties as a University of North Carolina professor from Devoto prison, but doesn't seem to have gotten the university to agree about this.
- There's a conference at DESY this week on Lessons from the first phase of the LHC, with talks on Friday discussing "Where could SUSY be hiding?" and "Searches for new physics at the LHC: some frustration, but no despair…". For some additional context to the SUSY issue, I recently ran across this talk from SUSY 02, 10 years ago, which argued that SUSY arguments implied that "superpartners are probably being produced" at a new collider that had been running for a year or two (the Tevatron Run II at that time).
- The SCOAP^3 consortium has announced a plan to support commercial journals publishing HEP papers, paying them 1000-2000$ per HEP paper they publish according to a complicated formula. Elsevier would get about $2.4 million/year for papers in Physics Letters B and Nuclear Physics B, but somehow reduce its subscription fees to compensate. I don't understand at all how this is supposed to work (obvious problems include that of why anyone would subscribe once it was all open access, and what the mechanism is to stop publishers from increasing revenues by publishing more second-rate papers). Nature has an article explaining more about what is going on here.
Steven Harnad describes the scheme as Unnecessary, Unscalable and Unsustainable, Peter Coles as "Particle physics volunteers to be fleeced…"
- String theory advertising available here, Sean Carroll commentary about this here.
- At *Foundations of Physics*, Gerard 't Hooft has a new paper which doesn't seem to be on the arXiv, On the Foundations of Superstring Theory (you may need a subscription to read it). Here's the abstract:

  > Superstring theory is an extension of conventional quantum field theory that allows for stringlike and branelike material objects besides pointlike particles. The basic foundations on which the theory is built are amazingly shaky, and, equally amazingly, it seems to be this lack of solid foundations to which the theory owes its strength. We emphasize that such a situation is legitimate only in the development phases of a new doctrine. Eventually, a more solidly founded structure must be sought.
  > Although it is advertised as a "candidate theory of quantum gravity", we claim that string theory may not be exactly that. Rather, just like quantum field theory itself, it is a general mathematical framework for a class of theories. Its major flaw could be that it still embraces a Copenhagen view on the relation between quantum mechanics and reality, while any "theory of everything", that is, a theory for the entire cosmos, should do better than that.

  There's a recent blog posting about this here, including commentary from 't Hooft himself.

- If you're trying to keep up on reaction to Mochizuki's claimed proof of the ABC conjecture, try looking here. Still I think a very long ways to go before experts understand this well enough to evaluate whether this is a solid proof.
- I recently heard from Nick Carlin, who has unearthed the following scientific documents: Strange Particle Interactions in a Bubble Chamber and The Angular Correlation of Polarization of Annihilation Radiation, from late 1977 or spring 1978. Handwritten commentary is from William J. Skocpol and Robert V. Pound.

Update: Some frustration, but no despair is now on-line. The first slide is pretty amusing…

Update: More news about the latest in Paul Frampton's case here.

Comments

1. **Tony Smith**
September 26, 2012

   As to SCOAP3 and
"… why anyone would subscribe once it was all open access …"
the Register has a 26 Sep 2012 article entitled
"High-energy physics opens up"
that says
"… Instead of fronting up for high subscription fees,
libraries will fund the per-article open access fees …
This will either reduce, or replace entirely, library subscriptions …"
so
it may be that individual users will now have to pay $30 per article
if they go to a university library to get papers from the web.

   Tony

2. **Peter Woit**
September 26, 2012

   Tony,

   The "libraries will fund the per-article access fees" is referring to the journals getting $1000-$2000/article, and in return making them available for free on the web. So, if you had to go to a university library to get access to such articles, once this goes into practice, you can stay home and get access from your computer for free. This is the positive side of this story.

   On the other side, there's the question of why, when some mathematicians and physicists are trying to get the literature out of the grips of Elsevier so that the scientific community would no longer have to pay them, this plan does the opposite, providing them with a $2.5million/year revenue stream to pay for "open access" to articles that are already available on the arXiv.

The article Tony refers to is at

http://www.theregister.co.uk/2012/09/26/open_access_high_energy_physics/

3. **Deane**
September 26, 2012

   I had a great time talking to your colleague Shouwu Zhang today at tea about the abc conjecture and number theory in general. He really can explain the whole history of number theory up to today more clearly than anyone else I've ever talked to.

4. **Peter Woit**
September 26, 2012

   Hi Deane,

   Well, does Shouwu believe it? In any case, we're hoping he sees the light and doesn't permanently move to Princeton…

5. **chris**
September 27, 2012

   what a wonderful paper – thanks for the link.

   i mean the one by 't Hooft of course.

6. **Raisonator**
September 27, 2012

   Indeed, a wonderful paper – found interesting new arguments.

   I am reminded of a statement by John Bell way back in 1990.

   Q: "I'm sorry, does that mean that you say relativity and quantum mechanics are not compatible?"
J. B.: "No no I can't say that, because I think somebody will find a way of saying that they are compatible. But I haven't seen it yet. For me it's very hard to put them together, but I think somebody will put them together, and we'll just see that my imagination was too limited. Well, as the people in that department work at present, they are not coming to this question, because the superstring is still formulated within traditional quantum mechanics, and you still have the superposition principle which is maybe the root of all these things. But it could be that as they go further into that, they find that it just won't work along the traditional lines, and at some point they'll have to give up the superposition principle."

7. **Clark**
September 27, 2012

   Vesselin has found a serious problem in the Mochizuki proof. Terence Tao believes :
" it would be difficult to be optimistic about the proof until this issue is somehow resolved "

8. **Peter Woit**
September 27, 2012

   Clark is referring to this:

   http://mathoverflow.net/questions/106560/philosophy-behind-mochizukis-work-on-the-abc-conjecture/107279#107279

   It's very hard to follow this discussion on mathoverflow, the format is really wrong for this. Instead of a chronological discussion, one just sees the latest version of a continually edited "answer to a question", with a random selection of comments that make no sense as such (one can get all the comments easily, but the ever-changing nature of the text they are referring to is a big problem).

   My understanding is that others have also tried looking at Mochizuki's paper by starting with a claim in it that is of a kind they are expert at, but that looks like it might me too strong. They find counter-examples, but then later realize that buried somewhere way back in Mochizuki's work was an explicit assumption that they hadn't noticed was being made, so there was nothing wrong with the claim. I'm curious whether this might be happening here. Maybe we'll know soon.

9. **harryb**
September 27, 2012

   Very interesting paper from 't Hooft – thanks – seems to be downloadable without subscription.

   't Hooft seems to have a live love-hate relationship with ST, summed up maybe by after noting he does not want to critique ST, he states later:

   "The reason for writing this note is simply that the author suspects that
superstring theory can be improved considerably, or can perhaps be replaced entirely by something better."

   We feel his pain. Good luck.

10. **John**
September 27, 2012

    Peter,

    Can you comment on this recent paper claiming that superstring theory is incorrect?
http://arxiv.org/abs/1209.5772

11. **Peter Woit**
September 27, 2012

    I've already deleted several off-topic comments today from people who want to discuss papers that make grandiose claims that are probably wrong, so should probably delete John's also. But since it's an overhyped claim about string theory, and it takes 2 minutes of looking at that paper to realize what is going on, here goes:

John,

The claims about superstring theory in that paper are nonsense. The paper is purely about classical physics, and the "string-like" classical field configurations discussed in it have nothing to do with quantum superstring theory, whatever it might actually be.

12. **Thomas**
September 28, 2012

Concerning Mochizuki's work: Aside the ABC conjecture, he writes about many other interesting issues, like his very interesting thoughts on how to see anabelian geometry, or on Arakelov theory and those deformations of number fields. As nice as a proof of the ABC conjecture would be, would such new ways to see things not be even more interesting?

13. **Deane**
September 28, 2012

Peter, I really hope Shouwu stays at Columbia but it's a tough choice for him. As for Mochizuki's claimed proof, he said that Mochizuki has to be taken seriously so he plans to work through the paper or papers very carefully.

14. **Jeff McGowan**
September 30, 2012

OK, question from a mathematician. I was bouncing around the links, and got from "Why String Theory" over to Joseph Conlon's homepage at Oxford. I glanced at his CV and noticed that he splits his publications into ArXiv and "other published papers" and the other papers consist of just 3, there are a whole lot of ArXiv papers. Do ArXiv papers really count in physics? I mean a mathematician would list ArXiv papers, even on a CV, but usually as "pre publications," and sometimes only if they have already been submitted somewhere. They certainly don't really count for anything, job wise. I can't imagine there's anyone in maths at Oxford who has only 3 refereed publications. I actually know of someone who didn't get tenure because they wouldn't count two papers that had been accepted but had not appeared yet.

15. **Paul Wells**
September 30, 2012

Peter,

Do you know if there has been serious attempt by the physics community to help Paul Frampton? Have there been any representations or petitions to the U.S or Argentinian governments ?

16. **tt**
September 30, 2012

looks like most of those arxiv papers are also published in peer reviewed journals

17. **Jeff McGowan**
September 30, 2012

tt, wow, right you are (well, more or less in one refereed journal, since almost all are in JHEP) Strange way to list them I guess, in math you wouldn't list ArXiv reference, though everything essentially is on ArXiv. Everyone just assumes that if for some reason you don't have journal access you'll just Google the paper to find the free version.

18. **Shantanu**
October 1, 2012

Peter and others,
people should have a look at Ed Witten's talk nearly 10 years ago
at Lepton photon 2003 symposium at Fermilab
http://vmsstreamer1.fnal.gov/VMS_Site_02/Lectures/LP2003/Witten/index.htm
He was worried that LEP had not discovered supersymmetry.

19. **Peter Woit**
October 1, 2012

Shantanu,

That talk was interesting, in that it was not just hype, but also explained some of the problems with SUSY. These have just gotten much worse since then (proton decay not showing up, flavor-changing processes not showing up, etc.)

"Looking back, for example, to the summary talk (by David Gross) at Lepton-Photon 1993, I see that by ten years ago SUSY was already described as the "standard non-standard theory" (he also gave a list of its successes and drawbacks rather similar to what I am explaining today) …. That is getting to be a long time."

If ten years is "getting to be a long time", what do you call twenty years?

20. **Michael Shain**
October 1, 2012

The Guardian of 27 September has a pithy blog posted by Lily Asquith: "Desperately Seeking SUSY"
http://www.guardian.co.uk/science/life-and-physics/2012/sep/27/susy-higgs-lhc

It sums up the present state of affairs very nicely.

21. **Clark**
October 14, 2012

Mochizuki has responded to the problem detected by Vesselin:

http://www.kurims.kyoto-u.ac.jp/~motizuki/Inter-universal%20Teichmuller%20Theory%20IV%20%28comments%29.pdf

Physics Frontiers Prize

October 1, 2012
Categories: Uncategorized

Yuri Milner's Fundamental Physics Prize Foundation announced today the process by which future winners of the $3 million Fundamental Physics Prize will be chosen (for more about this, see here), a process which involves setting up yet another prize, the Physics Frontiers Prize. The idea is that by the end of the year, the Selection Committee of previous prize winners will pick three winners of the new Physics Frontiers Prize, and these will be the candidates for the 2013 $3 million Fundamental Physics Prize. One of the three will get the $3 million, the other two will get $300,000 and automatically renominated for the $3 million prize each year over the next 5 years. So, I guess you might not want to win immediately, since if you get passed over the first time, you might end up with $3.3 million instead of $3 million.

There's also a separate $100,000 New Horizons in Physics Prize "targeted at promising junior researchers". Nominations for these two categories of prizes can be made by going to the Fundamental Physics Prize website.

The press release quotes Nima Arkani-Hamed, member of the Selection Committee as:

> This is a tremendous opportunity to recognize the highest levels of achievement in fundamental physics. We look forward to receiving nominations for outstanding candidates ranging across all areas of the field.

Arkani-Hamed is in India, where an interview with him appeared today (hat-tip an e-mail from him to Lubos Motl), with comments about the Milner prizes:

> I really think it's a fantastic thing for Physics—to have a showcase every year where scientists get to talk about the exciting aspects of the subject. I don't think any physicist or scientists are motivated to research by the thought of a prize or the money involved in it. But, it definitely helps in creating awareness among the youngsters, and encourages more people to take up the subject.

the Higgs:

> There are people trying to figure out the indirect effects between the different Higgs like particles. These are very difficult experiments and will take another 20 years before any confirmation is reached.

the future of particle physics:

> What's going on in particle physics is not just the evolution of the standard model but the rise of a new branch of physics that can solve some of the age old problems. Super symmetry is a very good example of what this physics should look like. For the first time we will have some evidence that there's actually really fine adjustments of the parameters of fundamental physics hardwired into the way nature works. This will be very shocking for many people and teach us something profound.

and string theory:

> In late 1990s one of the most important theoretical discoveries was that string theory and particle physics are not different but different descriptions of the same thing. All the good viable ideas people have had in the past 40 years are now branched together to seek the truth.

Update: Haaretz reports that Witten "said he would probably donate part of the $3 million he won in a surprise award to J Street, the liberal pro-Israel group."

Please note that any attempts to pursue, from either side, the Arab-Israeli conflict on my blog's comment section will be immediately deleted.

Update: Just realized that the Witten/J Street news is rather old, from shortly after the announcement of the original prizes. I didn't hear about it at the time, curious if there's other news about what plans the prize winner have for their winnings.

Comments

1. **Bob Jones**
   October 1, 2012

   I'd like to see these prizes awarded to more people like Kontsevich who do mathematical work. I'm thinking Connes and Drinfeld would be good candidates.

2. **Bob Jones**
   October 1, 2012

   Peter, I've noticed that sometimes you post quotes from string theorists without commentary. What are you implying exactly by quoting Arkani-Hamed on string theory?

3. **James Green**
   October 1, 2012

   @Bob Jones
   He posted the article…the context is pretty much obvious.

4. **Peter Woit**
   October 1, 2012

   Bob Jones,

   I'm not implying anything. We report, you decide…

   If you want my reaction to that quote, I think it's kind of a convention these days to refuse to acknowledge that string theory has failed as an idea about unification, and invoke AdS/CFT to try and argue that string theory now subsumes QFT. I don't agree.

   As for the "All the good viable ideas people have had in the past 40 years" business, I have no idea what he is referring to. Is string theory unification still viable? Is SUSY still viable post LHC? Are the extra dimensional models he became famous for still viable? Hard to tell. Given his current work on amplitudes, he may very well be referring to twistors, which now date from about 40 years ago and are very much a viable idea.

5. **Bob Jones**
October 2, 2012

"I don't agree."

You don't agree that string theory is a viable idea about unification, or that it subsumes QFT? Since string theory is a large-N limit of gauge theory, there is a sense in which string theory and particle physics are two aspects of the same thing. There's nothing technically wrong with that part of Arkani-Hamed's answer.

"As for the 'All the good viable ideas people have had in the past 40 years' business, I have no idea what he is referring to."

I'm not completely sure what he means here either. Probably he means that twistor theory, noncommutative geometry, supersymmetry, and supergravity were all successful ideas and loop quantum gravity was not.

You didn't mention the part where Arkani-Hamed refers to AdS/CFT as "one of the most important discoveries" of the late 90s. Does that mean you agree with him about that?

6. **chris**
October 2, 2012

"I don't think any physicist or scientists are motivated to research by the thought of a prizeI don't think any physicist or scientists are motivated to research by the thought of a prize"

i wonder if he kept a straight face saying this.

7. **Bernhard**
October 2, 2012

Bob Jones,

You mean IF (very big IF) "string theory is a large-N limit of gauge theory, there is a sense in which string theory and particle physics are two aspects of the same thing. "

AdS/CFT is an unproven conjecture, not a theorem.

8. **Bee**
October 2, 2012

Sounds like a good procedure if what you want is "more of the same."

9. **Peter Woit**
October 2, 2012

Bob Jones,

Yes, I agree that AdS/CFT was an important advance, a very interesting one. As for "string theory is a large-N limit of gauge theory", that's only understood at all for specific, very unusual conformally invariant theories such as N=4 SYM. For actual physical asymptotically free gauge theories like QCD, we still don't have an understanding of their large-N limit, in terms of string theory or anything else.

And even if string theory ever gives the large-N approximation to gauge theories, that just means that it's a useful approximation technique, not that it's the same thing as QFT. Again, I think what is going on here is an attempt to divert people's attention from failure.

10. **PMS**
October 2, 2012

@Bernhard:

Yes it is an unproven conjecture, but there now exist such a big mountain of extremely non-trivial and precise tests (and generalizations) of it that there is no doubt that there is some truth to the conjecture. But AdS/CFT correspondence is just the tip of the iceberg, the large N limit is an even smaller part of a much larger idea. The arguments for the holographic principle, by 't Hooft, relies on very general ideas that is independent of string theory but should be valid in any consistent theory of quantum gravity. The fact that there is a concrete realization in terms of AdS/CFT correspondence, is highly non-trivial.

I think it is completely fine to be critical of string theory, as any sane person should be, and even believe its highly unlikely to have anything to do with the physical reality. But its quite dishonest to be negative about anything that has to do with string theory just because you are against it due to some "religious" reasons, just like Motl is pro-string theory due to some "religious" reasons. One also has to acknowledge the fact string theory has certain success stories, in which AdS/CFT correspondence is just one (and it is very important since it gives a realization of the more general and possibly very fundamental principle of holography).

Sorry for the rant. I just got provoked by the "very big IF" comment, which either indicates you know nothing about the details of AdS/CFT correspondence or you are just as crazy as Lubos Molt. There are many things we know about physics which be believe in, which are not "proven theorems".

11. **Bernhard**
October 2, 2012

PMS,

Which "extremely non-trivial and precise tests " are you talking about? AdS/CFT has some interesting applications to heavy ion physics such as calculation of shear-viscocity, etc. I believe you are exaggerating with "big mountain of extremely non-trivial and precise tests". AdS/CFT should work for maximally supersymmatric theories, I see no way any test could be "precise" nor how do we have a "big mountain" of it.

In any case, I am not negative towards AdS/CFT at all. Quite the contrary, if there is any interesting result that came out of string theory to choose, it is definitely AdS/CFT. My comment was only that until the evidence in favor of AdS/CFT gets very compelling (and sorry to disagree with you here, we are not there yet for the simple reasons Peter mentions: What is the string or not-string dual of QCD in the large N-limit ?) using it as an argument for Strings = QFT is debatable to say the very least.

12. **PMS**
October 2, 2012

@Bernard:

no I do not consider the applications to heavy ion physics or condensed matter physics as tests of AdS/CFT. I don't even find them too convincing yet, but definitely potentially very interesting. There exist hundreds, if not thousands, of papers where very precise calculations has been done on both sides of the duality and 100 % match has been found (recent checks using localization are very interesting). If one thinks that AdS/CFT is only about N=4 Super YM in the large N limit, then one has stopped following the field since 1997/1998. There by now exist many other implementations of AdS/CFT, for example a new interesting development is a new conjecture of Gaberdiel and Gopakumar which relates higher spin gravity on AdS_3 to certain types of 2d CFT minimal models (so called W_N models). Here the dual theory is neither a gauge theory nor supersymmetric (the interesting thing is that the dual theory is essentially integrable, and thus one might possible be able to prove the duality in this toy model). There are of course many other generalizations which go very much beyond all this. Personally I have no doubt that there is something about this duality, the fact that you can derive OPE's, correlation functions, RG flows, partition functions etc. of highly interacting CFT's from pure gravity with 100 % match cannot simply be accidents. Especially since it works in many different generalizations which look very different from the original Maldacena conjecture, and don't even rely on string theory (at least in the limits where they are under control, for example the gravity side is classical).

Let me again emphasis that AdS/CFT correspondence is NOT just a strange duality which was found in string theory, and requires maximal supersymmetry (as you claim). The holographic principle has origins from black hole thermodynamics and information loss paradox, not string theory. In order to be consistent, 't Hooft proposed that gravity is in a certain sense non-local and one has to understand this non-locality in order to understand quantum effects. AdS/CFT is just one particular example that "proves" that 't Hoofts thought experiments where correct. Even if string theory turns out to be wrong, the holographic principle still stands!

Thus holography is not interesting because of string theory or applications to condensed matter physics, it is interesting because it is a generic feature of consistent theories of quantum gravity! I think many people misunderstand this and believe that holography is just a strange feature of string theory.

I am very sorry for this too long post, which contains too many repetitions.

13. **Peter Woit**
October 2, 2012

PMS,

There's no question that dualities in QFT are a fascinating and real phenomenon and well-worth investigating. That doesn't change the fact that there has been a huge amount of hype and mystification surrounding AdS/CFT, and I think it is this that Bernhard is reasonably reacting to. Instead of hype about heavy ions, high-temperature superconductivity, a solution to QCD, string theory and QFT "the same thing", etc., etc. it would be nice if people working in this area would stick to making claims that bore some semblance to reality. The kind of new relation between 3d and 2d QFTs that you mention is a nice piece of mathematical physics, but it and other advances of its kind don't support the sort of hype Arkani-Hamed and others are engaging in. Maybe it will someday lead to really understanding quantum gravity, but for now it has had no significant impact on our understanding of particle physics.

14. **vmarko**
October 2, 2012

@PMS:

Thus holography is not interesting because of string theory or applications to condensed matter physics, it is interesting because it is a generic feature of consistent theories of quantum gravity!

The crux of the matter, which a lot of people seem to be systematically avoiding, is really the following: what CFT (or otherwise) is dual to the ordinary general relativity in 4D, with a positive cosmological constant (or maybe zero cosmological constant)?

Until **that** duality is constructed explicitly, and until one can use it to calculate for example the entropy of an "ordinary" stationary Schwarzschild black hole in 4D, I don't quite see holography as a generic feature of quantum gravity (the most important/physically relevant one).

15. **Shantanu**
October 2, 2012

Peter, another OT comment.
I didn't see any single blog which mentioned about Leonid Grishchuk passing away (except on Peter Coles blog, but he was Grishchuk's colleague at Cardiff).
http://telescoper.wordpress.com/2012/09/14/r-i-p-leonid-grishchuk/
Was his work not well known among particle physicists?

16. **Peter Woit**
October 2, 2012

Shantanu,

I was not aware of Grishchuk's work, and I suspect he was little known among particle physicists, since his specialty was classical GR.

17. **Bob Jones**
October 2, 2012

"And even if string theory ever gives the large-N approximation to gauge theories, that just means that it's a useful approximation technique, not that it's the same thing as QFT."

I'm not sure what you mean here. The AdS/CFT correspondence does in fact say that string theory in anti-de Sitter space is equivalent to a quantum field theory. It sounds like you're defining QFT to be quantum chromodynamics, which is very strange…

"Again, I think what is going on here is an attempt to divert people's attention from failure."

So all those people working on AdS/CFT are just trying to distract us from the failure of string theory? Are you serious? What you're talking about here is the most important result of a forty-year research program and the most profound fact we know about quantum gravity. People are working on AdS/CFT because it's interesting. You make it sound like some sort of big conspiracy…

18. **Bob Jones**
October 2, 2012

"You mean IF (very big IF)… AdS/CFT is an unproven conjecture, not a theorem."

Bernhard, I am sorry, but it's very hard for me to take such concerns seriously. As PMS has already pointed out, there is an enormous amount of evidence that AdS/CFT is true. As a mathematician, I think rigorous proofs are very important, but there is no doubt in my mind that the correspondence is true and will eventually be proven. I think it's clear that Maldacena discovered a very deep relationship between two kinds of theories, and since this relationship is, to some extent, a definition of string theory, I'm not sure what it would mean for the correspondence to fail.

19. **Bob Jones**
October 2, 2012

"what CFT (or otherwise) is dual to the ordinary general relativity in 4D, with a positive cosmological constant (or maybe zero cosmological constant)?"

First of all, the AdS/CFT correspondence is essentially a result about quantum gravity with negative cosmological constant. You need that in order to talk about the conformal boundary of spacetime. There are things like the dS/CFT correspondence for positive CC, but this is not well understood. However, this does not make the correspondence uninteresting for people working on quantum gravity. It just means there are some cosmological problems that need to be worked out. It still gives you a nice dual description of quantum gravity on nearly flat spacetimes.

"until one can use it to calculate for example the entropy of an "ordinary" stationary Schwarzschild black hole in 4D, I don't quite see holography as a generic feature of quantum gravity"

Well, the holographic principle has actually been used to calculate the entropy of Kerr black holes via the Kerr/CFT correspondence. Since there are astrophysical Kerr black holes, this means that is does have some relevance to "real" gravitational physics. The AdS/CFT correspondence also shows up in three-dimensional quantum gravity as famously demonstrated by Brown and Henneaux, so I think it's fair to say that it is a very generic feature of quantum gravity.

20. **PMS**
October 2, 2012

@Peter

I could not agree more, string theory is without any doubt the most hyped field in physics. This hype has shortsighted advantages, but on the long run will just turn other physicists against the field. Personally I encourage people to fight this hype, but not turn against a field only based on that. I dislike all arguments for or against string theory, which are purely based on 1) feelings, 2) ignorance or just 3) craziness. For example Lubos Motl is a master of 3), even though he is ridiculously smart. I think string theory has put forward many new and deep insights, both of technical nature but also more importantly, conceptual ones.

Regarding the new AdS3/CFT2 dualities. I don't agree that these are only relevant for mathematical physics, they are toy models which show that holography works exactly as one expects even when there are no supersymmetry, gauge theory etc. and thereby putting the whole framework on a more solid state. It might also give hints about certain conceptual question we still don't understand, such as how does the extra dimension emerge from from the boundary point of view and how can we prove the duality? Toy models have played extremely important roles in the history of physics and still do. The Ising model and phase transitions is an famous example.

But let me repeat that I do share much of your frustration and worries about the state of the field, at least to some extend.

@vmarko:

First of all, the dual theory to our 4D universe/black holes are most likely not CFT's. The asymptotic symmetry of AdS is conformal group (and the whole Virasoro algebra, for AdS3), which is the reason the dual theory "on the boundary" has to be a CFT. AdS nor CFT are necessary for holography, since the principle should hold much more generally.

Regarding your point. Finding such a dual QFT is a very very difficult problem, not only due to technical difficulties but also because there are many conceptual problems about quantum gravity we need to understand better. The power of the holographic principle comes from the fact that it relies on quite general assumptions which are generally agreed upon, such as validity of General Relativity, Quantum Mechanics, black hole creation/evaporation is a unitary process and so on (http://arxiv.org/abs/gr-qc/9310026). This a conceptual breakthrough that deserves more detailed study. It takes time to understand these questions good enough to be able to calculate (microscopically) the entropy of the Schwarzschild black hole.

What I don't understand is, why do you believe the general arguments/thought experiments which form the basis of black hole thermodynamics. But you refuse to consider very similar types of arguments which form the basis of information loss paradox and the holographic principle…?

21. **Tmark48**
October 2, 2012

So in the end, real physicists (experimentalists and theoreticians) will still look forward to the Nobel prize, the rest will have to do with the Milner "pseudo-science" prize.

> One of the three will get the $3 million, the other two will get $300,000 and automatically renominated for the $3 million prize each year over the next 5 years.

Why on earth are the same candidates to be "automatically" renominated every year for the next 5 years. What kind of stupid decision is this ?

22. **Bob Jones**
October 2, 2012

vmarko,

I should also mention that the argument of Brown and Henneaux shows that any consistent theory of quantum theory of gravity in three-dimensional anti-de Sitter space has a CFT dual. It has nothing at all to do with string theory. When Strominger and Vafa used the holographic principle to compute the entropy of a black hole in string theory, their argument appeared to depend heavily on the details of string theory, but we now know that the holographic principle can be used to compute black hole entropy in any consistent unitary theory of gravity that admits black hole solutions.

23. **vmarko**
October 2, 2012

@Bob Jones:

First of all, the AdS/CFT correspondence is essentially a result about quantum gravity with negative cosmological constant.

That is precisely my point. The observed value for the cosmological constant is actually positive. So until someone successfully constructs the "dS_4/CFT_3" correspondence, I am not buying holography as a relevant principle of quantum gravity, let alone generic.

However, this does not make the correspondence uninteresting for people working on quantum gravity. It just means there are some cosmological problems that need to be worked out.

How do you plan to work out that "cosmological problem" of the wrong sign of CC? There is a very big jump from a noncompact to compact topology lurking in there. I am yet to see any serious proposal regarding this.

Well, the holographic principle has actually been used to calculate the entropy of Kerr black holes via the Kerr/CFT correspondence. Since there are astrophysical Kerr black holes, this means that is does have some relevance to "real" gravitational physics.

Umm, no, those are the **extreme** Kerr black holes, not the astrophysical ones, precisely because one needs the AdS structure. The only thing that even comes close to calculating the entropy of a BH with a small or zero angular momentum is arXiv:1004.0996, and the authors there openly admit that they still lack a tight argument for non-extreme angular momentum.

The AdS/CFT correspondence also shows up in three-dimensional quantum gravity as famously demonstrated by Brown and Henneaux, so I think it's fair to say that it is a very generic feature of quantum gravity.

Three-dimensional as in 2+1 spacetime dimensions? The theory which actually has no gravity inside? No propagating degrees of freedom? Theory where spacetime is always flat? Wow! 🙂 There are many very nice features of 2+1 gravity (for example, the absence of gravity…) that do not carry to four dimensions. Whenever I hear this kind of an argument, my basic reply is "3=/=4".

My point is that all examples of quantum gravity where holography principle holds turn out to be examples of **wrong or irrelevant** theories of quantum gravity. It is therefore quite far-fetched to call holography a "generic feature" of quantum gravity, since the main, physically relevant example is completely absent. In addition to that, there are many quantum theories of gravity (LQG, spinfoams, CDT, etc…) which do not have any connection at all to the holography principle.

I'd say holography is far from universal, and actually holds only in some neat example theories, but not in general.

24. **vmarko**
October 2, 2012

@PMS:

What I don't understand is, why do you believe the general arguments/thought experiments which form the basis of black hole thermodynamics. But you refuse to consider very similar types of arguments which form the basis of information loss paradox and the holographic principle…?

Well, shortly put, because BH information loss paradox has many possible avenues where a solution might appear (none completely satisfactory, of course). So I simply do not see holographic principle as the only possible resolution of the paradox. It indeed is one of the possibilities, but not the only one.

Of course, every opinion on an open question is based on intuition, general philosophical POV on what is important in Nature and what isn't, prejudices from early youth, etc… 😉

Don't get me wrong — I am not advocating that holography is dead wrong or uninteresting or something. I am just saying that "holography is a generic feature of quantum gravity" activates my "hype-overflow" alarm… 🙂

25. **Bob Jones**
October 2, 2012

"How do you plan to work out that "cosmological problem" of the wrong sign of CC?"

This is obviously a very important open question. I'm just saying that if you want to study short distance effects in quantum gravity (scattering of gravitons, etc.), then the solution is in principle given by the gauge-gravity correspondence.

"Umm, no, those are the extreme Kerr black holes, not the astrophysical ones"

In the paper arXiv:0809.4266 [hep-th] where the Kerr/CFT correspondence was first introduced, the authors point out that nearly extreme Kerr black holes have been observed in the sky, and they give GRS 1915+105 as an example. For such black holes, any corrections to the dual CFT representation should be small.

"The theory which actually has no gravity inside? No propagating degrees of freedom? Theory where spacetime is always flat?"

Actually, it does have gravity. The classical solutions of Einstein's equations in three spacetime dimensions are not flat; in fact they include black hole solutions. This makes three-dimensional gravity an important and nontrivial toy model for studying general features of quantum gravity.

"My point is that all examples of quantum gravity where holography principle holds turn out to be examples of wrong or irrelevant theories of quantum gravity."

All I can say is you're not going to get very far in your understanding of nature if the only theories you're willing to consider are completely realistic. Sometimes it's useful to study theories with certain simplifying assumptions.

26. **vmarko**
October 2, 2012

@Bob Jones:

I should also mention that the argument of Brown and Henneaux shows that any consistent theory of quantum theory of gravity in three-dimensional anti-de Sitter space has a CFT dual.

Sure, I know, but a 3D theory just doesn't cut it, IMO. 3D gravity is far too featureless (compared to 4D gravity) to be persuasive enough. I understand that some people consider it a strong hint, and it is a valid research topic, but I just don't share the opinion that holography principle is a settled matter.

27. **Peter Woit**
October 2, 2012

Please all,

There's some sort of law of nature that causes all discussion about theoretical physics to devolve into discussions of quantum gravity. Enough of this here for now please, it's completely off-topic.

28. **Stephen**
October 2, 2012

Obviously, you use the first 300K to hire two hit men (and a bodyguard).

29. **Bob Jones**
October 2, 2012

Just a small correction, if Peter will allow it. If we're talking about the vacuum Einstein equations in three dimensions with vanishing cosmological constant, then vmarko is correct in saying that the space of classical solutions is the space of flat metrics. I was just saying that three-dimensional gravity is interesting despite the unphysical simplifying assumptions.

30. **Peter Woit**
October 2, 2012

Bob Jones,

In my "what is going on here" remark the "here" is the topic of the posting, i.e. the quote from Arkani-Hamed about AdS/CFT meaning string theory = particle physics, not this area of research in general. I don't actually think there's any sort of sensible statement of any kind that can be applied to the general topic of research related to these dualities. By now, this involves probably tens of thousands of papers, with topics spanning the range from vague nonsense that belongs in the beyond the fringe science category to very serious mathematical physics, with everything in between.

To say something sensible, you need to pick a specific conjecture. Even for the one very specific original case of AdS/CFT, meaning superstrings on AdS^5xS^5/N=4 SYM, there's more and less meaningful conjectures to discuss. Since you don't know what non-perturbative string theory really is, making your conjecture to be vacuously true at weak CFT coupling by defining non-perturbative string theory = the right QFT isn't really something to promote as a great success.

31. **Bob Jones**
October 2, 2012

Tmark48,

Which of this year's winners is doing "pseudo-science"? What's your definition of a "real" theoretical physics?

32. **Bob Jones**
October 2, 2012

Peter,

I think the statement is not that string theory=particle physics but that string theory and particle physics are two aspects of the same thing. In other words, there is a common mathematical idea underlying them, namely gauge theory. If that's what Arkani-Hamed meant, then I don't think there's anything technically wrong with his answer.

33. **Peter Woit**
October 2, 2012

Bob Jones,

The question Arkani-Hamed was asked was:

"String theory or standard model, which offers a better explanation to our quest to understand the universe?"

Clearly the questioner was asking about the well-advertised claims for unification via string theory. Not answering "the standard model" to this is just intentionally misleading and less than honest. You can try and argue that the formulation "string theory and particle physics are not different but different descriptions of the same thing." is not technically wrong, but I think that's a strained argument. What Arkani-Hamed is doing here is just throwing sand in the questioner's eyes, trying to exploit conjectural and poorly understood relations between strong coupling QCD and string theory + true by definition conjectures about non-perturbative string theory being QFT to avoid acknowledging the obvious (standard model= huge success, string theory unification = miserable failure).

34. **Allan Rosenberg**
October 2, 2012

Peter,

Maybe the best strategy for broadening the scope of the prize beyond string theory is to nominate experimentalists. The only name that springs immediately to my mind is Alain Aspect, but surely somebody who reads this blog has to know who the top experimentalists are at CERN, for example.

I have to admit, though, that, just for laughs, I did toss Gordon Kane's name into the ring.

35. **MathPhys**
October 2, 2012

I was thrilled to read that the failure to explain the mass hierarchies using supersymmetry is an exciting development.

36. **anonymous**
October 3, 2012

"Maybe the best strategy for broadening the scope of the prize beyond string theory is to nominate experimentalists. The only name that springs immediately to my mind is Alain Aspect, but surely somebody who reads this blog has to know who the top experimentalists are at CERN, for example."

Of course Alain Aspect shared the 2010 Wolf Prize in Physics with John Clauser and Anton Zeilinger. All three of them as well as a dozen people working on the same or similar problems could get a Nobel Prize in the next year or 5. The trouble is that they are all at or approaching 70, not ideal for a New Horizons in Physics Prize.

If you want to step way outside the mainstream and award the Fundamental Physics Prize to an experimentalist whose work would be truly fundamental but would otherwise go completely unrecognized or dismissed, you could go with Yves Couder, Michel Gouanère, heck even a new unknown like Silke Weinfurtner for New Horizons. I'm certainly not going on record to nominate any of these people.

For experimentalists at CERN, look away from the LHC. You're just as likely to see some fun new stuff from Antiproton Decelerator physics, [any of the spokespeople](). Also very much looking forward to [ELI's]() fundamental science.

37. **A.**
October 3, 2012

@anonymous

Um, I'm not sure if the final line of your comment was a joke or not…. 🙂 Point is, the "fundamental science" part of ELI is almost certainly not going ahead. (For those not in the know: they were going to build a super-duper laser to do QED experiments with.) There are essentially two reasons why this project is imploding.

1) There's not much money around.

2) wait for it… too much _hype_ on the part of the guys pushing it. It's true. In an attempt to gather cash they went down the "flashy publicity" route, promising that they would "rip the vacuum apart" and other sensationalist fluff, and the community got fed up of hearing it. Those guys are increasingly regarded as crackpots who are hindering the field much more than they are helping it.

38. **anonymous**
October 3, 2012

Not a joke… just optimism. Maybe [this]() presents the more tempered version of the claims.

39. **M**
October 3, 2012

Physics is understanding nature. Awarding popular but wrong ideas with millions of $$$ surely is an exciting social game. But it is bad for good physics.

40. **Guy**
October 3, 2012

Edward Witten, according to Haaretz, plans to "donate part of the $3 million he won in a surprise award to J Street, the liberal pro-Israel group". So it's good the money's being used for peace.

On Lubos Motl's blog I commented on his 'Harvard' post this week. My comment was a direct excerpt of Witten's 2005 article from here:
http://peacenow.org/entries/archive296#.UGwdyq7DuuM in which he criticises Israel settlement building.
But Motl has blatantly deleted my 2nd comment in which I clarify Witten wrote that excerpt in 2005 (see for yourself), and called me an anti-Semite and because I agree with Witten's views. He has gone to the extent of saying my 2nd comment stated Witten wrote the comment today, which is a lie.

I hope Peter Woit you are open enough to publish this above material so it's clear I don't lie and who actually does. $3 million to be put in J Street shows it anyway.

41. **Tmark48**
October 3, 2012

@ Bob Jones :

Of course there is no such thing as a real theoretical physicist (as opposed to a false theoretical physicists). I just wanted to underline the fact that very few theoretical physicists are awarded the Nobel prize. And there is a reason for this, it's not just because the Nobel committee hates theoretical physicists. Theoretical physicists build models, models that are used to understand nature around us, models that CONNECT to experimental results and hopefully explain them by giving us a framework around which to understand those phenomena. And better yet, not only understand but predict new kinds of phenoma to be experimentally tested.
When such models are verified by experiment then those physicists are worthy of the Nobel prize. Does every theoretical physicists under the sun deserve a Nobel prize (because he is working on QLG, or some other exotic topic that will never ever in our lifetimes be even near to be experimentally explored) ? Of course not. Model building alone is not science, it is only a part of science, and without experiments you're left only with a nice scaffold and no content.
Conceptual revolutions are not a dime a dozen. They are very very rare in the history of science, and just because the 20th century happened to witness 2 such revolutions doesn't imply that every generation has to have such a conceptual revolution. Theoretical physicists exploring exotic topic today live in a bad era. An era were experiments cannot probe at all the "predictions" these model builders are advocating.
Maybe in a future, some theoretical physicist will come up with a new conceptual revolution and experiments at that time will corroborate his findings. Good for him, he will be awareded the Nobel prize. The rest are just collateral damage.

42. **Peter Woit**
October 3, 2012

Tmark48,
Some thoughts about this:

Given that theoretical particle physics is in some sense a victim of its own 20th century success, with new experimentally testable insights much harder to come by, if the Nobel committee sticks to the experimentally verified there will be fewer and fewer particle theory Nobelists around. Already, they're almost all getting pretty old, and even if Higgs et al. get a prize soon, that won't improve the age distribution. One could argue that standards for the prize need to change, with smaller increments of progress rewarded, including progress that moves us towards something experimentally testable, even if it doesn't get there. I think this idea is the sort of thing Milner is trying to do.

The problem then becomes: without experiment to keep you honest, how do you judge what is significant progress and what isn't? In a field of difficult to understand research, how do you stop prizes from going to those who are loudest and most politically savvy, rather than to what is truly significant? Knowing what is truly significant may well be beyond anyone's ability to judge. I don't think the Nobel committee should change its standards unless they can figure out how to resolve this problem, and I think Milner's decision to create extraordinarily large new prizes without addressing this problem is unwise.

Much of the story of the last 30 years is one of a huge investment of the particle theory community in a heavily overhyped research program that now has conclusively failed, with the death of hopes for electroweak-scale SUSY the final nail in the coffin. Leaders of the HEP theory community need to acknowledge this failure and draw some lessons from it, not be rewarded extravagantly for behaving like Arkani-Hamed, claiming all is well and refusing to acknowledge what has happened.

43. **Peter Woit**

October 3, 2012

Oh, and one more thing: the problem is not insoluble. Mathematicians have always lived without experiment to keep them honest, and manage to recognize and reward progress. They do have proof to keep them honest though…

44. **Friend**
October 3, 2012

Maybe if physics could be derived on the basis of logic alone, then we might have means of proof to keep physicist honest too. But who knows what logic reality could be based on, right?

45. **Tmark48**
October 3, 2012

@ Peter Woit :

I agree with you. Theoretical physicists can and should be awarded prizes. The thing is what do these prizes stand for ? If a theoretical physicist is awarded the Nobel prize then there is no way to take out the experiments from the equation. The Nobel prize not only awards the model building aspect but also the connection with experiments. Einstein was awarded the Nobel prize for the photoelectric effect and not for general relativity, even in the light of the Eddington expedition that "confirmed" one of general relativity's prediction. And the reason being that the results still had a noticeable margin of error that could invalidate Einstein's theory. So the Nobel committee was correct in its assessment as crazy as it may seem today. Of course general relativity was tested again and again many decades after Einstein getting the Nobel prize, and many decades after Einstein's death. Nowadays no one would think that general relativity is invalid and rightly so.

—

Theoretical physicists can be awarded different kinds of prizes. Clarification of mathematical principles that underlie physical theories, developping new mathematical tools for carrying out complex physics calculations, developping new mathematical frameworks etc… All these things can be recognised and awarded. But it cannot be called a physics science prize. A mathematical prize yes, but the moment you say physics prize it implictly assumes that those complex theoretical calculations in one way or another connect to experimental data.
—
Mathematicians are beholden to the concept of a mathematical proof which is a much more stringent criterion than what goes around in the physics community. Just because mathematicians deal with abstract objects doesn't mean they can prove arbitrary things.

46. **Bob Jones**
October 3, 2012

"Theoretical physicists build models… When such models are verified by experiment then those physicists are worthy of the Nobel prize."

Obviously, one needs experiments to test out new theories, but there's so much more to theoretical physics than model-building and predictions. After all, Noether's theorem is one of the most famous results of twentieth century physics, but there's no sense in which it's a "prediction" or something that needs to be tested. It's a purely formal statement about classical mechanics which can be proven mathematically, and when you formulate quantum mechanics, it's basically true by definition.

There are many other important results in physics that have nothing to do with predictions. Lagrangian and Hamiltonian mechanics are just reformulations of Newtonian mechanics, but they're among the most important theoretical tools that physicists use, and they provide the proper framework for understanding quantum mechanics. The technology of Feynman diagrams is another example. It's not a "prediction" or a "model" but an alternative point of view on quantum mechanics which is extremely important for making predictions.

I'm all in favor of people making testable predictions, but I think we should recognize more formal kinds of theoretical work as well. I think it would be disastrous for physics if everyone just tried to randomly guess how nature works.

47. **Bob Jones**
October 3, 2012

In response to your comments about mathematics, I should add that none of the formal work being recognized by the Milner prize is mathematics in the strict sense. Quantum field theory and string theory are not mathematics because they are based on abstract notions that do not exist mathematically. The notion of a Feynman integral is not something that you can make precise in full generality. It is an essentially non-rigorous, heuristic idea, and as such, it is not something that mathematicians can study. Quantum field theory and string theory have, of course, had a huge impact on mathematics, but that's because physical intuition has led to conjectures that have been recast in the precise language of mathematics.

48. **vmarko**
October 3, 2012

I completely agree with Bob Jones that there are some extremely important and insightful theoretical advancements in physics which have (by their nature) no relation to experiment. It's not mathematics, and yet it's also not experimentally testable stuff. So this kind of work does not qualify neither for the Nobel prize nor for the Fields medal, loosely speaking.

This is the void that Milner prize seems to fit in. While I don't exactly support the method for the winner decision process, the Milner prize still seems to have some legitimacy, because it aims to reward scientists which have given important theoretical contributions, but would be missed both by the Nobel and the Fields.

In that light, the idea seems to be legit and good. The implementation, however, isn't that great IMO.

49. **Anonyrat**
October 3, 2012

Feynman diagrams took off because Feynman used them to make precise QED computations, not because they were generically interesting.

50. **Anonyrat**
October 3, 2012

Likewise the Noether theorem gave a deeper insight into laws that were already known to be experimentally true.

51. **Bob Jones**
October 3, 2012

Anonyrat,

Yes, of course. They are a computational technique, just like the field theoretic dualities that people work on today. I was just saying that the method of Feynman diagrams is not itself a prediction or something that requires experimental confirmation.

52. **Bob Jones**
October 3, 2012

And about Noether's theorem, yes, I understand that. I was giving examples of results of physics that were formally deduced from pre-existing theories. These results are "mathematical" in that they do not postulate new physics.

53. **Peter Woit**
October 3, 2012

Anonyrat/Bob Jones,

Enough, go watch the debate or something…

54. **Peter Woit**
October 3, 2012

Guy,

Thanks. I added a link to the Haaretz story. Your comment was caught for a while in the spam queue. I had noticed earlier today that Lubos Motl was calling for your death based on the quote he didn't realize was from Witten. I guess you and Witten can join me and Smolin in the club…

As noted in the update: I want no part of the behavior that discussion of the Arab-Israeli conflict brings out in people. If you can make an interesting comment about the news of Witten's choice of what to do with his money without trying to score points for the Israelis or the Palestinians, that's fine. Otherwise, go argue about this elsewhere.

Oh, just realized this is rather old news, from early August…

55. **Anonyrat**
October 4, 2012

The Milner Prize for physics makes the World Wrestling Federation seem respectable, and that is an on-topic assessment (see Peter, what happens when you tell people to watch the debate….).

56. **Guy**
October 4, 2012

Thanks for the reply Peter and I'm still alive and in the club despite someone's death threat. To me any true physicist can't escape politics/justice issues which explains why we might see prize money going in part to social causes. Didn't realise article was from August.

On a side note, it's funny that you would need to solve 3 Millenium Prize problems to get the same money as Milner Prize. And even more ironic is that Milner Prizes have gone for string theory achievements, which itself is so much maths than experiment till who knows. At the end of the day it depends whether the billionaire likes tea or coffee.

57. **fuzzy**
October 5, 2012

the words can be misleading. apparently, these people speak of physics in the same sense as galilei, newton, einstein, pauli did… but even in finance and in mathematics the same word "derivative" is used, but the sense is slightly different

58. **Clyde Davies**
October 5, 2012

I have to say I think this prize is a stupid idea. There's too much speculation going in physics right now anyway, and not enough consolidation and verification. Why encourage, let alone reward it? But what would I know … I'm a chemist.

59. **Yatima**
October 6, 2012

For people interested in where the rubber hits the road there is a (too short – 4 pages) article in IEEE Software of September/October. "The Software behind the Higgs Boson Discovery" by David Rousseau, who managed Atlas offline software until March 2012 (http://ieeexplore.ieee.org/xpl/articleDetails.jsp?arnumber=6276293). IEEE has it hidden behind a paywall, but some google-fu may elicit a "liberated" version.

News from this weekend include the announcement that the Templeton Foundation is sponsoring the search for Dyson spheres (http://www.theregister.co.uk/2012/10/05/dyson_sphere_search_wins_funding/). This is has been done before with no conclusive results (http://iopscience.iop.org/0004-637X/698/2/2075/)

60. **Armin Nikkhah Shirazi**
October 8, 2012

I wonder whether the establishment of this new prize reflects the possibility that originally the FPP was offered to more than 9 people, since there is then enough money for 10 Frontiers prizes left over for each declined FPP, and if anyone really did decline, it would be really interesting to know the reasons for doing so

61. **Peter Woit**
October 8, 2012

Armin,

I have it on good authority that no one declined the prize. The amount of money to be devoted to these prizes I think is just Milner's choice: he isn't working with a fixed sum of money, but can devote some more to the prizes if he sees a good reason. The new prizes are probably an idea he liked that came up while trying to figure out the details of how best to choose the next year's winner (it's not at all obvious how to best have 9 people vote on this, having a "run-off" like this is one way to go).

Physics Nobel Prize 2012

October 8, 2012
Categories: Uncategorized

I had decided to retire from the Nobel Prize prediction business at the top of my game after my first prediction soon after this blog was started. I haven't heard anything about what tomorrow's announcement will be, but did just notice something that gave me pause, this quote in a Cosmos magazine article:

> "There's nothing stopping us from giving the prize to an organisation. But it has not been the custom in the scientific prizes," said Lars Bergstroem, secretary of the committee for the Nobel physics prize.
>
> "The Nobel Peace Prize has often been awarded to organisations. But in the science prizes we have tried to find the most prize-worthy individuals."

If there really is nothing but custom to keep them from awarding the Nobel this year to ATLAS, CMS, and CERN for the Higgs, I can't see a better occasion to break with the custom, and they've had a long time to decide whether or not to do this. So, here's a (probably wrong…) prediction for tomorrow: ATLAS, CMS and CERN as Nobelists.

Update: As predicted, that prediction was wrong: the prize went to Haroche and Wineland for work manipulating individual quantum states. Maybe next year for the Higgs…

Comments

1. **Garrett**
   October 8, 2012

   No way — too impersonal.

2. **no clue**
   October 8, 2012

   It's too soon to give a prize for the Higgs. But we'll find out soon enough. I'm willing to make a prediction it won't be Anderson, though.

3. **David Derbes**
   October 8, 2012

   I think Higgs, Englert and a surprise. Woulda been Higgs, Englert and Brout had Brout not died. Might be Anderson, might be out of left field, might just be the two of 'em. Could be Tom Kibble, I guess.

   If the Nobel folks wait till next year, and both Higgs and Englert die before October 2013, it will not reflect well on the committee and hence on the Prize. I'd be happy to see the ATLAS and CMS teams honored, but let's give the old guys their long-awaited prizes while we can, i.e. while they're still breathing. (I'm not impartial about this; Peter Higgs was my thesis supervisor.) I don't think it's too soon; you have evidence from three experiments (including Fermilab) and the damned thing was postulated nearly half a century ago. On the contrary, it may soon be too late.

4. **Bob Levine**
   October 8, 2012

   @David Derbes

   Good point! But Peter's point about the merits of awarding the LHC teams the prize seems persuasive as well. Why can't we have it both ways? The practice behind the Nobel group prizes, in the case of the Peace Prize, shows that such groups constitute a single (corporate) individual for prize purposes. So two individuals plus one group, or one individual plus two groups, should—going by the statement from the Nobel committee spokesman that Peter cited—have the same legitimacy as a Nobel award as giving the prize to three individuals, which they've certainly done in the past.

   So Higgs, Brout (or Higgs/Anderson or…) and the collective LHC experimental team would be a legitimate triple under this investigation. That would answer Garrett L.'s objection, and more importantly, would recognize that this extraordinary discovery has been a collaboration between brilliantly gifted individual theorists and spectacularly skilled experimental teams. It's time that the Nobel committee acknowledged, in their prize-awarding, that it's the irreducible collaboration between both sides of the line that leads to the great breakthroughs in the modern phase of HEP research….

5. **ckm**
   October 8, 2012

   Many Nobel Prizes are controversial (and I refer to physics, not peace). Consider the award to Kobayashi and Maskawa for the CKM matrix, omitting Cabibbo, who was still alive at the time. (The third recipient was Nambu.) That certainly reflected poorly on the committee. So `reflecting poorly' doesn't dictate the committee's decisions.

6. **Avattoir**
   October 8, 2012

   The quotes in the Cosmos piece include some obviously wrong (Brout's disqualified as dead.), and some just cryptic. But I'd put at least even money that our host is wrong on it being split among the three orgs. No way the committee awards for finding the Higgs without at least also honoring it's namesake. Two, more likely one org at most.

   Since it's still "Higgs-like" at this point, why not give all 6 surviving predictors a "Nobel-like" prize?

   Walter Haig's famous comment might pertain here: asked by a reporter why he was still partying it late night before the last day of an Open championship when the leader had gone off to sleep hours previously, Haig said: He may be in bed, but he ain't sleeping. It's just after 3 a.m. in Scotland right now; wonder if Peter Higgs is sleeping.

7. **Thomas Larsson**
   October 8, 2012

   I saw somewhere that only discoveries made before Dec. 31, 2011, can be awarded the prize. Higgs and Englert of course fulfil this criterion, but the experimental discovery does not. We will see.

According to the same reference, a NEW frequenter could be a hot candidate. (Hint: his first name is Peter and his last name consists of four letters).

8. **th-expt**
October 8, 2012

There will be separate prizes for Higgs theory and experiment. This has happened before. Glashow, Weinberg and Salam won for the electroweak theory in 1979, Rubbia and van der Meer won in 1984 for actually producing and detecting the W and Z. Lamb and Kusch won in 1955 for the Lamb shift and electron anomalous magnetic moment (expt), Feynman, Schwinger and Tomonaga won 10 years later in 1965 for renormalization of QED (theory). I believe Nobel prizes were awarded for experimental work on the photoelectric effect (not sure about this), Einstein won in 1922 for his theoretical explanation. Wien won for his expt work on blackbody radiation, Planck won for his theory of blackbody radiation.

9. **Grad student**
October 8, 2012

My money is on Clauser, Aspect and Zeilinger for entanglement. I think particle physics will need to wait a bit.

10. **AJK**
October 9, 2012

I vote for separate prizes for experiment and theory. The question is, how embarrassed would we be if Higgs (and others?) won the prize, and the particle turned out to not be SM Higgs, but some variant. How far off would make the prize seem, in retrospect, like a bad idea?

If what we've seen already is enough, sure, give it out, Higgs has waited long enough. We just need to acknowledge that this isn't necessarily a prize predicated specifically on the discovery of the Higgs, just one that acknowledges the colossal influence on particle physics that Higgs et al. have had, and that this has led to an important discovery which may or may not be SM Higgs.

11. **egan**
October 9, 2012

@grad student

I'm with you on this prediction. Aspect, Clauser and Zeilinger shared the Wolf prize in 2010 and it's often a hint of future Nobel prizes.

12. **BEC**
October 9, 2012

How about we remember that experiemental verification and demonstrated benefit are also part of the criteria. So far they have "Higgs like" particles. Perhaps it might be the year for an experimentally reproduced, novel discovery like that made by Lene Vestergaard Hau and team at Harvard. Stopping light in Bose-Einstein Condensates, turning it into matter, placing information on the copy, storing it, and re-converting it into light are all verified. The applications for quantum computing systems of the future are staggering.

13. **Colin Rosenthal**
October 9, 2012

I'm slightly amazed that Vera Rubin has never received a Nobel.

14. **David Nataf**
October 9, 2012

Peter,

Have you described your rationale somewhere for why the Higgs nobel prize should go the experimental groups that measured the Higgs, rather than the theorists who both postulated the Higgs, and computed how it could in principle be measured?

15. **David Nataf**
October 9, 2012

Colin Rosenthal,

The gravitational effects of dark matter were first inferred in 1933 by astronomer Fritz Zwicky, an eccentric figure who got a lot of things are right but was not as well respected (in his time) as his accomplishments would suggest.

http://en.wikipedia.org/wiki/Fritz_Zwicky

That might be why dark matter has not received a nobel prize. It could also be that the nobel prize committee isn't convinced dark matter is real, they may think modified gravity is still plausible and are awaiting experimental confirmation from "direct detection" experiments.

16. **MathPhys**
October 9, 2012

Minutes to go and I put my money on "Higgs related", with CERN as part of it as well.

17. **jon**
October 9, 2012

Just out: Serge Haroche and David Wineland, quantum optics…

18. **MathPhys**
October 9, 2012

Well, there is an element of lack of imagination here on part of the Nobel committee.

19. **fuzzy**
October 9, 2012

yes i also vote for a prize to the final proof of that model that was proven to be wrong by neutrino oscillations.

20. **Guy**
October 9, 2012

    Oh My God Particle…you weren't chosen this year!

21. **no clue**
October 9, 2012

    It's just a mistake to think that HEP is all of physics. There's a lot more going on in physics. So what if there was a big announcement at ICHEP in July? The Higgs particle has just barely been discovered, basic checks that it is the SM Higgs still need to be quantified. If the theorists are old, that's too bad.

22. **Tmark48**
October 9, 2012

    @ no clue : you can say that aloud that HEP is not all of physics.
    I'm happy that the Nobel prize went to people working in quantum optics. It's kind of sad that most mainstream expositions of "physics" are all about HEP, Strings and other highly controversial (as in not connected to experimental evidence) subjects.
    I'm sure that the HIGGS discovery will be rewarded, it's too big of a deal not to but it will have to wait for a full review on the properties of these so called HIGGS-like particles. We still don't know if what was discovered was a SM HIGGS at all. So good for the Nobel Committee not bowing down to hype.

23. **Peter Woit**
October 9, 2012

    David Nataf,

    The argument for priority of an experimental Higgs award over a theory one is mainly that the relevant theory one has already been given (to Weinberg/Salam for electroweak unification using Yang-Mills + Higgs mechanism). It's the Weinberg-Salam Lagrangian, extended to include quarks and QCD that determines the behavior of the predicted SM Higgs. There has been a lot of discussion about exactly who among the people who worked on the "Higgs mechanism" back in 1963-4 deserves a Nobel for it, but that work was on Abelian models pretty far from what is being seen now at the LHC (if it really is a a Higgs…).

    All in all, I think HEP theorists have a very high profile and get more attention than they deserve. In this case the huge recent development is the discovery of a new particle by the LHC experimentalists, in a technical tour de force. That deserves a Nobel if anything in HEP does. Maybe it is too recent, so needs to wait a year to satisfy the Nobel rules about that. Maybe the lack of specific people to give the prize to is an impediment that can't be overcome.

    In any case, the actual award is an interesting sign of the times, with attention in physics moving from HEP to techniques for manipulating quantum systems at a fundamental level.

24. **Phil**
October 9, 2012

    Leaving GHK off will be controvery enough in 2013. Politically too many people in Europe are pushing for Englert and CERN to now snub them. If they can award it to CERN they can modify the statutes to ensure all the theorists get recognized as well. 1964 PRL paper quality (GHK) should be considered at least as much as submission dates (Englert) and boson naming (Higgs).

25. **El-Coco**
October 9, 2012

    Every year Guth doesn't win the prize moves ever closer to being absolutely meaningless.

26. **Tmark48**
October 9, 2012

    @ El-Coco : didn't Alan Guth just win Milner's Fundamental Physics Prize ?
    I'd say we was rewarded handsomely for his theoretical breakthrough.

27. **Zathras**
October 9, 2012

    El-Coco,

    Nobel Prizes are almost always given for ideas that have both strong experimental evidence and a firm foundation in theory. Inflation certainly has the experimental evidence, but there is not enough of a firm theoretical underpinning of inflation for it to qualify.

28. **no clue**
October 9, 2012

    I have a question to the assembled company: has the recently found particle at 125 GeV been verified to have spin zero?

29. **Peter Woit**
October 9, 2012

    no clue,

    It must have even spin, has not yet been shown to have spin zero. Showing this is one target of ongoing analyses. No one really believes though that there is much likelihood it is spin two or higher.

30. **Pravda**
October 10, 2012

    "If there really is nothing but custom to keep them from awarding the Nobel this year to ATLAS, CMS, and CERN for the Higgs, I can't see a better occasion to break with the custom…"

What could be more inspirational than such an award going to huge corporate entities composed of many thousands of people, and which spent billions of dollars?

Anything.

31. **unpravda**
October 10, 2012

That makes no sense at all. The billions are well spent, not squandered. It makes far less sense to award the prize to spokespersons/project leaders. Those positions may even rotate … why are only the spokespersons deserving of Nobels?

But I was surprised by the statement. At at least for science there is a custom to award the prize to individuals, not organizations. It is only the peace prize, I believe, where awards have been made to entities such as the International Red Cross etc. Actually the will of Alfred Nobel stipulated only one individual for the awards.

32. **Colin Rosenthal**
October 12, 2012

"It could also be that the nobel prize committee isn't convinced dark matter is real, they may think modified gravity is still plausible and are awaiting experimental confirmation from "direct detection" experiments."

I'm not sure that that is particularly relevant. According to wikipedia, Rubin herself would prefer a modified-gravity explanation, but even if such a thing were possible it wouldn't make Rubin's observational analysis less important. "Sorry we can't give you a nobel because you've only overthrown GR"??

(The Zwicky question is a whole different thing. But I don't think a prize for Rubin could possibly be _more_ controversial than some of the other strange choices and omissions over the years.)

Post-discovery Higgs Books

October 11, 2012
Categories: Book Reviews

The Higgs particle has been the main player in various popular books about particle physics since before many of today's college students were born, with Lederman and Teresi's The God Particle going back to 1993. Last year's excellent The Infinity Puzzle by Frank Close (discussed here) was largely about the Higgs story, appearing just before the first experimental indications of the Higgs late last year.

I'm not the only one who was obsessively following the Higgs discovery story as it unfolded from last year until the final announcements this past July 4. Two of the others have already produced books on the topic: Jim Baggott's Higgs: The Invention and Discovery of the 'God Particle' came out last month, Sean Carroll's The Particle at the End of the Universe: How the Hunt for the Higgs Boson Leads Us to the Edge of a New World, will be in stores next month.

I've just finished reading copies of both of them, and they're both very good. They each cover the story of the Standard Model well, supplemented by extensive discussion of the Higgs discovery at the LHC and the background of how it came about. I confess that it's a bit eerie to see a lot of things that were day-to-day news and often grist for the blog now packaged between hard-covers as history, while I'm also happy to see that a good job is being done of it.

Baggott's book is quite a bit shorter, and has much more of a linear structure, taking the reader historically through the development of the Standard Model and its experimental tests, up through the LHC and the work of CMS and ATLAS that led to the Higgs discovery. You also get as a bonus a wonderful foreword by Steven Weinberg who, among other things, explains why quarks were not in his 1967 paper (he didn't believe in them). If you want the quickest possible journey through this material, definitely choose this one.

Carroll's effort is much longer, more non-linear and digressive. You get a significantly more in-depth version of parts of this story, with an organization that starts with the discovery and works outwards, explaining various topics needed to understand what this is all about, rather than following the line of historical development. I'm not really a good person to judge how this will work for those approaching this subject without a lot of background, but it seems to be as good a way as any to get readers into the subject. Among the topics Carroll has the space to cover in depth, he does a very good job with the history of the Higgs mechanism and the various claims to have done something Nobel-worthy, including the crucial role of Philip Anderson that often gets overlooked.

Since I'm known for my negativity, I'll add a few criticisms here of these otherwise excellent books. Baggott goes with the "God Particle" business in his subtitle, presumably for the same excellent reason that Lederman used it: anything with "God" in it sells more books. One of Carroll's digressions is about the "God Particle" business (he's strongly against it and God in general) but his "Particle at the End of the Universe" replacement doesn't seem to me to be much of an improvement. His subtitle and some of the jacket copy ("a doorway is opening into the extraordinary: the mind-boggling world of dark matter and beyond") oversells a topic he wisely devotes no more than a couple pages to in the text of the book, so-called "Higgs portal" models of dark matter.

Both authors write fairly extensively about the role played by bloggers in spreading news and rumors during this recent period, and I make an appearance in both books. This caused me to go back and recall some of the details of how this played out. Both Baggott and Carroll describe how the abstract of an internal ATLAS note was anonymously posted on my blog (see here). Carroll's version is slightly inaccurate, implying the entire memo was posted there, while it was only the abstract. The full note was sent to me privately by people who wanted me to have a better idea of what was going on, but I did not post that on the blog, and reading the full note made it pretty clear that while this wasn't a hoax, it also wasn't worth taking seriously. My impression is that the outraged reaction from various people at ATLAS to this leak was equal parts justifiable concern about keeping this kind of material confidential, and embarrassment about something this dubious seeing the light of day with the name of their collaboration on it. The unfolding of this story gave me a lot to think about, and I ended up deciding that I was definitely not comfortable being a public source of actual confidential documents, while at the same time seeing nothing wrong with providing accurate summary accounts of what the 3000 people in one of these large collaborations were all aware of and discussing. I offered to ATLAS people to remove the abstract if they asked me to, they decided it was best not to do this.

The first solid evidence for the Higgs that I heard about was in late November 2011 (see here and here), with a comment giving the right mass appearing at viXra log convincing me that the time had come to go public with some details. What was remarkable about this evidence was not that something was being seen at the 2-3 sigma level, but that both experiments were seeing something at almost the same mass value. This immediately convinced me that this was likely to be a Higgs signal, and the further details that came out over the next days up to the public announcement December 13 made for a rather strong case that the Higgs had been found.

In some sense the news this past summer was anti-climactic, just confirming that the strong 2011 evidence was the real thing. In early June news came from ATLAS that they were seeing the same gamma-gamma signal as in the 2011 data, just before I left for vacation (see here). When I got back from vacation, a lot more details showed that both experiments definitely had the thing in the bag. My posting about this got a lot of attention, including a link from the New York Times (where Dennis Overbye reported that Fabiola Gianotti of ATLAS was telling him "Please do not believe the blogs").

All in all, I'm fairly happy with my decisions about what to write and what not to write on the blog about not-quite-public results about the Higgs. There's been a certain amount of criticism about the terrible violations of confidentiality involved, but I can't help pointing out that the things I was writing about were at the time known to the majority of the HEP community: the 6000 physicists on ATLAS and CMS. Carroll has this to to report about the confidentiality question:

> I asked one physicist whether the results that ATLAS was getting were generally known within CMS, and vice versa. "Are you kidding?" I was told with a laugh. "Half of ATLAS is sleeping with half of CMS. Of course they know!"

For that quote, and many other stories worth reading about, if you're the sort who loves popular books about particle physics, both of these are worth buying. If you're only moderately interested, just pick one of the two and read it, you can't go wrong…

Comments

1. **hhgttg**
   October 11, 2012

   You may or may not know this (you do not say so explicitly) but "Particle at the End of the Universe" is taken from the Hitchhikers Guide to the Galaxy. Milliways is the "Restaurant at the End of the Universe".

2. **Peter Woit**
   October 11, 2012

   hhgttg,

   Yes, I was aware of that. Maybe my problem with it just has to do with not being much of a Douglas Adams fan…

3. **Robert Rehbock**

October 12, 2012

If one person knows something they do not share with others, that is secret. If two persons know something that neither share with others, that is a confidence. If three persons know something that none of them share with others, that is unlikely.

4. **BJM**
October 12, 2012

What about "Higgs Discovery", a short book by Lisa Randall?

5. **Peter Woit**
October 12, 2012

BJM,

I think Randall's book is rather different. It's very short: a couple chapters from her other books about the Higgs with a new chapter describing the story of the discovery. As far as I know, it's only available as an e-book.

6. **ed hessler**
October 12, 2012

I'm a K-12 science educator who reads NEW almost daily, not always understanding everything or expecting to or believing that it is your job. Today's post is one of many that explain why why I read it and look forward to it on nearly a daily basis. This thanks is long, way-long overdue but it is about time I said that. I also appreciate the way you keep the comments focused.

Cheers.

7. **Peter Woit**
October 12, 2012

Thanks Ed,

I hope there will be continue to be news as exciting as the past year's to cover here in the future, probably too much to expect though…

8. **Philip**
October 12, 2012

As long as that news isn't evidence for SUSY or string theory, right Peter?

9. **Peter Woit**
October 12, 2012

Philip,

Well, if the LHC finds SUSY or strings, people at ATLAS and CMS will likely send me the news and you'll read about it here first. More likely though, further strong evidence against SUSY (evidence against strings isn't possible, for obvious reasons…) will continue to accumulate, and that will get covered here, even if ignored elsewhere.

10. **Owen Patterson**
October 12, 2012

So now that the Higgs has been found, now what for this branch of science?

11. **Peter Woit**
October 12, 2012

Owen Patterson,

From the experimental side, investigate the properties of the Higgs. From the theoretical side, the LHC is killing off a wide range of bad speculative ideas. So, give up on those and find something better…

12. **B**
October 12, 2012

"…now what for this branch of science?"

writing books, apparently.

13. **paddy**
October 12, 2012

Kudos PW. Your site did indeed provide the best objective real time coverage of the Higgs search story this last year or more. If folks wish to equate "objective" (i.e., a skeptical no agenda approach) with "negative", then they have some self introspection to do. Thank you again for your insights.

14. **cormac**
October 12, 2012

Hi Peter, I read Baggot's book last week and I have to say I was a bit disappointed. It starts very well and has a strong theoretical basis, but I think there a lot of abstract theory for the lay reader.
Of course, it's very hard to tell the story of the SM without quite a bit of quantum theory. My solution in talks and suchlike is to concentrate on phenomenology, and tell the story of the discovery of particles, with only a little on qft. I get criticized for this (see current comment on blog), but I'm pretty sure the layman won't understand much of Baggot's book (my students didn't)

15. **Peter Woit**

October 12, 2012

cormac,

The problem is that the basic idea of the Higgs mechanism (spontaneous breaking of a gauge symmetry) is inherently an abstract and tricky one. You're probably not going to be able to communicate much about it to a lay reader, but if you just completely avoid it, you've written a book about the Higgs without actually explaining anything about what it is. You can't win here, but I think it's often better to leave readers aware that they don't really understand than to tell them a story which convinces them they have understood something that they haven't been told anything about.

16. **cormac**
October 12, 2012

Yes, I'm inclined to agree, I don't accept the mantra that the reader has to understand everything. However, I read Jim's book just before giving a talk on the subject myself, had the feeling it's more conscious of readers like you and me than a lay audience.
I suspect a lot of readers won't get past the half-way mark, but what do I know? It's certainly succinct, thank God for a release from the obligatory anecdotes!

17. **cormac**
October 12, 2012

P.S. Re ' completely avoid it', I'm not advocating such a thing, of course you can't tell the story without some reference to e-w symmetry breaking, My point is one of balance; I suspect Jim's book, like your own, has a little too much gauge theory for the lay reader, but that's entirely subjective!

18. **ScentOfViolets**
October 13, 2012

> The problem is that the basic idea of the Higgs mechanism (spontaneous breaking of a gauge symmetry) is inherently an abstract and tricky one. You're probably not going to be able to communicate much about it to a lay reader, but if you just completely avoid it, you've written a book about the Higgs without actually explaining anything about what it is. You can't win here,

In reply to Cormac, this sort of thing happens all the time when it comes to explaining even basic physics to the lay public. A case in point is the notion of negative temperature. In a quick exposition you can get the idea across that temperature is basically just how fast things move on average, both because it's easy to make little pictures in your head about what this means and because somehow it "makes sense". But to try to explain temperature as the change in heat wrt to the change in entropy? Try to communicate that intelligibly to a lay audience in a few paragraphs or pages.

Some stuff really is hard to explain, and it's not just that people who do this sort of thing for a living making a poor job of it. Hmmm . . . did Asimov ever make a stab at this. Be interesting to see how the Great Explicator did it.

19. **paddy**
October 13, 2012

On explaining the "Higgs mechansim" to laity: I've always been sure this is straightforward…right up to the point I try to do it. As an example of someone far better equipped than I attempting this, I note Matt Strassler's careful building up of a series a lecture articles (which are quite good) and which in the end should culminate in a "voila!" moment. Unfortunately, I suspect that said laity have long since lost the train of thought. Tomas Dorigo on the other hand (though likewise not successful yet) is struggling with finding the right analogy/metaphor for, if not the Higgs mechanism, then the concept of "natural". During a pedagogical explanation (such as our education and MS's approach) comes the problem that said laity are not students and may lose the train of thought. With a metaphorical approach comes a constant "not quite right" issue.

20. **Bernhard**
October 13, 2012

"From the experimental side, investigate the properties of the Higgs. "

Yes, well, the problem with this is that not all experimentalists can jump on this at the same time. Higgs was already a crowed subject in collaborations before the discovery. The Higgs properties must and will be measured, no danger there, but I guess this question really depends on the career stage you are. For very young experimentalists, jumping this Higgs crowd can perhaps lead to a job, if the person is very qualified, but I would think people entering the field dream with a bit more than that (in your mid-thirties that is probably your only dream, but anyway…).

@ScentOfViolets: I think negative temperature can be disposed of in just a few lines of explanation. By historical accident, we've been using the "wrong" variable T (temperature). The "right" variable is $\beta = 1/T$ (coldness). The second law of thermodynamics then states that thermal energy spontaneously flows only from low coldness to high coldness (valid over both positive and negative ranges). So, thinking in terms of negative β immediately explains some puzzling properties of negative T.

@paddy: Perhaps the difficulty in finding a common sense (yet non-fallacious) analogy/metaphor for naturalness is a signal of the actual unnaturalness of the concept.

22. **Spencer Tracy Jr.**

Has anyone seen Leonard Susskinds Higgs Lecture: http://www.youtube.com/watch?v=JqNg819PiZY
or the Cal Berkley Higgs lecture: http://www.youtube.com/watch?v=jchDY6xuiZ0&feature=related

23. **fuzzy**
October 15, 2012

paddy, Igor
i would be content with a physics explanation of naturalness, even if it were remote from common sense. i mean, something having to do with measurable stuff, rather than with mathematical constructs. in the last 20 years, i saw nothing like that, just the same lame arguments.

24. **paddy**
October 15, 2012

fuzzy,
I could probably blather on about your point…but in the end I agree with you.

25. **Tammie Lee Sandoval**
October 17, 2012

Dear Igor Khavkine

Thank you for that wonderful thought, that 1/T is “coldness”.
I teach high school physics
We have a thermodyamics seminar, and I’m going to use your idea.

26. **Chris Oakley**
October 17, 2012

1st law of thermodynamics: You can’t lose
2nd law of thermodynamics: Yes, but you can’t win, either
3rd law of thermodynamics: Except at absolute zero, and you can’t get that

27. **Igor Khavkine**
October 17, 2012

@Tammie, I hope you won’t use my blog comment as an authoritive reference! You may want to look up Appendix E in Kittel & Kroemer’s *Thermal Physics* textbook for a more detailed explanation of negative temperature along these lines.

- From commenter Clark here, news that Mochizuki has acknowledged that the problem pointed out by Vesselin Dmitrov with his proof of the abc conjecture on MathOverflow is a real one, but claims that the argument can be fixed, with fixes that he explains here. He is preparing updated versions of the papers containing flaws.
- As new negative results about SUSY keep coming in, Nanopoulos et al. issue new "predictions" of a SUSY signal just around the corner. In light of this from ATLAS, here's an updated list of "best fits" for SUSY (first posted here)

  arXiv:1007.5100 455 GeV ("Golden Point")
  arXiv:1009.2981 455-481 GeV ("Golden Strip")
  arXiv:1111.0236 512 GeV ("Universe F-U2")
  arXiv:1111.4204 518 GeV ("Profumo di SUSY")
  arXiv:1203.1918 610 GeV ("Aroma of Stops and Gluinos")
  arXiv:1205.3052 708 GeV ("The Sweet Fragrance of SUSY")
  arXiv:1210.3011 756 GeV ("Primordial Synthesis")

  The authors have stopped going on about how this all smells, but now are acknowledging help from Tommaso Dorigo (see here).

- Tomorrow at Boston University there will be a conference on quantum gravity, celebrating the 40th Anniversary of the First Osgood Hill Conference on Quantum Gravity.
- The Higgs continues to get lots of positive media attention. This week's episode of The Big Bang Theory was called The Higgs Boson Observation, and features lots of Higgs-related things on the blackboards.

  At the IAS in Princeton, Yuri Milner's multi-million-dollar men are giving public talks about the Higgs. Last week was Juan Maldacena on The Symmetry and Simplicity of the Laws of Nature and the Higgs Boson, next week it will be Nima Arkani-Hamed on The Inevitability of Physical Laws: Why the Higgs Has to Exist. At some point these talks may appear here.

- On Friday the Templeton Foundation handed out $5.6 million as part of its New Frontiers in Astronomy and Cosmology competition, some to students for writing essays, most of it to physicists and astronomers, many of whom promise to find ways of testing the Multiverse (grant winners are here). Intriguingly, David Spergel is not just "testing" the Multiverse, but "detecting or falsifying" it, I wonder what that's about.
- Lots of self-examination going on in the US HEP community about what to do post-Higgs discovery. Argonne had an HEP Higgs Retreat (no slides for "SUSY is Dead?" it seems). The past few days at Fermilab there was a DPF Community Planning Meeting, organizing activities to lead up to next summer's "Snowmass" Community Study , to be held in Minneapolis. What's long overdue but unlikely to happen would be a US Community Study of the implications of the SUSY/string theory fiasco for HEP theory.
- The Calculus of Love is a short film with a math theme involving the Goldbach conjecture.
- For a debate about Pythagoreanism, the idea that math is the key to the universe, see here. An interesting debate, but maybe they should have had some mathematicians involved…
- Last week I was up in Boston and went to some of the talks at a conference in honor of Daniel Quillen, who passed away last year. Quillen's remarkable and influential work was at the boundary of topology and algebra, in particular he was largely responsible for discovering how to properly define algebraic K-theory. An early version was distributed of material about Quillen that will appear in the November Notices of the AMS, including a long explanation by Graeme Segal of the high points of Quillen's mathematical contributions (*Note added: this is now available here*). I found the talks by Segal and Hopkins both inspiring and baffling, with Hopkins in particular starting off slow and comprehensible, but reaching escape velocity by the time he got around to what sounds like an exciting new result about the Brauer group in the context of stable homotopy theory. This is joint work with Lurie and Lieblich, but you're going to have to find someone other than me to explain it to you.
  This coming week I'll be in Toronto for the Fields Medal Symposium, which will cover all things Langlands. The opening public lectures will be live-cast, see here.

   Mathematicians (mathimatikoi – learners) are the descendents of a pythagorean sect. However, the present situation is complex: most mathematicians don't care much about philosophy, most philosophers are mathematically blind, hence somewhat clueless concerning pythagoreanism, with physicists in the middle position.

   There are exceptions. Here is a cite by Bateson ("Form, substance and difference", 1970):

   "In this history, there has been a sort of rough dichotomy and often deep controversy. There has been a violent enmity and bloodshed. It all starts, I suppose, with the Pythagoreans versus their predecessors, and the argument took the shape of "Do you ask what it's made of – earth, fi□re, water, etc?" Or do you ask "What is its pattern?" Pythagoras stood for inquiry into pattern rather than inquiry into substance. That controversy has gone through the ages, and the Pythagorean half of it has, until recently, been on the whole submerged half."

6. **paddy**
   October 16, 2012

   thomas,
   Well said. And their latest article reads like gobbledigook. Any paper that elicits "bayesian priors" when considering the "truth" of its ascertion is pathetic.

Templeton Funds Physics of Information

October 19, 2012
Categories: Uncategorized

FQXi has recently issued a Request for Proposals, using money from the Templeton Foundation to fund about $3 million in grants for research on the "Physics of Information":

- What is the relationship between information and reality? Can information exist without any "material" substance? Can matter exist without any information? Or, are information and reality two sides of the same coin?
- How does nature (the universe and things therein) process information? Are there fundamental limits? How is nature shaped and transformed by processing information?
- What are the fundamental differences between classical and quantum information?
- What can the physics of information reveal about black holes, singularities, physics at the Planck length, and the origins and fate of our universe?

This follows on the heels of $4 million in grants announced last week on the topic of New Frontiers in Astronomy and Cosmology.

Fields Medal Symposium

October 19, 2012
Categories: Langlands

I just got back from a few days in Toronto, where I attended the [Fields Medal Symposium on Fundamentals of the Langlands Program]. This is the first of a planned yearly series to be held a the Fields Institute, with the idea that each Symposium will focus on an area of mathematics crucial to the work of one of the recent Fields medalists. In this one, Ngô and his work proving the Fundamental Lemma in Langlands theory was the center of attention.

The talks were recorded, and I believe that video of them will soon appear. An effort was made to get speakers to give talks aimed at non-specialists, and the results were quite good. Among the talks I attended, I can highly recommend those of Sophie Morel, Edward Frenkel, Nigel Hitchin and Edward Witten, which covered some of the huge diversity of fundamental mathematics that goes into this subject. Unfortunately I only got to Toronto midday Tuesday, so missed all the Monday and Tuesday morning talks. I heard that the Tuesday morning talks of Richard Taylor and Michael Harris gave excellent introductory surveys on the number-theory Langlands program. Monday was devoted to more specialized talks on endoscopy and the fundamental lemma.

Ngô's talk was about some new ideas on how to go "Beyond Endoscopy", to extend previously successful uses of the trace formula to prove Langlands functoriality to a wider range of examples than those covered by the fundamental lemma. Another example of this sort of ongoing work mentioned by a couple speakers was work by Ali Altug, who has just finished up as a student at Princeton and started teaching here at Columbia this fall. Witten's talk surveyed the relationship between QFT and geometric Langlands, motivating clearly why the N=4, d=4 SYM theory appears. For more details about much of the more advanced material covered in his talk, see the write-up here of his lecture at Atiyah's 80th birthday conference.

Monday evening there was a big evening program for the public (which I watched some of from New York via web-cast), and Tuesday evening there was a special program for high school and college students, with Ingrid Daubechies and Frenkel giving talks, as well as a panel discussion with them, Ngô and James Stewart. A lot of students attended, and many stayed on for almost an hour to talk with the speakers. Ngô has a popular book out in Vietnam, which evidently has been a huge success. Frenkel has a book entitled *Love and Math* coming out next year, a chapter of it is available here.

Panelist Jim Stewart has them both beaten as a successful author. His excellent Calculus textbook may be the most widely-used one in the US, and evidently the financial rewards have been significant. He was one of the financial supporters of the symposium, and Wednesday night had many participants out to his amazing home in Rosedale for a banquet. It's a spectacular, award-winning piece of architecture he calls "Integral House", and its five stories and 18,000 square feet of space are perched over a ravine not far from downtown Toronto. Evidently it cost him about $24 million, as well as about ten years of his life in design and execution. For more about Stewart and Integral House, see here, here, and here.

Richard Cerezo was taking lots of pictures and has been posting on the Symposium blog here. A short video of me, Frenkel and Hitchin discussing the Symposium topic may appear there at some point.

Update: The conversation with Frenkel and Hitchin is now available here.

1. **Jeff M**
   October 20, 2012

   Peter,

   Sounds like fun, not that it's even vaguely related to what I do. On another note, Stewart's calculus excellent, really? I mean it's not too bad for a modern calculus book, but it's way too long, with all sorts of useless stuff in it, and it doesn't emphasize the important stuff nearly enough. I guess the "proofs," such as they are, are better than many other current books, since from what I remember they aren't actually incorrect, just often sloppy and incomplete. It's fine to have an incomplete proof, but if you do that you should say "this is meant to give you an idea of how the actual proof works." I guess that most of this isn't Stewart's fault, especially at this point, but still. You want a truly great calculus book, use Spivak.

2. **Bob Jones**
   October 20, 2012

   Yes! Spivak's calculus book is probably one of the greatest math textbooks ever written!

3. **Peter Woit**
   October 20, 2012

   If one wants a proof-based calculus book, yes, Stewart's not the way to go. But, I'd really rather not host a discussion here of Calculus books, unless it's somehow closely related to the Langlands Program, which is the topic of the posting….

4. **Jeff M**
   October 20, 2012

   Peter,

   OK, Langlands program. A quite well known mathematician once told me that he hated getting reference letters from Langlands, since all they ever talked about was how the candidate had advanced the Langlands program 🙂

5. **Richard Cerezo**
   October 21, 2012

   Hi Peter,
   Thanks for the post. I'm so glad that you enjoyed the symposium and that we were able to have some conversations. I'm glad to see that your blog pops up among the first few when I look for coverage of this FMS! There were quite a few reporters there on Monday evening and hopefully I can find something in English as most of them were Vietnamese news reporters.
   Unfortunately I missed Sarnak's talk and I heard that it was also very nice.
   As an aside, Spivak's Calculus is really quite phenomenal for a proof course, but as far as I know he didn't have that very impressive wall of his own books!

6. **Peter Woit**

October 21, 2012

Richard is referring to this

http://thestar.smgmedia.topscms.com/images/c6/0d/c868f86e476a931df0f06e7c012c.jpeg

Guests at Stewart's got to see his huge bookcase of Calculus and other course books, which this is a part of, the part containing his own books..

7. **Paul**
October 22, 2012

Peter,

I have an undergrad math background, but I know almost nothing about the Langlands program. Not to sound sarcastic, but what's so special about this topic anyway? I took a look at its Wiki page, but I couldn't quite understand it. And what applications (if any) does it have to physics?

8. **Peter Woit**
October 22, 2012

Paul,

The public program talks tried to give some motivation for the Langlands program, I think they're online. Richard Taylor's talk I think was also pretty general, should be online at some point.

To oversimplify dramatically, the Langlands program grew out of number theory, where it is a basic insight into the structure of numbers (relating the Galois group to Lie groups). The proof of Fermat's last theorem is based on it. It also has some geometric analogs, known as Geometric Langlands, and this geometry has turned out to be related to certain very special quantum field theories. Witten's talk covered that, but it's a long and rather complicated story.

9. **Richard Cerezo**
October 25, 2012

Thanks for posting the link! What did you think of the video? I have picked up a very nice book dedicated to Hitchin called 'The Many Facets of Geometry: A tribute to Nigel Hitchin'. It has a very nice article written by Witten on the Geometric Langlands! I will include my comments on it when I write about Hitchin's talk.

10. **Peter Woit**
October 26, 2012

Hi Richard,

I thought the video of us came out very well, thanks for arranging it and producing the great video.

The Witten article you mention is a nice review article, written earlier on and probably worth reading before the one that I mentioned, which corresponds more to his talk at the conference.

Looking forward to videos of the rest of the talks, I hope we get to see those!

Thanks Peter! I know what I'm doing for the next 10 hours . . .

Why Author Pays Open Access is a Bad Idea

October 20, 2012
Categories: Uncategorized

There's a wonderful piece of software out there I hadn't heard about, called Mathgen, which generates impressive looking mathematics research papers that are utter gobbledygook. A Mathgen paper on *Independent, Negative, Canonically Turing Arrows of Equations and Problems in Applied Formal PDE* was recently accepted (see the full story here) by the journal Advances in Pure Mathematics, one of many "open access" journals put out by Scientific Research Publishing. If you're looking for theoretical physics papers instead of pure math, Scientific Research Publishing has the Journal of Modern Physics. Some work on Mathgen is probably required before it is ready to submit papers to this journal.

These journals charge authors $500 to publish their papers, something which is now being sold as a wonderful mechanism for providing "open access" to the scientific literature. At the same time they make very clear what one big problem with this is: the financial incentive for the journal becomes to publish as many papers as possible, since that's the only way to increase revenue. Scientific Research Publishing does a good job of showing where this model for funding dissemination of academic research leads.

Comments

1. **Matt Leifer**
   October 20, 2012

   The fact that there are some unscrupulous open access journals with an author-pays business model does not automatically mean that the author-pays model is bad. These are extremely low-prestige journals that everyone already ignores. The only people likely to get duped are faculty hiring committees who simply count the number of publications, but, even then, I think that the likelihood of them not noticing that the publications are in junk journals is pretty low.

   On the other hand, there are some extremely good open access journals with an author-pays model. The New Journal of Physics is one such. It is currently ranked higher than most Physical Review journals, apart from Physical Review Letters, in almost every relevant metric (e.g. impact factor, average citation rate, number of paper downloads, etc.). Apart from PRL, the only journals in physics that do better are those published by the Nature group and Science.

   I agree that there is currently a kind of scam going on where a lot of new small open access have opened up with the aim of making as much money on author fees as possible with no regard for quality. I get emails from such publishers all the time, as I am sure many other academics do. However, it is pretty obvious to everyone that these are scams and we know who are the reputable publishers in our own fields. For those who do not know, it is fairly easy to look up journal rankings to see which are the good journals. Therefore, I don't see that there is a problem.

2. **Peter Woit**
   October 20, 2012

   Matt,

   Thanks for the comments. I agree of course that not all author pays journals are currently problematic. But I do think there's an inherent problem with that funding model. Under the old libraries pay, costs everybody more to print more papers model, there was a strong incentive to keep numbers of papers published small, and quality high. If quality went down, librarians would start canceling. Under this new model, the financial incentive is all towards accepting more papers. Those editing and running the journals may have other incentives that encourage them to keep standards high, but those may not win out in the long-term over the financial ones. I'd be curious to know if there are journals using the author pays model that recognize this as part of their charter and have put mechanisms in place to counteract it.

3. **Heikki Arponen**
   October 20, 2012

   Pretty much the only thing the author (or institution etc.) should pay for these days is the peer review, since most work is already done by the author himself… and maybe the peer reviewer should get a cut too!

   By the way… Peter, please consider joining Google+. This story has been circulating there for quite some time already! It's also a nice way for you to connect better with your audience.

4. **Toma Susi**
   October 20, 2012

   Peter, even though I agree that there are definitely problems along the lines you say, from what I've gathered of the current bundled subscription model, libraries don't really have any choice to cancel low quality journals, since partial subscriptions are priced outrageously high. The current system really doesn't work. I agree with Matt's comment, cases like these are easy to filter out and are not the real problem.

   I'll also emphatically second Heikki's request: Google+ **really** is worthwhile.

5. **john McAllison**
   October 20, 2012

   The obvious solution is for authors to pay for the journal's referees to assess the paper for academic importance sufficient for publication.

6. **Bob Levine**
   October 20, 2012

   "The obvious solution is for authors to pay for the journal's referees to assess the paper for academic importance sufficient for publication."

   But at the moment, the cost of refereeing for academic journals, so far as the journals themselves are concerned, is nil. Refereeing is typically viewed as a professional responsibility by academic departments, and having a sheaf of refereeing assignments from blue-ribbon journals of record is regarded an important indicator of one's status as an expert in the field, for P&T purposes, in pretty much every discipline I know about. As long as this continues to be common policy in academe, I don't see why authors ought to pay for refereeing on the open access model any more than they do on the commercial/university press journal model. I do a lot of journal refereeing and I wouldn't expect to be remunerated for my review work regardless of the journal format (though I'd be much happier doing work on behalf of an open-access venue than a subscription/paywall-protected venue…)

7. **Peter Woit**

October 20, 2012

Toma,

I agree that the current system is broken. My point is just that I see a lot of promotion of wonderful new "open access" models which sound great until you think a bit about it and see the problems. Looking at this case I think helps to make a problem clear, exactly because it is so extreme. If this is happening, are you really so sure that the financial incentive to publish more papers is not affecting at all how other journals behave? One may argue that whoever is behind Scientific Research Publishing is some guy who is just out for a buck, but a lot of the new "open access" being promoted is for journals run by Elsevier and the like. Can one rely upon them to ignore financial incentives and keep up standards?

About Google+,

I haven't gotten involved in that partly because I spend too much of my life on the internet, so avoiding all social media seems like a good idea to the extent possible. Maybe I'll find out there's some efficient way to get information from Google+ without wasting a lot of time and change my mind. But, another thing I think we all need less of in our lives is Google, I've seen enough of it recently to find it a very scary organization.

8. **Mark Hillery**
October 20, 2012

First, let me say that I am an associate editor of Physical Review A, so anyone reading my comments might want to keep that in mind.

I do not like the author-pays model. Presumably the money to pay the publication charges is supposed to some from a grant. Theoretical physics and mathematics are not particularly well-funded, so, in my experience, sometimes people have grants, and sometimes they don't. However, in these fields it is quite possible to do research without a grant, so if you have something you want to publish, and you don't have a grant, you will not find the author-pays model particularly agreeable. Personally, when I do have grant money, I would much rather spend it on a graduate student than on publication charges.

In regard to refereeing, yes the referees provide their services for free, but someone has to manage the process, and for that you need permanent people whom you have to pay. You can't run a journal with a real peer-review process for nothing.

Finally, I just do not understand the attraction of publishing a physics paper in a journal, such as the New Journal of Physics, that has a publication fee. If you want your paper to be freely available, you can publish it in the Physical Review for no fee, and put the paper on the archive. By the way, it is probably not that well-known, but if you publish your paper in the Physical Review and you want to make it freely available (that is available to people without a subscription), you can pay a fee and do so.

9. **Peter Woit**
October 20, 2012

Thanks Mark,

I should also mention some history which most readers are probably too young to know about. Until the late 60s-early 70s, the APS had the dominant (at least in the US) HEP journal Phys. Rev. D, which had a form of "author pays", called "page charges" (these charges didn't make the journal free, but subsidized it and kept subscription prices low). The European Elsevier journal Nuclear Physics B had no such page charges and from the early 70s on, this was one of the main reasons it became the journal of choice for authors to publish in, and Phys Rev D fell by the wayside in terms of quality. This is why the bulk of the best work in the field for several decades now belongs to Elsevier to exploit as it sees fit, rather than to the physicist-controlled APS.

10. **Sterling Clover**
October 20, 2012

Elsevier and other publishers of traditional journals have hardly done any better: This and this for example. (And there's plenty more where those came from).

Publishing nonsense has a strong economic incentive even without author-pays as long as you can push it into "bundled" journals that libraries are forced to buy.

11. **Low Math, Meekly Interacting**
October 20, 2012

Gotta go with Sterling. Perverse incentives abound (I mean, cripes, just look at all the retractions in bio lately), and I don't see any way to avoid them completely. I'd never argue that the author-pays model is perfect, but somebody has to pay something somewhere, and this model guarantees that even the poorest researcher can gain ready access to peer-reviewed literature. No pay-walls. No needless overhead. No bundling. It would be wonderful if the arXiv solved all problems, but reportedly it doesn't. What better solutions are there? If somebody comes up with a true panacea, count me in as a fervent supporter, but I'm not smart enough to dream one up on my own.

FWIW, in my field PLoS seems to be doing a pretty good job. They aren't publishing any more garbage than anyone else, at least, as far as I can tell.

12. **Matt Leifer**
October 20, 2012

Peter,

I think it is wrong to conflate open access charges with page charges from subscription journals. In the latter case, there is double dipping going on because the library is still paying for a subscription in addition to the author paying a fee.

Mark,

For the same reason, I don't think the hybrid model adopted by Physical Review is a great idea. Sure, authors can pay to make their work open-access, but so long as most authors do not the library still has to pay for a subscription and, as far as I can see, they are not getting a discount based on the proportion of articles that are open access. This is one reason why authors may prefer New Journal of Physics because in that case it is unambiguous that no library or indeed anyone else is ever going to have to pay for your work.

Personally, I have no problem with the green open access model of posting to the arXiv and then publishing anywhere you like, providing the journal I publish in is not involved in price gouging. We have to recognise though that this is part of a larger battle that includes other scientific fields, such as medicine, which do not have a preprint culture for a variety reasons. If we want them to adopt open-access then we should lead by example.

Peter again,

It is easy to discuss anecdotal evidence of extreme cases and scam artists. The argument you are making is analagous to arguing that, because there are a lot of scam conferences out there, the overall quality of scientific conferences must be decreasing. Now, we have all been getting those scam conference emails for far longer than we have been getting scam open access journal emails, and I don't think you would argue that conferences are a lot worse nowadays than they used to be. The fact is, people have enough intelligence to know the difference.

What we really need to do is to look at hard data to see whether open access has an effect on quality. Peter Suber quotes a lot of positive studies in his book, which I recommend by the way. Obviously he is an open access advocate so you may argue that he has an agenda, but I didn't get the impression that he was cherry picking. Regardless, the point is that this is a question to be answered scientifically rather than anecdotaly.

It is also worth pointing out that open access and author pays are not identical. For example, New Journal of Physics will waive publication fees for authors that do not have access to grants and funding. Most reputable open access journals do this, and there are even a few that charge no fees at all (I don't know of any in physics though).

13. **David Nataf**
October 21, 2012

When I read papers on the arXiv, I ignore whether the paper is submitted or accepted for publication. I trust the real peer review system: that of the community of peers, but if I find a mistake I take note and remember the authors' names. In general published papers are just as likely to have mistakes anyway, what quality comes down to is the author's regards for maintaining his or her own reputation.

Ultimately that may be the only solution moving forward.

The other issue with the peer review system is that it's rooted in 17th century science, when there was a smaller number of fields and it was easier to find a "qualified expert". Science also didn't progress as rapidly, there was not as much cost to waiting 6-12 months for the referee process to complete itself.

14. **Toma Susi**
October 21, 2012

Matt,

An example of a totally free physics journal (well, materials science anyway) is the [Beilstein Journal of Nanotechnology]. It's supported by the Max Planck Society. We recently published an article there (as have several of our colleagues) and had a good experience.

15. **A.**
October 21, 2012

@David Nataf:

Completely agree. Go to arXiv. Read paper. Confer with collaborators. Decide if paper is decent or not. Cite or not as appropriate.

@Matt: one reasons that I, personally, wouldn't send a paper to the New Journal of Physics is that I've never yet cited a paper published there. This, for me at least, is much more telling, and more important, than it's impact factor.

Alright, the next bit is very subjective but nontheless is going to play a roll in attracting authors to journals: the typesetting of NJP articles is atrocious. While APS Becaon (who typeset phys rev articles) drive me insane with the mistakes they introduce into my papers when preparing proofs, the final result does at least look like a research article. Whereas NJP articles look like they're been put together by someone with a 1995 edision of word and a couple of crayons. The journal _looks_ crackpot. IMHO. Why would I submit there, when I can do a better job of it with latex, on my mac, and then post to the arXiv? Job done.

On the other hand, I admit that if an arXiv paper is written in Word/has been sitting around for five years without being published/has been updated more than three times/ I'm automatically on my guard. Meh, there is no easy solution to this.

16. **Matt Leifer**
October 21, 2012

A,

The conventions of where people send articles obviously vary from subfield to subfield, so there will be some people who don't have a reason to cite articles in NJP, but that does not tell you about the overall quality of the journal. I can tell you that in quantum information, NJP is fast becoming more popular than PRA, which used to be the first-choice journal for physics-based papers in the field after Nature/Science/PRL. Again, it is a case where we should look at the data rather than anecdotal evidence and the data says that NJP is doing well, i.e. better than any non-PRL Physical Review journal in impact factor. I am not a shill for NJP, I send papers both there and to Physical Review journals. It is just an example of an open access journal in physics that does not seem to have a quality problem.

Regarding typesetting, it really is not much different from any other IOP journal, so are you saying that all IOP journals look crackpot to you? What is wrong with the typesetting of this (http://iopscience.iop.org/1367-2630/12/3/033024/pdf/1367-2630_12_3_033024.pdf) for example?

17. **Jan Velterop**
October 21, 2012

Peter, you say "the financial incentive for the journal becomes to publish as many papers as possible, since that's the only way to increase revenue." That's true, but it was always thus, also for subscription journals. Acquisition editors' task at most publishers was to increase the number of volumes to be published every year. More volumes means more papers, and given a number of subscriptions, more revenue. Journals are rarely cancelled because they grow. An example of the growth of a subscription journal: Discrete Mathematics — 1971 (its first year): 1 vol — 1981: 5 vols — 1991: 8 vols — 2001: 20 vols. These volumes all had 4 issues, of ca 10 papers each. Later the journal went to one vol/yr but with many more issues/vol.

The author-side payment is not an incentive in itself to grow a journal, and it certainly isn't very different from the incentives in the subscription system.

The flaw in both systems is that all the revenue is derived from published papers, instead of from papers 'processed' (i.e. submitted and for which peer-review has been arranged). A way out of that conundrum is to levy submission charges only, and pay the entire operation out of those. The risk for any publisher to start doing this is just too great, as paying and then still being rejected won't be popular (though it is very normal for, e.g. a driver's test).

18. **JGB**
October 21, 2012

How about doing a complete 180 and reject the ability of the free market to manage this proces at all? Both ends clearly lead to different ways of gaming the system. The government provides far and away the largest percentage of money whether in grants or library subscriptions. Collect the best journals that wish to and set both an expectation for articles reviewed and a max limit on articles per year. Undoubtedly there'd be some complaints, but you'd be forcing people to increase the quality of their submissions for peer review. help manage the workload of everyone. And cut way down on the silly transfers of money between government institutions that claim to maximize efficiency but clearly do not. Private journals wouldn't be illegal, but would only truly make it if they could actually offer something not provided for above. My guess is that very few would, and you'd see a much more productive splitting of peer reviewed highly vetted research, and other largely free distribution of working data (like Arvix)

19. **A.**
October 21, 2012

On the "who should pay" issue, publicly funded research should be publicly available. In fact is has to be, since otherwise other researchers can't get to your results, for example. Hence, awarding bodies should fund publication. The problem with this of course is that funding bodies will say "ok, but that means you're only getting enough money to fund a postdoc for 1.5 years instead of 2", which wasn't the plan at all.

What about paying the referees for their reports? A little naíve I feel. Physicists aren't noble go-gooders who bravely go out and fight the good fight FOR SCIENCE! and the advancement of humanity. They're just people, and as such have their own interests at heart. The "experts" in my field to whom my papers are sent for review are often my competitors. Why would they carefully read and evaluate my paper when they can instead find some shoddy excuse to delay it or reject it and get paid into the bargain? More to the point, why would I pay for that? We could all promise to be honest and fair, I suppose, but, ha, sorry, fell off chair laughing.

If only we had some huge repository where physicists decided, in a nice socialist fashion, to share all their new results for the rest of the community to look over and ponder. Oh wait we do. The facetiousness is warranted; the impression I get from talking to other physicists is that the older generation regards the arXiv as some sort of necessary but rather unsavoury "halfway house" on the road to the sobriety of publication. Whereas, the younger generation think of it as what it is: a great big, free, online journal.

In a few years time, once the younger generation start to get into tenured positions (if there are any left), I think we'll start to see much less importance placed on journals and publication, and more on how well cited a paper is on the arXiv.

(Obviously, this doesn't apply to other subjects: medicine is a totally different kettle of fish.)

@Matt: sorry, not rising to the bait re: typesetting. Even though I set the hook.

/end nautical analogies.

20. **Peter Woit**
October 21, 2012

Jan Velterop,

Yes, there has always been an incentive to grow journals, if you did this you could use it as one excuse to justify higher subscription costs in the future. But, in the traditional model, each year you had a fixed amount of subscription revenue, independent of how many papers you published, and each additional paper cost money to process, print and distribute. The immediate financial incentive was to keep the number of papers down.

Matt,

I don't think looking at past data is relevant, since my concern isn't so much with the history or current situation (which is very much in flux, with print about dead and library budgets unclear), but with the future that people are setting in place now. My point is just that "open access" evangelists need to acknowledge that some of these models provide strong financial incentives towards publication of ever larger amounts of lower and lower quality papers. In the long run, the built-in financial incentives matter, a lot.

The argument that people should do this to provide an example for those in medicine to follow doesn't seem like a good one to me. I'm not convinced even that math and physics should follow the same model, much less medical research, which is a completely different kettle of fish (luckily people don't die because of wrong math papers, nor are important ones worth billions of dollars to someone).

21. **Matt Leifer**
October 21, 2012

Peter,

I guess we are not going to reach agreement, but open access journals are not, at this point, a new idea and there are already quite a lot of them, so if there is a trend towards reduced quality then we should be able to see the beginnings of it now. As we have seen in the deabate on this thread, it is certainly not obvious to everyone that the financial incentives work out in the way that you suggest, with some even suggesting that traditional journals are just as bad. Therefore, I still maintain that this question needs to be settled by data rather than opinion and anecdote. If historical data does not convince you then we need to make sure that we are collecting and monitoring data on publishing practices as this change takes place so that we can take action early if a trend is identified. However, based on what we know so far, I would say that goal of increasing access to scientific research outweighs any doubts I might have at the moment.

Finally, I want to point out that open access is only a waypoint in a more general disruption of academic publishing that is enabled by the internet. It is something that campaigners focus on because it is well-defined enough for stakeholders (academics, funding agencies, governments, publishers, etc.) to actually do something about it right now. However, there are other proposals on the table to deal with quality assessment in a more efficient manner than traditional peer review (see Tim Gowers writings on this issue for example) so I am not too worried about the long-term future. Given the ease of distributing information, it does not really make sense to do quality filtering prior to the distribution of articles. If there is a lot of junk out there then I don't really care. I can just ignore it. It is not as if someone is going to deliver a telephone directory sized book of new academic papers to my door every day. Instead, we need a way of filtering post-publication so that high quality articles rise to the top. Tim's proposal of having a peer review layer on top of the arXiv makes a lot of sense in this regard.

22. **Peter Woit**
October 21, 2012

Matt,

From what I've observed, especially in theoretical physics, we're already effectively in the post-journal phase, with the arXiv the main source everyone is using to get access to papers, and peer-review a broken system for quite a while (see Bogdanov (2002)). For the life of me, I can't figure out why anyone is paying for now or making plans (SCOAP3) to fund in the future Elsevier to produce Nuclear Physics B.

A future journal system or its replacement that provided peer-review vouching for accuracy of mathematical proofs and similar difficult to evaluate arguments, as well as identifying the highest quality work for non-experts (experts don't need this) would be valuable, but not if it's largely set up along a vanity publishing model, with incentives to concentrate on extracting money from authors for not necessarily reliable evaluation of work.

23. **somedude**
October 21, 2012

To David, you claim: “The other issue with the peer review system is that it’s rooted in 17th century science, when there was a smaller number of fields and it was easier to find a “qualified expert”.”
Peer review is very much a 20th century phenomenon. When Albert Einstein was peer reviewed and his results on the non-existence of gravity waves were found to be wrong, he did not like it. Before that if the chief editor liked you, you got in. Even before that, the few scientists just sent eachother mail. The old fashioned paper variety. 🙂
The Bernoulli’s are known to not have even sent their results, just the claim that they could prove something and taunting the other if he could prove it as well.

24. **Mateus Araújo**
October 21, 2012

Although A.’s point about NJP’s typesetting was not very good, I think it is interesting to think about why he felt so disguted by it, which might help us overcome resistence to NJP in particular and open access in general.

A simple explanation is that the APS is more famous than the IOP, and as a young grad student he grew up reading APS’s papers, and internalized REVTeX as “the” scientific format. Well, that’s at least what happened to me.

But apart from that, I think that there are some objective problems with NJP’s typesetting:

1 – The first page that identifies the downloader. I know that it’s standard for IOP (and still ugly), but particularly insane for an open-acces journal.
2 – Colourful logo and colourful typesetting. Come on.
3 – iopart.cls does not play well with amsmath. And if I recall correctly, it had some technical issues with more modern LaTeX packages.

But back to the relevant point: I dare to hope that an author-pays model actually increases quality, by disincentivizing the author to publish as many papers as he can about a subject. It might be completely subjective, but the quantum info papers I read at the NJP tend to be like more complete treatises about a new idea than the piecemeal reporting that I often find at PRA(L).

25. **Bob Levine**
October 21, 2012

The pointedly-ignored elephant in the living room of this discussion is the fact that post-circulation/publication refereeing will never be a practical possibility as long as academic culture continues to be what it’s been for a long time now. Tenured members of academic units do not want to determine the tenure cases of their probationary colleagues based on their own assessments of those colleagues’ research. In most cases, they do not feel competent to do so, and for good reason—there may at most one or two others in a given department qualified to carry out that assessment. And no one feels that the reports from the externals should be allowed to completely determine their colleague’s fate (especially as its not unusual for the externals to disagree rather spectacularly, reflecting their own scientific agendas). What everyone wants—faculty P&T committees, academic administrators, university legal departments—is an ‘industry standard’ criterion that they can point to to defend their up-or-out tenure decisions, and the prime standard is the hierarchical ranking of publication venue, based to a large extent on the severity of the latter’s refereeing criteria. That’s the dynamic that Elsevier and its ilk prey on, and the reason that you’re just not going to see ‘after the fact’ refereeing adopted as common practice. Open access is the wave of the future, no question; but P&T considerations are going to ensure that serious refereeing, and ranking of OA venues, is going to be an integral component of that wave.

26. **A.**
October 22, 2012

@Bob: indeed, agree that the higher-ups need a number to point at in order to justify their lunch-meeting cheese and wine decisions. However, that number can be taken from the arXiv. Total citations, h-index, it’s all there.

I’d also suggest that we already have “post-circulation/publication refereeing”, it’s a part of the arXiv: has the paper been withdrawn, are there comments, what does it’s citation count look like, etc.

In case it wasn’t totally obvious, “go arXiv! Boo to Elsevier!”, etc

@Peter, Bob,

One of the benefits of having some sort of formal refereeing layer on the top of the arXiv might would be that it might help convince the higher-ups that the arXiv is a bona-fides system/journal. Getting the balance right will be tricky since, I imagine, it would be very easy to start down the slippery slope of turning the arXiv into a traditional journal with, for example and god forbid, access restrictions. (Although, I don’t really believe that pleasing the higher-ups is a good motivation for doing anything at all.)

27. **fuzzy**
October 22, 2012

i think that open access system needs to give more importance to referees. in this system, the editors are in a position of conflicting interest, being payed by those who publish. it is like a tribunal where the judge will be payed in one of this two manners; cash by the accused defendant–called “submitter”–or after very long time by its abstract (and almost absent) opponent–called “science”. a recent experience of mine: i was requested a report and i have sent a detailed one, that meant “reject” or at least “major revision”. the editor has cutted it dramatically, giving no explanation, and then has asked the author: if you want please take into account these minor remarks. maybe this is the right way to advance the physics of high energies, but i do not think so

28. **M**
October 22, 2012

Under SCOAP3, some journals will get about 1000$ per accepted paper.
Most of the work is done by referees, who get nothing.
Why should a referee do unpaid work to make publishing companies rich?

29. **Oceanographer**
October 22, 2012

Here you can see a good example of author pays journal that is becoming more and more successful
http://www.ocean-science.net/
even if the average price per publication is much more than 500$ and they charge in advance even if the paper is rejected (in such case it is still available in the ocean

science discussions together with the reviews and discussion)
You can look at some papers there- it is an interesting model. Also there are other journals of the European Geosciences Union following the same model- the open peer review process is a key factor here for the absence of junk papers.
So the author pays model is also viable in my opinion.

30. **Allan Rosenberg**
October 22, 2012

Il est tout à fait certaine que Prof. Rathque avez obtenu des résultats nouveaux et utiles….

31. **Ptrslv72**
October 22, 2012

BTW, there is a blog fully devoted to tracking "predatory publishers" that abuse the OA system:

http://scholarlyoa.com/

Perhaps it has already been mentioned in the thread, apologies if I missed it.

32. **Peter Woit**
October 22, 2012

Ptrslv72,

Thanks. However looking at that web-site makes clear that the problem I'm worried about is already with us. They try and distinguish between "predatory publishers" and legitimate ones, but the distinction to me seems to be becoming increasingly unclear.

Look at:

http://scholarlyoa.com/2012/09/18/two-publishers-each-have-a-journal-with-the-same-title/

to see that a "predatory" publisher started an author-pays open access journal called "Journal of Cloud Computing" in 2011. Soon thereafter, Springer started an author-pays open access journal with the same name. It appears to be much more respectable, with a legitimate editorial board. But it's one of many new "SpringerOpen" journals, and starting lots of new journals all of a sudden with this "author pays" model makes one wonder how high their standards will be. Did all of a sudden a lot more high-quality papers get written? Or will these journals just publish lots of things that would have had trouble getting published in the past, now sped along into publication by funds put up by the author. How different is this from vanity publishing?

For a list of the SpringerOpen journals and what they are charging, see

http://www.springeropen.com/about/apcfaq/howmuch

The "predatory journals" at least are cheaper….

33. **Mathematician**
October 22, 2012

I think author-pays will be a disaster in a theoretical subject like mathematics.
It might work in other subjects where there is a _real_ need for editing on the
part of the journal and large grants riding on publishing, or perhaps where
publishing in widely-read journals enhances the possibility of industrial
application. But in mathematics the situation is clearly different; for one
thing, a lot of mathematics is simply about aesthetics, and so the money stakes
are generally low… (at least, I'm not in on it). I can't help but compare the situation to, say, a newspaper or a magazine that demands payment for publishing contributed articles: What would one think of such a thing? My guess is that most people will have little respect for it, even if the author payment is supposed to make it free. Also, I don't think that it's a good idea to re-enforce the image that mathematicians live in intellectual ivory towers by turning their publication process ever so close to vanity publishing.

34. **srp**
October 22, 2012

This is isomorphic to the problem that a university faces in maintaining its reputation. Yes, Harvard could sell out its undergraduate spots to the highest bidder, but in short order their reputation and ability to charge for those spots would decay. The same holds for any journal that uses an author-pays system. Sure, they could fill up the journal with crap, but if it becomes known as a repository of crap no one will be willing to pay much for a slot in it. It's inherently self-policing.

35. **Peter Woit**
October 22, 2012

srp,

Harvard isn't run as a profit-making organization making decisions solely based on whether they maximize revenue. If it was, they'd be doing some very different things (e.g. eliminating financial aid and raising tuition). Some of these might cause their reputation to take a hit, but they'd end up in a sustainable business model that would bring in much more revenue.

If journals were all run by non-profit organizations, with missions and incentives other than maximizing profit, I'd be much less worried about the author-pays model of financing them.

36. **OMF**
October 23, 2012

Why are universities not obliged to publish and host journals themselves, in house, or as part of a collective? Why must publicly funded research be published in privately owned journals (B cuz der fee-mrkt lulz).

This whole situation is increasingly absurd. Personally, I feel that if research academics feel they need to keep publishing in private journals, then the public should no longer feel obliged to pay their salaries. I think that's what it's going to take to change people's minds.

37. **Low Math, Meekly Interacting**
October 23, 2012

Obviously there also needs to be reforms in the system of peer review, but I have a hard time getting my head around the notion that people can get jobs based on something like their arXiv submission record alone. I guess in theory and maths, where the standards for validation can be quite different than for experimental fields, a referee-free body of literature is a workable solution. But even among theorists, cannot the number of people who are highly qualified to assess the minutiae of an argument often be rather small? For those making hiring decisions, without some sort of "gold standard" like publication in high-impact journals, the whole process could change considerably. Of course I'm in no position to speak with any authority on how hiring is done in the fields of mathematics and theoretical physics. But if there are any similarities to the fields with which I am familiar, when you change the world of publishing as we know it, you change many other things.

Not that that would be bad. At all. But what the best replacement should be seems like a very complicated problem that, again, I'm not sure a preprint server like the arXive can fully address, at least not without some other profound systematic advancements. I used to think that the arXiv was the perfect model for other disciplines, but I'm no longer so sanguine after seeing many comments online about its purported shortcomings.

38. **Orr Shalit**
October 23, 2012

I agree with Peter that "author pays" is a bad direction to be heading in. Following what OMF wrote above, I think that the direction to be going in is towards not-for-profit journals which are funded directly by universities and public bodies (such as Documenta Mathematica, and there are others). The only role journals play right now is in coordinating the peer review process (plus the quick rejections that editors make). Paying for your paper to be published is nothing more and nothing less than buying a bit of the journal's reputation (whatever it is worth).

Above Matt wrote: "These are extremely low-prestige journals that everyone already ignores". Until recently I thought that author-pay was an indicator for extremely low prestige and a solid reason to ignore a journal.

39. **Bob Levine**
October 23, 2012

@Orr:
"Until recently I thought that author-pay was an indicator for extremely low prestige and a solid reason to ignore a journal."

Ah, but it sounds as if you've seen the error of your ways, eh? 😉

Seriously, some extremely prestigious OA journals charge high, even absurd fees (though they probably don't see it that way). Take a look at the following survey of prices:

http://www.lib.berkeley.edu/scholarlycommunication/oa_fees.html

The cost-to-author numbers top out at around $5K; PLoS, which has a tremendous reputation especially in biosciences, as I understand it, will take you up to almost 3K. The assumption is that you're going to be shelling out from your grant $$, which is a bit rough on people whose research is not of the kind for which huge grants are appropriate to begin with….

40. **Neil**
October 24, 2012

To play devil's advocate, in *principle* it should work. No author should want to pay to publish in a shoddy journal, and no university should put much weight on publications in shoddy journals. The only way a pay-to-play journal should make a big profit is for it to have a reputation for high quality, in which case authors should be willing to shell out the big bucks, and institutions should weight the publications highly. Only if the profession can't tell shoddy articles from good should there be a problem.

All the "shoulds" are intended.

41. **Orr Shalit**
October 24, 2012

@Bob:
Well, it appears that some author pay journals have good reputations, so I guess I was mistaken about that. Also, ignoring this phenomenon doesn't seem like a good idea any more.

@ Neil:
Suppose all journals were author pay, and journals prices corresponded to reputation. Even if there was no problem of journals having a high incentive for publishing "gobbledygook", and even if they never do, I still do not see how someone can feel comfortable paying 5K out of their publicly funded grant (instead of, say, 1.5K) just to be in a more prestigious journal.

42. **chorasimilarity**
October 24, 2012

Journals were invented for disseminating knowledge. This is now an obsolete method. It means that the system, as it is now, will (slowly) die. Fact!

This "authors pays open access" is just a perverse effect. Pay for what, exactly? If it is for having refereed papers, pray tell me how much a referee is payed?

43. **srp**
October 25, 2012

Peter says:

"srp,

Harvard isn't run as a profit-making organization making decisions solely based on whether they maximize revenue. If it was, they'd be doing some very different things (e.g. eliminating financial aid and raising tuition). Some of these might cause their reputation to take a hit, but they'd end up in a sustainable business model that would bring in much more revenue.

If journals were all run by non-profit organizations, with missions and incentives other than maximizing profit, I'd be much less worried about the author-pays model of financing them."

You're almost certainly wrong about Harvard's profit-maximizing strategy. High tuition and financial aid (which are complements, not substitutes) enable the university to price discriminate successfully, charging lower prices to more price-sensitive customers and higher prices to less-sensitive ones. In addition, the high demand for Harvard's slots is largely a function of its perceived exclusivity and student quality. The main thing that a profit-maximizing Harvard would do would probably be to expand the class size, which they could probably do by 50% without lowering average student quality or exclusivity by a measurable amount.

But regardless, I don't see what the problem is with a multi-tier journal system in which the most prestigious ones charge more (with financial aid for those who can prove hardship–i.e. price discrimination) and the less-prestigious ones command a smaller price from authors. Readers will know which ones are the good ones, the not-so-good-ones, and so on down the line. Why would this scenario have any negative effect on the progress of science?

It seems you are assuming that readers will not fairly quickly pick up on which journals are worth reading and which ones aren't, and that lousy journals will somehow confuse or pollute the knowledge stream. But that argument proves too much–Frank Wilczek has pointed out that almost all published physics articles now are "attractively published junk" (in his Longing for the Harmonies, where he attributes this wisdom to David Gross, then his advisor). Sturgeon's Law is perhaps even more inexorable than Parkinson's or Murphy's. Author-pays-and-readers-have-open-access seems to me no worse on quality and certainly better on dissemination than author-gets-a free-ride and reader must pay.

44. **Costas**
October 25, 2012

October 27, 2012

Testing the Finch Hypothesis on Green OA Mandate Ineffectiveness

We have now tested the Finch Committee's Hypothesis that Green Open Access Mandates are ineffective in generating deposits in institutional repositories. With data from ROARMAP on institutional Green OA mandates and data from ROAR on institutional repositories, we show that deposit number and rate is significantly correlated with mandate strength (classified as 1-12): The stronger the mandate, the more the deposits. The strongest mandates generate deposit rates of 70%+ within 2 years of adoption, compared to the un-mandated deposit rate of 20%. The effect is already detectable at the national level, where the UK, which has the largest proportion of Green OA mandates, has a national OA rate of 35%, compared to the global baseline of 25%. The conclusion is that, contrary to the Finch Hypothesis, Green Open Access Mandates do have a major effect, and the stronger the mandate, the stronger the effect (the Liege ID/OA mandate, linked to research performance evaluation, being the strongest mandate model). RCUK (as well as all universities, research institutions and research funders worldwide) would be well advised to adopt the strongest Green OA mandates and to integrate institutional and funder mandates.

Gargouri Y, Lariviere V, Gingras Y, Brody T, Carr L & Harnad S (2012) Testing the Finch Hypothesis on Green OA Mandate Ineffectiveness *Open Access Week 2012*

48. **LOL**
November 1, 2012

This "Advances in Pure Mathematics" journal sent me an e-mail today in which they invited me to submit an article. I responded to the e-mail and jokingly told them that I wanted to submit a Mathgen article. I just got back the following from the journal:

Dear author,
Glad to hear from you.
Kindly be informed that you can send your new paper which has not been published to us.
We look forward to your paper.

Please feel free to contact us if you have any questions.

Best Wishes

49. **S Halayka**

Categories: Uncategorized

- On the LHC front, new results will be announced at the Hadron Collider Physics Symposium in Kyoto, which opens November 12. Jester has a good summary of what to look for on the Higgs front here. The new results should be based on about 12-13 fb^{-1} of 2012 8 TeV data (this past summer's used about 5 fb^{-1} each of 2011 7 TeV data and 2012 8 TeV data). Unblinding of the results should have taken place recently, so soon about 6000 physicists will know what the news is and start talking about it…
- The latest Scientific American has a cover story about particle physics that comes under the "This Week's Hype" heading. It's called "The Inner Life of Quarks" and discusses models in which quarks and other elementary particles of the standard model are composites of more elementary objects called "preons". The fact that the papers on the subject it refers to are from 1979 should make one suspicious: an idea that hasn't had major developments in 33 years is a dead idea. Besides the overwhelming experimental evidence against preons (with the LHC bringing in many new much stronger negative results), the idea has huge inherent problems. The main issue is that one is trying to put together composites with masses as small as MeVs (or lower, if you try to do this with neutrinos) while the data says that things are point-like up to TeV scales, with just the forces you know about up to such scales.
- For the latest on Paul Frampton's troubles as the victim of a scam that has left him in an Argentine jail, see this article entitled Imprisoned UNC professor thinks he deserves a raise. I'm assuming this was before his trip to South America, but at some point Frampton clearly did some extensive research, comparing his salary ($107K) to those of some of his illustrious peers ($203K-$532K according to him, just using data from public universities). Not clear though that this was really something to bring up in his argument about whether the university should still pay him even if he's in jail.
- I only recently heard the old news that Fields Medalist Vaughan Jones has left Berkeley to take a job at Vanderbilt University. Evidently one reason for doing this was a salary number of the sort that Frampton covets.
- Freeman Dyson has a piece in the New York Review of Books about Jim Holt's new book Why Does the World Exist (see my take here). Not much in the review actually about Holt's book, but Dyson takes the opportunity to enter the ring in the fight over nothingness with some late blows aimed at the philosophers. He doesn't think much of modern philosophy, ending with:

  > The great philosophers of the past wrote literary masterpieces such as the Book of Job and the Confessions of Saint Augustine. The latest masterpieces written by a philosopher were probably Friedrich Nietzsche's Thus Spoke Zarathustra in 1885 and Beyond Good and Evil in 1886. Modern departments of philosophy have no place for the mystical.

  There's a Chronicle of Higher Education piece about this here, Brian Leiter's blog hosts a discussion here.

- I'm loathe to post anything about US politics here, since it's a depressing and omnipresent topic these days, but for an HEP angle, see this in Science from Adrian Cho, and this in the NYRB from Steven Weinberg. Don't even think though of posting comments about politics here…
- Greg Moore recently gave the Felix Klein lectures in Bonn on Applications of the six-dimensional (2,0) theory to physical mathematics . Video here, lecture notes here.
- This week at Stony Brook there's a conference in honor of Blaine Lawson's 70th birthday. Lawson is a great person and a wonderful geometer; I very much enjoyed getting to know him a little bit during my days as a physics postdoc at Stony Brook. He was one of several examples that convinced me that leaving physics for mathematics would at least promise hanging out with nicer people. I've been too busy this week to get out to Stony Brook, had formed a crazy plan to bike out there this weekend for Nigel Hitchin's talk Sunday morning, but a nasty cold has put an end to that plan (Sunday's weather prediction for an approaching hurricane might in any case have made a long bike trip not the best idea in the world). Videos of the talks are available here.

  Happy Birthday Blaine!

Comments

   October 26, 2012

   It's JIM Holt, Dr. Woit.

2. **Peter Woit**
   October 26, 2012

   Oops, fixed. Thanks!

3. **Joe**
   October 26, 2012

   Peter,
   Thanks for the links. It's always a pleasure to read your posts.
   One question: When exactly will we be able to know Higgs' spin?

   Best

4. **Peter Woit**
   October 26, 2012

   Joe,

   Thanks. I haven't paid much attention to the spin measurement issue, since as Jester points out, it seems highly unlikely to be anything but zero. Maybe someone better informed than me can comment, but I'd guess that since I haven't seen any analysis of this in this summer's data, the modest amount of new data since then isn't going to make enough of a difference for CMS or ATLAS to be able to say something about the spin next month.

5. **Dario**
   October 27, 2012

   "2008 data" should be "2012 8 TeV data" probably.

6. **MathPhys**
   October 27, 2012

   Any clue who makes $532,000 as a physicist in a public US university?

7. **MathPhys**
October 27, 2012

Right. Of course. I should have known. Because when I first heard about it, it was described as “More than the football coach”.

8. **Shantanu**
October 27, 2012

Peter, since I don’t have subscription to scientific american, who wrote the article?
Also did the article claim that this isa prediction of string theory?
I do hope people complain about such articles.
shantanu

9. **Peter Woit**
October 27, 2012

Dario,
Thanks, fixed.

MathPhys,
Yes, it’s Weinberg. The UT football coach however makes $5.2 million/year.

Shantanu,
The author is Don Lincoln. String theory doesn’t really play a role, although I think he mentions that string theory could explain preons (also that LQG could…)

10. **Steve L**
October 27, 2012

Hi Peter, I love your site. I took undergrad complex analysis from Prof. Lawson at UC Berkeley in 1974 or so. Even back then I believe he was well known in the minimal surfaces biz. He was an excellent teacher, very clear and full of enthusiasm for the subject, friendly and approachable. Glad to see him mentioned on your site. Happy birthday Professor Lawson! Students never forget a good teacher.

11. **Tienzen (Jeh-Tween) Gong**
October 28, 2012

Preons are dead, but prequarks are not.

12. **Dario**
October 28, 2012

Peter:

this edition by Scientific American http://www.sciamdigital.com/index.cfm?fa=Products.ViewIssue&ISSUEID_CHAR=51440409-237D-9F22-E8A91238D0D12A7B is even worse…

Gong Tienzen:

of course prequarks are dead as well, and for the same reasons as preons are. Quarks are not composite, as experiments on their size, magnetic moment and interactions show. There is no hint of compositeness, and worse, there is not even a way to consistently *imagine* compositeness of quarks. Quarks are not composites of other particles.

13. **Peter Woit**
October 28, 2012

Dario,

Your SciAm link goes nowhere for me. Is this to the Don Lincoln story?

14. **BJM**
October 28, 2012

Dario’s link worked for me. Maybe you can get to it via

October 28, 2012

BJM,

Thanks. I'll look and see if I can find a copy of that, but it looks like it's a collection of old articles, some of which were featured here as "This Week's Hype"…

17. **Jim Martindale**
October 28, 2012

http://www.scientificamerican.com/article.cfm?id=the-inner-life-of-quarks
will get you a taste of Don Lincoln's article. The preview has a comment section.

For those without access this is from beyond the pay wall:

The first is size. The Standard Model treats the quarks and leptons as pointlike—that is, particles with zero size and no inner structure. Finding a nonzero size for those particles would provide powerful evidence for preons. Measurements have shown that protons and neutrons have a radius of about 10–15 meter. Experiments at the world's leading particle colliders, past and present, have searched for evidence that quarks or leptons also have a measurable size. Thus far all the data are perfectly consistent with zero size or with a nonzero size as small as about 0.0002 to 0.001 times the size of a proton. To distinguish between those two possibilities (zero size versus very, very tiny), we need to make more precise measurements. The LHC is a discovery machine, and the huge amount of data expected from its current collisions and a scheduled upgrade in the accelerator's energy are two ways in which we can expect to learn more about the size of quarks and leptons.

then

The future of hunting for structure within the quarks and leptons is brighter than it has been for a long time. As you read this article, my colleagues and I are combing through the huge amount of LHC data already taken. We are searching for evidence that quarks and leptons have a nonzero size. We are looking for a fourth generation of quarks and leptons and for some evidence that the force-carrying particles also have generations—that the W and Z bosons, which mediate the weak nuclear force, have heavier cousins.

18. **braiding**
October 29, 2012

Do these objections to preons and pre-quarks also apply to Bilson-Thompson braiding?

19. **Kavanna**
October 29, 2012

There's zero evidence for quark or lepton substructure. How to get MeV masses from TeV+ dynamics? Pack a powerful spring into a small space, use E=mc^2, and you get a correspondingly large mass. Hard to see how this doesn't create another hierarchy problem, and a gratuitous one to boot.

The philosophers who push the "why is there something?" idea are a sad lot. They seem not to understand why questions of this sort cannot be answered as framed, as if Hume or Kant had never lived. This rot is a product of Heidegger and his acolytes, not the Anglo-American "analytic" philosophy that once dominated many philosophy departments. Unfortunately, Heidegger et al. is the origin of the post-modernist disease that has destroyed much of the humanities in the US and elsewhere in the last 30 years. Dyson is right — the last great Western philosopher was Nietzsche. In the 20th century, only Wittgenstein can even be thought of on the same level.

(Peter – I've liked Not Even Wrong since it was published. Your book, and Smolin's, said out loud what so many were saying in private, but couldn't risk saying publicly. It also helped me to understand what had happened to the once-productive, open, and competitive world of high-energy physics I was once a part of and how it became a closed cult.)

20. **Anonyrat**
October 29, 2012

Offtpoic, hope you are weathering Hurricane Sandy well!

21. **Peter Woit**
October 30, 2012

Anonyrat,
Thanks, but I'm in Nebraska. When classes were canceled I decided to start a short planned trip to Yosemite early, rented a car and started driving west. Wyoming tonight Yosemite Thursday night.
Back in NYC next week where it seems to be quite a mess.

22. **David Nataf**
October 31, 2012

What does it mean for a proton to have a "size" of 10^-15 m and for an electron to be "point-like"?

Protons don't have a "size", they have an interaction-dependent cross-section, and so do electrons.

What am I missing?

23. **Yatima**
October 31, 2012

@Kavanna:

“Dyson is right — the last great Western philosopher was Nietzsche.”

Maybe so; then there is Sartre and Alissa Rosenbaum. Now, I would like to imagine Nietzsche’s disgust when told that the world can – as far as we know – be accurately and objectively described by appropriate mathematical formalisms that instead of “a will to power” seem to exhibit “a demand for symmetry” instead. He would probably pop a vein in his forehead.

24. **adsfasdfsss**
November 1, 2012

loath not loathe

25. **Chris Austin**
November 1, 2012

David,

The non-zero spatial extent of atomic nuclei was first detected by observing that for elastic scattering of electrically charged particles on fixed targets, the measured scattering cross section at the largest scattering angles was, for sufficiently large projectile energies, smaller than the Rutherford scattering cross section calculated for a point-like nucleus. The reduction in the large-angle scattering is due to the electrostatic potential energy of the projectile, e.g. an electron, no longer increasing with decreasing distance between the projectile and the centre of the target nucleus once that distance is smaller than the nuclear radius, so that Coulomb’s law no longer applies below that distance.

If electrons were made of preons, then the preon distribution would have some non-zero spatial extent, and Coulomb’s law for the electrostatic potential energy between an electron and a positron would no longer apply for separations smaller than that spatial extent, which would again result in reduction of the elastic scattering cross section at large scattering angles in comparison to the result expected for point-like electrons and positrons, for high enough energies of the electrons and positrons in a colliding beam experiment such as LEP.

The same principle would apply if quarks or gluons were made of preons, since the scattering cross sections of individual quarks and gluons can be indirectly detected by the “jets” of hadrons they lead to, at the LHC.

26. **harryb**
November 1, 2012

Peter, as ever, great set of issues to delve into and follow – many thanks. In Europe, this blog is continually quoted as a key “hard” science venue. Now, at the risk of your wrath re not commenting on politics after mention of the Weinberg NYRB article, let me try a quick reference to Nate Silver’s new book, The Signal and the Noise – would be interesting to get your thoughts on it. Two reasons: one, its a very good read on statistics and probability, and the second half of the book is a very convincing case for approaching nature, and life in general, from poker to probability of extra-terrestrial life using a Bayesian framework. Two: he is a huge proponent (on this basis) of demanding that any premise or theorem be based on a falsifiable prediction. To this end, his increasingly well-known fivethirtyeight blog – http://fivethirtyeight.blogs.nytimes.com/ – sticks its neck well out on the upcoming US election (spoiler – 80% likelihood Obama re-elected).
Finally – a rigorous Bayesian approach to String Theory seems well overdue. Lack of evidence of SUSY at the LHC should cause any prior probability of ST being valid now downgraded to a (much?) lower posterior.

27. **jg**
November 2, 2012

To add another potentially useful link for readers, the Royal Society has made most of its publications open access until 29th November 2012, so if (for example) you ever wanted to compile a collection of every Dirac paper published in ‘Proceedings A’ go here

28. **layman**
November 2, 2012

I hope you did not miss this one

http://arxiv.org/abs/1211.0004

and will comment on it.

29. **Gert**
November 3, 2012

Peter,

maybe the lack of LHC Higgs rumors is due to a disappearing Higgs signal. Is all of CERN now busy covering up the result that the bump is getting smaller and smaller?

30. **Peter Woit**
November 3, 2012

Gert,

Maybe the lack of Higgs rumors is due to CERN covering up the disappearance of the Higgs, maybe it is due to my being on vacation. Let’s see what happens later next week…

31. **A.J.**
November 4, 2012

@harryb:

That evidence computation is rather non-trivial. To do it from first principles, you’d need to start with a definition of string theory, and work out the probability of various TeV scale experiments. This is effectively impossible, even if you’re willing to take a matrix model as a non-perturbative definition; we simply do not know how to do these computations. Instead, people make additional assumptions, such as “string theory is well-approximated at low energy by the perturbative MSSM, with the following susy breaking pattern”. This gives you an (uncontrolled) approximation to the true evidence function, and now you can turn the Bayesian crank. But you’re now testing the joint hypothesis “string theory is true” AND “my uncontrolled approximation is accurate”.

This fact is what makes arguments about string theory so boring. We can't make unambiguous Bayesian judgements (in this sense the theory is certainly 'not even wrong'), so we're reduced to arguing about our priors on the conditional distribution of our ancillary assumptions.

32. **harryb**
    November 13, 2012

    @ A J
    Understood and thanks
    Yet given latest SUSY probability downgrades you'd think the trend is just instinctively against ST
    And maybe your greater point is that if any theory resists a reasonable Bayesian test you should be deeply suspicious – a la Mr Woit
    By the way – Nate Silver did good on the prediction front.

A Lost Generation?

November 4, 2012
Categories: Uncategorized

I'm in Northern California, on a vacation originally intended to be short, but started early due to the storm in New York. I wanted though to recommend reading something that a commenter here pointed to. It's an article by Mikhail Shifman (author by the way, of an excellent recent textbook I somehow haven't found time to discuss here) about the current state of particle theory that he has just posted on the arXiv, with the title Reflections and Impressionistic Portrait at the Conference "Frontiers Beyond the Standard Model," FTPI, Oct. 2012. The reference is to this recent conference, held at his institution.

Shifman surveys the current state of particle theory, with a range of interesting comments about the paradigms of grand unification, extra dimensions, supersymmetry and string theory that have dominated the subject for nearly 30 years. The negative LHC results provide a serious challenge to these paradigms, although I'd argue that they have been in trouble for a very long time, with the LHC just the final nail in the coffin. Much of the activity among theorists reported at the conference referred to by Shifman revolves around attempts to prop up some of these ideas. This is going to be increasingly unsustainable as stronger and stronger LHC bounds emerge. Where will this leave the field? Shifman argues that this is a time of opportunity, with the death of old paradigms opening the way for new ideas. I hope he's right. Here are his final comments, of a sociological nature:

> It is easy to estimate the total number of active high-energy theorists. Every day hep-th and hep-ph bring us about thirty new papers. Assuming that on average an active theorist publishes 3-4 papers per year, we get 2500 to 3000 theorists. The majority of them are young theorists in their thirties or early forties. During their careers many of them never worked on any issues beyond supersymmetry-based phenomenology or string theory. Given the crises (or, at least, huge question marks) in these two areas we currently face, there seems to be a serious problem in the community. Usually such times of uncertainty as to the direction of future research offer wide opportunities to young people, in the prime of their careers. To grab these opportunities a certain reorientation and reeducation are apparently needed. Will this happen?

HCP2012

November 9, 2012
Categories: Experimental HEP News

The Hadron Collider Physics Symposium will be next week in Kyoto, with announcements of new results from the LHC, some details of which are starting to trickle in. Chris Quigg explains what to look for here.

The LHC has just recently passed the milestone of 20 fb^{-1} of data at 8 TeV this year. Perhaps this will get up to 25 fb^{-1} by the end of this run later this year. After a heavy ion run early next year the machine will go into a long shutdown (until late 2014) for repairs to allow operation at close to design energy (probably at 13 TeV). Next week results will be reported based on 12 fb^{-1} (CMS) and 13 fb^{-1} (ATLAS) of this year's 8 TeV data (compare to this past summer's results based on 5.3 fb^{-1} (CMS) and 5.9 fb^{-1} (ATLAS)). Expect results from the full 2012 data at Moriond in March, with an official combination of results from the two experiments next summer.

On Monday LHCb will report the latest results on B(s)->mu+mu-, and the latest Higgs news should come at the Higgs parallel session on Wednesday. There will also be quite a few new, stronger limits on SUSY.

I'm hearing that these new results already can rule out the idea that this new particle is a pseudo-scalar. There will be no confirmation of an unexpectedly high gamma-gamma rate. Some excesses in the tau-tau channel are being seen, of roughly the size you would expect for a SM Higgs. So, all in all, things are still consistent with a SM Higgs. If not, please let me know….

Update: The B(s)->mu+mu- results from LHCb are out (see here), providing good agreement with the SM, and new, strong limits on possible SUSY models (see the last slide). More from Matt Strassler and Michael Schmitt.

For another source for new LHC results, together with interpretation of their signficance, the Chicago 2012 Workshop on LHC Physics is starting today.

Comments

1. **Anonymous**
   November 9, 2012

   I wonder if Atlas will report the 3 GeV difference they observe in the Higgs peak for different channels…

2. **Kernel**
   November 9, 2012

   Dr. Woit, your writings over the last year make it seem as though CERN is pretty close to being able to refute SUSY. I'm curious to know what you think will be the timeline for the death of SUSY, and maybe what you think the community reaction will be. You've posted some interesting examples of denial, but when do you think a prominent SUSY theorist will come out and say that this is probably not the way our world works?

   I'm somewhere between a layperson and a physicist (I'm a PhD candidate), and I have seen no evidence to believe in SUSY. I don't believe in it because the little I have comprehended seems 'not crazy enough' (as Wheeler once said). When can I claim that my view is scientifically valid?

3. **Peter Woit**
   November 9, 2012

   Kernel,

   Since the "death of SUSY" is a topic covered to death on this blog, I'd rather not go on about it more at this time, but stick to the topic of the upcoming conference. The progress of the SUSY community through the various stages of grief, from denial to acceptance, has already started, but I've no predictions about how it will play out over the upcoming months and years (other than the obvious one that some people will never give up, no matter what the evidence against them is…)

4. **anon**
   November 9, 2012

   can you please be more specific on "There will be no confirmation of an unexpectedly high gamma-gamma rate. "

5. **Peter Woit**
   November 9, 2012

   anon,

   Not unless someone sends me some more specific information. One rumor though is that there's still some argument on the numbers that will be reported about this…

6. **King Ray**
   November 9, 2012

   Like other wrong ideas, SUSY will die one supersymmetrist at a time.

7. **another anon.**
   November 9, 2012

   Rumor has it ATLAS is going to be cautious about saying things because their measured Higgs masses in the ZZ and gamma+gamma channels differ by enough that they're concerned about miscalibration somewhere. Rumor also has it that at CMS, the gamma+gamma excess is smaller now. As most reasonable people would have expected….

   (I hadn't heard the tau news. That'll be a nice addition to what we know.)

8. **MathPhys**
   November 9, 2012

Kernel,

There is in principle no way that LHC or any other machine that operates at a certain finite energy can refute supersymmetry, since one can always claim that susy is broken at a sufficiently higher energy level to be observed.

What one can do is to argue that susy is broken at such a high energy that its presence makes no difference to observable phenomena. When that is the case, the only justification of susy becomes the mathematical consistency of certain models, such as strings.

9. **Bob Jones**
November 9, 2012

"Like other wrong ideas, SUSY will die one supersymmetrist at a time."

Sorry, I don't think it's possible for SUSY to die at this point. It makes no difference if it doesn't show up at the LHC because supersymmetric quantum field theories are important for theoretical reasons. For one thing, they're the easiest theories to analyze mathematically because you have techniques like localization at your disposal. Supersymmetric theories have applications in physics (like Witten's proof of the positive energy theorem in classical general relativity), and they also have many applications in pure mathematics (proofs of the Atiyah-Singer index theorem, the Morse inequalities, applications to elliptic cohomology, Donaldson theory, and the geometric Langlands correspondence). If you really think SUSY is going to die, you're getting too much of your information from this blog…

10. **hank**
November 9, 2012

@Bob:

If it can't die, it's not science. (Sorry for the repetition. On the one hand it's not going to make a difference, on the other hand it has to be said.)

An interesting question would be: Should we keep an idea alive in physics because it seems to be fruitful in certain branches of mathematics?

11. **Thomas Larsson**
November 9, 2012

Bob Jones, thank you for the illustration.

12. **Bob Jones**
November 9, 2012

"If it can't die, it's not science."

I completely agree.

"An interesting question would be: Should we keep an idea alive in physics because it seems to be fruitful in certain branches of mathematics?"

That is an interesting question, but it's also somewhat hypothetical because ideas like supersymmetry and string theory are not only useful in mathematics. They also have tons of applications in physics. In addition to the examples I gave above, you also have applications of N=4 gauge theory to QCD. That's a hugely important topic in physics where supersymmetry comes up.

13. **johnmcAllison**
November 9, 2012

The latest LHC schedule:

https://espace.cern.ch/be-dep/BEDepartmentalDocuments/BE/LHC_Schedule_2012.pdf

So two more weeks of running, adding another 2/fb, and then final three weeks for major machine development and 25ns development. It looks as if they should deliver between 22.5-24/fb for 2012

14. **Peter Woit**
November 10, 2012

Please, enough about SUSY unless it's about the HCP2012 conference.
My reference to "death of SUSY" was short-hand for "death of SUSY extensions of the SM that have dominated the field of BSM physics". The fact that there's a much more complicated and interesting story about SUSY in general is one reason I don't think it's a good idea to discuss it here, where it's far off-topic, and the actual topic is I think both interesting and highly timely.

15. **Kinshasa**
November 10, 2012

Bob Jones wrote: "Supersymmetric theories have applications in physics (like Witten's proof of the positive energy theorem in classical general relativity)".

It is quite a stretch to call Witten's positive energy proof an application of supersymmetry. True, Witten's original article discusses a motivation coming from supergravity (quote: "a few speculative remarks will be made about the not altogether clear relation between the previous argument and supergravity"). But that is certainly not the most natural way to think about it. The natural way to think about it is this: In the early 1960s, Lichnerowicz — not thinking about SUSY in any way whatsoever — had showed by spinorial methods that certain closed manifolds do not admit Riemannian metrics of positive scalar curvature. Witten's proof is closely analogous to Lichnerowicz' argument, dealing with asymptotically flat manifolds instead of closed ones.

If you really want to interpret Witten's proof in a field-theoretic way, you should notice that the only field involved is purely fermionic: a spinor on a 3-dimensional spacelike surface.

I would argue that certain other presumed applications of supersymmetry in mathematics, for instance Seiberg-Witten theory, do not have to do anything with SUSY either. Yes, Columbus found America while he wanted to get to India; but America is very far from India, and travelling westwards from Europe, you arrive at it naturally, no matter whether you are heading for India, China, or the setting sun.

Saying that Witten's positive energy proof or the Seiberg-Witten equations are applications of supersymmetry is like claiming that Teflon was a spin-off of the NASA space missions, or that Newton's gravity theory would not have been discovered without apple trees.

16. **Hal Porter**
November 10, 2012

I presume that doubling the data will fine up the range of potential masses and other characteristics of the particle. The existence of the Higgs itself, and a general mass range are of obvious importance and appears to have been achieved.

Which leaves the question, (which I hope is not too far off topic): how much practical, computational (?), difference will the reduction of the + or – of the mass by a couple of percentage points mean vis a vis any current theoretical perspective?

If any.

17. **Peter Woit**
November 10, 2012

Hal Porter,

The interest now isn't so much in getting a more accurate Higgs mass, but in seeing the Higgs in different channels and measuring the production cross-section x branching ratio in each of those channels. Any deviation of those from the SM predictions will indicate new physics: either new particles, or a different coupling between the Higgs field and other SM fields than expected.

November 12, 2012

Slides have appeared for today's talks here http://kds.kek.jp/conferenceDisplay.py?confId=9237 and those on new results for B(s)->mu+mu- by Johannes Albrecht seem to say: (1) first evidence for decay (3.5σ level) (2) data disfavours constrained SUSY at high tanβ.

22. **A.**
November 12, 2012

The BBC have picked up on this, reporting that "[The existence of SUSY] would help explain why galaxies appear to rotate faster than the Standard Model would suggest".

http://www.bbc.co.uk/news/science-environment-20300100

23. **Anant**
November 12, 2012

Dr. Woit I'm curious to know: what in your view will probably replace SUSY in being a solution to a variety of problems?

24. **Casey Leedom**
November 12, 2012

Ha. Funny. Even The Register has gotten in on this one:

http://www.theregister.co.uk/2012/11/12/supersymmetry_not_quite_dead

Casey

25. **Peter Woit**
November 12, 2012

Anant,
I don't think SUSY ever actually provided a solution to important problems in HEP. This is a long story, which I wrote about extensively in my book (written ten years ago). I pointed out that the case for SUSY was weak back then, it certainly hasn't gotten any stronger.

SUSY in the Hospital?

November 13, 2012
Categories: Experimental HEP News

HCP2012 Higgs results will be announced Wednesday (I'm hearing that CMS tau-tau signal is .7 +/- .5 x the SM value), but interest may focus much more on the strong SUSY exclusions being announced there. So far the LHCb result on B(s)->mu+mu- has been the one getting all the attention, with a BBC News story describing it as "a significant blow to the theory of physics known as supersymmetry". In the story experimentalist Chris Parkes describes the current situation as "Supersymmetry may not be dead but these latest results have certainly put it into hospital." John Ellis is having none of this though:

> Supporters of supersymmetry, however, such as Prof John Ellis of King's College London said that the observation is "quite consistent with supersymmetry".
>
> "In fact," he said "(it) was actually expected in (some) supersymmetric models. I certainly won't lose any sleep over the result."

The story has been picked up by Slashdot, and the Register (which has Supersymmetry takes an arrow to the knee).

The bad news for SUSY out of Kyoto however does not end there. ATLAS and CMS are both coming out with new analyses using this year's 8 TeV data which significantly expand previous limits on SUSY, getting close to ruling out popular last-ditch efforts to save the theory. For the latest, look at this HCP2012 page, this ongoing Chicago workshop, and CMS results announced here (like this), ATLAS results announced here.

The last ditch effort to save the idea that SUSY solves the so-called hierarchy problem goes under the name of "Natural Supersymmetry". It involves moving most superpartners to high masses where the LHC can't see them, keeping only the stop, sbottom, gluinos, and a couple neutralinos at LHC accessible masses. If you look at the bounds given on these masses for instance here, and compare to the latest LHC results, you'll see that there's trouble on all fronts for this idea, which is now very close to being essentially ruled out.

Gordon Kane is fighting back against the BBC by going to Lubos Motl's blog to argue that the LHCb result is no problem for his string theory "predictions". You see, his "prediction" is now that most superpartners are way beyond what the LHC can see, so not only is the LHCb result not negative for SUSY, but it "adds to the evidence for supersymmetry and for M/string theories". Kane doesn't mention any of the other SUSY excluding results coming out this week, or their implications for his "prediction" of the gluino mass. Last year Kane was telling Tommaso Dorigo

> I and others expect this decay to tops and bottoms is the signature by which gluinos will be found, with masses well below a TeV

and his slides had a gluino mass prediction of about 600 GeV. Late last year he was arguing that the gluinos would be seen by this past summer. More recently, he's modified the graph in his slides to move the gluino up to 1 TeV. This week ATLAS reports a new gluino mass limit of 1.24 TeV, so Kane will have to modify his slides yet again.

The combined effect of the bad press and the devastating experimental results on the 30 year old SUSY juggernaut will be interesting to follow. At this point, it is hard to see how one could rationally expect anything positive for SUSY to come out of further analyses of the 7 TeV and 8 TeV data. I suppose many will try and delay acknowledging failure by saying one must wait for the 13 TeV data, which we won't see until 2015 or so, but I don't think this is going to convince many people.

Update: Matt Strassler objects to the BBC article, on the grounds that one should not describe what is happening to SUSY in terms of "blows" or it getting hurt. Instead, one should stick to saying it is getting "cornered", and he agrees that "the cornering of supersymmetry is well underway". The question this raises though is what happens to SUSY once it is cornered if you object to it getting hurt. I suspect the hope of many SUSY theorists is that even once cornered, SUSY will continue to be well-treated, receiving annual $3 million prizes and being taught to new generations of graduate students.

Update: The Daily Mail covers this, with the non-tabloid-like headline Experts take conflicting opinions as to how far results support the theory of super symmetry. Oliver Buchmueller joins Gordon Kane in the bizarre game of claiming negative results as positive for SUSY, making the argument

> 'This is another piece in the puzzle and with it the world appears even more SM-like,' he said. 'It supports SUSY, because that is the only theory that can include the Standard Model in a wider concept of New Physics.'

Update: More about this from Matt Strassler, who writes about Theory Killers at the HCP conference. I guess it's still all right to kill "theories", as long as SUSY herself doesn't get hurt.

Update: The rather odd controversy over the BBC story goes on, with Lubos Motl and Matt Strassler continuing to argue that the scientific method implies that SUSY can't get hurt. I would have thought that it was uncontroversial that if proponents of an idea claimed that it would be vindicated by an experiment, and the experimental result came back negative, that was not good for the idea, but, at least for SUSY, that doesn't seem to be the case. Yes, SUSY comes in infinite varieties, many of them never testable, but the experimental results shooting down its versions sold as the most well-motivated ones do have implications for its health. I see no reason why one needs to wait for the LHC to examine every possible remote corner of parameter space that it can access before remarking on what has happened.

Update: It is being pointed out that the BBC story is inaccurate: the LHCb bounds on Bs meson decays that rule out a large chunk of SUSY theory space were already there in March. So, on this front SUSY entered the hospital in March, not this past week. Of course, an even bigger inaccuracy in the BBC story was describing SUSY as an idea that has only encountered serious health problems recently, rather than many years ago…

Update: There's now a fourth rant from Matt Strassler about the LHCb result, a topic on which he has become a bit of a zealot. The point being made is that SUSY was already so badly injured pre-LHCb that they didn't make things any worse. It's quite possible he's right about this, would be interesting to hear a response from the LHCb people.

Update: A characteristically lucid posting on the topic from Jester: BS and SUSY.

> To conclude, you should interpret the LHCb measurement of the Bs→μμ branching fraction as a general, strong bound on theories on new physics coupled to leptons and, in a flavor violating way, to quarks. In the context of SUSY, however, there are far better reasons to believe her dead (flavor, CP, hierarchy problem, direct searches). So one should not view Bs→μμ as the SUSY killer, but as just another handful of earth upon the coffin 😉

Comments

1. **qwerty18**
   November 13, 2012

   Hi Peter,
   Could you be a bit more precise about what you call "SUSY" here ? Is it the general idea of supersymmetry ? Some specific SUSY breaking models ? The MSSM ?

Thanks

2. **chris**
November 13, 2012

Well, the Machiavellian in me tells me to let them pursue SUSY further. All the better for me – less competition on interesting subjects.

3. **John A**
November 13, 2012

These attacks on string theory are giving Sheldon Cooper heartburn.

Personally I remain completely unimpressed by the constant retreat of SUSY and string theory to energy levels that are currently inaccessible. Any theory that can seriously do that without serious questions or even doubts is moving away from science and into the world of mysticism.

It's like the "God of the Gaps" retreat of religious claims in the face of scientific inquiry.

I suspect that the only way string theory goes away is when the mainstream academic institutions decline to pay for it any more. There needs to be a "Come to God" meeting of theoretical physicists to stop this useless hypothesis draining any more money away from the rest of physics.

4. **Bernhard**
November 13, 2012

I thought Ellis was going to give up on SUSY if it didn't show up until end of this year? Wouldn't now be the time to start saying this is becoming more and more likely? Actually I think what he said was for lower luminosity and center-of-mass energy so….

5. **MathPhys**
November 13, 2012

My private prediction is that SUSY will rise from the experimental ashes as a theoretical necessity. The argument will be that you don't need to see supersymmetry in the lab, but you need to assume that it's there or your models make no mathematical sense.

The reasoning will be that if you want to use quantum field theory, you must make sense of the divergences, which requires an embedding in a string theory, which requires supersymmetry.

6. **Roger**
November 13, 2012

As a HEP experimentalist I'm baffled by the extent to which my community pursues SUSY. Its been "around the corner" for as long as I've been in the field (coming up to 20 years now).

As a field, we have long played a scientifically dangerous game of ranking speculative theories we might see. TeV-scale SUSY has regularly topped the league table owing to it (a) providing a DM candidate (b) unifying the couplings and (c) addressing the hierarchy problem. This is the standard stuff that comes on our opening slides when we present our searches. We seem to have forgotten (or just plain ignore) that (a) works so long as we arbitrarily choose a certain LSP and hope that R-parity isn't violated and that WIMPs can account for dark matter. Similarly (b) works so long as one isn't particularly choosy about having an exact unification and is willing to buy the argument that no new physics is around for over 10 orders of magnitude of energy which would disturb the running couplings. As for (c) most experimentalists don't get that this is *the* reason for the theorists liking TeV-scale SUSY. The reason they don't get it is that they themselves are not particularly convinced by the argument.

We apply extremely rigorous reasoning in our own world i.e. in the preparation of our results. Its therefore odd that we allow ourselves to be seduced by speculative arguments when it comes to the topics we address.

As I mentioned at the start, ranking speculative theories is a dangerous game since it eats up finite resources when it comes to data analysis. There may be signatures of new physics sitting in our data which we have missed because of this. We'll likely catch these signatures anyway sooner or later but it would have been good if the experiments had, at the start, worked out what possible signatures they could observe and studied these without even attempting a ranking as to which are "best motivated" and therefore worthy of more attention.

7. **Bernhard**
November 13, 2012

Roger,

I agree SUSY is a saturated subject in collaborations, but given 30 years of theoretical propaganda it is difficult not to pursue this to the point of exhaustion. I mean, I am of course afraid sometimes on trigger bias based on SUSY models but for the time being it' s difficult not to do this. On the theory side that is a different story, but for experiments I think they are doing what they should – massacring SUSY without mercy.

8. **Pete**
November 13, 2012

I agree with Bernhard – just because SUSY does not exist, does not mean we experimentalists should not search for it. This is useful because at some point (if we don't find it…) theorists ought to go back to the drawing board and come up with a new idea. They probably won't do that, unless as Bernard says we "massacre it" with experimental results showing it is extremely unlikely to exist.

Of course the only worry is if that SUSY is completely wrong, we did produce the new physics in the LHC data, but failed to record any of it because we did not know how to look for it.

9. **Roger**
November 13, 2012

Bernhard and Pete
I'm certainly not proposing that we don't look for SUSY – part of my own research involves falsifying bits of SUSY parameter space. However, the obsession of SUSY has led to the field of exotics searches becoming lopsided in favour of chasing after models which we consider to be "well motivated". A well designed set of generic searches would have been more efficient and be as relevant for SUSY as for other approaches (including those we're not yet able to dream up). There was no need for us to catch the SUSY bug and we should have resisted.

10. **Roger**
November 13, 2012

There is also a more insidious side to this. Whenever I applied for grants, fellowships etc I would emphasise that my work could be used find supersymmetry. To not have played the "topical buzz word" card may well have led to my applications being rejected. I've also sat on committees where candidates have been turned down because their proposed searches were considered to be "unpromising".

We all pay lip service to the idea that we should be prepared to look for the unexpected and that history tells us to expect surprises etc etc. However, in reality, the field can be very conservative and the SUSY obsession, offering a "safe" research plan with lots of exclusions for legions of interested theorists to play with, is a part of that.

11. **Michael**
November 13, 2012

Hi Roger,

I appreciate your point very well. But to me it seems a little overstated. Sure there are lots of papers about "SUSY" searches, but most of those searches are able to pick out evidence for New Physics that does not come from Supersymmetry. The advent of the generic models, addressed regularly in the CMS and ATLAS papers, indicates a major shift away from theory-driven searches toward more signature-based searches. (Sorry for bringing in yet more buzz words.) I believe that most of the signatures that we experimentalists can think of are addressed in one way or another, within the constraints imposed by the triggers and event reconstruction. Perhaps I lack imagination, but it is not easy for me to come up with signatures – or perhaps "event topologies" is a better term – that are not covered somewhere, somehow. If you know of searches that someone could do but can't because the community still invests too much in SUSY, please say what they are. I'm sure many people would be interested. 😉

Michael

12. **Eric**
November 13, 2012

In light of the 126 GeV Higgs signal, it appears to me that the most likely scenario involving low-scale supersymmetry is that the superpartners have masses in the range 3-7 TeV. Furthermore, it seems very likely that R-parity is violated at some level. Given this, it is not at all surprising that supersymmetry has not been seen yet at the LHC. However, there is a very good chance that it will turn up in the next run when the LHC will run at somewhat higher energy.

13. **justin**
November 13, 2012

Is Gordon Kane the Karl Rove of superstring theory?

14. **Justin**
November 13, 2012

@Woit: SUSY may be hospitalized, but this raises the question of what should one work on? String theorists have always said that if you don't like their theory, then what do you have that's better? I've always thought that if someone came up with something viable, then string theory would be far less researched. But, it's a good question of: if not SUSY, then what? Until someone or some people come up with something that actually works, I think we'll continue to see many young and old physicists continue to waste their time on this fantasy.

15. **Peter Woit**
November 13, 2012

Justin,

I don't disagree that the main reason SUSY continues to get attention is a lack of promising ideas for BSM physics. This is an argument for continuing to do SUSY searches (the discussion between commenters above was quite good about this).

From the point of view of theorists though, the lack of a better idea is no justification for refusing to admit failure. Intellectual dishonesty is not a likely way forward towards a more promising research program.

16. **emile**
November 13, 2012

I can't think of a SUSY search being performed right now that should not be done even if one assumes there is no weak-scale SUSY. The problem has been in the past that sometimes parts of phase space were being ignored because MSUGRA did not provide a solution there. But in any case, I think it is important to convey to the wider audience that these searches are not a waste of time. The SUSY searches cast a wide net. Something other than SUSY could be picked up in that net.

@Mathphys: your theoretical necessity idea should be discussed within the field of philosophy or maybe math, and the associated research should not be supported by physics grants. I have the highest respect for my philosophy colleagues, so I'm not trying to demean the field at all, I just want to make it clear that once you take experimentation out of the picture, it is not science.

17. **Justin**
November 13, 2012

@Woit: I agree that SUSY proponents are being dishonest, [deleted]. But, my question is still this: is there any direction a young researcher might pursue if he or she wants to come up with something new?

18. **Igor Khavkine**
November 13, 2012

@Justin, I'm in no way an authoritative voice, but I think the only sensible answer to your question is to look at the data. Look at the data and try to figure out what is not accounted for by what we already know for certain. As far as I understand, every "new physics" discovery came about in this way. An alternative to that is to shift the focus to mathematical aspects. Theoretical physicsits move fast and often leave mathematical gaps in the theories that they are already convinced of by the data. Patching up these gaps does not require any new experiments, only serious thinking. (Incidentally, I've personally chosen to adopt the latter approach.)

Otherwise, sitting in your office and trying to imagine what new physics might be like is unlikely to get you very far, at least scientifically. I wouldn't be able to judge the effect on your career path.

19. **Peter Woit**
November 13, 2012

Justin + Igor Khavkine,

I'd rather people stick to the topic of the new SUSY results and not try and start an open discussion of "what should theorists work on". As I keep pointing out, this isn't a general physics discussion board…

20. **Shantanu**
November 13, 2012

Peter,
could you comment on effect of lack of evidence for SUSY (so far) on GUT based
theories and if there has been any discussion of this apart from Misha Shifman's proceedings
Many Thanks
shantanu

21. **Peter Woit**
November 13, 2012

Shantanu,

The LHC results don't have much to say one way or another about GUTs (I don't think GUTs make any testable predictions about LHC physics). One of the standard arguments given for SUSY is that the running of the U(1), SU(2) and SU(3) coupling constants in SUSY theories causes them to come together more accurately at the GUT scale than if you stick to the Standard Model, allowing a simple construction of SU(5), SO(10) and other SUSY GUTs. One problem with this is that the bounds on proton decay are starting to get significantly in conflict with this idea. Another is that it also requires believing in a "desert" of no new physics that affects the running of coupling constants between the TeV and GUT scales. For these reasons, this always seemed to me a rather weak argument for SUSY (although arguably the strongest one). That the arguments for SUSY all turn out to be quite weak, and that the LHC sees no evidence for it is a quite consistent situation.

22. **tulpoeid**
November 13, 2012

"Without it, you would have smart people saying smart things and stupid people saying stupid things. But for smart people to say stupid things, that takes susy."

23. **vmarko**
November 13, 2012

@MathPhys:

The reasoning will be that if you want to use quantum field theory, you must make sense of the divergences, which requires an embedding in a string theory, which requires supersymmetry.

Making sense of divergences has nothing to do with string theory, nor with supersymmetry. The Standard Model is renormalizable as it stands. The real theoretical issue that might serve as motivation for both SUSY and strings is the fact that gravity is perturbatively nonrenormalizable. And that problem can be attacked in many ways, SUSY/strings being only one of many possibilities.

So, neither SUSY nor string theory can ever be considered a theoretical necessity, unless they are backed up by experimental data. And that somehow is just not happening, as we can see…

24. **fuzzy**
November 14, 2012

"I would be more inclined to trust lawyers claiming for justice if I could believe that they gain nothing by doing that."

25. **King Ray**
November 14, 2012

Perhaps the only way to save SUSY is mouth-to-mouthino resuscitation . . .

26. **MathPhys**
November 15, 2012

@vmarko,

Okay, let's say that one requires "renormalizability, even in the presence of quantum gravity".

27. **P**
November 15, 2012

Hi Peter,

I'm confused by some of your statements and criticisms.

Which of the "infinite varieties" of SUSY that you mentioned are "never testable"?

And how many of the $3 million recipients work regularly on the types of SUSY theories you discuss on this blog, rather than the many other types?

P

28. **Peter Woit**
November 15, 2012

P,

Neither of those statements was intended as a crucial part of a serious argument about anything, but I think “never testable” pretty well describes SUSY theories with high enough SUSY breaking scales. Such theories seem to be more popular now that it is becoming clear the SUSY breaking scale can’t be low enough to solve the hierarchy problem.

As for $3 million prize winners, my comment was about future ones. The Milner prize is rather explicitly aimed at fundamental research not vindicated by experiment, but considered important by the leaders of the HEP theory community. If you’re someone with major contributions to SUSY research as your main professional accomplishment, your shot at the $3 million requires that the “SUSY is dead” meme not get traction among your colleagues. We’ll see what happens, but the lack of any successful BSM ideas coupled with yearly $3 million prizes for fundamental research targeted at HEP theorists may mean you’ll have a yearly competition to be seen as the person who had the least bad unsuccessful but high-profile idea, with SUSY part of the mix.

29. **P**
November 15, 2012

Hi Peter,

Okay, I agree with your clarified sentiment regarding testability – “never testable” really means “never testable if we don’t build sufficiently big colliders.”

Regarding the hierarchy problem, there’s a sliding scale, right? Even with O(TeV) SUSY breaking, there was still the little hierarchy problem. LHC might put bounds at O(10TeV) SUSY breaking, which we might call the “even bigger little hierarchy problem.” I know you don’t agree with the premise, but with this premise its not quite right to say that LHC will make SUSY unable to solve the hierarchy.

Regarding Milner prizes – I guess, but the “SUSY is dead” meme, if it gains traction, will only do so in the realm of N=1 BSM physics with low SUSY breaking scale for the sake of solving the hierarchy problem. Nearly all of the winners who won the prize have significant contributions to other areas of supersymmetric field theories, and the success of this work and future work on non-BSM SUSY stands firm regardless of the conclusions of the LHC. This is an important distinction to make, I think.

In any case, I agree with you regarding this prize and SUSY extensions of the SM. However, it’s hard to imagine someone getting the prize “aimed at fundamental research” for such work (at least, as their primary contribution) without experimental vindication.

30. **Bernhard**
November 16, 2012

P,

Logically speaking is a sliding scale yes, but why should anyone believe this will happen? So, it is not a matter logical possibility, it is a problem with the motivations for SUSY becoming increasingly weaker without its proponents admitting it for some reason. Look what happened with R-parity. Before the LHC results R-parity violating SUSY was ratter unpopular because it is required for the “explanation of dark matter”, now suddenly R-parity is old news and this particular motivation was just thrown under the bus. The biggest motivation is by far naturalness and as you correctly point out the little hierarchy problem is getting bigger. It is a logical possibility of course the SUSY is there with very heavy superpartners but the motivations used for that being a likely result are clearly being weakened by experiment. One could think this would lead legions of young and creative theorists to think “probably the answer is somewhere else” and show new exciting possible solutions, but instead what we see are theorists claiming SUSY suffered no scratch and this is simply plain wrong.

31. **P**
November 16, 2012

Hi Bernhard,

Thanks for the reply.

I agree with most of the things you say. Certain low energy SUSY models are definitely being cornered / “suffering a scratch”, and as these theories are cornered more and more some of the motivations for BSM SUSY particle physics begin to go out the door, on a sliding scale as we have agreed.

Re: “the answer is somewhere else” . . . the answer to what? The hierarchy problem? BSM physics in general? People have been looking at non-SUSY extensions of the SM and also non-SUSY solutions to the hierarchy problem for years. I don’t disagree that young particle theorists should be open minded, but am only pointing out that other many other possibilities have already been considered. Data is coming in and is constraining both SUSY and non-SUSY possibilities. Very exciting!

Cheers,
P

32. **Bernhard**
November 17, 2012

P,

I agree…

33. **Kenneth W. Regan**
November 17, 2012

Saw this via “Marginal Revolution”. What about the hypothesis expressed in Leonard Susskind’s *The Cosmic Landscape* that SUSY holds only in the “dead” ground-state of the meta-stable sequence? Is that being “cornered” too, or only whether SUSY holds in our world (where we have Lambda > 0 etc.)? In any event, my impression from the book was definitely not to expect any our-world experiments upholding SUSY.

34. **P**
November 17, 2012

Kenneth,

Peter would probably object to this thread going down the direction you’ve suggested, since it brings on a whole host of other issues – but it suffices to say that (based on context) the SUSY you bring up is a reference to a SUSY vacuum in a landscape of metastable SUSY breaking vacua. This is something different: our world is definitely NOT in a SUSY vacuum, and moreover this isn’t really the context in which SUSY is being tested at LHC.

— P

35. **Peter Woit**

November 18, 2012

Kenneth,

At one point Susskind had hopes that you could make statistical arguments based on the Landscape, such that you might find it was statistically probably that SUSY would be seen at LHC energies (or that it was statistically unlikely). Turns out this doesn't work, the Landscape can't be used to say anything about this one way or the other (or about anything else, this was supposed to be the most likely thing that could be predicted this way). So, landscapeologists like Susskind would happily claim SUSY as evidence for string theory if it appears, also claim it is no problem for string theory if it doesn't.

I wrote about Susskind's book here
http://www.math.columbia.edu/~woit/wordpress/?p=307

in particular:

Susskind talks about the LHC and the question of whether the fine-tuning problem of the Higgs mass will be resolved by supersymmetry or is anthropic. He acknowledges that, based on Landscape arguments:

"My original guess was that supersymmetry was not favored, and I said so in print. But I have changed my mind — twice — and probably not for the last time."

36. **fuzzy**
November 18, 2012

i think that when we call "susy" that stuff we use an improper name. (btw, do you know who created this acronym? i heard it was john ellis, but is it true or just a rumor?) i think that a much more apt acronym would be "seotsmjatewsawrpifabmtanfal" =supersymmetric extension of the standard model just above the electroweak scale and with r-parity imposed forcefully, advocated by many theorists and not found at lhc. i can admit that the name "seotsmjatewsawrpifabmtanfal" is not as appealing as "susy", but it is honest: indeed there is no convincing theoretical reason why the supersymmetric extension should be at the electroweak scale (the scale of mass is not predicted) or why r parity should be conserved (gauge invariance would suggest that it isn't). furthermore, if we will find something like that at lhc, we will remove the "n", the acronym will reduce to "seotsmjatewsawrpifabmtafal", and its appeal will grow in an adequate manner.

37. **John Adams**
November 19, 2012

Rather new to all this, I'm afraid. But I do have a simple question. If supersymmetry is not found, or even proven incompatible with new evidence, would that in itself kill off superstring theory and all its close relations – M theory and the like – or have these theories developed in such a way that they could survive the death of supersymmetry?

38. **Peter Woit**
November 19, 2012

John Adams,
Superstring theory/M-theory unification predicts essentially nothing (I wrote a book explaining more about this…), so you can't kill the idea with experiment. There was a day when string theorists would often object to this claim by pointing to SUSY, but not these days. However, if SUSY is found, I can predict that you definitely will hear a lot again about how this is evidence for string theory…

39. **John Adams**
November 19, 2012

Peter,

Thanks for the reply. I've ordered and am currently awaiting the arrival of your book. From what I can gather string theory makes essentially no predictions, so I understand your point. And I certainly understand that string theorists would be doing somersaults if supersymmetry was found. But my point is does string/M theory absolutely *require* supersymmetry. What would happen to string/M theory if it were demonstrated scientifically that supersymmetry was impossible.

Let's take an outlandish example to make my point. Imagine that tomorrow Ed Witten discovered beyond any shred of doubt that an overlooked part of supersymmetry demanded that the speed of light was minus 1 metre per second. We can all accept that then SUSY would be dead. But what would it mean for string/M theory. Would they fall too, or have they been developed the last couple of decades in ways such that they could bear SUSY's death?

40. **Shantanu**
November 20, 2012

John, This has been discussed several times on this forum. string theory is consistent with everything, including mutually opposite ansatzs

41. **Peter Woit**
November 20, 2012

John Adams,

The problem with supersymmetry is that it must be a broken symmetry, and the problem with string theory is that, to the extent it requires supersymmetry, it says nothing about the breaking scale. It could be at the Planck scale, completely irrelevant to any conceivable observation.

42. **P**
November 21, 2012

John,

Here's a bit more precision. String theory does NOT require spacetime supersymmetry, but broad classes of compactifications do give rise to N=1 supersymmetry in four dimensions.

Regarding the LHC and experiments, the question then is the SCALE of supersymmetry breaking, as Peter points out. It's too vague (and one could argue incorrect) to say that string theory says nothing about the breaking scale.

The key point is that, as in quantum field theory, is that one has to study the vacuum state. Individual string vacua make very concrete predictions – I'd be happy to tell you about them and cite papers – including the SUSY breaking scale, if it is broken at all. In most vacua the SUSY breaking scale is high, "irrelevant to any conceivable observation", as Peter points out.

It's too vage, misleading, and fundamentally incorrect to make the blanket statement "string theory does not make predictions." The problem of predictions in string theory is NOT that individual vacuum solutions don't make low energy real-world predictions, but instead that there are an extremely large number of vacuum states. This observation applies to predictions about the SUSY breaking scale (hence Peter's objection), and also predictions about the low energy gauge theory, for example.

43. **H Luce**
November 21, 2012

http://www.youtube.com/watch?v=KuStsFW4EmQ neatly summarizes the response of the established string theory community to any challenges… never mind that their hypotheses are untestable.

44. **john McAllison**
November 21, 2012

Peter,

I think you're letting yourself down a little by describing Matt's update on SUSY as a "rant"; I'd describe it as a fourth installment. He's just presenting his side to the argument in a calm rational way and I'd hate to see you lower your current high standards of fairness compared to those of others I can mention. It's impressive the way you link to Matt's and, unbelievably, Lubos's blog for example.

45. **Peter Woit**
November 21, 2012

John McAllison,

Perhaps you should take that description as somewhat tongue in cheek… Any one who cares though is encouraged of course to follow the links and see what Matt and his commenters have to say. The whole SUSY business seems to me to have led to some rather odd behavior among physicists, but others can judge for themselves.

46. **zevans23**
November 23, 2012

BBC Radio 4's "Material World" weekly radio magazine has a good high-level interview with Dr Tara Shears, and does convey the "not even wrong" message well. Essentially the conclusion is "wait for higher energy."

Podcast (available to all countries!) here

47. **Kavanna**
November 30, 2012

Does SUSY have feelings? Have those feelings been hurt? Or is the damage more serious, more physical?

Here's the thing about SUSY: the general idea of supersymmetry is probably right. It's the last major symmetry that grows out of spacetime that hasn't been seen. But you can't test a general idea, just a specific theory. And, unfortunately, theorists long ago painted themselves into a corner by narrowing SUSY to a very specific implementation: quasi-perturbative, closely paralleling the non-SUSY Standard Model.

So what if that implementation of SUSY isn't seen? Maybe SUSY is manifested in some very different way. SUSY is neat; breaking SUSY is an arbitrary mess. Maybe Matt has something to say about this 🙂

New Higgs Results

November 13, 2012
Categories: Experimental HEP News

New results about the Higgs should appear over the next day or so, perhaps first here and here. First to appear is the CMS tau-tau result which is a signal strength of .72 +/- .52 the SM value.

Will update this posting with the results as they appear.

I guess the rumors were right: no update from ATLAS for gamma-gamma, they're just presenting the earlier data: signal strength of 1.8 +/- .5 times the SM value. "Ambitious campaign underway to include a larger data-set."

ATLAS WW channel signal strength is 1.5 +/- .6 times the SM value (see here). For some reason they are only using 2012 8 TeV data, not combining with the 7 TeV data.

Atlas tau-tau signal strength is .7 +/- .64 times the SM value (see here). Very similar to the CMS value. They are not yet sensitive to the bb channel, where the Tevatron has the advantage and has evidence of a signal.

Update: All new results are out now, but rather anti-climactic since neither CMS nor ATLAS is reporting new results for the channel with the strongest signal (gamma-gamma), where the signal strength may be anomalously high. ATLAS is also not reporting for the other high statistics channel (ZZ). CMS is, with signal strength .8 +.35/-.28 the SM value. They also claim to rule out (at 2.5 sigma) the hypothesis that this is a pseudoscalar rather than scalar. Everything reported is in line with the SM, but for the most interesting numbers we may have to wait until next March (Moriond).

For much more details about all this, see Tommaso Dorigo here and here, Matt Strassler here and here, Philip Gibbs here. For primary sources, CMS here, ATLAS here, presentations here.

Update: For another excellent source, see Jester, who has the scoop on why ATLAS and CMS didn't update some channels:

> It came to a point where the most exciting thing about the new Higgs release was what wasn't there 🙂 It is difficult not to notice that the easy Higgs search channels, $h\to\gamma\gamma$ and ATLAS $h\to ZZ\to 4l$, were not updated. In ATLAS, the reason was the discrepancy between the Higgs masses measured in those 2 channels: the best fit mass came out 123.5 GeV in the $h\to ZZ\to 4l$, and 126.5 GeV in the $h\to\gamma\gamma$ channel. The difference is larger than the estimated mass resolution, therefore ATLAS decided to postpone the update in order to carefully investigate the problem. On the other hand in CMS, after unblinding the new analysis in the $h\to\gamma\gamma$ channel, the signal strength went down by more than they were comfortable with; in particular the new results are not very consistent with what was presented on the 4th of July. Most likely, all these analyses will be released before the end of the year, after more cross-checking is done.

Update: Two interesting workshops on prospects for a Higgs factory are being held at Fermilab this week. See here for one that is on-going, see here for Tuesday's one-day mini-workshop on prospects for a muon collider Higgs factory. I'd never seen much before about the idea of using a gamma-gamma collider to study the Higgs, curious if that's really technologically viable.

Comments

1. **Stephan**
   November 13, 2012

   Peter,

   this all looks as if the experiments really might have a problem with the signal strength of the Higgs bump. Any rumors on whether the Higgs is disappearing or is confirmed?

2. **Peter Woit**
   November 13, 2012

   Stephan,

   The rumor about ATLAS is not that the signal is going away, but that they were worried about calibration problems due to seeing peaks at different masses in gamma-gamma and ZZ. It would of course be very interesting to hear more about what is really going on. I also hear that CMS has some concerns about their gamma-gamma signal, we'll see soon how much they report.

   Part of the problem here is probably the way they are trying to do blinded analyses, relatively quickly. If you don't unblind until right before the date you need to have a result, when something confusing shows up when you unblind, you may not have time to figure out what is going on. One thing you don't want to do is publicly release data that has some sort of consistency problem that you don't understand.

4. **tt**
   November 14, 2012

   there has to be a ZZ-top quark joke somewhere.

5. **Thomas Larsson**
   November 15, 2012

   It seems to me that the SM is looking more and more like epicycle theory, in a good way: an ad hoc model with a limited set of parameters that quantitatively predict thousands or millions of observations to high accuracy. If this analogy bears out, it is bad news for BSM physics in general. There was never any beyond epicycle physics; Kepler did not observe any qualitatively new phenomena, but merely looked at the old data in a new way.

6. **A**
November 15, 2012

So if the gama gama signal is problematic or starting to dissapear, does that mean the Higgs is beeing undiscovered? Gamma was the strongest signal. Are they going below 5 sigma?

7. **Thomas Larsson**
November 15, 2012

According to Jester, nobody cares if it's 5 sigma or 11 sigma – Higgs is there. Decreasing gamma-gamma means that Higgs becomes even more SM-like, I think.

8. **Peter Woit**
November 15, 2012

A,

The new ZZ results that CMS reported strengthen even more the Higgs signal. If it was going away, it would be going away here too.

Given that the gamma-gamma signal was higher than the SM prediction, if it is a SM Higgs it's not surprising that the signal would go down in the new data. If the reason for the earlier signal being high was not just a fluctuation but a systematic problem with the analysis, it's also not surprising that with more data, this problem becomes more obvious. That most likely is all that is going on, with figuring it out a time-consuming business.

Of course, since we haven't seen either experiment's new gamma-gamma results, who knows, maybe there's more to it. But I haven't heard such rumors, and if there were a serious chance that the gamma-gamma would completely go away, that would be hard to keep 6000 people quiet about…

9. **A**
November 15, 2012

Wait. It was not the decrease in the gamma gamma that worried me but the size of it. I understood Jester to write that at CMS the signal decrease is substantial. Too much for comfort. To the point of beeing inconsistent with the July results. So one naturally wonders if these sytematic problems affect other channels as well.

10. **Peter Woit**
November 15, 2012

A.,

I don't see any reason to believe there's a problem which is going to affect both of the main channels at both experiments (and CMS explicitly is claiming no problem in the ZZ channel by releasing that analysis).

This situation still looks to me like something not unexpected when you have a large collaboration with many cautious people trying to do an analysis on an extremely tight schedule. The way these people work they really hate to release something publicly unless pretty much everyone is happy that things are well-understood.

11. **JollyJoker**
November 16, 2012

How significant is the difference between 123.5 and 126.5 GeV for relative probabilities of the different channels? I find it intriguing that they both feel something's wrong with their analysis of gammagamma. As if the Higgs is different from the SM one in ways no one expected 🙂

12. **N.**
November 17, 2012

Hi all,

PhyOrg says this is a hint towards SUSY.

http://phys.org/news/2012-11-confining-supersymmetry-lhcb-evidence-rare.html

Is there something to it?

13. **Peter Woit**
November 17, 2012

N.

The story says exactly the opposite

"The result further shrinks the region in which scientists can still look for supersymmetry."

Please see the previous posting for extensive discussion of this.

14. **N.**
November 17, 2012

Sorry,

got it wrong.

:(n.

15. **DB**
November 18, 2012

Much as I would like to see the construction of a muon collider, and the low mass of the Higgs perfectly suits such a machine, I very much doubt if any serious attention will be paid to building one unless the LHC uncovers anomalous behaviour of the Higgs which could only be investigated by a high-precision examination of Higgs properties and decay modes.

16. **fuzzy**
November 18, 2012

just one remark on big machines and hep. everybody knows which are the machines that helped the field to progress. now, we can check on the "inspire" database how many conferences have their name in the title. some outcome is,

LHC 268
HERA 50
LEP 43
Neutrino factory 25
Muon collider 16
SPS 12
Kamiokande or Super-Kamiokande 0 (=naught)

17. **Tmark48**
November 18, 2012

@ DB : don't you think it's a bit hasty to start building a muon collider ?
First lets use the LHC to its full potential, then when it starts becoming obsolete either tecnologically and/or scientifically we can begin financing a new collider. But I don't think it will happen for at least a good decade. Or we could ask the Americans to build one. Europe has done its fair share building colliders, wouldn't it be time for the American hep community to take up the slack ?

18. **Peter Woit**
November 18, 2012

Tmark48,

As far as I know, there's no danger of anyone starting to build a muon collider soon, the technology is just not ready.

The more serious issue DB is alluding to is that of whether one can justify building any sort of Higgs factory if the LHC data on the Higgs shows no signs of a deviation from SM expectations.

19. **Anonymous**
November 18, 2012

Re: No funding for a post-LHC collider. Hasn't the Japanese government all but volunteered to fund one if it's placed in Japan? Unless that changes, isn't the ILC or a muon collider probably a go? Or is there reason to worry that a no-obvious-deviation Higgs might be so uninspiring as to make even a large percentage coming from the Japanese government insufficient?

Latest from Arkani-Hamed, Ellis and Gross

November 20, 2012
Categories: Uncategorized

Three of the leading figures in HEP theory have today or recently spoken about their current view of SUSY in light of the negative LHC results, here's a report:

- At the IAS recently, Nima Arkani-Hamed spoke on The Inevitability of Physical Laws: Why the Higgs Has to Exist. Yuri Milner was in the audience, and I gather that this (and Maldacena's recent similar talk) was intended to fulfill the promise of giving a public talk that came with their receipt of $3 million Fundamental Physics Prizes.

  Both Arkani-Hamed and Maldacena talked not about their own work, but about the Higgs, with Maldacena emphasizing the importance of gauge symmetry, Arkani-Hamed the constraints imposed by unitarity and Lorentz invariance. At the end of his talk, Arkani-Hamed gave a big advertisement for SUSY, with a new and somewhat bizarre argument I hadn't heard before. He argued that since QM + special relativity imply that elementary particles must have spin 0,1/2,1,3/2,2, and until recently 0 and 3/2 were missing, the fact that 0 (the Higgs) has now been seen implies (by the "totalitarian principle" that everything that can happen must happen) that the next thing to be discovered will require a spin 3/2 particle and this needs SUSY. Of the various weak arguments put forward for SUSY, this seems to me to be the weakest yet.

- At CERN today there was a 70th birthday celebration for Chris LLewellyn Smith. I didn't watch John Ellis's talk, but his slides are here. Evidently he argued that SUSY is not dead yet, pointing to the latest paper from the MasterCode collaboration. Their most recent CMSSM SUSY "predictions" have gluinos at either 2000 GeV (hard for the LHC to see at full energy after 2014) or 4000 GeV (impossible for the LHC ever to see).

  No mention was made of the similar pre-LHC predictions (see here and here) which had the Higgs at around 113 GeV, gluinos at 700 GeV or so, and squarks lighter than this, all of which have been shown to be radically mistaken. For some perspective on this on an even longer time scale, take a look at this 1984 survey article, Supersymmetry – spectroscopy of the future? : or of the present?. It gives much the same enthusiastic motivation for SUSY that we still get in all SUSY talks, with Ellis optimistic that the latest data had hints of SUSY with sparticle masses around 40 GeV ("nicely compatible" with the recent discovery of a 40 GeV top quark…).

- Also speaking today was David Gross, and I did get a chance to watch his talk. He commented on Ellis's claim that SUSY was not yet dead by noting "we see no signs of life either", then went on to lay out two "extreme scenarios". The pessimistic one would be nothing but the SM at LHC energies and no detection of dark matter. In that case, about SUSY he commented that it "could be that Nature does not take advantage of this", which I think is the first time I've ever heard him raise this possibility. The optimistic scenario was the usual picture sold pre-LHC: detection of SUSY and dark matter, non-SM Higgs. Gross said that he's an optimist, but gave no argument for the optimistic scenario beyond the one that it's a good idea in life for a scientist to be an optimist.

Update: More at Nature about SUSY's problems and quotes from its defenders.

Update: Over at the Simons Foundation web-site, there's an excellent new article about the SUSY debate by Natalie Wolchover.

Comments

1. **Roger**
   November 20, 2012

   Spin 2 is missing also, as no one has seen a graviton.

2. **Paul Titze**
   November 20, 2012

   @Roger,

   The effects on a particle (change in position or spin) by a single graviton is indistinguishable from quantum fluctuations and since they have no electric charge do not interact with photons either.

   How would one be able to observe a single graviton? (not gravitational waves).

   Cheers, Paul.

3. **Peter Woit**
   November 20, 2012

   I realize that no matter what I post about, people will want to discuss quantum gravity. Sorry though, that's off topic. Find somewhere else to argue about the graviton.

4. **Bob Jones**
   November 20, 2012

   "He argued that since QM + special relativity imply that elementary particles must have spin 0,1/2,1,3/2,2, and until recently 0 and 3/2 were missing, the fact that 0 (the Higgs) has now been seen implies (by the 'totalitarian principle' that everything that can happen must happen) that the next thing to be discovered will require a spin 3/2 particle and this needs SUSY."

   Peter, I think you're really twisting Arkani-Hamed's words when you say this. He was not using the totalitarian principle to argue for SUSY; in fact, he never even mentioned the totalitarian principle. This phrase did appear on one of the slides that he skipped, but it looks like it was a slide about quantum mechanics, not SUSY.

   His actual argument was something very different. He was saying that there are theoretical reasons why we can only discover elementary particles having spins 0, 1/2, 1, 3/2, and 2, and SUSY is required for spin 3/2. So because of theoretical constraints, SUSY is one of the very general ways in which new physics can show up in particle accelerators, and that's why people are looking for it. In Arkani-Hamed's own words,

   "The reason why there is so much excitement about supersymmetry is—it doesn't mean that it has to be right—it's the last remaining thing. It's the last thing that nature could do, in principle, that we haven't seen it do. And we saw something fairly dramatic with the Higgs already. We saw the zero option used, so it's not crazy that it's going to come along with the whole thing, we'll finally see the whole panoply actually used in the way nature works."

   At no point did he say that SUSY was definitely going to be discovered, or that it had to exist for theoretical reasons. All he said was "We haven't seen it yet, but it's something that we are looking for."

5. **Peter Woit**
   November 20, 2012

   Bob Jones,
   Perhaps you're right that the "totalitarian principle" business had nothing to do with the argument for SUSY, it was on a slide he didn't have time to explain so one can't be sure. But I don't think I'm really misrepresenting his argument. I just looked at it again, and it's clearly that spin 3/2 is the only non-observed spin on the list compatible with QM + special relativity and you need SUSY to get spin 3/2 consistently. Of course this is not an argument that you MUST have SUSY (none of the arguments for SUSY have ever been that you MUST have it), it's an argument for likelihood of SUSY. And, if you ask me, a weaker one than any of the other standard ones for the likelihood of SUSY. Anyway, people interested are encouraged to see for themselves, it's the last few minutes of the talk.

6. **Bob Jones**
   November 20, 2012

   "Of course this is not an argument that you MUST have SUSY (none of the arguments for SUSY have ever been that you MUST have it), it's an argument for likelihood of SUSY."

   Well, what you said was that, according to Arkani-Hamed, the discovery of the Higgs "implies" that the next thing to be discovered will be a spin 3/2 particle. When you say that a statement A implies another statement B, you mean that B necessarily follows from A. It doesn't just mean the B is possible.

   Also, I don't think that the discovery of the Higgs makes it more likely that we'll see a particle with spin 3/2. Arkani-Hamed is just saying it's worth looking for because it's one of the only ways for new particles to exist. The discovery of the Higgs shows that it's reasonable to look for new particles whose spins lie in this small set of possibilities.

7. **Peter Woit**
   November 20, 2012

   Bob Jones,

   Yes, I was not using "implies" in the mathematician's usage of logical implication, rather the colloquial usage of "suggests". It didn't occur to me that anyone would think this was a context where a claim of logical implication was being discussed. I did, I think accurately, describe it as an "advertisement".

   Also note that I wrote "the next thing to be discovered will require a spin 3/2 particle" (i.e. a form of SUSY with a spin 3/2 particle), not "the next thing to be discovered will be a spin 3/2 particle". The particles SUSY enthusiasts expect to show up in LHC data don't include the spin 3/2 one (the gravitino) itself.

8. **martibal**
   November 20, 2012

   Peter, I am a bit confused:
   "you need SUSY to get spin 3/2 consistently"
   then
   "note that I wrote "the next thing to be discovered will require a spin 3/2 particle" (i.e. a form of SUSY with a spin 3/2 particle), not "the next thing to be discovered will be a spin 3/2 particle""

   Excuse the naive question, but is SUSY the only way to have spin 3/2 particle in QM + special relativity ? (so, say, in QFT) ? I am not asking if this is the most common way explored by physicist, but if this is the unique way. If yes, then the argument does not seem so weak, at least it raises an interesting question: why spin 0, 1/2, 1 and – assuming graviton – 2, but no 3/2 ? Why a gap in the spectrum of the spin ?

9. **Peter Woit**
   November 20, 2012

   martibal,
   I'm no expert in the kind of argument that Arkani-Hamed was referring to claiming you need SUSY for spin 3/2, and don't have time now to look this up, maybe someone else can get you a reference, and/or comment on the strength of such arguments.

   I just don't see the spin 3/2 "gap" as much of an argument. Part of this is a philosophical difference with Arkani-Hamed (I think the fields of the SM have specific and fundamental geometrical significance, with no particular reason to go to the kind of supergeometry where you get spin 3/2, whereas I would guess his is an effective field theory philosophy where the SM fields are nothing particularly fundamental). However, even if one accepts effective field theory philosophy, I still don't think the argument is strong: the list of things we don't understand about a more fundamental theory could include an explanation of why no spin 3/2.

   Finally, all this has the problem that, unlike the hierarchy argument, it says nothing about the scale of SUSY breaking, so gives no indication of what energy scale one would see this spin 3/2 particle at. Arguments about how we must have SUSY, but which say nothing about its breaking just seem to me rather empty.

10. **P**
    November 20, 2012

    martibal,

    The spin-3/2 analog of the Dirac equation is called the Rarita-Schwinger equation. Some quick looks around the web show (arXiv and Wiki) that when coupled to electromagnetism there are certain modes with propagate at faster than the speed of light.

    On the other hand, supergravity definitely requires spin-3/2 fields and is consistent. Maybe someone can chime in some details about Vasiliev theory . . .

    P

11. **Dave Miller**
    November 20, 2012

    Peter (and anyone else),

    I'm confused by the claim that you cannot have fields higher than spin 2. Obviously, there are composite particles with spin 5/2, 3, and so on to enormously higher values. I thought it was obvious that such particles could be represented by quantum fields.

    Of course, their interactions are going to be a mess, but is there any objective criterion of simplicity that rules such interactions out of court?

I thought the whole idea of effective field theory was that the "real" underlying theory was God-only-knows-what, so that the "elementary" particles might be some weird incomprehensible sort of composites, but that our effective field theories nonetheless worked well enough at energies we can probe. And, so, there ought to be effective field theories to deal with the existing spin 5/2 or greater particles.

I assume I am missing some subtlety or fine distinction here: my education is so ancient as to pre-date the growth of the effective field theory idea (although I did take QFT from Steve Weinberg, whence I acquired the idea that *anything* can be represented by a quantum field!). I hope someone can fill me in on what I'm missing.

Dave Miller in Sacramento

12. **A.J.**
November 20, 2012

@Dave Miller:

A more precise statement is that you can't have such fields in a continuum QFT satisfying the conditions for the Coleman-Mandula theorem (which says basically that there would be so many conserved currents that the scattering matrix would have to be trivial). It's fine to have such fields in effective field theories, and it's fine to have them in QFTs where Coleman-Mandula doesn't apply.

13. **Noah Smith**
November 20, 2012

There is something soul-crushingly sad about watching SUSY theorists try to claim after the fact that the predicted the Higgs mass…

14. **Peter Woit**
November 20, 2012

Noah,

Not really sure who you have in mind. The only one of the three theorists in the posting who had a precise Higgs prediction pre-LHC was Ellis, who was claiming that just about the LEP limit was the most likely value (that didn't work out). Lots of SUSY theorists though have claimed vindication that the mass came out not so high that it couldn't be reconciled with the MSSM.

15. **jinb**
November 20, 2012

If one takes a predictive model with free parameters and fits the indirect and direct constraints from experimental data, then one gets a chi squared for the range of these parameters, with a best fit point. With new data these fits can be updated to give a new best fit point.

When you do this exercise with the standard model before the LHC, the best fit point is under 100 GeV. With more data and direct searches, this best fit point moves up. With a lack of signal and a larger portion of the parameter space being constrained, you could also call that a desperate attempt to move the "prediction" to keep the theory alive.

But it's not, it's just updating the best fit of the free parameters, in the case of the standard model the only free parameter being one: the higgs mass. When gfitter kept updating their electroweak fits pre-Higgs discovery and their Higgs mass "predictions" kept moving up in light of LEP constraints, it wasn't regarded as an arbitrary post-diction.

Doing these best fits for various minimal models of supersymmetry, with many more parameters of course, is no different. As more direct and indirect constraints are applied, the best fit points will shift, so the gluino mass will move up and so on. The best fit point by definition is the "more likely", it's just the minimum of the chi squared that comes out of the parameter fit to data, not a post-dicted "prediction" of where we will definitely find e.g. The gluino!

Before the higgs discovery the best fit to data for the one parameter model of a standard model Higgs was no different in spirit to the many-parameter fit of the CMSSM of e.g. Mastercode. How strongly one views these best fits as closing in on the gold coin hidden in the cake or evidence of a lack of gold coin is down to personal opinion, but if you belong in the latter camp it's just dishonest to report these best fits as desperate attempts to keep a theory alive or change predictions, which then gets picked up by sensationalising science journalists and writers who get their information disproportionately from this blog.

16. **Peter Woit**
November 20, 2012

jinb,

In the case of the Higgs, electroweak fits did a good job of, yes, predicting where the Higgs would be (the mass range it was likely to be in). If the Higgs had turned out to be at, say 300 GeV, they would tell us that there was something seriously wrong with the SM.

I'm not sure what the point of the SUSY fits now is. pre-LHC, they were advertised as predictions of SUSY spectra. What's the lesson to be drawn from the identified likely regions being excluded (which is not what happened in the Higgs case)? Is it just that one needs to do new fits?

17. **chris**
November 21, 2012

why in all the world would no susy and no DM be "pessimistic"?

i guess hep theorists are becoming lazy (or just old on average). the excitement of a 40 year old theory (SUSY) or a 80 year old (DM) being vindicated is not exactly the optimistic scenario i am dreaming of. as an optimist i hope that from experimental evidence we get some really new knowledge about a yet unknown principle of nature. susy and dm are actually really boring.

18. **chris**
November 21, 2012

"it's clearly that spin 3/2 is the only non-observed spin on the list compatible with QM + special relativity"

actually … for m=0 there is no half-integer restriction to the spin of a particle. why don't we see any of these?

19. **Dave Miller**
November 21, 2012

A.J.,

As I assume you (and everyone else) know, Coleman-Mandula rules out mixing internal and spacetime symmetries in non-trivial ways. (Of course, SUSY evades that with the anti-commuting, fermionic symmetries.)

But, I do not see how or why Colemna-Mandula rules out higher spin fields. In fact, the point I took away from my QFT class with Weinberg is that you can *always* construct such fields to represent composite systems. Of course, you may choose to build those fields out of "simpler" fields. Or not.

Now, maybe Steve was just way off base. And, I certainly may really be missing something. I'd appreciate it if anyone could tell me just where Steve (or perhaps my (mis)understanding of Steve) is wrong.

Thanks.

Dave

20. **A.J.**
November 21, 2012

@Dave Miller:

The point is that C-M restricts the kinds of conserved currents you can have in the QFTs to which it applies. This is a problem if you want higher spin fields in your theory, because you'll need to couple these fields to a current which C-M says can't exist. Why? It's a generalization of the argument that spin 1 particles need to couple to conserved currents. There are terms in the Fourier space propagator that don't fall off fast enough with momentum and so will give divergences in loop integrals if they isn't gotten rid of by coupling to a conserved current. This works OK for spin 1 theories; you can couple to a curren with 1 vector index, and the conserved charge will generate an internal symmetry. For spin 2, you are stuck coupling to the stress-energy current. Any other conserved tensor current would give a Noether charge that wasn't energy-momentum; this is the argument that any 'fundamental' spin 2 particle must be a graviton. (For spin 3/2, you can couple to the super-current, if you have one.) For higher spin, you'd get conserved currents whose dotted and undotted indices number at least 3. C-M says there aren't any.

My understanding is that this argument is due to Weinberg — at least the spin 2 part — but I don't know the original literature.

There are ways around this argument, of course. You can work in a cut-off theory, and the loop integrals won't get to cause trouble. This covers all the cases involved in nuclear physics. You can introduce towers of higher spin fields, like in string theory, and arrange for the bad terms terms in the propagators to all cancel out. You can work in theories with no mass gap, like CFTs, and then you'll have a few more currents available.

21. **Peter Shor**
November 21, 2012

Did David Gross leave out the detection on non-SUSY dark matter by the LHC? Does he believe this is unthinkable? It seems to me that it would be even more of a blow to SUSY than his worst-case scenario of not seeing anything. (Although it would presumably be great for high-energy physics in general.)

22. **Peter Woit**
November 21, 2012

chris/Peter Shor,

To be fair to Gross, his discussion of the "optimistic scenario" was very short, and he clearly didn't intend to characterize discovery of non-SUSY new physics at the LHC as not falling under this scenario. I'm pretty sure most SUSY advocates would drop it like a hot potato if there is solid new physics to investigate that clearly doesn't fit at all in the SUSY framework.

23. **Chris Oakley**
November 21, 2012

Chris Llewellyn Smith obviously did some great work at CERN – their appreciation comes across clearly in the slides. More puzzling, though, is his subsequent career: he became Provost of University College London, but this was a poisoned chalice as it was in this capacity that he was responsible for cutting everyone's budget. A palace coup followed and he was forced out. He then re-surfaced in something completely unrelated to High-Energy Physics: director of the UK fusion program. Don't ask me how this happened: I was not even aware that he had an interest in the subject.

24. **Shantanu**
November 21, 2012

chris, its good to remember that there is absolutely ZERO evidence from astronomical observations alone that dark matter has electroweak interactions or anything to do with
TeV scale physics. (The only argument given is the "WIMP miracle", but I think that is completely oversold and the limits from direct DM are already killing this strawman argument).
It could very well be all axions or all primordial black holes.

25. **Dave Miller**
November 21, 2012

A.J.,

Thanks for going to the trouble to fill in the details I was asking for — I appreciate it.

If you or anyone can remember any references that explain all this in more detail, I'd be interested in seeing the references. I'll check and see if I can find any of Steve's stuff that goes into it — this whole issue does seem to be something that has preoccupied him off and on over the decades. (Here is a popular article where he discusses his interest in the composite vs. elementary particle issue over the years: http://www.slac.stanford.edu/pubs/beamline/27/1/27-1-weinberg.pdf.)

Thanks again for your replies.

Dave

26. **Chris Austin**
November 22, 2012

Weinberg's original paper showing that massless spin 2 particles can only couple to the energy-momentum tensor is:

S. Weinberg, "Photons and Gravitons in S-Matrix Theory: Derivation of Charge Conservation and Equality of Gravitational and Inertial Mass," Phys. Rev. 135 (1964) B1049-B1056.

The argument applies only to couplings that result in Coulomb-like or Newton-like long-range forces, and Weinberg points out that under similar assumptions, there is nothing for massless particles of integer spin 3 or higher to couple to.

27. **Bernhard**
November 23, 2012

"I'm pretty sure most SUSY advocates would drop it like a hot potato if there is solid new physics to investigate that clearly doesn't fit at all in the SUSY framework."

And what sort of new physics that one can see at the LHC that could not possibly fit a SUSY framework?

28. **Bob**
November 23, 2012

Peter, as you claim, if this 3/2 argument is the weakest of all the arguments for susy, then that actually makes the sum total of the arguments for susy very very strong, i.e., if this is, as you claim, the "lower bound" on the quality of susy arguments, then that is quite impressive, since by definition, all other arguments must be even a lot stronger. If on the other hand this was the "upper bound" on the quality of susy arguments, then one might think the remaining arguments to be pretty weak.
In summary, I am quite surprised to see Peter to be so supportive of susy for a change.

29. **Peter Woit**
November 23, 2012

Bob,

I described the 3/2 hole as the weakest of various weak arguments. I suppose how one orders in strength a list of not very good arguments is to a large degree a matter of taste. One reason for putting this in the weaker category is that it says nothing about the energy scale of SUSY breaking (unlike the hierarchy, wimp miracle, coupling constant unification arguments, which require low scale SUSY breaking and supposedly explain something about the world we see).

Actually I think the 3/2 hole argument is just a variant of the standard argument "SUSY is a consistent extension of known symmetries and more symmetry is good and will be used by nature", but weaker (so there's a 3/2 hole? so what?).

30. **Marcel van Velzen**
November 25, 2012

Hello Peter,

As a field theory based on the Poincare-group (like the Standard Model) doesn't allow a well behaved spin 3/2 particle, it is actually the absence of a spin 3/2 particle in Nature that confirms that the fundamentals on which the Standard Model has been constructed are sound!

31. **Chris Austin**
November 25, 2012

Peter,

"unlike the hierarchy, wimp miracle, coupling constant unification arguments, which require low scale SUSY breaking"

Nima and Savas argued in hep-th/0405159, the original split supersymmetry article, that split susy is consistent with coupling constant unification, because the heavy squarks and sleptons come in SU(5) multiplets, and do not affect unification at one-loop order. The second Higgs doublet of the SSM is also heavy, and they claimed on page 7 that its absence might actually improve the unification prediction over the SSM when two-loop contributions are included.

32. **Peter Woit**
November 25, 2012

Chris,

Yes, but the point of split SUSY is that it keeps the gauginos at TeV-scale in order to preserve coupling constant unification, and I'd describe that as "low scale SUSY breaking". If you give up on low scale SUSY breaking completely (and do "supersplit supersymmetry", which is an April Fool's joke, not a theory…) you lose coupling constant unification. And, with split SUSY, you already lost the explanation of the supposed hierarchy problem.

33. **fuzzy**
November 28, 2012

Hi Peter
sorry to contradict you but you can have a nice SO(10) unification without any need of supersymmetry. And please consider that SO(10) helps to understand neutrinos masses, the only solid fact on "beyond the standard model physics"; on the contrary, SU(5) happilies marry with supersymmetry, but doesn't help with neutrino masses.

34. **Peter Woit**
November 28, 2012

fuzzy,

I didn't really intend to say anything one way or another about non-SUSY theories, the comment was about different SUSY variants. But, is there really still a viable SO(10) GUT that doesn't have problems with proton decay? My impression was that both SU(5) and SO(10) GUTs had such problems, worse in the non-susy case, but I haven't followed this recently.

35. **fuzzy**
November 29, 2012

hi peter
proton decay is not a problem is the only experimental test. i know we are theorists but should agree on the definition what "physics" is don't you think so? in my view,

the problem is that the efforts put in supersymmetry and strings stopped the progresses in gauge theories — the only successful thing we have — so i hope that sooner or later we will come back to discuss this. anyhow, putting aside these general issues, some work is still being done on so(10); curiously even the simplest theories are not fully analyzed see e.g., http://prd.aps.org/abstract/PRD/v85/i9/e095014

Scrutinizing the Cosmological Constant Problem

November 20, 2012
Categories: Uncategorized

Normally I do my best to ignore claims to have figured out the vacuum energy problem. There's an endless number of them, mostly looking pretty dubious, and the world is full of people much more expert on the subject than me, so it seems that my time would be better spent elsewhere. I did however just notice a new preprint making such claims, [Scrutinizing the Cosmological Constant Problem and a possible resolution], by Denis Bernard and André LeClair, and am curious about it. Unlike most of such things, the authors seem to know what they are talking about, and the whole thing looks not implausible to my non-expert eye. Can an expert tell me what is wrong with this (or, alternatively, tell me and my blog readers that it's a new good idea, or an old one that is not well known)?

Comments better be about the Bernard/LeClair paper and well-informed, or will be ruthlessly deleted.

Comments

1. **Chris Herzog**
   November 20, 2012

   Joe Polchinski has an interesting discussion of various theories of the cosmological constant at the beginning of his talk. In particular, page 4 seems relevant in the current context.

2. **Bee**
   November 21, 2012

   I haven't read this paper. I seem to recall however Claudio Dappiaggi making the point that if you do your qft in curved space carefully, the cc appears as a renormalization constant and there's really no reason for it to be at the Planck scale. Forgot details though. He's got several articles on the arxiv, but I don't know which one might be useful. This might give you a flavor.

3. **Sesh**
   November 21, 2012

   As I understand their argument (and I may be wrong) the vacuum energy is supposed to be proportional to k_c^2H(t)^2 at all times. If the momentum cutoff k_c is taken close to the Planck scale, this means that \Lambda is proportional to H(t)^2, so one obtains the correct order of magnitude relationship \Lambda \propto H_0^2 today.

   If that summary is correct then – without reference to the field theory arguments – one can rule it out empirically. As this paper points out in a footnote (it was probably well known before this), having \Lambda \propto H(t)^2 at all times amounts to a renormalization of M_P in the Friedmann equation; this is inconsistent with nucleosynthesis.

4. **theoreticalminimum**
   November 21, 2012

   Sesh,

   I think you're right about \rho_{vac} ~ H(t)^2 being assumed for all time t, although strictly speaking there's also a \ddot{a(t)}-dependence; at least, that's also how I understand it from equations (24) and (35). Looks like their proposition is ruled out then…

   NB: The footnote Sesh refers to is on page 3 of the preprint to which he provides a link.

5. **Alex**
   November 21, 2012

   I don't think there's really anything new in this paper. They claim to propose the "new" idea that Minkowski spacetime should be a stable solution to the semi-classical Einstein equations. In the discussion section:

   "…we proposed the principle
   that empty Minkowski space should be gravitationally stable in order to fix the zero
   point energy which is otherwise arbitrary."

   But this idea was proposed long ago by Robert Wald, it might even be older than that.
   See page 7 of
   http://www.springerlink.com/content/v8k661364hv52444/
   Its also in the lecture series he gave, "Quantum FIeld Theory in Curved Spacetime and Black Hole Thermodyanmics"

6. **Nameless**
   November 21, 2012

   The "cosmological constant problem" is really not one but two problems. The first one is, "why is the cosmological constant 120 orders of magnitude smaller than we expect from QM?" The second is, "since the cosmological constant is constant and density of the universe varies by the factor of 10^120 over the course of history, why is the cosmological constant the same order of magnitude as density of matter today, what's so special about today"? (The second question is also known as "the coincidence problem".)

   It is tempting (especially for particle theorists) to propose, like here, that the constant is not a constant but a variable that scales as some function of time (or H(t), a(t), etc.) A quick arxiv search will yield lots of hits. A choice of Lambda ~ H(t)^2 is particularly convenient because then Lambda is, in essence, defined to be forever proportional to the density of matter, simultaneously solving questions 1 and 2. Numerical coincidences in the article (e.g. (12)) are the manifestations of this definition.

   Unfortunately, as Sesh points out, these solutions are constrained by Big Bang Nucleosynthesis as well as by observations of supernovae and CMB. While some degree of variation is permitted, the naive "no-coincidence-problem" H(t)^2 has been ruled out observationally. (E.g. http://arxiv.org/pdf/astro-ph/0702015v3.pdf) Among other reasons, the fraction of dark energy, currently ~0.7, is constrained by BBN to be <0.05 at T~1 MeV.

   Their article says that H(t)^2 is only the rate of change in "later" times, but, as far as I understand, their idea of later times go almost all the way to Planck time.

My personal opinion is that, in order to resolve the coincidence problem, we have no choice but to resort to anthropic principle. According to an old argument by Weinberg, there simply wouldn't be any observers in the universe if the cosmological constant were even three orders of magnitude larger than it is now.

7. **Nameless**
November 21, 2012

P.S. I don't find the statement in the footnote of Sarkar's article convincing. The reference cited states that BBN constrains Newton's constant to within 10% of its current value at the time of BBN (~100 s). If Lambda~H^2, that puts Lambda at ~ 1e-16 GeV^4 at that time. I don't see it how this value would result in a greater than 10% shift in G_N or M_P at the MeV scale, and it is not explained in the article.

8. **bob**
November 21, 2012

On first impression, this paper does not seem very original, it is observationally ruled out by assuming a time dependent vacuum energy, and appears to miss all the important problems of the cosmological constant problem; for instance, the higgs potential adds a ~(100 GeV)^4 contribution, which would have existed in the early universe; why should that just disappear? I don't think they address any of the real issues, and seem to sweep all insights from effective field theory aside, which is to ignore most of the relevant discussion.

9. **Kurt**
November 22, 2012

A cosmological constant that decreases with time, or increases with the Hubble constant, is NOT ruled out observationally. I have discussed this issue with all astrophysicists I could get hold of, and they all agreed on the point. Observationally, nothing is known about the time-dependence. (Are there any new developments? Can anybody comment?)

There might be theoretical arguments from nucleosynthesis that suggest problems, but these arguments are NOT observational; they just show that one idea contradicts another. Now, we know that QFT is wrong at high energy, because QFT predicts a huge vacuum energy, whereas measurements show that it is small. Thus QFT is wrong at high energy; and it makes no sense to use a theory that makes wrong statements as an argument against solid observational data – even at the time of nucleosynthesis.

10. **Thomas**
November 22, 2012

I agree with their statement in the abstract "In classical and quantum mechanics without gravity, there is no definition of the zero point of energy." However, I think one should take this more seriously.

First one has to admit that the usual argument that "QFT predicts a large cosmological constant" is probably not very convincing as we can only really motivate a bold Planck scale cutoff from effective field theory ideas after we understood well what is going on "beyond the Planck scale". From a different perspective one could just say that the fact that the cosmological constant is computed to be ridiculously large in QFT does not imply that QFT is wrong but that the computation does not make sense / is based on false assumptions.

Instead it seems convincing to take the above mentioned point of view that there is no way to set a zero point on the energy scale if one considers the coupling of matter to gravity. In the lab, we compare the energy in different states, e.g. in a two particle state and the vacuum, thus we measure energy differences. The Einstein equation though measure the absolute energy (density) of whatever fills the universe. Within QFT we can not define the corresponding zero point unambiguously, thus we have to admit that any definition / computation is correct up to that ambiguity, which can be argued to parametrised by four parameters (c.f. Robert Wald's paper mentioned by Alex). One of those is the Newton constant, and another the cosmological constant.

Thus for me the most convincing attitude towards the cosmological constant is that it is to the best of our knowledge just a constant of nature we have to measure, much like the Newton's constant. Of course we might hope to predict it within a quantum gravity theory at some point, but not within QFT; just as QFT does not predict the Newton's constant either.

11. **Sesh**
November 22, 2012

To the second Nameless: the first Nameless has answered your question already. (Unless you are both the same Nameless, in which case the source of confusion is unclear to me.)

Put simply, if \Lambda~H^2 at all times, then dark energy constitutes a large and constant fraction (~0.7) of the energy budget at all times, including at nucleosynthesis, thus drastically changing the expansion history. Since \Lambda~H^2 two terms in the Friedmann equation can be rearranged to give something that is essentially the same as the Friedmann equation with no cosmological constant term but with a rescaled Newton's constant or M_P. So the observational constraint on the allowed shift in Newton's constant at the time of BBN is directly translatable into a constraint on the fraction of the energy density that was in dark energy at that time.

12. **Nameless**
November 22, 2012

@ Sesh: we're all the same Nameless (not to be confused with Anonymous). Your argument is valid, the source of confusion is the term "renormalization", which normally means something entirely different.

13. **Bob**
November 22, 2012

@kurt, you are simply wrong. While of course the dark energy can be an extremely slowly varying function of time, i.e., there are always error bars, the error bars are not big enough to allow Lambda~H(t)^2. This would ruin, amonst other things, large scale structure formation, it would mess up the CMB data, and so on.

14. **Nameless**
November 22, 2012

@Bob/Kurt, if I'm not mistaken, from the early-universe perspective, Lambda~H^2 is just outside the error bars. Constant Lambda of 10^-47 GeV^4 is effectively zero in the early universe (it is vanishingly small compared to matter and energy density), and even a time-dependent Lambda that falls off slightly slower than H^2 would be so much smaller than matter density at the time of CMB decoupling as to be unobservable.

Astronomical observations are a different and complicated story. There are numerous different models (e.g. is the cosmological constant simply a number that changes with time? or is it a new energy field? If so, what is its equation of state, and does it interact with, or decay into, dark matter?) And observational points are fairly noisy. I've seen claims that most of the parameter space is excluded, and I've seen claims that a model where Lambda~H and the cosmological constant field decays into dark matter is supposed to fit observational data slightly better than the standard Lambda-CDM model.

15. **vmarko**
November 22, 2012

Nameless:
The "cosmological constant problem" is really not one but two problems. The first one is, "why is the cosmological constant 120 orders of magnitude smaller than we expect from QM?" The second is, "since the cosmological constant is constant and density of the universe varies by the factor of 10^120 over the course of history, why is the cosmological constant the same order of magnitude as density of matter today, what's so special about today"? (The second question is also known as "the coincidence problem".)

There is a critical review on both of these problems given in 1002.3966. In short, the authors argue that the coincidence problem is not actually a problem, because the "today" covers a period of ten billion years (or so), so there is no unnatural coincidence happening at all. As for the QFT prediction for Lambda which is off by 120 orders of magnitude, they argue that there is no mystery in that either, since we do not know how to perform renormalization in curved-space QFT. So the 120 orders of magnitude is a problem of applying flat-space QFT in a regime where it is obviously not applicable, and then wondering why the result is wrong.

I think it is an interesting paper to read.

16. **Anonyrat**
November 22, 2012

Rovelli and Bianchi seem to be arguing that since the physical effect of the cosmological constant cannot be observed at small scales on which space time is approximately flat, and thus QFT calculations of the c.c. (dominated by much shorter length scales) should viewed with extreme skepticism.

17. **Kurt**
November 23, 2012

@Bob, your answer mixes two things. It might be that experimental measurements do not allow a slowly varying Lambda. But structure formation of galaxies is NOT a experimental measurement, but a theoretical model.

My point is: is a slowly varying Lambda against measurements? You might be right that it contradicts CMB data, though I know people claiming that it doesn't (at least for Lambda proportional to H).

Nobody cares whether a non-constant Lambda contradicts some model – that model might be wrong. The issue is whether it contradicts some actual measurements of Lambda at different distances/times. I think this is the main issue to be settled. Writing "and so on" is not an argument for the constancy of Lambda.

18. **Shantanu**
November 23, 2012

Hi guys,
you can see a nice discussion of Rovelli/Bianchi paper on cosmocoffee.
http://cosmocoffee.info/viewtopic.php?t=1531

19. **Bob**
November 23, 2012

@kurt, your response is very strange when you say "nobody cares whether some non-constant Lambda contradicts some model", when that is the whole point of this blog entry! LeClair and bernard laid out a MODEL, namely a universe with Lambda~H(t)^2, plus ordinary GR, ordinary matter and radiation. So what does their model predict? Well it dramatically changes CMB data, large scale structure, weak lensing, lyman alpha forrest, etc. It is very strange that you would keep defending their claim despite all the evidence pointing against it (and this is setting aside all the theoretical problems of Lambda~H(t)^2).

20. **bob**
November 23, 2012

@Nameless, not sure what the reason for your comment was — you say that if dark energy is less than H(t)^2 then it is observationally allowed by being orders of magnitude smaller than the rest of the energy of the universe at time of CMB. ok…but that is NOT the LeClair/Bernard model that is the topic of the blog entry. They claim, as Sesh quite rightly points out, that dark energy is ~ H(t)^2 and so remaining 0.7 the energy budget of the universe at all times. This is not just outside the error bars as you strongly claim, but is clearly ruled out by a range of observations.

21. **Onlooker**
November 23, 2012

Sesh:

On p.9 they make this statement: "We also argue that when H=a(dot)/a is large, the first Friedman equation sets the scale H~k_c, which is the right order of magnitude if k_c is the Planck scale."

I'm over my pay-scale here, but I'm wondering if that solves the dilemma you point out above.

22. **Igor Khavkine**
November 24, 2012

As Bee and others have already pointed out, any attempt to solve the cosmological constant problem beggs the question "Is there an actual problem to be solved?". I think that failure to answer the latter question positively dooms any remaining arguments to inconsequence. To the point, the "size" of the cosmological constant can only be sensibly assessed if one had at least two physically meaningful quantities to compare. However, the comparison is usually only made between the measured value (physically meaningful) and a bare, cutoff-dependent, unobservable parameter (not physically meaningful). In short, I think the whole enterprise fails due to the inability to meaningfully state what the "problem" is. This is discussed in more detail in the previously linked CosmoCoffee thread.

Also, the idea of fixing the cosmological constant (or any other renormalized parameter) in a way coherent across different spacetime backgrounds is definitely not new and is used in an essential way in the modern understanding of renormalization in curved spacetimes. In particular, the application of this idea to the cosmological constant was discussed in this Gravity Research Foundation essay by two major contributors to that field:

Quantum Field Theory Is Not Merely Quantum Mechanics Applied to Low Energy Effective Degrees of Freedom
Stefan Hollands, Robert M. Wald
http://arxiv.org/abs/gr-qc/0405082

The upshot is that, according to the authors, the result (which does not depend on any cutoffs) is actually much much smaller than the observed value. In other words, even in that setting, the cosmological constant needs to be introduced as an external parameter, with a value that could not have been deduced other than from experimental input.

23. **Peter Woit**
November 24, 2012

Thanks to all for the interesting comments about the paper. Please, no more comments that aren't explicitly about that paper.

24. **LeClair**
November 25, 2012

These comments have been informative, thank you. But I feel I should clarify at least one point. The conversation got side tracked by the idea that we proposed the vacuum energy was proportional to H^2 and there is a problem with this varying in time. Perhaps this was gleaned from the abstract, but it is not what we proposed at all, and it is nowhere written in the paper. Rather the result we do propose is that the vacuum energy is proportional to this quantity "A", which is a linear combination of H^2 and \ddot{a}/a. A major point of our paper is that consistency requires that this is indeed independent of time, which turns out to be the case in a matter dominated era. We are not at all well informed on BBN etc, but the remarks above about the vacuum energy being proportional to H^2 and that being ruled out are not very relevant to what is in our paper. We certainly cannot claim a solution to the CCP, there could very well be some problems with our proposal that are not obvious now, at least to us, but I don't think this is one of them. Thank you for the interest in any case.

25. **Bob**
November 26, 2012

LeClair, the reason people are not persuaded by these arguments is 2-fold
1). In your paper you have a contribution to the vacuum energy which goes as kc^4, with kc~Mp, which you simply dispense with. This really sweeps the whole fine tuning problem under the rug, because the CCP is the question of why that term cancels.
2). The next term you focus on is kc^2 R. And you claim that this gives the right order of magnitude for R~H^2, with H evaluated today. This really sweeps the whole coincidence problem under the rug, because this just assumes a coincidence between the dark energy and the matter density today.
The reason everyone was thinking Lambda~H(t)^2 is because it seems you can play the same game at ANY moment in time. Why is today special? Why not redo your arguments at the time of CMB? Then you will get the wrong answer because H changes in time.

26. **Nameless**
November 26, 2012

OK, then it looks like everyone, including myself, totally misunderstood the article. (The statement that Lambda~H^2 is a logical, but, apparently, wrong interpretation of the text on page 8.)

According to your definition and the Friedmann equations, A = 8 pi G (Lambda – rho_radiation). For any function of A that vanishes in Minkowski spacetime, as long as there's no radiation and you discard higher-order terms in A in the Taylor expansion of that function, its value will be constant in time. It would be more interesting if one could calculate rho_vac ~ A exactly, with vanishing higher-order terms.

- Paul Frampton has been found guilty on drug charges in Buenos Aires, looks like he will be able to serve out his sentence under house arrest, get released sometime in 2014. It's unclear at this point how the University of North Carolina will handle this. For details, there's Physics World, the Daily Mail, the Winston-Salem Journal, and Clarin.
- Erik Verlinde over the past couple years has gotten 6.5 million euros in prizes and grants to fund his work on entropic gravity (see here). Now, he'll head up a new institution, the Delta Institute for Theoretical Physics, funded with 18.3 million euros from the Dutch scientific funding agency NWO as part of its Gravitation Programme.
  There's an interview with Verlinde here. He says he's working on explaining dark matter with his entropic gravity ideas. There's no paper about this, I guess because:

  > There are some small gaps in my reasoning and things that I still do based on intuition. I'm trying to fill in those gaps.

  but he thinks these ideas about dark matter will be tested in "no more than 10 or 15 years".
- Another new theoretical physics institution is The Higgs Centre for Theoretical Physics in Edinburgh, where they're hosting an inaugural symposium in January.
- The latest TEDYouth is online, see here. It seems that they may think that Youth these days is pretty ADD, since they have all presentations limited to six minutes. In one of them (around 3:50) they've got Clifford Johnson explaining the exciting new idea of replacing particles by strings moving in extra dimensions.
- Mochizuki's claimed proof of the ABC Conjecture still seems to be resisting the attempts of experts to understand and evaluate it. He has put on his web-site some slides for a talk next month, and promises a survey article next March.
- Easier to follow in principle, but at 367 pages still pretty daunting, is a new paper from Laurent Lafforgue, chronicling his attempt to develop "non-linear" versions of the Poisson formula that would imply Langlands functoriality.
- If you were wondering about that tatoo in Edward Frenkel's film, see Mathematics, Love and Tattoos for an explanation.
- In other film news, there's the Colliding Particles project for a film about the Higgs. They've got a new segment up, several more coming soon at one/week.
- The debate in the HEP community about the death of SUSY goes on, and will undoubtedly continue along the same lines for quite a while. Latest is from New Scientist, which has Steven Weinberg describing the situation in a way that that can't be argued with:

  > SUSY's plausibility is reduced, but not to zero.

  For the argument over whether SUSY was and is an overhyped, implausible idea, on one side there's Michael Peskin, with:

  > I think that the serious effort given to SUSY is appropriate…"

  and on the other, taking the *Not Even Wrong* side of this argument, there's Matt Strassler with:

  > The theory, specifically as something we would observe at the LHC, was wildly over-promoted.

Update: One more. A Science magazine article about the problem with "Open Access" journals discussed here. According to Science:

> Meanwhile, the OA industry is becoming increasingly diverse; it includes traditional powerhouses, such as Germany's Springer, which now publishes about 300 OA titles, as well as a vast array of newcomers. OA publishers have a built-in incentive to lower the bar, Dupuis says, because in contrast to subscription journals, an OA title earns more revenue with every paper its editors accept.
>
> Moreover, many so-called predatory publishers—which often eschew peer review, use fake editors, or contain plagiarized papers—have flooded the market, says Jeffrey Beall, a librarian at the University of Colorado, Denver, who keeps an online list of these dodgy outfits.

Comments

1. **Bob**
   November 23, 2012

   Wow, I didn't know that about Verlinde receiving many millions for his ideas about explaining dark matter with entropic gravity. I thought his ideas about gravity being entropic had been debunked a while ago. But it is particularly ridiculous to richly finance his claim that dark matter can be replaced by modified gravity.

   Verlinde has given talks on this, and it appears to be just the old Milgrom idea of declaring Newton/Einstein gravity wrong on galactic scales, and replacing F=ma, by some other law, when 'a' drops below a critical value. This forces individual galaxies to get roughly the right rotation curve. The new twist on Milgrom's idea is that Verlinde attaches this to entropy in some weird way.

   While this was an interesting idea by Milgrom back in 1981, I don't think it is interesting anymore; the jury is in: such a model *does not work*. It is incompatible with a host of observations, including large scale structure formation, CMB data, weak lensing, lyman alpha forrest, bullet cluster, etc. I don't think there are many decent cosmologists who take the modified gravity models seriously anymore. Instead, dark matter is unavoidable and explains many of these different observations beautifully. So it is shocking that the Dutch are unaware of this and are just pumping millions into this 30 year old dead idea.

2. **jg**
   November 23, 2012

   Yes Bob, but the fact that the LHC has failed to show even a tiny possibility of a dark matter Lightest Supersymmetric Particle kinda helps promote alternative explanations of dark matter.

   I hope you aren't arguing that Verlinde's ideas must not be pursued simply because experimental evidence is against it – I mean, imagine what that would that do for SUSY and String Theory research funding

3. **Bob**
   November 23, 2012

   @jg, your comment was one of the more bizarre I have seen. 2 comments:
   1) I didn't mention anything to do with SUSY whatsoever. Unlike you, I am not advocating SUSY.
   2) Absence of evidence is not evidence of absence — the dark matter particle can just be very weakly interacting and this is compatible with all the data. But my main

point was that for Milgrom models of modified gravity, the jury is in; it is ruled out by the data.

4. **jg**
November 23, 2012

eh,

I was just responding to you very forceful arguments that Verlinde's ideas are dead and the possibility that anyone might fund his research is irresponsible.

Anyway, a few other comments on threads mentioned:

ABC Conjecture: give it up already, either prove it elegantly or go do your obscure maths ideas in another area.

Edinburgh: You could have done this a few years ago really.

5. **Michael Tyson-Grothendieck**
November 23, 2012

jg: "ABC Conjecture: give it up already, either prove it elegantly or go do your obscure maths ideas in another area."

Come here and tell me that… You can't last two minutes in my world.

6. **jg**
November 23, 2012

Michael

I lived through Wiles proof of FLT, really, I was at the universities involved over the Summer and Autumn (and subseqent Spring), I was as excited and thrilled as anyone could be, and lived through the doubts and final vindication.

This ABC "proof" doesn't taste anything like it, Wiles' proof was backed up by a huge amount of accepted theory, and was in fact (eventually) a fantastic validation of much of 20th century PURE mathematics.

7. **nbutsomebody**
November 23, 2012

Verlinde got a video out in bigthink:
http://www.youtube.com/watch?v=hByJBdQXjXU&feature=relmfu

The video has 200K+ views. It is sad to see how speculative nonsense is presented to common mass as a legitamate science and that too by prominent scientists.

8. **jon**
November 24, 2012

Regarding Langlands and L.Lafforgue, there's also been a recent preprint by V.Lafforgue, a younger brother of the former, which apparently proves a generalisation of his big brother's famous 2002 results with new different ideas, see http://arxiv.org/abs/1209.5352 (all this is way over my head, just noticing).

9. **Teleos**
November 24, 2012

Bob, your arguments are simply ridiculous. Nobody working on MOND these days claims that this formula explains everything. What it does not explain, it does not explain. And it is *not* a theory at this stage. But the formula, simple as it is, explains a *lot* of things and does this in an impressive manner, which plain simple collisonless CDM cannot do at the moment, and will probably never do. It is an incredibly weak argument to pretend that "MOND just makes rotation curves flat", "was designed to fit galaxies" or stupidities of that kind… These arguments only reveal a very embarassing lack of reflection of its authors on the topic, and a refusal to read or try to understand all the serious papers referring to it. For instance, there has been a recent review in LRR showing what MOND does, and why it is still taken seriously (yes, seriously enough to have an invited LRR review about it): http://relativity.livingreviews.org/Articles/lrr-2012-10/ This article is not putting the problems of MOND under the carpet. To make a long story short, MOND proponents fully agree that some sort of dark matter does exist, but what they think is that it is *not* made of CDM particles. The reason for this is that MOND is right *as an empirical scaling relation* in galaxies, whatever dark matter's deep nature is. Even the most fanatic (but educated) CDM afficionados cannot disagree with this. But cosmologists seem to deliberately ignore this fact, because, to quote them, "they do not care about the details of messy astronomical systems such as galaxies"… And this might be a big mistake, because what the success of MOND might tell us about the nature of dark matter might really be fundamental… And how much you think the latter sentence is true depends on how far away from the galactic scale your main research interests lie. What strikes me is that when people say "MOND is wrong" or "MOND is right", they dont necessarily mean the same thing, because some think it is a synonym for TeVeS, and those people are mostly *NOT* working on galaxies (and obviously they are mostly finding problems with the whole modified gravity approach), while some others (mostly working on galaxies) just think it is the most awesome scaling relation to date, summarizing almost all scaling relations of both spiral and elliptical galaxies, let alone dwarf spheroidals, but including tidal dwarf galaxies that are much less well understood in the CDM context. While they all agree on the problems to explain the CMB and clusters of galaxies, they simultaneously think "MOND works too well in galaxies to be meaningless". Again, this absolutely doesnt mean "dark matter doesnt exist". There is a big difference between believing in dark matter, and believing in the current LambdaCDM model. As a conclusion, the success of MOND as an empirical relation in galaxies is just a huge fine-tuning problem that we need to understand, as there are many in physics. The problem right now is a majority of astronomers and cosmologists *completely* (and often deliberately) ignoring this fine-tuning problem. In this sense, Verlinde is a light in the dark!

10. **Bob**
November 24, 2012

Teleos, your comments are irrelevant. You say "MOND proponents fully agree that some sort of dark matter does exist". Fine. But Verlinde does not. Verlinde believes in the old Milgrom story of no dark matter at all. And, as I pointed out, this contradicts CMB data, large scale structure formation, weak lensing, bullet cluster, lyman alpha forrest, etc. So that is definitely a dead idea. Please try to read and comprehend before responding in the future.

11. **Teleos**
November 24, 2012

Bob, Verlinde is *not* saying this, and MOND proponents do not either. MOND *is* a success as an empirical formula in galaxies and one has to understand this, one way or another, fullstop. Please read the relevant serious litterature if you wish to debate further.

It might well be that we will understand why galaxies behave in this way within the CDM context, but one still has to demontrate how, and pretending that we right now do understand this would be of the utmost intellectual dishonesty. An interesting review, very optimistic for CDM but also quite honest about the current lack of understanding of large number of phenomena on galaxy scales is for instance given in: http://arxiv.org/abs/1207.3080 Knowing that Silk and Mamon have long been defending CDM, the simple fact of saying "Whether appeal to alternative gravity is justified by inadequate baryonic physics is a question of judgement at this point" reveals that they are not as sure of themlselves as uneducated people like Bob.

12. **Bob**
November 24, 2012

Teleos, I attended a talk where Verlinde said that in his model there is no dark matter.

13. **Peter Woit**
November 24, 2012

Please, enough about MOND. If someone has a well-informed comment about Verlinde's ideas that's great, but this kind of argument over MOND is both off-topic and unenlightening.

14. **Anonyrat**
November 24, 2012

Useful: discussing gravity with Verlinde
http://www.scilogs.eu/en/blog/the-dark-matter-crisis/2012-06-28/discussing-gravity-with-eric-verlinde

15. **Teleos**
November 24, 2012

To end-up this discussion, I hope it is not too much off-topic to say that Verlinde's approach to the DM problem should very likely be in the spirit of http://arxiv.org/abs/1005.3537

16. **Samuel Prime**
November 24, 2012

Concerning SUSY, I've read in the book by Cottingham and Greenwood ("An Introduction to the Standard Model of Particle Physics") that SUSY requires energies near 14 TeV to be observable (page 18). But so far the LHC has reached 7 to 8 TeV. So why the discouragement? Is it that some of the superpartner particles were expected to show up at current LHC energies? (I guess this might depend on which version of SUSY one is talking about.)

17. **Peter Woit**
November 24, 2012

Samuel Prime,

You're misreading the book you quote, which says

"It is also widely believed that the physics of Supersymmetry, which perhaps underlies the Standard Model, will become apparent at the energies, up to 14 TeV, which will be available at the LHC"

Note the "up to". The arguments for LHC-scale SUSY (either things like the MasterCode fits, or the idea that SUSY would solve the hierarchy problem and avoid fine-tuning), all predicted that seeing SUSY would not require the full 14 TeV, but be visible at 7-8 TeV (a factor of 3.5-4 above the Tevatron energy). Whatever they're saying now, I don't think one can find any SUSY enthusiast who a couple years ago, just before the 7 TeV turn-on was saying "too bad, that's not enough, it's not until 14 TeV that it will show up".

18. **Samuel Prime**
November 24, 2012

Yes, when they say that SUSY will become apparent at energies "up to 14 TeV," I'd hardly think that they're saying they would be expected to appear at 7 or 8 (or lower). It means one should allow up to 14 TeV energies before can exclude the idea. It is true, though, that it's not looking too good (but at one point the discovery of the "Higgs boson" didn't look good either). One thing that does seem more clear is that some models that require some masses for superparticles have been excluded by the LHC.

19. **Peter Woit**
November 24, 2012

Samuel Prime,

The only reason the 14 TeV number is in that sentence is because it is the design energy of the LHC, not because it has anything to do with SUSY. You're trying to put words in the mouths of those authors which they did not intend. When they were writing, no one knew about the magnet interconnect problems and everyone assumed the LHC would quickly run at or near design energy.

Yes, as a matter of logic, until one runs the LHC at design energy one won't be able to exclude the possibility of the LHC discovering SUSY. This doesn't change the fact that pre-LHC the predictions for SUSY were for it to be visible at 8 TeV, not for it to require 14 TeV.

20. **chorasimilarity**
November 25, 2012

The Science magazine article reminded me about this joke

Gold open access: enter the mouth

21. **MathPhys**
November 25, 2012

Maybe someone can clarify the following to me. I heard a talk by E Verlinde in which he explained DM using the off-diagonal components of the matrices in matrix models of strings. There was no mention of entropic gravity, or gravity as an emergent phenomenon in any form. He seemed to be using those degrees of freedom in matrix models that are usually discarded. But since these are models of strings, the graviton is non-emergent.

Am I right? or do I miss the point?

22. **chris**
November 26, 2012

There is nothing ridiculous in what Verlinde is trying to do – in fact, if you look at the "entropic" derivation of the Einstein equations, it is the most natural thing.

The only strange aspect is that this is not Verlindes idea. The idea is from Ted Jacobson and goes back to 1995.

23. **Proudmemberofthecult**
November 26, 2012

Please note that the 18 million euro's is not quite 'Verlinde's' money: it's a 10 year grant to cover quite a big field in a collaboration which involves 6 profs – one of whom is 't Hooft. Yes he's involved. No, it's not his personal pot of gold.

24. **MathPhys**
November 26, 2012

@chris I may be wrong, but I think that T Padmanabhan's work on the subject is earlier than T Jacobson's. I also find his papers clear and well thought-through.

25. **Yatima**
November 27, 2012

Aha … http://en.wikipedia.org/wiki/Thanu_Padmanabhan

Well, I certainly hope for the success of this program. And if not, I'm sure there will be things learned.

26. **Yatima**
November 27, 2012

In the Scientific American article linked from the Wikipedia entry, Padmanabhan has this to say about the history of the "gravity as an emergent phenomenon" idea:

"This idea that gravity is an emergent phenomenon has a long history. It was first introduced by the Russian scientist, Sakharov, in 1968. Another intriguing connection, suggesting similarity between the surface properties of black holes and fluid mechanics was investigated by T. Damour, Kip Thorne, W. Price and their collaborators in the eighties. An attempt to obtain Einstein's equations from a thermodynamic perspective was made by T. Jacobson in 1995. Other approaches, very similar in spirit, were developed by G. Volovik and Bei-Lok Hu. My collaborators and I [Thanu Padmanabhan] started on a concrete programme to explore this idea in 2002. More recently, E. Verlinde has tried to reassemble many of these ideas from the perspective of string theory."

27. **Anonyrat**
November 27, 2012

New form of matter at LHC?
http://idealab.talkingpointsmemo.com/2012/11/large-hadron-collider-may-have-produced-new-matter.php?ref=fpb

28. **GB**
November 28, 2012

According to the report linked above, the new form of matter from LHC was submitted to "Physical Review B". This is interesting ! But when I clicked the arXiv link, the paper was sent to Physics Letters B. In fact, I think PRB might actually be a suitable place for this work. Maybe at this level, there is already some new emergent physics which is independent of the underlying constituent particles. And it would be cool that LHC publishes something on PRB.

29. **lun**
November 28, 2012

Since you mention big private grants for theorists, you might want to also mention that
whole accellerators are
facing the axe due to "austerity".
Both RHIC and B-physics were in the past thought to be likely places where string theory/SUSY were to "confront experiment", but it now looks like these experiments wont even take place.

30. **Peter Woit**
November 28, 2012

lun,

Thanks. I've been having trouble following the US budgetary issues, since it seems unclear what the budget situation will be in a month or so, much less in the longer term.

About the Italian decision canceling SuperB, besides the Physics World article, there's also some discussion of this at Tommaso Dorigo's blog, see

http://www.science20.com/quantum_diaries_survivor/superb_factory_killed-97250

31. **Bob**
November 28, 2012

Chris, the most natural thing is that dark matter is a boring old stable neutral particle. The least natural thing is that it is an artifact of entropy and string theory as Verlinde claims it is.

32. **Stefan**
December 3, 2012

I was wondering why Verlinde's work creates these more emotional responses from the physics community. Would it be possible to point out a good paper with a line of argument why his hypothesis is now referred tot as "dead" or "debunked"? If it is proven wrong, are there still lessens learned? I am just interested in the idea and wonder how much effort I should spend following Verlinde's thesis. There seem to be a mismatch between the excitement in public media and the more critical statements from the scientific community.

33. **JR**
December 3, 2012

Stefan, Please see these links for interesting reactions:

http://physics.stackexchange.com/questions/4289/is-gravity-an-entropic-force-after-all

http://arxiv.org/abs/1108.4161

The neutron argument seems to go right to the heart of whether or not we really understand any entropic force: i.e. can they be reversible, do they have to de-cohere a wave function?

Cheers
JR

34. **Stefan**
December 4, 2012

JR, thank you so much! This helps me a lot! thanks 🙂

News from CERN

December 5, 2012
Categories: Experimental HEP News

Very light posting recently, partly due to being busy keeping up with my class, but more due to just not noticing anything particularly newsworthy. Matt and Lubos have quite a lot to say about Time magazine's not describing the Higgs mechanism accurately, but I find it hard to get too excited about that, with my sympathies lying with any poor journalist given the impossible task of explaining this in a few words to the public.

Today at CERN there's an LHCC meeting, with status reports on the machine and the experiments available here. The 8 TeV proton-proton physics run has just about ended, with the next week or so to be devoted not to luminosity production, but to machine studies. The integrated luminosity for the run will be about 23 inverse femtobarns, significantly above the original plan for the year. A heavy-ion run will end in February, after which the machine will be shut down for a long period in order to fix the magnet interconnects and other problems, to allow running at or close to the design energy of 7 TeV/beam. The current plan has proton-proton physics at 6.5 TeV/beam starting again about April 2015.

It seems likely that there will be no new results about the Higgs until the Moriond conference in March. CMS and ATLAS will then have quite a while to work on doing the best possible analysis of their 7 and 8 TeV data for information about the Higgs. From now on, attention will focus on what CMS and ATLAS have to say about the signal sizes in the various channels where the Higgs is supposed to show up, as well as theoretical studies of how possible next generation accelerators would perform in terms of doing better at these measurements than the LHC. The LHC Higgs Cross Section working group is meeting today and tomorrow on this topic, talks are available here. Next week the KITP will host a similar workshop.

The continuing big story from the LHC is that of no SUSY or other BSM physics showing up. The LHCC ATLAS slides have

> Physics beyond the SM did not show up yet. There is no need for preliminary conclusions. Let's continue our work and look were we haven't looked so far.

but theorists are definitely starting to draw preliminary conclusions, needed or not. At Scientific American, Glenn Starkman has a piece entitled At CERN: Down in the Mouth in Paradise which paints a sorry picture of the situation caused by SUSY not showing herself:

> The Standard Model is absurdly fine-tuned, we were told – balanced on a knife-edge off which it has no right not to tumble. It has an un-natural hierarchy of scales. It has too many free parameters, and some of them are very, very small. Why, the electron mass is less than 0.00001 times the weak scale (the energy scale governing weak interactions such as the W and Z boson masses), which is itself 10^{-17} (that 0.00000000000000001) times the Planck scale (the energy scale governing gravity)! And speaking of gravity, the Standard Model can't accommodate quantum gravity. We need Low-Energy Supersymmetry, or Technicolor, or Large Extra Dimensions, or … One of these MUST be found at the LHC!
>
> Forty years of theoretical work has been based on these expectations. Papers with thousands of citations have been written. Courses taught. Textbooks published.
>
> Prizes awarded! Illustrious careers navigated! And yet despite all this build up of theoretical expectations, there is no experimental hint of anything outside the Standard Model at the LHC. Hence the long faces and worried words wherever theorists gather to drink coffee. Hence the disappointment in the eyes of the young experimentalists looking forward to the next accelerator, the next frontier where their mark will be made…
>
> Walk the halls, go to theory seminars, have lunch with a theorist, or an ambitious young experimentalist. Look for the classic symptoms of grief.
>
> Denial. Vigorous debates about whether the fact that the dog did not bark in the night suggests that it is a Chihuahua or a Rottweiler. My friends – at some point if there is no barking, we must conclude there is no dog.
>
> Anger. At those of us "misguided" enough to doubt the imminence or even the necessity of Beyond the Standard Model physics.
>
> Bargaining. Perhaps BSM physics has not been discovered because we've been demanding too much explanatory power from science. If we just relax our expectations for the predictivity of science, and introduce a multitude of universes in which we occupy a particular one best suited to our existence, then we can let our extensions to the Standard Model be un-natural, many of their properties unpredictable, and explain why they haven't been discovered yet!
>
> Depression…
>
> We're not ready for Acceptance! At least, sitting here listening to the LHC hum, I can still hope.

Comments

1. **Nick M.**
   December 5, 2012

   And so the "nightmare" begins!

2. **cormac**
   December 5, 2012

   …'At some point we must conclude there is no dog?'
   Oh please. At what point exactly?
   Ruling things out is a very long and laborious process, not helped by commentators anxious to jump the gun. The history of particle physics is littered with examples of phenomena that took many many years to show up, many of which are now taken for granted.
   Glenn Starkmann needs to remember that it took decades to find the atom, decades to find the neutrino and decades to find the Higgs….what exactly were you expecting?

3. **Shantanu**
   December 6, 2012

   cormac, by this logic we should continue to design experiments designed to look
   for magnetic monopoles (and so on).
   shantanu

4. **Thomas Larsson**
   December 6, 2012

It has taken decades to not find susy.

5. **Jose Ignacio**
   December 6, 2012

   There is a great experimental evidence that there is physics beyond the standard model: dark matter. The standard model is unable to explain the 80% of the matter of the universe.

6. **Simon**
   December 6, 2012

   Shantanu
   There are very good reasons to look for magnetic monopoles.

7. **srp**
   December 8, 2012

   From the SciAm post:

   "Fifty-one years after its basis was explored by Sheldon Glashow, forty-five years after the full theory was proposed by Steven Weinberg (and independently the next year by Abdus Salam), the Standard Model has successfully accounted for or predicted all calculationally tractable experimental results in particle physics. "

   Note the loophole there.

8. **emile**
   December 8, 2012

   Let's wait just a few more years before getting too depressed. Once the LHC has run for a few years at full energy, and that the Higgs couplings are still consistent with the SM, that no signs of BSM physics has appeared, we'll know we are living with the nightmare scenario. In the meantime, other experiments could turn up surprises.

9. **Shantanu**
   December 8, 2012

   Jose,
   at the risk of repeating what's been said many times, there is absolutely NO evidence
   from astrophysical data alone, that dark matter has anything to do with SUSY or weak interactions or physics beyond standard model.
   It could very well be an axion or primordial black hole or a massive graviton.
   The WIMP miracle argument has been oversold and in its simplest version is already ruled.

Forty Years of String Theory

December 5, 2012
Categories: Uncategorized

The journal *Foundations of Physics* has been promising a special issue on "Forty Years of String Theory: Reflecting on the Foundations" for quite a while now, with a contribution first appearing back when it really was 40 years since the beginnings (more like 43 now). The final contribution has now appeared, an introductory essay by the editors ('t Hooft, Erik Verlinde, Sebastian de Haro and Dennis Dieks).

The overall tone of the collection is one of defensive promotion of the subject. The fact that string theory's massively overhyped claims to give a unified theory of particle physics have led to miserable failure is mostly completely ignored. From the introductory essay one would never guess that string theory was ever supposed to have something to do with explaining the Standard Model of particle physics and that there were hopes that it would find some sort of vindication at the LHC, perhaps via the discovery of SUSY (the LHC is not even mentioned in this essay). String theory is presented purely as a theory of quantum gravity that has led to new insights in mathematics and had various other applications through the dualities it has uncovered. It's main shortcoming is described as

> the lack of directly testable experimental predictions that would signal 'string physics'

which seems to me intentionally misleading, implying that string theory makes indirectly testable predictions. The problem with string theory is that it makes no predictions about anything, not that it only makes indirectly testable ones.

Three of the eleven articles in the collection are described as representing critics of string theory. The first, from Carlo Rovelli, does do a good job of explaining many of the problems of string theory. Lee Smolin's contribution is not much about string theory, but more an examination of the general issue of the "Landscape problem", comparing a range of different theories in which the laws of physics are different outside our observable universe.

't Hooft's On the Foundations of Superstring theory calls for more attention to the lack of any fundamental description that tells us what string theory really "is", taking the point of view:

> we conjecture that the "true theory" is something totally different from superstring theory (and certainly also different from gravitating quantum field theories), but that string theory may approximate the truth to various degrees of accuracy in one or several of its compactified realizations, just as it does for some condensed matter systems and QCD.

He ends with an argument (which he notes is "one where only few readers will follow me") that one problem with string theory is that it uses the conventional quantum formalism, which he feels is flawed, needing replacement by an "emergent" version of quantum mechanics. For more about the sort of thing he has in mind, see here.

Two articles by philosophers of science, Dean Rickles and Richard Dawid address the question of how to evaluate a supposedly scientific theory that, like string theory, makes no experimentally testable predictions. Both pieces seem to me to suffer from a rather uncritical attitude towards various forms of string theory hype. For Rickles, the dominance of string theory can be justified by its "mathematical fertility", for Dawid the justification is "the assessment of scientific underdetermination" (roughly, there aren't any other good ideas). That it has led to some interesting mathematics and that there's not a lot of good alternative ideas out there are perhaps the two best arguments for pursuing string theory, but in both cases the situation is far more complicated than string theory advocates would have one believe.

The articles by string theorists (Balasubramanian, Giddings, Gubser. Martinec, Susskind and Duff) have a range of interesting things to say, sometimes amidst large dollops of string theory hype. Almost all evade serious discussion of string theory's failure to say anything about the Standard Model (although Susskind argues, a la Multiverse, that this a positive feature of string theory). Giddings perhaps makes the most serious criticism of string theory in the entire volume, discussing its problems as a theory of quantum gravity, where other authors see a big success and the theory's main selling point.

The article by Duff is by far the most bizarre thing in the volume, and I wrote about it extensively a year ago here. As Duff sees it, the problem is just that critics of string theory are misguided and misinformed. He includes a three page denunciation of Garrett Lisi which has nothing to do with string theory, characterizes the major recent research directions in string theory as fluid mechanics and the black hole/qubit correspondence, and has an appendix about the press release Imperial College put out making absurd claims that he had finally figured out how to make predictions from string theory (see here). The editors of the volume seem to be rather defensive about publishing such a thing, noting

> Needless to say that the opinions expressed in this paper are entirely the author's own and that it is not our intent to spark new popular or otherwise heated discussions.

but justifying it as

> we are happy to include this paper in our special issue as addressing questions that are important not only to scientists but also to the wider public, which was among our initial intents.

and ending with

> We warmly recommend Duff's very readable and playful contribution.

Nothing about Duff's piece struck me as "playful", but that the editors see it as some sort of joke would explain why they thought it worth publishing.

Update: Over at The Browser, Steven Gubser recommends that people should read *The Elegant Universe* and four string theory textbooks. Asked about the "no predictions problem", Gubser does his best to mislead, claiming the situation is just like that with QED that Feynman got the Nobel Prize for. As for SUSY, if the LHC finds it, that's evidence for string theory, if not, no problem. There's the old favorite "the LHC might produce microscopic black holes". About whether string theory makes testable predictions about the heavy ion physics the LHC is studying

> String theory might predict that such and such number is one, and the experiment might say well it's about two, but it could instead be one. That's the kind of accuracy with which things can typically be done.

Comments

1. **Bob Jones**
   December 5, 2012

   "String theory is presented purely as a theory of quantum gravity that has led to new insights in mathematics and had various other applications through the dualities it has uncovered."

Most people would say that string theory is an idea about quantum gravity. During the past fifteen years, most string theorists have been using the theory as a tool to study very general conceptual issues in quantum gravity and to understand the relationships between different quantum field theories. You can complain all you want about the lack of testable predictions in particle physics, but these objections seem pretty irrelevant since most string theorists aren't trying to do phenomenology and since string theory has achieved so much success in other areas…

2. **OMF**
   December 6, 2012

   I think Theoretical Physicists need to take a time out for a few months studying spinning tops.

3. **Friend**
   December 6, 2012

   I don't know how String Theory could have ever been considered as fundamental. It seems to me that a fundamental theory will have to explain why the universe is quantum mechanical to begin with. And ST is only an added layer on top of QM; it does not even attempt to explain where QM came from. It seem that alone should have raised suspicion against its claim of being a fundamental theory of everything.

4. **Girlfriend**
   December 6, 2012

   It soberly is true, what you say, Friend.

5. **Peter Woit**
   December 6, 2012

   Sorry, but those who want to discuss why they're unhappy with quantum theory need to find another place to do this, it's off topic here, unless it's specifically about 't Hooft and his attempts to bring string theory into it.

6. **Bernhard**
   December 6, 2012

   One thing I don´t get it is why there was no contribution from Witten? Perhaps he refused?

   String theory is already in pieces and while there is no need to beat a dead horse, the fact that the bunch of crap Duff wrote actually got published as a representative contribution to celebrating 40 years of string theory is good evidence of the moribund state of the theory.

7. **A.J.**
   December 6, 2012

   Maybe Witten was busy writing the roughly 400 pages of detailed technical notes on superstring perturbation theory that he just put on the arxiv?

8. **Bernhard**
   December 6, 2012

   A.J.,

   Since is Witten we are talking about, I´m sure he could have done both.

9. **no one of consequence**
   December 7, 2012

   Epicycles were an example of "mathematical fertility". Yet they were wrong.

   For a supposed whole branch of theoretical physics to consume a generation of minds / carreers, shouldn't there be something of substance to even hint at relevance in the measurable physical universe?

   Back in the late 70's in the Berkeley Physics department, I was a dubious observer who inelegantly suggested that studies of this kind belonged elsewhere in the philosophical realm, until such hints presented themselves. Since that time I've seen nothing to change that inate skepticism.

   And while I can understand the collective embarassment not wanting to cede ground, perhaps BSM and other grand schemes … should just be pursued when we have a long confirmed discrepancy, as in the past? Rather than assumed as to be present?

10. **fuzzy**
    December 7, 2012

    dear no one of consequence, i feel that neutrino masses and dark matter are recent achievements that do not belong the standard model. i am not fully sure of what to think about the issue of strong CP, but it is also a stimulating point where we can proceed experimentally. several other appealing issues in cosmology (inflation, present day accelerated expansion, speculations on the origin of the matter etc) have been also clarified since 70's. i would say, very few of them have received the slightest contribution from the stringy ideologists — an exception is goodman-witten's contribution on direct dark matter search.

11. **fuzzy**
    December 7, 2012

    ps perhaps this is the reason why witten is not in the book?

12. **Chris Oakley**
    December 7, 2012

    These denunciations of epicycles fail to take account of the fact that an ellipse is a circle with a single epicycle

13. **Bob Jones**
    December 7, 2012

    no one of consequence,

Has it ever occurred to you that there might be some good reasons for doing string theory? Do you really think the subject has survived for forty years with no results? Do you really think string theorists are that dumb?

14. **Peter Woit**
December 7, 2012

All,
One can argue about what if any role "dumb" plays in the string theory story, but this discussion is fairly deep in the "dumb" category. I realize that this is by now a very tired subject, but still… There's a lot of material in this volume, if you read some of it and have an interesting comment, please contribute it, otherwise, please spare the rest of us…

15. **Armin Nikkhah shirazi**
December 7, 2012

Peter,

It seems to me that String Theory does make at least one definite prediction:
Like any other mainstream theory of quantum gravity (that I have heard of), it predicts that the gravity field of an object in a quantum superposition is also in a superposition.

While I don't see the significance of this pointed out very often, to me that constitutes a profound claim about the world which has as yet not been directly tested. I think the importance of this may be minimized by three factors: First, it is probably at the level of present technology impossible to perform a direct unequivocal experiment to test it; second, there are good indirect reasons (e.g. conservation of momentum coupled to the fact that objects in a quantum superposition are affected by gravity fields in exactly the right way) to expect that if such an experiment could be performed, the prediction will be confirmed and third, there is no mainstream rival hypothesis which makes a different prediction (and any framework which does so would automatically be considered non-mainstream).

But, given that this claim enjoys such a central position at the core of any quantum theory of gravity, should we not refuse to settle for anything less than a direct test before we dismiss any doubts about its correctness? Rather than testing predictions which rule out regions of the parameter space in which the models based on a framework are still viable, yet leaving virtually infinitely many possibilities open at higher energy scales, would it not be far more definitive to identify a falsifiable prediction which does not permit any such adjustment? Surely, if this central claim were found to be false, it could not be compensated for by modifying string theory because that is part of the very essence of quantum gravity. Changing *that* aspect of string theory is to kill it.

That means a falsified result would lead to nothing short of a scientific revolution, and it helps to keep in mind that these usually happen when something that was universally regarded as "obvious" turned out to be a false assumption about nature.

Ideally, recognizing this claim as a prediction should have spurred the development of new experimental techniques by which one might eventually be able to test it. Alas, who is going through all the trouble of tackling a practically impossible experiment for the outcome of which no one expects a surprise?

Sometimes I think that it sure was a good thing that the Michelson Interferometer was not impossibly difficult to construct, otherwise the aether might have stayed with us much longer than it did. In fact, it does not seem preposterous to me to imagine that parameter adjustments analogous to what one sees today might even have allowed an aether theory to survive (probably in a very complicated form) up to today as the dominant space-time paradigm.

But, we were lucky that it is in fact relatively easy to build a Michelson Interferometer. We do not appear to be so lucky when it comes to building a device that could measure the existence of gravity fields in a superposition.

I'd be interested to know whether you consider the superposition of gravity fields a prediction of string theory and if not, why.

Thanks,

Armin

16. **Peter Woit**
December 7, 2012

Armin,

This really has nothing much to do with string theory but is generically about quantum theory, so I don't want to encourage discussion of this here. Generic questions about quantum gravity are a huge topic, one I'm not very expert in.

The way you're trying to relate this to string theory is kind of like the way I've seen some prominent string theorists argue with people who say string theory is not falsifiable, by saying that if people observe violations of the axioms of QM in tabletop experiments, that would falsify the current understanding of string theory. First of all, my guess is that if a tabletop QM violation was found, there would quickly be papers out there explaining it with some exotic version of string theory. Secondly, this is all a bit like saying "my theory is falsifiable, because if God emerges from a collision at the LHC with a sign saying my theory is wrong, that would show it was wrong". The falsifiability criterion is intended to refer to distinctive aspects of a theory that differentiates it from others, not generic properties common to all known theories.

17. **Bob**
December 8, 2012

Yes if QM was violated then string theory would be dead. If local lorentz invariance was violated, then it would be dead too.

On the latter point, there are alternative theories out there, such as LQG, that predict violations of lorentz invariance, and these claims have been falsified. So string theory certain makes predictions that distinguish it from other theories. Other theories commonly predict a breakdown of lorentz invariance, and some violate quantum mechanics or the equivalence principle badly, and have been ruled out. So certainly the evidence is pointing towards string theory at this stage, but who knows what future experiments will reveal?

Also, Peter what do your favorite theories of QG predict, other than what I have mentioned so far?

18. **Peter Woit**
December 8, 2012

Bob,

I don't have a "favorite" theory of quantum gravity. The LQG vs string theory hype-filled arguments like the ones you are making about "my theory sucks less than your theory" just don't interest me at all.

19. **Bob**
December 8, 2012

Peter, okay. But just a question: do you know of any predictions coming from any of the QG theories? (I am mainly curious about theories other than string theory here).

20. **Peter Woit**
December 8, 2012

Bob,

I don't know of any "prediction" from a quantum gravity theory that isn't an abuse of the term.

21. **fuzzy**
December 8, 2012

hi bob, a good example of prediction in the field you mention has been done by one contributor to this book: http://arxiv.org/abs/arXiv:1110.0521. it was shown that neutrinos can be superluminal, and the doubts raised by the other investigators were irrelevant.

please, try to imagine the impact of this paper on experimentalists and on a wider public, in the moment when the experimental claim was made. then, judge by yourself the scientific value of such a "prediction".

22. **Yatima**
December 8, 2012

Off-topic but …

The epitaph of an anomaly which was pretty much improbable to begin with:

http://www.science20.com/quantum_diaries_survivor/operas_final_word_operas_superluminal_neutrinos-98408

And another interesting anomaly vaporizes into its error bars:

http://spectrum.ieee.org/aerospace/astrophysics/finding-the-source-of-the-pioneer-anomaly

23. **Peter Woit**
December 8, 2012

fuzzy,

That's not the only volume contributor who weighed in on superluminal neutrinos. According to Mike Duff, string theory could explain them (although he did say he didn't believe the result or that string theory was the explanation, just that it could be…)

24. **fuzzy**
December 8, 2012

the "prediction" i quoted is published: i mean, several colleagues have pondered and decided to leave their findings to posterity, independent editors agreed this was useful, some referee implied in judging, a lot of readers, and all that. but i agree that mod phys lett is less authoritative than prl, thus your duff probably wins the context http://arXiv.org/abs/arXiv:1005.4915 (even if, counting citations, my smolin should do, and the stringy prediction published on prl concerns something else)

25. **Armin Nikkhah Shirazi**
December 8, 2012

Peter,

Thank you for your response. I won't prolong the discussion on this but let me just note that ultimately, when the consistent response to contradictory empirical data is that only a subset of of all possible models based on a framework has been falsified where the entire set may well be infinite, then it seems to me one has to consider falsification at a more generic level, so in that sense I do see this question as quite relevant to string theory.

And, in my view, your last sentence, that this is an aspect of "all known" theories is an overgeneralization. It is just a feature of all current mainstream approaches to understanding the relation between quantum theory and general relativity.

Bob,

It appears to me that you are implying that failure to observe gravity fields in a superposition is on the same footing as a violation of quantum mechanics or local Lorentz Invariance.

We have overwhelming evidence that the latter two are correct descriptions of nature, but we have never observed a gravity field directly in a superposition. We have indirect arguments suggesting that this may be the case, but the superposition of gravity fields is emphatically not on the same footing as standard quantum mechanics or local Lorentz Invariance.

I don't know if you did this on purpose, but in the second paragraph you exactly illustrated the string theorist argument Peter mentioned in his reply to my comment. If his argument, that there are exotic versions of string theory which could explain any violations of QM at all, is true, then it seems to me a rather definitive refutation that this constitutes a falsifiability criterion.

26. **Bob**
December 9, 2012

Armin, my understanding of string theory is that it exactly respects QM. Peter is the only person I'm aware of who appears to be advocating alternative string models that somehow violate QM. It is a weird proposal by Peter, but I can't comment further on his model.

27. **Dim Reg**
December 9, 2012

Bob,

LQG does not break local lorentz invariance. It was beleived that since it predicted a minimum length eigenvalue, that length must have been invariant (just like how c is the maximum velocity, so it has to be invariant). But that is wrong because the probabilities are transformed, not eigenvalues, like how you can't just boost away the vacuum energy. I also beleive that one can spontaneously break lorentz invariance in string theory, so those experimental results have told us very little about these two theories of quantum gravity.

Peter,

I seriously doubt it is possible to find an exotic form of string theory that isn't quantum mechanical. Formulating a theory in terms of non-zero commutators and hilbert spaces builds uncertainties and superpositions into the theory, and this is done when constructing string theory. I don't see how any clever trick could remove either of these things, though perhaps I'm just not clever enough.

28. **Bob**
December 9, 2012

Dim Reg, I don't know of any serious proposal to break the local lorentz invariance in string theory. This is especially dangerous as it is needed for the theory to carry the general coordinate invariance in the usual way, and it surely carries this. You refer to spontaneous breaking, but that, by definition is a property of low energy or long distance physics, so can't be relevant for the local, i.e., short distance, physics.

With regards to LQG, it was repeatedly claimed by Smolin that it would alter the photon dispersion relations, and this claim was falsified. Maybe there are other proposals to avoid this, I'm not sure, but certainly the evidence is disfavoring LQG at this stage.

29. **Peter Woit**
December 9, 2012

Bob and Dim Reg,

I don't even know what it would mean for an experiment to "violate QM". 't Hooft claims to have a possible non-QM foundation for the superstring, and it's well-known that the experts all say that we don't know what string theory "is": the issue of its foundations is still up in the air.

If tomorrow there's a solid report of an "experimental violation of QM", which do you think is more plausible:
1. string theorists wholesale tell the media the theory has been falsified and stop work on it.
2. dozens of papers start appearing on the arXiv purporting to explain the experimental anomaly in terms of string theory models or "string-inspired" physics.

Responding to someone asking if string theory makes predictions by saying "no, not now, but I think for reasons X it is the best thing to work on to try to get to a better theory, one that would make predictions" is honest. Saying "string theory does make predictions" and pulling out something like the QM business just isn't.

30. **lun**
December 9, 2012

People who talk about "violations of QM in gravitational systems" need to understand two issues: Firstly, gravity is only detectable in macroscopic systems, where in any case QM is in any case"violated" through processes such as decoherence (perfectly consistent with quantum mechanics, producing classical-looking results).
Secondly, no quantum theory of gravity (and that includes string theory) is sure what either the Hilbert space or the observables of quantum gravity are.
Therefore, it is wrong to think of "violations of quantum mechanics" as if this was a well-defined experimental signature.

31. **Dim Reg**
December 10, 2012

Bob,

It looks like I stand corrected on string theory. I'm certainly not an expert in that field and your arguments make sense to me. My point with LQG was that it was never a correct reading of the theory to say that it broke lorentz invariance. Lee Smolin was just making LQG hype, trying to say that his theory was better because it made currently testable predictions. Regardless, I don't intend to champion LQG (I don't actually think they are right), and this certainly wouldn't be the place to do that.

Decay: The LHC Zombie Film

December 8, 2012
Categories: Film Reviews

Today is the release date for the film Decay, described as "a zombie film made and set at the LHC, by physics PhD students". It's available for download here, on Youtube here.

The plot is summarized as

> The film follows a small group of students (played by physicists) after a disastrous malfunction in the world's biggest particle accelerator. As they try desperately to escape from the underground maintenance tunnels, they are hunted by the remains of a maintenance team, who have become less than human.

It's quite professionally done, on a remarkably low budget of about $3000, and of course the science is way, way better than usual for a Hollywood film. Highly recommended. Note that

> This film has not been authorized or endorsed by CERN

For something more reality-based, try the latest episode of Colliding Particles, entitled "Blogs", which features Philip Gibbs and his role in blogging the Higgs and putting together unofficial combinations of results. *Not Even Wrong* puts in a cameo appearance in the background…

Comments

1. **Plutonium Archimedes II**
   December 8, 2012

   "The film follows a small group of students (played by physicists) after a disastrous malfunction in the world's biggest particle accelerator. As they try desperately to escape from the underground maintenance tunnels, they are hunted by the remains of a maintenance team, who have become less than human."

   Sounds fun! But do they (the film-makers) understand that there are going to be people who will think that they (the film-makers) are warning against a possible scenario that might actually happen as a result of the operation of the LHC?

   Although, really, such a misinterpretation sounds fun too!

2. **Low Math, Meekly Interacting**
   December 9, 2012

   This is just about the best thing I've seen on the interwebs in a very long time….which is kind of pathetic, but anyway, many thanks for the link!

3. **chris**
   December 10, 2012

   why didn't they cast the resident string theorists as the zombies?

4. **Chris Oakley**
   December 10, 2012

   Chris, you obviously did not follow the story. In order to become zombies, they have to be walking around the *experimental apparatus* underground.

   Must admit, I did not make it past about minute 35. It seemed a lot like *Shaun of the Dead* but without the humour. Oh, and since when was *A Clockwork Orange* deep? Maybe that *was* the humour.

5. **DON Murphy**
   December 10, 2012

   A little surprised to hear you say, ". . .and of course the science is way, way better than usual for a Hollywood film." with reference to a movie about zombies. However, all in good humor I suppose.

6. **Tmark48**
   December 10, 2012

   I saw the whole film. Have to say it was pretty entertaining and the end well it's not your typical Hollywood ending that's for sure. The premise of the story while not realistic was fun, and real life location sure beats CG sets.

This Week's Hype

December 10, 2012
Categories: This Week's Hype

Space.com has a new story entitled Space Bursts Provide Insight to Theory of Everything, which has been picked up elsewhere as "evidence for string theory". For instance Physicists Find New Evidence Of A 'Theory Of Everything' In The Wreckage Of Dead Stars tells us:

> Physicists studying the rotation of minuscule particles fired by exploding stars light years from Earth have found new evidence for a so-called 'Theory of Everything'.
>
> Researchers have been frantically studying ways to reconcile two apparently contradictory pillars of modern physics for decades.
>
> Put simply, those are Einstein's theory of relativity – which covers the interaction of space and time on a large scale – and quantum theory, which covers the strange ways that sub-atomic particles behave.
>
> One of the ideas mooted as a possible explanation is string theory, a framework which proposes that all of matter is made up of loops of vibrating strings…
>
> What is relevant for this story is the proposal in superstring theory that every particle of matter has an equal and opposite 'anti-matter' particle, which if time were reversed would behave in exactly the same way as normal matter.
>
> And it is this that new observations by the Japanese Aerospace Exploration Agency's Ikaros spacecraft could help reinforce…
>
> Using their Gamma-Ray Burst Polarimeter, the scientists are studying how those particles rotate. If the rotation of their polarity had changed even slightly, it would indicate a lack of symmetry if time were reversed – thus evidence against superstring thory.
>
> And, luckily, the reported conclusion is that no change was detected. The team said that they are confident to one part in 10 million that the symmetry is consistent – a new record.

So the idea seems to be that CPT symmetry is evidence for string theory. Kind of like how it has become popular to claim observations being consistent with quantum mechanics as "predictions of string theory".

The Space.com story seems very confused: string theory predicts no CPT violation, but finding evidence for it would support string theory:

> The findings could have implications for superstring theory — the idea that all fundamental particles are actually loops of vibrating string — which is one attempt to unify nature's forces and create a theory of everything. If the idea is right, it would help reconcile two contradictory theories: Einstein's general relativity, which describes things that are very big, like gravity, and quantum mechanics, which describes the realm of the very small…
>
> Superstring theory scientists predict that if particles and anti-particles (antimatter is an opposite form of normal matter) traded places and time was reversed, the world would still look the same. If any evidence is uncovered that matter and antimatter actually act differently, or violate their apparent symmetry, it could offer support for superstring theory.

They also link to a new story about 5 reasons we may live in a Multiverse.

What's generating these stories is this press release from the University of Tokyo, based on PRL acceptance of this paper. It's about an interesting test of CPT invariance, but bringing string theory into it is bizarre, and even the authors aren't clear about whether string theory says CPT or no CPT. From the paper:

> Lorentz invariance is the fundamental symmetry of Einstein's theory of relativity. However, in quantum gravity such as superstring theory , loop quantum gravity and Horava-Lifshitz gravity , Lorentz invariance may be broken either spontaneously or explicitly. Dark energy, if it is a rolling scalar field, may also break Lorentz invariance spontaneously. In the absence of Lorentz invariance, the CPT theorem in quantum field theory does not hold, and thus CPT invariance, if needed, should be imposed as an additional assumption. Hence, tests of Lorentz invariance and those of CPT invariance can independently deepen our understanding of the nature of spacetime.

and the press release:

> Some quantum gravity theories, trying to unify Einstein's theory of relativity with quantum mechanics, (e.g., superstring theory) predict that structures of space-time at extremely short distances may be totally different from what we think we know. On the scales treated by terrestrial experiments, the world looks exactly the same as its mirror image if the roles of particles and anti-particles are exchanged and the direction of time is reversed (i.e., CPT symmetry is conserved). If this symmetry is broken at extremely short distances, as predicted in some quantum gravity theories, polarization of photons from distant celestial objects would rotate during its long journey to us.

I was starting to get more optimistic that the days of nonsensical "tests of string theory" might be over, but it looks like this phenomenon is here to stay.

Update: Scientific American has the same story, headed with:

> Gamma rays emitted during the formation of neutron stars and black holes allow scientists to study fundamental principles like superstring theory

Comments

1. **Low Math, Meekly Interacting**
   December 11, 2012

   According to the SciAm article, GRBs are so powerful they can "accelerate photons almost to the speed of light." Mmm.

2. **Bee**
   December 11, 2012

   Nick Mavromatos has been on the topic of CPT invariance violation for a while, based on what he calls "stringy" models. Maybe that's the origin of this?

First Results from the Large Hardon Collider

December 10, 2012
Categories: Experimental HEP News

There's a conference in Bad Honnef going on now entitled First Results from the LHC, with a website that carries two different interpretations of what "LHC" stands for (see the screenshot below):

The talks are here. Yesterday CERN DG Rolf Heuer gave a summary talk about The Terascale after 2 years of LHC. Tomorrow some SUSY enthusiasts will be summarizing their view of the current situation, with John Ellis scheduled to talk on "What is it? What else? What next?".

In other news, I'm hearing rumors of a big announcement tomorrow at CERN. The rumor is that Yuri Milner has decided that not all prizes should go to theorists, and that the Nobel committee not awarding prizes for the Higgs discovery is something that he can help fix. We'll see tomorrow if this pans out…

   DJBunk,

   All I'm doing is linking to the conference web-site, and that's how they titled their web-page, so, what can I do?

New Milner Prizes

December 10, 2012
Categories: Uncategorized

The New York Times is reporting that tomorrow Yuri Milner will be announcing the award of a new set of prizes for fundamental physics work, this time including some experimentalists as recipients. The awards are

- $3 million for the experimental discovery of the Higgs at CERN. This will be split into three parts: $1 million to Lynn Evans for his work building the machines, $1 million to ATLAS current and ex-spokepersons Fabiola Gianotti and Peter Jenni, and $1 million to CMS current and ex-spokepersons Joe Incandela, Michel Della Negra and Tejinder Virdee. I'm suspicious that the NYT has missed CMS ex-spokesperson Guido Tonelli, who was on the list I heard about earlier today from a source at CERN.
- $3 million to Stephen Hawking for his work on black holes.
- Three "New Horizons" prizes of $100,000 each to younger theorists working on string theory and SUSY: Niklas Beisert, Davide Gaiotto and Zohar Komargodski.
- Two "Physics Frontiers" prizes of $300,000 each to string theorists Alexander Polyakov and Joe Polchinski, with a third $300,000 prize going to a group of condensed matter physicists (Charles Kane, Laurens Molenkamp and Shoucheng Zhang) who work on "topological insulators" among other subjects.

Polyakov, Polchinski and the group of condensed matter physicists are now the contenders for the $3 million 2013 Fundamental Physics Prize which the NYT story says will be awarded "by a vote of the judges on the morning of March 20 at CERN and announced in a ceremony that evening."

The special award to the LHC physicists should help make up for the problem that no Nobel prize may end up going to the Higgs discovery because too many people were involved. Milner has the advantage of not being bound by long tradition and arguably out of date rules the way the Nobel Committee is.

On the theory side though, these awards make it clear that the Fundamental Physics Prize story is likely to be heavily dominated by awards from string theorists to string theorists for work on string theory. Besides Hawking, all the recipients have some connection to string theory, with the condensed matter physicists working on a hot topic which many string theorists see as the future of their subject. For more about the recent history of the string theory/condensed matter connection, see this article from last year in *Nature* which includes this, which refers to certain books published in 2006:

> "It's hard to say whether the interest in condensed-matter applications is a direct response to those books because that's really a psychological question," says Joseph Polchinski, a string theorist at the Kavli Institute for Theoretical Physics in Santa Barbara. "But certainly string theorists started to long for some connection to reality."

Update: The NYT article has been revised to include Tonelli.

Update: The press release with more details is here. There's a story at the Guardian here. CERN has more here, including interviews with the LHC winners. They comment on the fact that they are getting awards that belong to much larger groups, with Incandela and Gianotti saying they are trying to find a way to distribute the money to younger members of the collaboration who most need it. Lyn Evans comments

> I will not be driving around CERN in a Ferrari. That would be very bad for my image.

The Guardian has Hawking saying his plans for the money include helping his daughter who has an autistic son, and maybe a new vacation home.

About the question of what the previous Milner prize recipients are doing with their $3 million, I've heard rumors that the one mathematician, Kontsevich, has been giving it away to others. From the physics side, the only thing I've seen was that Witten planned to give some to J Street, a group working for peace in the Middle East.

Update: For commentary on whether ATLAS and CMS spokespersons should keep the money, see Tommaso Dorigo.

Comments

1. **Heidar**
   December 10, 2012

   I am not sure I agree that all the theoretical prices (except Hawking), are directly based on string theory. For example Zohar Komargodski (one of the brightest people I have ever met), is mostly famous for work on field theory rather that string theory (proof of a-theorem for example, which is quite an important achievement). Also much of his work on SUSY is based on understanding non-perturbative aspects of field theory better, and not directly having string theory in mind.

   As for the condensed matter award (for discovery of topological insulators) I disagree even more. These states are very interesting by themselves, and has almost no connection to string theory. They are not so interesting to study for AdS/CMT correspondence, since they are just gapped free-fermion theories and not some exotic strongly interacting gapless theories. The only paper I really know where people try to connect topological insulators to string theory, tries to draw a line between the K-theoretical classification of topological insulators to the K-theoretical classification of non-BPS branes, RR-fields etc.. Its an interesting idea, but I am afraid that the connection is not too profound, but rather about 2=2 and 8=8 (complex and real Bott periodicity, respectively). Can you elaborate in what sense you think topological insulators will connect to string theory?

2. **Interested Layman**
   December 10, 2012

   Why is it that Peter Higgs himself was not awarded any prize?

3. **Peter Woit**
   December 10, 2012

   Heidar,

   I didn't say they were "directly based on string theory", but had "some connection" to it. Keep in mind that these days, what string theorists think of as "string theory" covers quite a lot. I'm no expert in condensed matter theory, and make no claim to understand what the prospects for techniques growing out of string theory are in different parts of that field. My observation was just the sociological one that many string theorists see applications to condensed matter as the hot topic and future of their subject, so this is a topic they take an interest in. To the extent they work in this area and have any success, it may of course be due to purely field-theoretical techniques.

   Put differently, it looks like HEP phenomenology will be completely locked out of this. All the jobs may be going to phenomenologists, but that doesn't mean the Fundamental Physics laureates are going to vote for them for awards.

4. **Peter Woit**
December 10, 2012

Interested Layman,

I think Milner is concentrating on making awards that complement the Nobel. An award for Higgs or others is exactly the kind of thing the Nobel committee normally does, so I'm guessing Milner has decided to leave Higgs up to them. He also seems to be more interested in rewarding relatively recent work, not octogenarians for things done 50 years ago (although Hawking is no spring chicken…)

5. **King Ray**
December 10, 2012

Perhaps Higgs didn't win a Milner prize because he committed the faux pas of predicting a particle that actually ended up being observed. Quel outrage! 😉

6. **M**
December 11, 2012

prize to spokepersons?
Why not giving the prize to television journalists who spoke about the Higgs?

7. **P**
December 11, 2012

M,

The spokepersons are actually professors and practitioners of high energy physics. They rose to their positions through years of hard work in the field and communicate results to the public due to scientific expertise. Though it is strange to reward one person in a collaboration of thousands, the analogy (even tongue in cheek) to journalists isn't a good one.

Cheers,
P

8. **Simon**
December 11, 2012

This could be a problem if the spokespeople use the money for their own personal benefit. They are only several among a long list of people who played key roles in the experiments and the discovery. They're aware of this and don't try to hide it. If they keep the money this will make life a little difficult on the collaborations. Were I to have received the money it wouldn't be an easy decision to make to give it away (we all have mortgages to pay).

As was mentioned earlier, its very easy to destabilise a well functioning institution by pouring in money without too much prior thought.

9. **anon**
December 11, 2012

The argument that he leaves Higgs for the Nobel Prize is not really consistent with the award for the solid state experimenters. Their work should also be eligible for a Nobel Prize.

Concerning the three younger theorists, I'm with Heidar in that they are dominantly field theorists in my opinion (including supersymmetric field theories of course).

Congratulations to all of them!

10. **Bernhard**
December 11, 2012

Peter,

I remember when I said "this will become a string theory prize" you disagreed with me

http://www.math.columbia.edu/~woit/wordpress/?p=4953&cpage=3#comment-119763,

but perhaps I was too vague. That, for the theory prizes, nearly all have "some connection" to string theory is no surprise and the kind of thing I had in mind…

I still have the feeling this whole story of this Milner Prize is undermining the importance of a real prize (the Nobel). Society is money driven and people simply don't know how careful and long the process of choosing a Nobel Laureate is compared to the Milner Prize, which on the theory side is a "my pals get the prize" thing. And of course is worsen by the fact that is bigger money.

Even worse, since the prize for experimentalists ended up being decided by theorists who are in general clueless about how a modern collaboration really works, they had no other choice than do the most anachronic thing possible, which we were hoping the Nobel would correct, which is to give the prize to the spokespersons instead of to the collaborations or "to CERN" for that matter.

I admit I would never refuse the cash if I was the one receiving it and is only understandable the contenders are happy with it, but that I have to read from Heuer that "This prize recognizes the work of everyone who has contributed to the project over many years" is laughable. It also gives a clear message to young experimentalists that the way to success in collaborations is only by being a spokesperson which of course are not just about being a good scientist but also about charisma.

This whole thing is really depressing. Money talks everywhere, but should not talk so loudly in science.

11. **Mark**
December 11, 2012

Both spokesperson have said they will not keep the prize for personal use:

http://www.guardian.co.uk/science/2012/dec/10/stephen-hawking-physics-prize

12. **Bernhard**

December 11, 2012

Mark,

I agree this is really noble of them and not something everybody would so. To be clear, they are really not to blame for getting a prize and certainly being a spokesperson of a HEP collaboration is not without merits. Still, my hope was that none of this would be actually necessary and that people would start viewing the collaborations as the semi-headless living organisms they are. The Milner Prize is no a step forward to achieve this goal.

13. **nessuno**
December 11, 2012

Dear Peter,
I am pretty sure that Evans will give the money to CERN, to partially pay back for his share of responsability in the 2008 LHC incident, caused by the negligence of him and of some other highly placed people. The incident material damage was estimated at 28.000.000 CHF, without counting one additional year of delay. An article on the Cern Courier had warned years in advance about the consequences of not carefully testing each LHC interconnection; yet, to save time, they skipped these tests. Here is the link
http://cerncourier.com/cws/article/cern/29012
Best regards,
nessuno

14. **Bernhard**
December 11, 2012

sorry, *not something everybody would do*

15. **Mark**
December 11, 2012

Yes I agree, its not great that they only acknowledge one person amongst several thousand (many of whom will have made significant scientific and other contributions to the Higgs discovery) and gives the wrong idea to outsiders about how things work.

16. **Marcel van Velzen**
December 11, 2012

It used to be Nature that told us who are the greatest theoretical physicists!

17. **Bee**
December 11, 2012

The AdS/CFT for cond matt stuff is interesting… but really what have we learned from this so far other than that there's a lot of string theorists who have hammers and are looking for nails? It seems somewhat premature to hand out awards for this, same with susy and black hole evaporation – the way it looks right now this "fundamental physics" prize runs high risk of becoming a "mathematical physics" prize, or maybe not even that.

18. **Heidar**
December 11, 2012

@Bee

Which of the prizes have anything to do with AdS/CFT for cond matt…?

19. **Esteban**
December 11, 2012

Given all the prizes awarded I find it odd no Milner Prize was awarded to the five remaining Higgs theorists (Englert, Higgs, Guralnik, Hagen, Kibble). Especially since there is this issue of "3" for the Nobel Prize.

20. **Peter Woit**
December 11, 2012

Esteban,

One issue is that not everyone is convinced that all of those people deserve a Nobel Prize or something paying 3 times more.

Also, the Milner theory prizes have been restricted to topics that don't have experimental confirmation of the sort the Nobel requires (or have even been for work that has found experimental disconfirmation…). If Milner starts going back to the early 1960s to find theorists to reward, including ones whose work never led to experimental confirmation, even he might start running out of money.

21. **Esteban**
December 11, 2012

I think the original theorists for the Higgs deserve a significant prize – especially if we are awarding prizes for the experiments. Pretty tough to determine who deserves most credit for this topic among the theorists and more broadly had a better physics career across those five. Also, having a low H-index should not exclude Peter Higgs from the Milner or the Nobel Prize.

22. **anon**
December 11, 2012

The prizes for the senior physicists all make sense in absolute terms, representing diverse directions, though many great contributors to the field are not included. The young guys are also all good choices, but reflect a clear bias for those who have gone through the IAS and work on formal supersymmetric quantum field theory. Young researchers from other institutions have made recent breakthroughs in well-motivated quantum field theory problems with real applications. This all has elements of a reality show, and I hope it does not deter talented physicists from pursuing a wider variety of important problems.

23. **Bob Jones**
December 11, 2012

“The AdS/CFT for cond matt stuff is interesting… It seems somewhat premature to hand out awards for this, same with susy and black hole evaporation”

Okay, first of all, the idea that these condensed matter prizes were awarded for work related to string theory is pure speculation. The citation for the prize says nothing about string theory. Secondly, the prize winners who study SUSY are working on formal aspects of SUSY, not speculative extensions of the standard model. Davide Gaiotto has done a lot of work on the six-dimensional (2,0)-theory for example, and his work has applications to the study of wall-crossing phenomena. This sort of work doesn’t require experimental verification, so I’m not sure how the prize could be premature. Finally, black hole evaporation is something that we will probably never observe, so it’s obviously being recognized as a formal result which has had a huge impact on quantum gravity research. I’m not sure how it’s premature to give an award for this.

“the way it looks right now this ‘fundamental physics’ prize runs high risk of becoming a ‘mathematical physics’ prize”

High risk? What’s wrong with mathematical physics?

24. **layman**
December 11, 2012

This is ridiculous. The work of the condensed matter guys has absolutely no direct connection to string theory, and to even hint that they got the prize because string theorists believe there may be a connection in the future borderlines in insanity and complete delusion (or schizo). A condensed matter person got the prize last year, some got it this year, and some will get it next year. There is no conspiracy here, except in Peter’s mind.

In addition, the work on the a-theorem mentioned above was neither motivated by nor related to string theory. Finally, Gaoitto’s work with collaborators on dualities across dimensions is a purely field-theoretic result, that involves non-SUSY 2d models that are extremely important in many branches of physics.

I have been following this blog for a while, and I must say that this post is a real peak in the amount of odor of delusion coming from it.

I hope Peter would be kind enough to leave this comment in place, so that the public knows better.

25. **Bernhard**
December 11, 2012

layman,

Even if the condensed matter guys have no connection with string theory this is still the “Physics Frontiers” prize not the “Fundamental Physics” prize, and this is the one that interests me because this is the one outsiders + media will be mostly looking at, simply because is THE big cash money.

My bet is that the condensed matter guys are there as a way to pretend this is not what is is: a string theory prize. In my view they don´t really have a chance. The big prize goes either to Polchinski or to Polyakov. Time will tell if I´m right.

26. **observer**
December 11, 2012

Layman,

The stringy types around my way at least are doing almost exclusively what they call condensed matter nowadays and have been working and publishing on topological insulators and other related topics inspired by them. And Charlie Kane et al are on clear track for a real Nobel, so it does make you wonder why they should be singled out for such recognition by a prize supposed to be somehow compensatory for lack of Nobel-rewardability.

27. **Bob Jones**
December 11, 2012

“The big prize goes either to Polchinski or to Polyakov. Time will tell if I´m right.”

And are they not deserving candidates?

28. **Bernhard**
December 11, 2012

Bob Jones,

Sure they are. But if only deserving string theorists get the prize as opposed to deserving theorists no matter their field, than one might as well change the name of the prize to the “Stringy Prize”. We are not there yet, so let´s hope I´m wrong.

29. **layman**
December 11, 2012

Bernhard: Polyakov’s seminal contributions from the 70s,80s are about CFTs etc, which is nowadays a cornerstone in condensed matter. His contributions to *condensed matter physics* arguably exceed those of the pure condensed matter guys who got the prize. Needless to say, Polyakov’s work on CFTs and minimal models (which describe all the basic spin systems at criticality) is familiar to every theoretical condensed matter physicist, so I wont be surprised if he gets the big cash in the end of the day. It would be totally justified.

Observer: none of the stringers on the committee worked or works on the connections between strings and condensed matter. (Perhaps there is one tangentially related paper by one of the committee members that I wont mention, but definitely none of them embarked on a line of research in this direction.) In fact, I know that many of them consider this activity disagreeable.

This is why the suggestion that condensed matter people are involved because this is where the committee sees the future of string theory is of utmost absurdity.

I dont think the prize is supposed to be a consolation prize, it is supposed to *supersede* the Nobel prize.

30. **A.J.**
December 11, 2012

Many of the best theoretical physicists of the past few decades have worked on string theory. Giving these people the prize doesn’t make it a string theory prize. It just reflects the history of the discipline. In 10 years, you’ll probably see a lot fewer prizes for string theory.

You could argue, I suppose, that the Milner Prize should be given to less formal, more phenomenologically oriented theorists, but I don't see the point of this. At least the people doing formal theory have taught us a few things about the behavior of QFTs in general, whereas it's looking like HEP phenomenology hasn't made a correct prediction about TeV scale physics since the Standard Model was put in place.

31. **Peter Woit**
December 11, 2012

layman,

To be clear, I'm well aware that most of what many people generally described as "string theorists" do these days has nothing to do with string theory. When I point this out, I get attacked as denigrating string theory, now you're attacking me for the opposite reason, for implying a connection to string theory of the work of Beisert, Gaiotto and Komargodski.

Gaiotto is an excellent example. I agree that his very interesting work, which is cited as "far-reaching new insights about duality, gauge theory, and geometry, and especially for his work linking theories in different dimensions in most unexpected ways." is based in field theory, has little to nothing to do with string theory. And yet, Gaiotto has been a speaker at Strings 2008, Strings 2009, Strings 2010, Strings 2011 and Strings 2012. I haven't checked, but it's possible there's no one else close to him except maybe Witten in terms of having this kind of dominant presence in recent years at the main Strings conference.

Komargodski spoke this year at Strings 2012, Beisert at Strings 2007 and Strings 2011. All of them have strong connections to the IAS, with Komargodski a current Member there, Gaiotto one until recently, and Beisert at Princeton from 2004-2007. Trying to claim that this list of three young people is not a list of people who have been working in what is referred to as "string theory" these days is absurd. As a list of the best young theorists in the world, it's incredibly narrow in scope, and incredibly IAS-centric. Does this have anything to do with so much of the panel that made these decisions being IAS string theorists?

As for whether the fact that certain topics in condensed matter theory are the latest trend in string theory these days has anything to do with a panel of string theorists deciding that out of six awards, the only one not going to string theorists should go to one of those topics, people can make up their own mind (and decide for themselves who is "schizo"). About the accusation that I'm claiming the condensed matter work has "direct connection to string theory", for the second time, please read what I actually wrote.

32. **Bernhard**
December 11, 2012

"I dont think the prize is supposed to be a consolation prize, it is supposed to *supersede* the Nobel prize."

Well, this is what this prize is, a consolation prize for high profile people without a Nobel.

Supersede the Nobel, give me a break…

33. **Bob Jones**
December 11, 2012

"But if only deserving string theorists get the prize as opposed to deserving theorists no matter their field, than one might as well change the name of the prize to the 'Stringy Prize'."

Yeah, but the prize has already gone to theorists who don't work on string theory per se, so I don't know why you're worried about that. You also have to realize that string theory is a well established part of physical mathematics, so it's inevitable that many of the people who have made important contributions to fundamental physics have also done work in string theory.

34. **Bob Jones**
December 11, 2012

"Gaiotto is an excellent example. I agree that his very interesting work, which is cited as 'far-reaching new insights about duality, gauge theory, and geometry, and especially for his work linking theories in different dimensions in most unexpected ways.' is based in field theory, has little to nothing to do with string theory."

Of course it's related to string theory! The reason those dualities and connections to geometry exist is that the theories Gaiotto is studying come from a consistent six-dimensional supersymmetric theory which is equivalent to M-theory!

35. **Peter Woit**
December 11, 2012

Bob Jones,

Maybe you and "layman" can fight out the Gaiotto issue and let me know who wins.

36. **Bernhard**
December 11, 2012

Bob Jones,

Strictly speaking nobody really got this prize yet. In the the first year the contenders were chosen by Milner and one can argue that this is more like choosing a committee, since Milner is himself nobody in position to decide anything about theoretical physics. It´s the coming years that are important in what concerns this prize, so let´s see what happens from now on.

I will try to keep in mind that "many of the people who have made important contributions to fundamental physics have also done work in string theory" even though in the case of Polchinski and Polyakov this kind of coincidence is harder to swallow.

37. **youngtheorist**
December 11, 2012

It looks like the new horizons prizes are for theorists under 35.
The euro phys society has a prize every two years for exactly this age range. The last three winners were Gaiotto, Cachazo and Beisert. (Cachazo is now probably over 35, also was at IAS for many years). So two of the three winners were given young theorist prizes by an international group. Komargodski's work on the a theorem is a major development, makes perfect sense to recognize it. I don't see an IAS conspiracy here.

38. **Bob Jones**

December 11, 2012

Peter,

If layman is saying that Gaiotto's work is related to string theory, then I can certainly pursue the discussion with him or her. But I'm more interested in your thoughts about about this prize. What difference does it make if it is mostly awarded to people who work on string theory? You apparently find their work very interesting, and we have every reason to believe that the prize will continue to have high standards.

Bernhard,

The fact that Polyakov and Polchinski work on string theory and made important contributions to fundamental physics is not a "coincidence". These topics are not mutually exclusive…

39. **Bob Jones**
December 11, 2012

Oops, I meant to say, "if layman is saying that Gaiotto's work is NOT related to string theory…"

40. **Peter Woit**
December 11, 2012

Bob Jones,

I just think it's a very unhealthy situation to have theoretical and mathematical physics so heavily influenced by the idea that only things with some connection to an overhyped, failed idea about physics are worth pursuing. The large sums of money being thrown at this and the very narrow choices being made about what sort of young researchers deserve recognition aren't helpful at all.

41. **Allan Rosenberg**
December 11, 2012

Experimentalists and condensed matter theorists? Do they even count as physicists? Next year it will probably be lumberjacks, used car salesmen, and CERN's lawyers.

42. **layman**
December 11, 2012

"Maybe you and "layman" can fight out the Gaiotto issue and let me know who wins."

This is ridiculous, instead of looking for interesting science to write or think about, Peter wants to see blood. A gossip blog of the best kind.

Anyway, the work of Davide and Zohar has addressed issues that existed even before string theory was popular, and they have nothing to do with string theory. The work of Davide led to some insights about conformal symmetry in 2d (which as I mentioned is ubiquitous in many branches of physics and mathematics), especially the structure of conformal blocks. The work of Zohar address questions about RG flows that existed in principle since the time Wilson wrote his seminar papers, much before string theory, and completely unrelated to it.

43. **piscator**
December 12, 2012

This is all terribly depressing – everything that was said originally about the narrow IAS-centric scope of the original Milner prize awards has turned out to be true. The whole thing smells cheap and sleazy.

Arguments about whether or not the work is string theory or nor miss the point. The real issue is that you have a big money prize where a precondition for receiving the prize is that you are an approved favourite son of one of three of four people. It distorts the subject, it doesn't look remotely independent, and it stinks of cronyism.

44. **M**
December 12, 2012

dear P., I know what a spokeperson is (somebody good both in experiment and in politics) and I also know who did the real work (as I am a theorist experienced in collecting rumors).
The discovery of the Higgs was a huge collaborative work with individual contributions below the 1% level. I think it is a real mistake to give awards based on visibility when joung bright experimentalists cannot get the recognition they deserve and somebody abandons disliking internal burocracy and Fordian workflow.

45. **Peter Woit**
December 12, 2012

layman,

You definitely lack a sense of humor. No one here is calling for blood. I am however making fun of your claim that the work of a speaker at Strings 2008, Strings 2009, Strings 2010, Strings 2011 and Strings 2012 has nothing to do with string theory. Not that I disagree with this claim, just pointing out it's a schizo world we live in…

46. **Bee**
December 12, 2012

Ah, sorry, I just simply misread what Peter wrote. But, eh, treat it as a prediction 😉

47. **P**
December 12, 2012

M, I think we are in agreement, after all.

Piscator, I think you're mistaking correlation for causation. Gaiotto and Komargodski do have IAS affiliations and certainly are some of the "favorite sons" of some of the famous older theorists there. But it is pretty much universally accepted in top theory groups that their works are seminal contributions in quantum field theory, though sometimes motivated by strings (As Bob Jones pointed out, the (2,0) d=6 theory Gaiotto uses is believed to be closely related to the worldvolume theory of an M5-brane and leads to many beautiful dualities in d=2,3,4), and as such many would think they deserve their prizes.

48. **John Preskill**
December 12, 2012

All of the awardees are outstanding scientists with wonderful achievements, and I'm glad they are getting this recognition. More comments here: http://quantumfrontiers.com/2012/12/11/fundamental-physics-prize-prediction-polyakov/

49. **Heidar**
December 12, 2012

For those who are interested, John Preskill has written about the awards here http://quantumfrontiers.com/2012/12/11/fundamental-physics-prize-prediction-polyakov/ (see also http://quantumfrontiers.com/2012/12/10/stephen-hawking-wins-3m-milner-prize/). He predicts Polyakov will win the full prize, I cannot agree more. His extremely deep contributions to theoretical physics is matched by very few others, even if one neglects all his work on string theory.

50. **Heidar**
December 12, 2012

Wow, that was spooky.

51. **Peter Woit**
December 12, 2012

John,
Thanks for that link!
Heidar,
Yes, even spookier if you were sitting at my computer working and those two comments popped up on the screen within seconds of each other…

52. **piscator**
December 12, 2012

P: with respect, I think this is a loss of perspective. Compared to the stated remit of the prize – `our knowledge of the Universe at the deepest level' – all three prizes cluster in a very narrow area – formal properties of formal quantum field theories, with limited application to any actual physical problem. Furthermore, in terms of area, each prize also maps closely onto one identifiable IAS theorist.

I'm not saying these aren't good people – but these are all people doing one very particular flavour of theoretical physics, and this flavour is branded IAS particle theory.

53. **GB**
December 12, 2012

Is it true that the award intended for contributions to topological insulator only includes those three physicists ? I am thinking Zahid Hasan's pretty pissed off now…

54. **srp**
December 12, 2012

Is Milner really Eris, the goddess of discord, in disguise? Prize=golden apple. Only a few more plot points to go and we'll have thousands of ships being launched on Lake Geneva and a dramatic siege of CERN.

Spoiler alert: DON"T BRING THE GIANT WOODEN MODEL OF A QUARK-GLUON PLASMA INTO THE ACCELERATOR BUILDING!

55. **fuzzy**
December 13, 2012

i don't like this, i want my revenge. so, i will create a new prize, awarded for the most silly prize in physics. nobel's gone, milner wins–but he would have won anyways. prosit!

56. **tulpoeid**
December 13, 2012

Slightly off-topic, but…
Yawn. Given that we talk about September '12, which Higgs discovery, exactly? For how longer will bloggers and journalists make the nobel committee pay for continuing to be scientific when faced with an extraordinairy chance to stop doing so?

New Higgs Results Tomorrow?

December 12, 2012
Categories: Experimental HEP News

As part of the CERN Council activities this week, there will be a session held with a live webcast tomorrow on Status of the LHC and Experiments. I'm hearing that there will be news about the Higgs from ATLAS: new results for the high statistics gamma-gamma and ZZ channels. These were expected for HCP2012 last month but not ready then.

If you can't watch the CERN talks, the KITP tomorrow at 11:15 am has scheduled a talk on "New (!!) ATLAS Diphoton and ZZ Results".

Update: This promises to be quite interesting. ATLAS is seeing a 3 sigma difference between the Higgs mass seen in the gamma-gamma channel and in the ZZ channel. They've been trying hard to check all possible systematic effects that could explain this, but it won't go away, so they've decided to go ahead and report the results tomorrow. Probably nothing, but if CMS is seeing anything similar and it is still there in their analysis of the rest of this year's data, that would be huge. I don't know of any sensible model that would lead to a real effect like this, but who knows…

Update: The new ATLAS results don't seem to be available online anywhere, but Jester and Matt Strassler report the details from today's webcast. ATLAS has the Higgs at 126.6 GeV in gamma-gamma, at 123.5 in ZZ, difference is 2.7 sigma. The ZZ signal strength is right in line with SM predictions, the gamma-gamma signal strength is about 2 sigma high. Odd parity or spin two strongly disfavored.

Nothing news about this from CMS. What they have released doesn't at all confirm the ATLAS mass difference, with them seeing the ZZ peak at 126.2 +/- .6 GeV, gamma gamma around 125. So their masses are compatible and in the middle between the two extreme ATLAS values.

All in all, still looking like a garden-variety SM Higgs. Next update with lots more data likely to be in March at Moriond.

Comments

1. **David Nataf**
   December 12, 2012

   Peter,

   Can you tell me if this scenario is remotely plausible:

   1) Astrophysicists are seeing evidence of a dark matter particle at 130 GeV, which is close to 125 GeV.
   2) It's very rarely produced in the LHC, it hasn't been explicitly caught because there's no search algorithm that would find it.
   3) When it is created, it decays into photons.
   4) 130 GeV is close to 125 Gev, and the resolution is not sharp, so it looks like a single bump at 127 GeV with higher-than-expected normalization.

2. **Peter Woit**
   December 12, 2012

   David,

   You need someone more expert on dark matter than me to address that. If it is sensible there should be half a dozen preprints on the arXiv about it tomorrow night…

3. **anon**
   December 12, 2012

   @David

   if the 130 GeV particle decays to two photons, it can not be dark matter, since the latter must be stable on cosmological timescales.

4. **Marc**
   December 12, 2012

   Peter—It was rumored last month that ATLAS is seeing the ZZ signal at about 123 and the gamma gamma at 126. But CMS clearly shows ZZ at 126, with over 4 sigma. So they can't agree. Still, wouldn't it be fun if CMS sees gamma gamma at 123 🙂

5. **Z**
   December 12, 2012

   The 130-135 GeV Fermi line is still controversial, and possibly spurious since it's also seen in the Earth limb data. cf
   http://fermi.gsfc.nasa.gov/science/mtgs/symposia/2012/program/fri/AAlbert.pdf

6. **Dan D.**
   December 12, 2012

   I'm no particle physicist, but from what I understand, the putative DM particle at 130 (actually 135 based on updated official Fermi analysis) annihilates to two photons, not decays. The particle itself is (presumably) stable.

7. **Bob**
   December 12, 2012

   Peter, are you saying the cross-section is larger by 3sigma, or that the best fit higgs values are different in the 2channels? What are the central values of each channel? It seems crazy to have bumps at different energies in different channels. Something seems fishy…

8. **Peter Woit**
   December 12, 2012

   Bob,

The best fit mass values differ by 3 sigma in the two channels, and the numbers Marc mentions above are about right.

Not as hard to believe as superluminal neutrinos, but still seems almost certain to be something that will go away.

9. **vortex1**
   December 12, 2012

   Could they be seeing different higgs in each channel? multiple higgs?

10. **chris**
    December 13, 2012

    FTL neutrinos reloaded? i hope they go "public" with less hype surrounding it.

11. **nabil**
    December 13, 2012

    What are the models that might produce something like this?

12. **Marc**
    December 13, 2012

    Nabil—you could horrendously fine-tune a two-Higgs doublet model (with some additional particles, perhaps) to explain a gam gam peak at 126 and a ZZ peak at 123. However, CMS sees ZZ at 126, so the experiments themselves are contradictory (if you take the < 3 sigma effect seriously). Of course, if the Higgs mass itself gradually changes as one gets closer to Paris……

13. **Bob**
    December 13, 2012

    Yes marc, your idea that the higgs eats crossaints as it get closer to paris is currently the leading explanation

14. **Jon Lennox**
    December 14, 2012

    Marc: sounds like Henri IV was more correct than we knew.

Arkani-Hamed on Naturalness

December 13, 2012
Categories: Uncategorized

For the latest SUSY enthusiast take on the implications of what the LHC has been (not) seeing, your best bet might be yesterday's talk at the KITP by Nima Arkani-Hamed on Naturalness. An hour and 40 minutes, no slides, nothing much on the blackboard, just him talking about how he now sees things. Some high points:

- If the Higgs turns out to have spin two, he'll quit physics.
- If the Higgs turns out to be a techni-dilaton, he'll kill himself.
- At this point, a natural theory would have to be rather baroque, so he favors abandoning naturalness in favor of simplicity.
- The simplest thing is the Standard Model, but that requires too much fine-tuning. He won't completely abandon naturalness: one part in a million fine-tuning is fine, but the SM fine-tuning problem isn't. This is the point where he loses me (going from the SM to the vastly more complicated SUSY theories with the needed SUSY breaking seems to me not close to being worth the supposed improvement in the fine-tuning).
- He complains that "Some BSM theorists are giving our field a bad name" by repeatedly making SUSY predictions that turn out to be wrong and changing their story.
- He's not one of those: he still favors split SUSY, and has since 2004.
- Split SUSY makes a falsifiable prediction: no Higgs gamma-gamma excess. This is of course the same prediction as the Standard Model.
- In his favored version of split SUSY, all SUSY partners are much too heavy to ever be observable except the wino, bino and gluino. He had a lot to say about what observing these would tell us, but not much about what the implications are of not seeing them in the LHC 8 TeV run. Would this just mean "surely they'll show up at 13 TeV"? Is seeing nothing at 8 TeV consistent with split SUSY? What about seeing nothing at 13 TeV?

In any case, giving up on SUSY is definitely not on the agenda as far as he's concerned.

Comments

1. **BrianW**
   December 13, 2012

   Hmm, I thought much of the talk was merely politics. I'm not sure he really believes the old susy stuff anymore. At the end, he does consider the possibility that all these favoured susy ideas are ruled out for good, which sounds to me like he's betting on a new top down twistor picture, but of course not willing to say so.

2. **lun**
   December 13, 2012

   :If the Higgs turns out to be a techni-dilaton, he'll kill himself.

   ???????????????
   Unlike _any_ scalar field theory, "technicolor" (Asymptotically free theories with a Gauge group) is known rigorously to be non-trivial and stable (in a Renormalization Group sense). What exactly is the problem?

3. **Hmunu**
   December 13, 2012

   Are these long rambling talks the norm for theoretical particle physics or is this specific to Arkani-Hamed? You have posted links to a few talks of his here and each time, I am amazed at the sophomoric quality of the presentation. I realize that the primary focus of a particle theorist isn't to give PowerPoint presentations that would make a marketing firm jealous, but I feel like this talk suggests a lack of seriousness about communicating one's ideas to the unconverted.

4. **MathPhys**
   December 14, 2012

   I think it was Feynman who said that one doesn't need more than one argument if one has a single good argument.

   There is an element of using the audience as sounding boards in these talks. On the other hand, I'm sure people at KITP and elsewhere are more than happy to help him articulate his thoughts, no matter how long that takes.

5. **Mark**
   December 14, 2012

   Hi Peter,

   I wonder what you think people should work on if they give up on SUSY? What I wonder is if there is anything else that already hints at another way forward for BSM@TeV type scales (not including the usual things people work on like large extra dimensions, ZPrimes and so on – all of which of course have also not been observed so far) that we can look for at the LHC, or if SUSY is not there we really need some idea that has not been thought of at all (given most of the mainstream ideas I know of are also heavily constrained by LHC searches).

6. **not a fun of big names**
   December 14, 2012

   All Nima's models are wrong, how dare he blames the rest of the BSM community??? Enlarging (the energy level) of new particles/predictions is the way of doing physics (of course one reason for this is we need to ask funding from government), think about the time before people discovered top quark. By the way, 10^-6 is UN-Naturalness, everyone knows that!

7. **chris**
   December 14, 2012

   "a natural theory would have to be rather baroque"

   i wonder how many people can truly appreciate the subtle irony of this sentence.

8. **JR**

December 14, 2012

Hmunu, Good questions. NAH seems to be one of few people who can ramble and still remain riveting! As for power point, I have never seen him use that, he makes nice carton drawings with a real actual felt pen! Makes me feel like I am back in 1985!. Somewhat refreshing really. Regarding talks with no prepared material, this is mostly the domain of the rich and famous, not recommended for job talk! Also it is not reserved for particle physics, Bob Laughlin used to give wonderful talks on condensed matter theory. He might scribble something like H*Psi=E*Psi on the board but that was it!

JR

9. **Tienzen (Jeh-Tween) Gong**
December 14, 2012

Thanks for the link.
I am a linguist. Thus, I will not comment on the physics. But, I can decode messages. Seemingly, Nima tried to convey two points in his 100 minutes long talk.
a. He just delivered a great eulogy for his pet SUSY.
b. He is making an announcement for joining the Technicolor camp.

10. **Eric**
December 14, 2012

Regarding naturalness, how do we know that supersymmetry doesn't naturally solve a different hierarchy problem in a hidden sector, and electroweak symmetry breaking is simply a secondary effect ? From this perspective, there would be no naturalness problem as the electroweak scale would be only weakly correlated with the mass of the superpartners. However, there would be a different scale, perhaps associated with dark matter, which is strongly correlated with supersymmetry. Presumably this other scale would then somehow trigger EWSB. It really make no sense to be overly concerned with naturalness until we have a complete picture of all physics rather than just the small SM sector which makes up only 3% of the universe.

11. **tt**
December 15, 2012

a different problem in a hidden sector ?
so its a solution looking for a problem ?

12. **Eric**
December 15, 2012

tt,

No, that is not what I am saying. Supersymmetry still provides the explanation for why the Higgs mass is light and thus solves the hierarchy problem. My point is that the scale of the superpartners does not have to necessarily be strongly correlated with the electroweak scale as there could be lots of other physics happening that is not apparent at the present time. So what may appear to require a small amount of fine-tuning, the so-called little hierarchy problem, may appear completely natural when the full picture is in view.

13. **Bernhard**
December 15, 2012

Eric,

"Lots of other physics" (whatever that is) could also show SUSY is unnecessary and by itself solve all problems, including the hierarchy problem, wouldn't you agree? Not that I want to discuss about nothing, but if the game is to claim some vague undiscovered physics to rescue SUSY one my well take a shortcut and use it to solve whatever problems the Standard Model might have.

14. **Bernhard**
December 15, 2012

sorry, *might well take*

15. **Hmunu**
December 15, 2012

@ **JR** – As a graduate student born in the mid 1980s, talks with transparencies conjure up professors giving the same physics lectures that they gave when first granted tenure in the 70s. And I have never found a rambling technical talk riveting, even in my own sub-field, because all I end up thinking is "get to the point!" I wasn't saying that this issue is exclusive to particle theorists, but I am always amazed that high profile people in this field just fly by the seat of their pants when giving a talk.

–

I sort of understand the appeal of nostalgia, but I must wonder if Professor Arkani-Hamed would find this type of talk acceptable by one of his graduate students. If the answer is yes, then that explains many other theory talks I have read and witnessed that lack a coherent structure. They just have been taught that this presentation style is right way to give a talk. That is pathetic and sad.

–

@ **MathPhys** – While presentations during workshops will naturally have less structure then an APS plenary, usually they aren't this free-form. Trying to start a discussion doesn't mean you don't prepare slides to keep the discussion on track. If someone needs assistance to work out the details of a model, do it with colleagues while relaxing on the beach or in the local pub. Maybe I just don't like theory talks that amount to "My Thoughts About the Universe."

16. **Peter Woit**
December 15, 2012

Hmunu,

This was a weird and unusual format for a talk. Then again, he's in a pretty weird and unusual situation right now: he just got a $3 million check for ideas that don't work and that are in the middle of getting clobbered by experiment. So, he's got some explaining to do…

17. **Tienzen (Jeh-Tween) Gong**

December 16, 2012

@Hmunu,
American President seldom use slides for his policy arguments. There is no need of using slides for some important announcement. Nima's Susy was well-known, and he was not trying to promote it anymore. His points were very clear, no slide is needed.
a. Although we can arbitrary push the susy scale to 1000 Tev or higher, it (susy) always has a "tail" trapped at or below one Tev region. That is, no tail at LHC, no susy.
b. If the LHC data shows b or c (which are now the hints in the data), then not only is Nima's pet a goner but also are all its variants.
c. Seemingly, Nima did not like Technicolor before. But, in this talk, he mentioned that the techni-type solutions rescued physics three times in the past. He also admitted that Technicolor "should" be correct although … . He mentioned Technicolor almost 10 times in this talk.

Nima is the first one openly announcing the beginning of the end of a long susy era (over 40 years long). I congratulate him.

18. **rrtucci**
December 16, 2012

This reminds me of the film "The Caine Mutiny"
http://qbnets.wordpress.com/2012/12/15/the-cern-mutiny/

19. **Jim Akerlund**
December 16, 2012

I just saw the video and at the 88 minute mark a women in the audience is reading "Not Even Wrong" on her computer. The camera operator seems to be trying to show this by the long screen time spent with her computer centered. I recognized your page by the "First Results from the Large Hardon Collider" picture she has on the computer.

20. **Chris Oakley**
December 16, 2012

Yes – I am sure that if they had spelled "hadron" correctly, it would not have attracted all this prurient interest.

21. **Peter Woit**
December 17, 2012

Jim,

Yes, took a look and that's definitely NEW she's paying attention to, not Nima. Very funny…

22. **plm**
December 22, 2012

Jim and Peter:
It would have been funny if you had put an embedded link to the video and the woman had been seeing herself on NEW seeing herself on NEW seeing herself on NEW… in real time. She could have eventually discerned "Not Even Wrong" written with composite Higgs in a tiny video.

Quantum Mechanics Fall Class Lecture Notes

December 14, 2012
Categories: Uncategorized

Classes are over for the semester, and I've put together the lecture notes for my undergraduate "Quantum Mechanics for Mathematicians" course, which are available here.

The idea for the course was to try and explain the basics of quantum mechanics, from the point of view of unitary representations of Lie groups. While this is a rather advanced topic, I made an effort to do things quite concretely and start at the most basic level (the only prerequisite for the course was calculus and linear algebra). I hope the notes will be useful both to mathematicians trying to learn something about quantum mechanics as well as to physicists who would like to better understand the mathematics behind the way symmetry principles get used in the subject.

More to come next semester. The initial plan is to start with the fermionic oscillator, move on to path integrals, then relativity, the Dirac equation, and U(1) gauge theory (E and M), ending up with some very basic quantum field theory (non-interacting fields). We'll see how that turns out and at what point I run out of energy and stop writing.

Any corrections, comments or suggestions about how to improve these notes are most welcome.

Update: Thanks to all for comments, I'm quite pleased to see how many people have been looking at these notes (6600 downloads and counting!). They've also made an appearance in surprising places, including here.

Comments

1. **mario fuenzalida**
   December 14, 2012

   Hermano, esto es justo lo que buscaba, soy ingeniero de 62 años al borde del retirement y fisico frustrado llegue hasta la path integral y deseo comprender mejor la mecanica cuantica, gracias, un abrazo desde calama, chile

2. **Peter Woit**
   December 14, 2012

   de nada!

3. **Zoltán Suhajda**
   December 14, 2012

   Dear Peter,

   I have really enjoyed the quick review of the Lecture Notes above. I was looking for such an accurately aimed document about QM from the aspect suitable for veterans of informatics. I do not yet plan to drop from the computing systems and applied informatics, and I feel a need to catch up for quantum computing, which I think is the only fundamental advance in the field of computing for a long time ago.

   So thank you for posting this, and I know I will be really happy when your second semester Lecture Notes will be available.

   Please continue with remarks to applied QM like quantum computing as you did in the current document.

   Best regards,
   SuhesZ from Subotica, Serbia

4. **Yatima**
   December 14, 2012

   quantum computing, which I think is the only fundamental advance in the field of computing for a long time

   Really! This is clearly off-topic but one might as well complain that fundamental physics hasn't seen much progress because there are still only three colors for the strong charge.

   Even disregarding the enormous practical advances and explosion of engineering approaches, principles and philosophies that the field has seen in the last 40 years, and considering only advances in theoretical computer science and complexity theory, it certainly looks to me that there were serious advances indeed.

   As for quantum computing, one could do worse than check out the complexity class BQP, then become a reader of Scott Aaronson's blog, where many surprises await. In particular, his attempt at a timeline of computer science, which probably needs review.

   And does anyone know what Schoonship is?

5. **Peter Woit**
   December 14, 2012

   I fear those looking to me for a text on quantum computing will be sorely disappointed…

6. **M Uppal**
   December 14, 2012

   Dr. Woit, will you be teaching this class again next year (for the Fall 2013 – Spring 2014 terms)?

7. **Zoltán Suhajda**
   December 15, 2012

   Dear Peter,

   do not burden yourself, your current work is enough to correctly recognize the place of the "qubit black-box" within the QM. For the text on quantum computing someone would look elsewhere. Your notes are as good for students of informatics as you have it aimed for mathematicians.

Of course I have found and now following this Web site driven by my skepticism toward the string theory and SUSY (it would be too long to explain why I'm involved in this) not by my before expressed efforts to understand quantum computing.

8. **Blablon**
   December 15, 2012

   Dear Peter,

   On page 9, there is strangely truncated sentence

   > "In this very special case, all the entries of the matrix will be 0 or 1, but that is special to the permuta"

   So something like "tion groups" is missing.

9. **a reader**
   December 15, 2012

   Just to say: thank you. I downloaded it and I much look forward to finding time to read it.

10. **david**
    December 15, 2012

    Another thanks. Section 12 is brilliant.

11. **Aaron Sheldon**
    December 15, 2012

    Thank you,

    Looking forward to going through this over the holidays.

    I have one small quibble with the last part of 1.3: for the equivalence between isometric linear operators (preserving the the inner product) and unitary linear operators, the vector space must be strictly finitely dimensional. In infinite dimensional vector spaces isometric linear maps are not necessarily invertible linear maps.

    For example consider the space of square integrable functions on the positive real line (modulo measure zero functions) ; the positive translation operator is a linear isometry, yet is not invertible.

    While seemingly arcane, such considerations could be important when considering translations of a wave function along a geodesic that intersect with a boundary or singularity.

12. **Peter Woit**
    December 15, 2012

    M Uppal,

    Probably will teach something else next year, but there's no definite plan for 2013-4 classes yet.

    Blablon,

    Thanks! fixed.

13. **Peter Woit**
    December 15, 2012

    Aaron,

    Thanks. I should perhaps make it more clear that for the first half or so of the class, the state spaces under consideration are all finite-dimensional.

    And, when infinite dimensional spaces do come into the game, there should be a huge warning label on the text that I'm no analyst and the standard being aimed for is not precise statements, but statements that are morally true and could be made precise without a lot of effort (unless it is made clear that the statement is highly non-trivial and requires serious work to prove).

14. **David Nataf**
    December 15, 2012

    How did you manage to compose 180 pages of rigorous material in just a few months?

    What make of coffee do you drink and where can I get some?

15. **Friend**
    December 15, 2012

    Dear Peter,

    I'm curious to know how many complaints you get because students think QM is illogical or not well founded? What's would you guess the drop out rate is? Are students stunned by the complexity without reason? Or has everyone pretty much accepted that this is the way it is? How needed is a better conceptual foundation for QM? Thanks.

16. **Matt Grayson**
    December 16, 2012

    I sat in on the first few lectures of Peter's (excellent) course, but then appeared to drop out. I took a similar course 30 years ago and completely failed to understand it. Once Peter explained the connection of representations to QM, I was satisfied that I now "get it", and continued to follow from his online notes and Shankar's book.

Peter, thank you for clearing up a decades-old confusion!

17. **Michael Thaddeus**
December 16, 2012

Hi Peter — in section 2.1, you should either require your representations to be unitary, or your group to be compact, or define "irreducible" to mean simply that there is no proper subrepresentation. The 2-dimensional representation of the additive group C given by t |–>
[1 t]
[0 1]
is irreducible in the sense you define but clearly violates Schur's lemma.

18. **Peter Woit**
December 16, 2012

Thanks Michael,

I was trying to avoid getting into the indecomposable vs. irreducible business, but you're right, I need to say something there.

The only example later on where this turns up is when I mention the 3d Heisenberg group (thought of as upper triangular matrices) action on 3d vectors, and that it's not unitary so not relevant in QM.

19. **Prof. David Edwards**
December 17, 2012

Superposition is a more complicated concept than most physicists realize. If f & g are wave functions, then g*e^(i*c) represents the same state as g; but f+g*e^(i*c) defines a one-parameter family of different states! This obvious truism-which physicists all know-is conveniently forgotten when they try to explain Q.T. Even Feynman's axioms for his path theoretic approach ignores this point. Just like one should start from pseudo-Riemannian geometry in systematically developing General Relativity, one should start from von Neumann's quantum logics in systematically developing Quantum Theory.

20. **Anant**
December 17, 2012

Would it be possible for someone in his 2nd year course (of Bach. in Physics) to follow these lectures?

21. **Peter Woit**
December 17, 2012

Anant,

I've tried to write the notes so that only linear algebra and calculus are required, no physics beyond the most elementary. Physics students may find the mathematical abstraction hard to follow, especially for the first part of the notes, where I'm trying to explain the crucial concept of a representation of a Lie group.

22. **NewComer**
December 18, 2012

Dear Peter,

Being a mathematician with (ugh..) not very good physical background, I truly enjoyed when I took a quick look at these lecture notes.

My suggestion or to say more correctly my wish is that you include an explanation of spin manifold from the physical point of view if you find it relevant, as somehow I can't find it in the literature.

23. **Peter Woit**
December 18, 2012

Newcomer,

These notes are all in Euclidean or Minkowski space, not trying to do things on manifolds, so spin manifolds don't come into it.

However, there is a great deal in the notes about the relation of Spin(3)=SU(2) and SO(3), and the necessity of using Spin(3) rather than SO(3) to describe one of the most fundamental things we know about: spin-half particles.

24. **Zathras**
December 18, 2012

These are really excellent notes. Any inclination towards publishing them?

25. **Peter Woit**
December 18, 2012

Thanks Zathras,

Maybe someday, but I'd want to make sure there will always be a version available on the web. For now, I'll see how much more material I can write over the next semester, then see what this looks like after that.

In an ideal world, at some point while teaching the class again I'd go through the whole thing and rewrite it, based on what I learned by doing this the first time. Seems likely to me though that I'd never have the energy for that.

I've almost finished going through notes one last time for typos, inconsistencies, etc. There's a short list of things I'd like to add, sometime soon I'll stop making changes on those notes and concentrate on thinking about next semester.

26. **Zathras**
December 18, 2012

So how did the undergrads do in your opinion? Were they able to follow the material satisfactorily?

27. **Peter Woit**
December 18, 2012

Zathras,

It was a small class, so I don't think I have any idea how this would work with a large group of typical students. I think they did well and learned a lot, it's quite challenging material. Especially difficult was the way they course started off, throwing them into very unfamiliar material: Lie groups, algebras and representations. It's the kind of thing you can only really start to understand once you've seen the crucial examples, so very confusing at first. Maybe some more effort should have been put into motivating this at the beginning.

28. **srp**
December 18, 2012

Would there be any complementarity with Fulton and Harris's (1991) Representation Theory: A First Course? I found a used copy and it seems very example-oriented.

29. **Peter Woit**
December 19, 2012

srp,

Fulton and Harris is also about Lie groups and representations, but mostly covers different material. They're aiming for the general case of semi-simple Lie groups and their representations (for example, the group SU(n) for arbitrary n). I'm sticking to the specific low dimensional Lie groups that are basic for physics: U(1), SU(2), SO(3), and the Heisenberg group. Some of this overlaps with Fulton and Harris, especially the first half of what I was doing, but the second half is quite different than what they do.

30. **Michel**
December 19, 2012

Thank you for uploading your material. Would it work as a preliminary reading to Hatfield's Quantum Field Theory of Point Particle and Strings?

31. **Peter Woit**
December 19, 2012

Michel,

That's really a QFT and string theory book, you certainly should have a good understanding of quantum mechanics itself before studying those subjects. I think my notes are best used in conjunction with a standard QM book, they emphasize aspects of QM that aren't emphasized in the standard treatments, don't go into much detail on issues that are well covered in the usual textbooks.

32. **mo**
December 19, 2012

Dear Peter,

When trying to see where your lecture notes fit in the general scheme of things, I noticed something.

On the very first page, you write upfront: "In quantum mechanics, the state of a system is best thought of as a different sort of mathematical object: a vector in a complex vector space." No other formulations of quantum mechanics are mentioned. For an inventory of various formulations of quantum mechanics, see e.g. Daniel F. Styer et al., Nine formulations of quantum mechanics, Am. J. Phys. 70, p. 288-297, March 2002.

Apparently all states you deal with are pure ones, but it is not explicitly stated, mixed states and density matrices are not mentioned.

One of the best expositions of quantum mechanics for mathematicians that naturally comes to mind is Mackey's Mathematical Foundations of Quantum Mechanics, which is missing from the bibliography. Mackey offers a very general axiomatic definition of quantum states that encompasses both mixed and pure states which seems to be a better way to proceed when lecturing to mathematicians.

33. **Peter Woit**
December 19, 2012

mo,

Thanks, that's an excellent comment. I should probably add this somewhere in the notes to make clear what I'm trying to do, but the decision to not discuss mixed states and density matrices was intentional. Those are important if you want to construct a framework which includes both classical mechanics and quantum mechanics, and/or understand measurement theory and see how classical states emerge as certain mixed states.

My point of view is that such material makes things much more complicated and doesn't belong in the foundations of the subject, but should be put off until one addresses the difficult issue of measurement theory and the relation to classical mechanics. Bringing these issues in at the beginning to my mind obscures what are the fundamental mathematical structures involved.

34. **David Metzler**
December 22, 2012

Peter, do you have a suggestion for a text that covers the fundamentals of QFT from a point of view that would be pleasant for a mathematician? Essentially something that would come right after what you're planning for the next semester. I have forgotten most of what I learned in haphazard fashion 20 years ago. I would want something more mathematically oriented than most of the standard physics texts, but not so abstract and high-level as the IAS QFT/String 2-volume set.

35. **Peter Woit**
December 22, 2012

David,

Of the things I've looked at, Folland's "QFT: A tourist guide for mathematicians" is the best I've seen along these lines. I'll try and cover some of the basics next semester, which would be a good background for reading Folland.

Folland doesn't get to many of the things that would most interest mathematicians: non-abelian gauge field theories, 2-d conformal field theories and affine Lie algebras, and TQFTs. Some of those topics are in the IAS volumes.

36. **David Metzler**
December 23, 2012

Thanks Peter, that looks like exactly what I'm after, and I know Folland usually writes well. I'll take a look at it.

37. **Anonyrat**
December 26, 2012

Page 43, the argument that the adjoint representation is a real representation could possibly be made clearer (unless it is in the exercises, which I haven't yet looked at).

38. **Peter Woit**
December 26, 2012

Anonyrat,

Thanks, that is a confusing point. I did go over it in more detail in class (perhaps confusing the students even more). I'll think about what can be done to improve that.

There are actually two confusing things going on here: the first is that, even when dealing with a group defined by complex matrices (like SU(2)), the Lie algebra I'm talking about is a real vector space (real linear combinations of i times Pauli matrices). All complex linear combinations of Pauli matrices is the Lie algebra of SL(2,C), not SU(2). The second confusing thing is that to get raising and lowering operators, you want to complexify and go to the Lie algebra of SL(2,C) anyway.

- This week there's a conference in Oxford I'd have loved to have been at. Slides from some of the talks are already posted here. The conference is in honor of Graeme Segal's 70th birthday. Happy Birthday Graeme!
- Physics Today has a very interesting piece about the current state of HEP posted today by Burton Richter, focused on the topic of Should the US join CERN?. On the ILC, with Japan the prospective location, he takes the point of view that it's most likely to be interesting as a Higgs factory, so a 250 GeV machine will suffice:

  > The ongoing International Linear Collider (ILC) program is aimed at building and running a 500-GeV machine by 2020. A new ILC design study is scheduled for release in a few months, but by 2020 the LHC should have delivered enough cumulative output to make anything the ILC can produce irrelevant beyond what its lower-energy Higgs-factory option can do.

  Besides this, at the energy frontier the LHC is the only game in town, with HL-LHC and HE-LHC challenging and expensive projects that will dominate the future of the subject. If the US wants to participate, Richter argues that a new, closer formal relationship is needed. The politics here is likely to be tricky, with the US Congress not exactly keen on spending money outside the US, through an organization where the US has little influence.

  About the future he's most worried about the too high cost of getting to higher energy permanently delivering us into the hands of multiverse mania:

  > If our only theory of everything comes down to the landscape model, where we are only one of a zillion universes with the parameters we see as only a statistical accident necessary for life, the game is over. I hope not.

- One of the landscapeologists whose influence Richter is worried about is Joe Polchinski at Santa Barbara. Courtesy of the Milner prize competition, Polchinski is in line for about $3 million more influence if he beats out his two competitors next March, and UCSB has a press release about this. The press release explains that Polchinski is being rewarded for his discovery of "one of the basic building blocks of space time"

  > According to the award citation, the Physics Frontier Prize recognizes Polchinski's broad contributions to fundamental physics, most notably the discovery of D-branes. These have been shown to provide the atomic structure of black holes, predicted long ago by Stephen Hawking, and, as such, are one of the basic building blocks of spacetime.

  One goal of the Milner prize is to raise the profile of work that is not Nobel-worthy because it isn't testable science, by creating a bigger prize for it than the Nobel. Unfortunately I think one side-effect of this is to blur the distinction between things we have evidence for and those that are pure speculation (with "D-branes=basic building block of spacetime" the latter, being promoted to the public as if it were the former).

- Steven Weinberg's graduate level text on QM, Lectures on Quantum Mechanics, is now out, and I'm very much looking forward to getting a copy soon.
- The Higgs boson is Time Magazine's Particle of the Year, Fabiola Gianotti runner up for Person of the Year.
- I recently read Benoit Mandelbrot's posthumously published autobiography The Fractalist: Memoir of a Scientific Maverick, but don't really have the time or interest to write a review here. Mandelbrot has an unusual life-story, starting with being hidden in war-time France to escape the Nazis.

  The thing that struck me most about the book though was that I had always assumed he was an academic outsider, but the true story is quite different. His family was academic mathematics royalty, with uncle Szolem Mandelbrojt a highly influential French mathematician at the College de France guiding him closely. A big theme of the book is Mandelbrot's detailed explanation of the debates involved at each stage of his life over what would be his best next career move. There's more about this than about the mathematics.

  Another reason not to write a review is that I can point to two interesting ones already out there. The Wall Street Journal got Stephen Wolfram to write one, see here, and American Scientist has one by Brian Hayes here. Hayes isn't exactly kind to Mandelbrot, emphasizing his egotism and desire for recognition:

  > Mandelbrot begins one chapter of his memoir with the declaration: "A blessing throughout life: I never wonder who I am." He is untroubled by doubts or regrets, and untainted by false humility. In these pages you will find no self-effacing disclaimers about standing on the shoulders of giants; if Mandelbrot has seen a little farther, it is because he's taller. From an early age his scientific hero was Johannes Kepler, and his goal in life was to accomplish something worthy of a modern Kepler, overthrowing an outworn orthodoxy. By his own account, he succeeded brilliantly, with quite a number of "Kepler moments." (As far as I know, Kepler himself had only one.)

- For another, mathematically more interesting, discussion of a recently departed mathematician with an amazing career, see the AMS Notices article on I. M. Gelfand. Gelfand's career and influence is a huge topic, so this is just Part I.
- A significant new advance in representation theory is explained nicely by its authors here in terms of the general philosophy of representation theory laid out by Gelfand. A standard topic in representation theory courses is to classify the unitary representations of compact semi-simple Lie groups (highest weight theory), but the question of what happens in the non-compact case is much, much more difficult and still open, with one problem that the representations are infinite-dimensional. This latest paper reports "a finite algorithm for computing the set of irreducible unitary representations of a real reductive group G" with the authors describing their result as follows"

  > The third step in Gelfand's program is to describe all of the irreducible
  > unitary representations of G. This is the problem of "finding the unitary dual"
  >
  > $G^{\wedge}_{u} =_{def}$ {equiv. classes of irr. unitary representations of G}
  >
  > It is this problem for which we offer a solution (for real reductive G) in this paper. It is far from a completely satisfactory solution for Gelfand's program; for of course what Gelfand's program asks is that one should be able to answer interesting questions about all irreducible unitary representations. (Then these answers can be assembled into answers to the questions about the reducible representation π, and finally translated into answers to the original questions about the topological space X on which G acts.) We offer not a list of unitary representations but a method to calculate the list. To answer general questions about unitary representations in this way, one would need to study how the questions interact with our algorithm.
  >
  > All of which is to say that we may continue to write papers after this one.

  This sort of representation theory is ferociously technical, with many papers in the subject appearing to have been written only to be read by the very small number of people expert in all these technicalities. This document is surprisingly different, starting off with an accessible introduction to the subject, and then devoting a lot of space to a careful, readable exposition of the details of the necessary technicalities. The subject is still ferociously complex and technical, but this paper gives one a fighting chance to actually understand what is going on if one has the time and energy to read one's way through it. An admirable and unusual choice of how to write a modern math paper.

Update: A commenter points out a nice article that just appeared in Scientific American, Strange and Stringy, by Subir Sachdev, who explains some recent ideas about using dualities to understand certain condensed matter phenomena.

   I commented also on Gelfand here: Gelfand, the Renaissance Man .

2. **Bernhard**
December 20, 2012

   "It's a quirk of CERN that team leaders like Gianotti — with their power over so many people and so much machinery — do not have titles like chief scientist or project director. They are simply called spokespeople"

   It is actually a quirk of the reporter who wrote this article, that clearly has no clue how a HEP experiment is actually run. Spokespersons are called this way, because this is actually what they do, speak for the collaboration. Somehow this Jefrey Kluger fellow think Gianotti or Incandela had actually something to do with the Higgs discovery. Very funny…

3. **Yatima**
December 20, 2012

   String Theory and Condensed Matter Physics meet in the January 2013 issue of SciAm: String Theory Helps To Explain Quantum Phases Of Matter by Subir Sachdev.

   We read:

   "For my purposes, the picture of strings dancing in some higher-dimensional spacetime is not important. It does not even matter to me whether string theory is a correct explanation of particle physics at very high energies. What is significant is that the duality lets me exchange a mathematically intractable problem for an easy one.

   When electrons in crystals have only a limited degree of entanglement, they can still be thought of as particles (either the original electrons or pairs of them). When large numbers of electrons become strongly entangled with one another, however, they can no longer be viewed as particles, and conventional theory struggles to predict what happens. In our new approach,
we describe these systems in terms of strings that propagate in an extra dimension of space.

   My Harvard University colleague Brian Swingle has drawn an analogy between the extra spatial dimension and the network of quantum entanglement. Moving up and down the network is mathematically just like moving through space. The strings can wriggle and fuse together within the extra dimension, and their motion mirrors the evolving entanglement of particles. In short, the spooky connections that troubled Einstein make sense when you think of the degree of entanglement as distance through an extra spatial dimension."

4. **Peter Woit**
December 20, 2012

   Thanks Yatima,
Nice article. I'll add this to the posting itself.

5. **bjm**
December 20, 2012

   Bernhard said, "Somehow this Jefrey Kluger fellow think Gianotti or Incandela had actually something to do with the Higgs discovery. Very funny…"

   She had nothing to do with the discovery? Now I'm really confused. Maybe it's different in Europe, but in the US, a spokesperson is not assumed to have any managerial responsibility. Other statements I've seen convinced me that at CERN the "spokesperson" was actually the project manager Now, your quote above implies she did have no managerial responsibility for the team the co-discovered the Higgs. Confusing.

6. **P**
December 21, 2012

   Bernhard,

   "Somehow this Jefrey Kluger fellow think Gianotti or Incandela had actually something to do with the Higgs discovery."

   Define "had to do with," or this statement runs the risk of sounding *really* silly.

   I'm not sure about Gianotti, but Incandela is a HEP professor and it is safe to assume that he has been guiding his group in building the CMS detector and analyzing data for the last number of years. Senior members of experimental HEP groups at universities are crucial in organizing younger members to execute on the building and commissioning of an experiment, and also in data analysis. If I understanding correctly, sokespeople are handed the reins after years of hard work.

   P

7. **Simon**
December 21, 2012

   At a HEP experiment, the spokesperson is the de facto chief executive. However, as mentioned in a previous comment, a large collaboration behaves pretty much like a semi-headless organic entity. The leader does play an important role but I think it would be fair to say that the Higgs-like object would have been discovered if they had been replaced with any number of their equally well qualified colleagues. The scientist who spent his/her nights ensuring that, eg, the calorimeter read-out works has just a great a claim on the discovery.

   It should also be pointed out that I've never seen spokespersons behave in any way which suggests that they feel a greater ownership of an experiments' physics results than any other member of the collaboration.

   This whole business of awarding prizes to the bosses puts them in a difficult position.

8. **Bernhard**
December 21, 2012

P, Simon, bjm, et al,

Yes, this statement was actually silly one, one that I have no real intention to defend it… I was being flippant on purpose.

I exaggerated what I had in mind to compensate I found no other way of expressing my frustration with this whole business of giving the experiments spokespersons more credit that they deserved. This is not to say they don´t deserve some credit, of course they do… But in terms of who should really be right on the spotlights, I´m sorry, it should not be them, and I´m uncomfortable with this. The people who did the work and its direct leaders (of the ATLAS and CMS Higgs groups) should be those really getting the biggest attention, in my view. The spokespersons had they share of contribution but it´s way smaller then those people, in comparison. The general public has really no idea how this works. Reading the article, one might for example think that a spokesperson actually is leading a Higgs analysis. While they definitely have a say on what goes out or not from ATLAS and CMS I know they were not in front of the actual work (and with actual work I mean, the event selections, understanding the systematics, doing the actual statistical analysis and the plots). This is what I had in mind. I think, no, I know, that the people doing the hard work are not being properly acknowledged for that and this will just be forgotten from history. What will remain is just the spokespersons and to me this is both sad and unfair. I will not defend my stupid comment further than that, but hopefully you can understand my frustration…

9. **P**
December 21, 2012

Bernhard,

Your frustration is totally understandable. Sorry to jump on you – a few times already I've heard some sentiment of "the spokespeople don't actually do any science, and feel the need to correct it. Clearly you know what you're talking about, seeing your recent response 🙂

For awhile I believe they were considering the boson itself for "person of the year." If they were willing to break with tradition there, why not break with tradition and consider the entire ATLAS and CMS collaborations? Or maybe ATLAS + CMS + accelerator guys without whom none of this would happen?

Cheers,
P

10. **emile**
December 21, 2012

Awards and other forms of public recognition like Time Magazines' "person of the year" are aimed at individuals, not groups. The media in particular want a "human story" which you can't tell if you give it to 7000 people. For prizes like the Nobel or Milner, I really wish the collaborations could receive them. But I'd rather have one or two experimentalists get those prizes than to see those prizes go to theorists only. And if you are going to pick one person from an experimental collaboration, the spokesperson is the logical choice.

11. **Noah Smith**
December 21, 2012

Seems like the scientific revolution started by Galileo, Bacon, Newton, etc. might be over.

12. **Bernhard**
December 21, 2012

emile,

I ´m not sure it is really the logical choice. One could think that different ideas could go for different persons. Assume one discovers besides the Higgs, SUSY and other BSM physics that are Nobel worthy. Should all these go to spokespersons? If one face no other choice than giving the prizes to "leaders", than the logical choice would be, to me, the conveners, not the sppekespersons. The thing with spokesperson is not one of logic, but of tradition, one that I advocate should be broken to adapt to the reality of the modern HEP collaborations.

13. **chorasimilarity**
December 21, 2012

Here is a link Peer-review turned on its head has market value

which might be interesting for those who appreciated the post
Why Author Pays Open Access is a Bad Idea (which has comments closed).

14. **Trevor**
December 21, 2012

The piece by Richter was interesting and raised some good points but I think his take on CERN isn't really justified. It's not fair to lump all of the European member states into one group that simply has one vote. I believe that most of those nations contributed independently of each other.

15. **Marcel van Velzen**
December 22, 2012

Hello Peter,

I already have Weinberg's book on QM at home and read large part of it 🙂
It says "First published 2013"!

Great book, reads well, too many good things to enumerate. The more advanced parts are similar to his "The Quantum Theory of Fields".

One of the last problems asks you to calculate the decay rate of the 2p-1s transition in hydrogen. It leads to a funny formula with 2 and 3 to the power eight! I already asked this on Matt's blog but want to ask it here also. Everyone seem to agree that it corresponds well to the experimental value but I can't find the experimental value anywhere on the Internet. I get the impression it has never been measured and people just use the calculated value assuming that it is correct. The best thing I could find is this: http://adsabs.harvard.edu/abs/1983ZhPmR..38..347P
but formally it is calculated there also, although it has to be more or less correct to lead to the right frequency. So if anybody knows where to find it, thanks.

16. **Chris Oakley**
December 22, 2012

> It says "First published 2013″!

I am impressed already. Weinberg has clearly mastered something that other physicists only talk about – closed timelike lines.

17. **Serge**
December 23, 2012

Just interesting fact – Gelfand's "Linear Algebra" was basis (pan intended) for Linear Algebra courses for all Soviet Union technical colledges("Institutes").

18. **Martin**
December 23, 2012

Merry Christmas, Peter.

I read your blog for two years and I am glad that I have this source of informations. I wish you merry Christmas and happy New year.

Martin

19. **crossing symmetry**
December 24, 2012

To all the desperate phenomenologists out there who are waiting for the appearance of another anomaly so that they can do some "science", ATLAS experiment is seeing a resonance of the same-sign dimuon at 105 GeV. With 13fb-1 data, the significance of the bump is 5.02 sigma–around 14 events at the resonance. I hope this will keep our brilliant phenomenologists busy over the holidays in a race to build model.
My personal hunch: looks like nature has Higgs triplet for us, the signature looks very similar to the doubly charged Higgs. If that is the case, as Philip Gibbs has written in his blog, a doubly charged Higgs would explain the H->gg excess.

PS: Dear Peter, I have been following your blog for quite some time. I got the information from on my friend who works in the atlas collaboration. I hope out of courtesy, my IP address will not be released.

20. **Peter Woit**
December 24, 2012

Crossing symmetry,

Thanks! Looking a bit at published results, it seems that conventional wisdom is that 105 GeV is much too light to be a doubly charged Higgs, such a thing should have been visible at the Tevatron.

Looking at the published ATLAS results based on 5 inverse fb, there does appear to be an anomalously high number of events around 100 GeV (but also around 60 GeV), see
http://arxiv.org/abs/1210.5070
I'd guess people are not taking this too seriously, assuming that new physics at that mass would have shown up earlier. The big question of course is whether CMS sees the same thing, but the only relevant CMS results I could find don't even plot data at that low a mass.

Don't worry, the only time I would ever disclose anything about the identity of an anonymous commenter is if they were behaving extremely obnoxiously, and spreading rumors doesn't qualify at all as far as I'm concerned, quite the opposite if they're well-informed…

Merry Christmas to all!

21. **Robert Rehbock**
December 25, 2012

@Chris Oakley:
But Weinberg will, like the LHC spokespersons, need find an appropriate way to share the credit for publishing in the future with the many proofreaders and editors at his publishing house without whom this would not have been possible.
A special Happy Holidays to you and yours. You may recall our meeting last year , or was it next year time gets so uncertain now. 🙂

22. **Chris Oakley**
December 25, 2012

Robert,

Of course.

Happy Christmas 2016!

23. **Peter Woit**
December 26, 2012

About the rumor from "crossingsymmetry".

This has propagated to some other blogs, but from what I've been able to gather, this rumor should be taken with a large grain of salt. It doesn't seem to correspond to anything known to many people at ATLAS (or CMS for that matter).

24. **Yatima**
December 30, 2012

A bit late: Rolf-Dieter Heuer in Nature's [Ten People Who Mattered This Year]

25. **camillo vidani**
December 30, 2012

> The media in particular want a “human story” which you can’t tell
> if you give it to 7000 people.

Well, the media is very much concerned with team sports, and people seem to like stories about it and find plenty of “human factor” in them. These are quite smaller teams, granted, but I think it wouldn’t be so difficult to explain to journalists that experimental physics is a team sport now, and not about single geniuses.

If we wanted to.

Obviously, the leading figures still like the genius mystique very much 😉

East Coast versus West Coast

December 26, 2012
Categories: Uncategorized

Back when I was a student I remember learning that there were two possible sign conventions to use for the Minkowski space metric: the "East coast" one, mostly + signs, favored by relativists and Steven Weinberg, and the "West coast" one, mostly – signs, which was the one in Bjorken and Drell. Then, as now, the big centers of influence in US particle theory were on the coasts: Princeton and Harvard on the East coast, Berkeley, Stanford and Caltech on the West (these days one might want to add the KITP at Santa Barbara). I was educated by the Eastern establishment (who sometimes used the "West coast" sign convention), where gauge theory and the new standard model were the order of the day. The West coast, with its remaining pockets of S-matrix theorists and authors of popular books like "The Tao of Physics" and "The Dancing Wu Li Masters", was considered to be rather behind the times and a bit soft in the head, perhaps attributable to too much time spent in hot tubs at Esalen and too much use of the agricultural products of Mendocino and Humboldt county.

Remarkably, these days the two coasts remain dominant, with US Fundamental Physics Prizes going only to theorists living within a relatively short drive to an ocean beach. An East coast – West coast disjunction in interests remains, one that it remains tempting to speculate may have something to do with California's main cash crop. For quite a few years the West coast has been the center of multiverse-mania, and I've often wondered what the theorists there would turn to when that lost its "new cutting-edge theory" shine.

It remains unclear what will happen in the long-term, but there's now a new hot topic in California these past few months. It was the subject a few weeks ago of a workshop (AKA "brain-storming session") with 50 or so in attendance at Stanford, and is being described by Raphael Bousso (across the Bay at Berkeley) as "this is probably the most exciting thing that's happened to me since I entered physics." A full-blown conference is rumoured for April.

LA-based science writer Jennifer Ouellette does a characteristically excellent job of covering the story, starting here by explaining the appeal of the subject (as well as the problem with explaining it):

> To include every last detail, the piece would have had to be a good 6000 words long, and frankly, very few general readers would care to slog through all the gory details. So why even bother to try, if one can't be comprehensive? Because FIREWALLS! That's why! Seriously, how cool is this concept? There's nothing more crowd-pleasing than death by black hole (just ask Neil de Grasse Tyson) and now there could be more than one way to die. Spaghetiffication, or incineration? Take your pick.

Another version of that post, which includes an excellent set of references is here. For her full treatment, see the version at Simons Science News.

All of this started with "AMPS" a July paper by four Santa Barbara physicists that already has 25 citations and counting (although of the three papers on the topic by Susskind, one is already "Withdrawn because the author no longer thinks it is correct"). For more on the topic, you can try Bousso's Strings 2012 talk, blog entries by Polchinski at Cosmic Variance, Caltech's John Preskill at Quantum Frontiers, Santa Barbara's Aron Wall at his Physics and Theology blog, or Robert Helling here. I haven't myself tried reading these papers, partly because I strongly suspect that I'd end up with the same reaction as Robert:

> Now, of course I had to read (some of) the papers and I have to say that I am confused. I admit, I did not get the point. Even more, I cannot understand a large part of the discussion. There is a lot of prose and very little formulas and I have failed to translate the prose to formulas or hard facts for myself. Many of the statements taken at face value do not make sense to me but on the other hand, I know the authors to be extremely clever people and thus the problem is most likely on my end.

The problem may be that Robert isn't in California, but, like me, is too far East. Someone else brought up in the East coast tradition (and now so far East he has kind of fallen off the edge…) is Lubos Motl, whose reaction to this topic is that the whole thing is Peter Woit's fault:

> AMPS isn't as bad or as obviously wrong as "gravity as an entropic force" but it's still wrong and what's worse about it is that it is pushed by some of the names that are more famous than Erik Verlinde's name. None of those bad apples would really destroy an otherwise healthy research community but the main problem I see is that the bad apples can no longer be efficiently wrestled with. Or it's not happening. It doesn't look like anyone cares at all. Instead, it seems to me that people are defending their subjective and increasingly non-quantitative (and often downright wrong) ideas and these people's connectedness to the journalists and other folks outside the research community itself and the related populism – instead of the scientific evaluation by those who actually understand the things as experts – have become the key determinants of success.

Will firewall-fever spread from the West coast, or is it just a flash in the pan? Time will tell…

On a personal note, blogging may be lighter than usual for the next couple weeks or so, as I travel further East for a vacation in Spain, Portugal and Paris.

Update: Bee's comment reminds me that I had planned to include a link to George Musser's SciAm piece about this.

Comments

1. **Anonyrat**
   December 26, 2012

   Well, it is quite sane to believe that but for Woit and Smolin, who have to sign off on all funding and tenure decisions in all North American HEP departments, particle physicists would be safely working on string theory, instead of on useless thought experiments at black hole horizons. 🙂

2. **Aaron Sputzland**
   December 27, 2012

   Peter, are you suggesting that West coast physicists are all potheads?

3. **Bee**
   December 27, 2012

   It did spread to Stockholm. If you have a lot of time, watch this

   http://www.youtube.com/watch?v=QQ9EGezGvNc

   (Don't ask, I wasn't there and I didn't watch it.)

4. **Bee**
   December 27, 2012

Btw, you can avoid the whole "firewall" issue by just accepting that the BH entropy does not count the number of microstates. Unfortunately, this discussion is dominated by string theorists who can't get themselves to even think about this possibility, which I think is the obvious one.

Also, George Musser wrote a very readable summary here

http://blogs.scientificamerican.com/critical-opalescence/2012/12/14/when-you-fall-into-a-black-hole-how-long-have-you-got/

5. **Lee Smolin**
   December 27, 2012

   I've read several of the firewall papers and it seems to me this is the reducto of two assumptions 1) as Bee says, that the BH entropy counts the number of possible states in the interior of the horizon rather than the entanglement entropy or channel capacity of the horizon and 2) that all the information must get back out to scri-plus so evolution neglecting the region to the future of the singularity is unitary.

   The problem is that they are focusing on the horizon rather than where the real quantum gravity physics must take place, which is the singularity. It is remarkable that the authors of this paper believe they can resolve the puzzles of black holes while ignoring the only region of strong fields, which is the singularity. It is natural to suppose-and model calculations support-the hypothesis that in quantum gravity the singularity is removed and everything that approached the singularity and the information it carries proceeds to a new region of spacetime to the future of the singularity. There is no conflict with QM-evolution including this new region can be unitary.

   Some object to this scenario with arguments about remnants but these are unconvincing as we explain in detail with Hossenfelder in arXiv:0901.3156.

   Whether the region to the future of the singularity becomes classical and develops into a baby universe which is permanently disconnected or reconnects to future infinity, as shown in detail by Ashtekar et al in the CGHS model, depends on the details of the quantum geometry dynamics. But in no case is there conflict with the principles of QM, with the equivalence principle or with usual notions of locality.

   Thanks,

   Lee Smolin

   ps see recent papers of Bianchi for new evidence BH entropy is entanglement entropy.

6. **Peter Woit**
   December 27, 2012

   Lee,

   Thanks a lot for your take on the issue.

   Bee,

   Thanks for the links, I was planning to include George Musser's article, will add that to the posting.

   Also worth pointing out is this from Bee:
   http://arxiv.org/abs/1210.5317

7. **Peter Woit**
   December 27, 2012

   Aaron,

   Certainly not. I don't have any data on the question of why the Multiverse and black hole firewalls are mostly popular on the California coast, maybe others do. Could be lots of reasons: a friend who grew up in California, then moved to Princeton and finally England, told me that the main differences noticed while moving East were that members of the opposite sex got less attractive, and the cheddar cheese got better. So, could be one of those…

   Besides the Scandinavian connection pointed out by Bee, there are other non-Californians involved, including the Dutch here
   http://arxiv.org/abs/1211.6913
   which would argue against this having to do with local California culture. Then again, I just remembered some of the local Amsterdam culture I once encountered…

8. **Aron Wall**
   December 27, 2012

   Lee,
   I think the AMPS argument uses your assumption #2, but not necessarily assumption #1. So long as the infalling observer always sees an approximate vacuum, the Hawking radiation coming out near the horizon is thermal, but if the radiation coming out is thermal, then the information doesn't leak out.

   I say this because Don Marolf and I have been arguing for a viewpoint where any information that falls into the black hole from outside will always escape, but there can still be information in the interior which cannot be measured from outside at any time (if you consider all possible black hole states, not just those that formed from collapse). See http://arxiv.org/abs/1210.3590 and some previous cited work by Don. This would imply that #1 is false but #2 is true.

   I think you're right, though, that the AMPS argument might not apply if the information doesn't come out until after the remnant forms. Seems to me that people on the "West Coast" disbelieve in remnants primarily on the basis of AdS/CFT.

   Peter,
   Thanks for noticing my blog! I've been thinking about linking to your blog for some time now, seeing as I follow it, but I haven't gotten around to doing it yet. I went to grad school at Maryland, partly because I wanted to study quantum gravity at a place that wasn't completely dominated by string theorists. But since then I learned which kind of string theorists are worth talking to about fundamental conceptual issues, and I'm very happy here at UCSB.

9. **lun**
   December 27, 2012

   Judging from
   http://arxiv.org/abs/1212.5605v1.pdf
   the East Coast (with a fluctuation towards the north-center) is steadily falling into a black hole of mathematically sophisticated analysis of non-existent theories.
   It remains to be seen how thick is the firewall separating this black hole from the real world.

10. **P**
December 27, 2012

lun,

in which sense you do mean “non-existent theories?” Please prove me wrong, but essentially any way I slice it, this seems like a pretty ignorant comment.

Nima and company are arguing that this is a generic structure of QFT – yes, they use N=4 (which DOES exist as a theory, though doesn’t decribe particle physics) SYM as an example, but they go into detail about how to generalize to theories with less or no supersymmetry. It is far too premature to make the claims you are making. Time will tell how applicable these techniques are to non supersymmetric theories, but the techniques are deep and potentially very important.

Lee,

“The problem is that they are focusing on the horizon rather than where the real quantum gravity physics must take place, which is the singularity. It is remarkable that the authors of this paper believe they can resolve the puzzles of black holes while ignoring the only region of strong fields, which is the singularity.”

Your slightly condescending tone is also remarkable. Isn’t their whole point that new physics was never expected to be encountered at the horizon!? Telling them that the singularity is the issue seems to be dodging their entire argument. They’re not claiming to solve every “puzzle” of black hole physics, as you imply, by focusing on the horizon – but are merely pointing out that there is an issue with our current conceptual understanding of horizon-scale physics. Of course these authors know that the singularity is important for issues of quantum gravity . . .

11. **Peter Woit**
December 27, 2012

P and lun,

Enough about the “positive Grassmanian” paper here. I’m all in favor of an informed discussion of that topic at some point (maybe someday I’ll know enough about the subject to host such a thing..), but it’s an extremely technical one, and I see no value to this kind of arguing about it.

12. **Bob Jones**
December 27, 2012

The mathematical techniques that Arkani-Hamed and his collaborators are developing is useful for studying all sorts of thories — not just N=4 SYM. As pointed out by P, their results can be used to study scattering amplitudes in non-supersymmetric theories. The cluster algebra formalism that they’re using is also important in two-dimensional conformal field theory, wall-crossing, and other areas.

Sorry to keep harping on this paper, Peter. But lun’s comment is just outrageous…

13. **lun**
December 27, 2012

Since you are allowing a whole bunch of critical comments, I hope a reply is also acceptable. What I meant by “non-existing” is that theories examined in 99% of that paper, as far as I know, do not exist. Real QFTs, as far as we know, are far away from the planar limit and do not have any SUSYs. There might be profound reasons for this, or not, we do not know. Something relevant to the real world might be derived from this or not (read my comment, I say this explicitly), we do not know. Any applications of these techniques to understanding non-planar non-SUSY theories (you know… the real world) are at the moment remote.

That such a profound amount of work has gone into a deep mathematical understanding of such non-existing (in the above sense) theories is remarkable. Since these theories are not realized in the real world, all this might be as “scientific” as the multiverse or firewalls, so it is not irrelevant to this discussion.
It also has a direct connection to the East-West Coast issue, since these techniques descend, in their philosophy, from the S-Matrix approach (rather directly, read the introduction about what is relevant and what isn’t in a theory!), yet the best East coast physicists are now working on this.

Its amazing how many feathers one can ruffle by saying non-controversial truths.

14. **Peter Woit**
December 27, 2012

OK, enough about this, really.

I do think though that the historical comment is correct: this latest East coast effort is a descendent of the West coast S-matrix theory program of the 60s. Whether the arguments about the desirability of abandoning local field theory will work out better this time around is still to be seen.

15. **Yatima**
December 27, 2012

Okay, so the gravastar idea is back?

Note that a “firewall” used to designate a fire-resistant partition in a building. Now it designates a membrane when/where you are instantly de-rezzed.

Oh Tempora, Oh Language Perversions.

16. **Michael Welford**
December 28, 2012

Peter,

Your list of West Coast books leaves out “Quantum Reality”. It’s the best popular account of quantum theory that I’ve ever read. And it would still be the best book even if it didn’t include the best description ever of nonlocality.

I noticed that one of the preconditions for the firewall is the principle of Conservation of Information, a string theorist fantasy that they’ve somehow bamboozled real physicists into believing is an actual law of nature. In fact, Rolf Landauer established the relation between irreversable information changes and irreversable thermodynamic changes back in 1961. And this didn’t come from out of the blue. Chemists had figured out decades before that increasing entropy was associated with information loss and physicists had built much of the mathematic needed. Since Shannon gave the expression for information entropy in 1948, this discovery was arguably a decade overdue. In the years since no has built a computer or discovered a biological process that defies Landauers Principle.

By an odd coincidence, recently I was watching one of the principals on the Firewall Debate, John Preskill, lecturing on quantum information. It was boring, so I skipped through it in case he said something interesting. Nope! But then I saw this post, and decided to give the lecture another chance. And I fell asleep. But third time is the charm and the lecture turned out to be more or less adequate. Funny thing though, the lecture was explicitly about quantum information, but there wasn't a word about information conservation. Could it be that Preskill accurately gauged the reaction from theorists at having one of the fundamental principles of their discipline contradicted?

And speaking of quantum computing/information theorists, it's past time that the Big Names got off their asses and raised a howl about this Conservation of Information business. Or better yet, they should get their asses back in their swivel chairs and type up some refutations.

17. **Bee**
December 28, 2012

Aron: "People on the West Cost" don't believe in remnants primarily because of the "pair production problem", which however has never been shown to exist under reasonable conditions. The only cases I know where it occurs assume the validity of effective field theory and treat the inside of the remnant as having a small volume. Now it is not clear exactly why effective field theory should fail at the horizon far away from the Planckian curvature regime, but nobody seriously expects effective field theory to be valid in the strong curvature regime, which is what you have to deal with if you have Planck scale remnants. So why does anybody care about an argument that creates an alleged problem based on a method that one expects to fail? It's a mystery to me.

18. **Ian Durham**
December 28, 2012

@Michael Welford: Just out of curiosity, why would anyone in quantum information even *attempt* to refute information conservation? It would invalidate large swaths of our work. Personally, I'd be open to the idea, but it would require some major reconsiderations of our not just our results but our methods as well.

Personally, I think one of the major problems in this debate is that quantum theory and relativity treat space and time in fundamentally different ways. Thus, it's really a debate between what [Chris Granade]() has called the (in an intentional pun) ["psi-ontologists"]() and the psi-epistemics. The former believe that the spacetime manifold, not to mention fields in general, possess some ontic status. This sort of world view is built right into relativity itself. As it relates to the firewall problem, this means that the event horizon represents something about space and time itself.

On the other hand a psi-epistemicist might be persuaded that the event horizon represents, rather, something about an *interaction* and thus can be interpreted as some kind of information-theoretic boundary. This is attractive if spacetime is an emergent phenomenon and there is, indeed, a growing feeling that it very well may be.

My own feeling (though I am not the first or only to consider this possibility) is that the interior and exterior of the horizon represent different superselection sectors and thus there is a superselection rule in place that manifests itself classically as this apparent loss of information. On the other hand, quantum resource theory includes techniques that can be used to overcome such superselection rules and thus the information can be recovered in a quantum information theoretic kind of way.

That's a very rough and brief summary of the idea and there's much more to it, but it at least may give an idea of why some of us have no desire to jump on the refutation bandwagon.

19. **Ian Durham**
December 28, 2012

I should note that the superselection explanation only works if one takes a psi-epistemic view. The difference between a timelike and a spacelike geodesic couldn't be ontic.

20. **Aron Wall**
December 28, 2012

Bee,
Of course there is more than one person on the West Coast, and even when they believe the same thing they don't necessarily believe it for the same reason. From my limited perspective here at UCSB, most people here (except Steve Giddings) seem to regard AdS/CFT as a more definitive refutation than the pair production argument, which as you say makes some assumptions from field theory which might well not be valid.

As for the information question, I am a *reluctant* convert to the idea that information isn't lost. Most of the arguments against info loss are rather silly (it's not any more a "violation of quantum mechanics" than the other view) but Don Marolf's argument for holography here: [arxiv:0808.2842]() is hard to get around since it follows almost trivially from the facts that (i) the energy can be measured at infinity in general relativity, and that (ii) the energy generates time translations in quantum mechanics.

Now that firewalls have come along, I'm reconsidering whether I should convert back, but I still don't see any good way around Don's argument.

21. **Michael Welford**
December 28, 2012

Ian,

The Landauer Principle has real world consequances. Todays computer chips are only a couple of orders of magnitude from theoretical limits on energy consumption. And we probably won't get all that efficient, because a low energy chip is a reversible chip is a slow chip. Once we approach the Landauer wall we'll need all sorts of optimization decisions: getting by with smaller registers?, strategic use of qbits?, how about analog?, new fabrication technologies? Now imagine some funding functionary telling you that your proposal is irrelevant because information is conserved so we've already achieved perfect efficiency.

With regard to your deeper remarks, I would like to point that I am well acquainted with the epic-ontic controversy. I just can't remember which is which.

Ending this comment before Peter slaps us both down for drifting off topic.

22. **Peter Woit**
December 28, 2012

Yes, I really can't moderate a general discussion of quantum theory. If it's not about firewalls or East/West coast physics, find someplace else to discuss it…

23. **Daisuke**
December 28, 2012

A couple odd thoughts–

Is it actually certain that EP=no horizon wall? There are some rather dramatic phenomena in classical black hole dynamics, the inner horizons of charged and rotating holes for instance–you'd certainly expect matter falling into a near-extremal black hole to encounter a "wall" of that sort under the event horizon. IIRC the long-term evolution of a BKL singularity, while lacking a "creep" outward to the event horizon, tends toward some sort of abrupt "wall" rather than a drawn-out "spaghettification" near the final approach. Given the generally poor state of understanding of the evolution of BH interiors, is it possible that the classical evolution of the interior could produce a horizon wall of some sort by the Page time, thereby preserving the EP?

Bousso's preferred solution to firewalls seems to be a limited relaxation of normal causality requirements, which brought to mind the Feynman-Wheeler absorber model of radiation–and now I'm wondering how that would behave in highly curved spacetime. The behaviour of advanced waves "approaching" an event horizon would have to be peculiar indeed…

24. **Ian Durham**
December 28, 2012

@Michael (and Peter): My comments were about the firewall issue specifically (I really have no opinion on the East/West Coast matter). Discussing the Landauer Principle would be getting off topic and I have no intention of debating that topic here.

But the superselection question is very germane to the firewall question as is the ontic v. epistemic debate since which view one holds determines the route one takes to attempt to solve the firewall problem (as I clearly pointed out above).

25. **Peter Shor**
December 29, 2012

If you were a firm believer in black hole complementarity (and I believe that the West Coast was the epicenter for this belief), then the quantum information argument showing that something is really wrong with the traditional view of black hole complementarity needs to be addressed. Firewalls seem to me to be a desperate attempt to preserve some of the ideas of complementarity, although my intuition is that they really can't work.

26. **Fry and Laurie**
December 30, 2012

How do you know so much about Mendocino and Humboldt counties?

27. **Spencer Tracy Jr.**
January 2, 2013

I myself don't know anything about those counties – but I'm thinking seriously about heading out there to see if I can find a good looking woman and some bad cheddar.

28. **OldStuff**
January 2, 2013

There are some matters of detail in which the firewall guys are different, but the basic idea that classical gravity can have corrections already at the horizon scale is something that Samir Mathur has been saying for a long time, and the string theory "establishment" has been consistently hostile to.

The real reason why most string theorists are suddenly taking the firewalls seriously is because Polchinski is one of the authors.

Of course Polchinski himself is a very fair person and he gives adequate credit to Samir in all the talks I have heard. But some of his collaborators on the other hand, try to revise history and present it as though all Samir did was to come up with one of the qubit toy models for black holes.

Pretty dishonest, if you ask me.

29. **MathPhys**
January 3, 2013

Of course Polchinski himself is a very fair person and he gives adequate credit to Samir in all the talks I have heard. But some of his collaborators on the other hand, try to revise history and present it as though all Samir did was to come up with one of the qubit toy models for black holes.

Don't worry about it. It's been always like that.

30. **Jean**
January 3, 2013

Don't know whether it's worth posting but Peter's blog has been mentioned in the list of mathematics blogs here-> http://www.talkora.com/science/List-of-mathematics-blogs_112 (look for entry #2 in the list.)

31. **Miguel Carrion**
January 3, 2013

I'm going to have to read the papers in some detail because for the life of me I can't imagine what would prompt Polchinski to write that "the infalling observer encounters nothing unusual at the horizon" is the most easily dropped assumption in the firewalls paper, and that "perhaps the most conservative resolution is that the infalling observer burns up at the horizon".

Maybe this is just philosophical prejudice on my part, but it seems to me that the regularity of the Eddington–Finkelstein coordinates around the horizon uncontroversially implied the horizon could be crossed, at least by a physical system small enough not to be destroyed by tidal forces there.

32. **DaveH**
January 4, 2013

Peter Woit,

I thought your East/West and signature intro was interestingly correlated with your following discussion of AMPS for a couple reasons. First, the t/r signature actually flips at the event horizon (so East becomes West there I guess 😉 (Tongue in cheek, and to avoid "helpful" replies, I know about better coordinate choices; but also see MTW section 31.3 which gives the flip more of a physical interpretation nonetheless.) Secondly, I always thought the convention difference was more GR guys vs QFT guys, not East vs West, to me the split in interpretation also seems to track this better than East vs West.

D

33. **Low Math, Meekly Interacting**
January 4, 2013

I don't know if Dr. Woit is a connoisseur, but horticulturalists, being who they are, always strive to breed better crops. And how. SoCal has its rivals, but even locavores of today are getting a product that is astonishingly potent compared to what was available in the 70's. If these advancements have continued to impinge on physics in any way, their effects are likely to be amplified.

34. **Sebastian Thaler**
January 4, 2013

Off-topic, but I can't resist: http://news.yahoo.com/atom-smasher-hiatus-sets-stage-more-discovery-134311023.html
I can't wait for early 2015, when the LHC "atom smasher" will be "unlocking more mysteries," just as last July's discovery of the Higgs "promises a new realm of understanding of the universe," and when it's gained the "capacity to simulate the moments after the Big Bang nearly 14 billion years ago."

35. **Small Bang**
January 7, 2013

Indeed why not? It's a reasonable article. Read the last paragraph:

"It will bring you more collisions. Which means that the more collisions you have, the more likely you are to see rare events," he said. "The Higgs particle was just one of many on the wish list that we'd like to find, so higher energy increases your discovery potential."

That is a very fair statement. (BTW all of these machines are known as atom smashers. Get used to it. And don't get picky that `atom bombs' are really 'nucleus bombs'.) The SSC was openly advertised as creating conditions not seen since the Big Bang. All of the quark-gluon plasma business is similar `not seen since the Big Bang' stuff. Perhaps you would prefer to say "We have no clue what any of the output from the LHC means"? The obvious riposte to which is "Then why are you doing HEP?"

What *Should* We Be Worried About?

January 14, 2013
Categories: Uncategorized

Back from vacation today, so regular blogging likely to resume. Will start with something quick, a link to material that was posted today.

The Edge web-site annual question feature is out today, with this year's question [What *Should* We Be Worried About?](). I wrote [something]() about the "Nightmare Scenario" that HEP is facing if the LHC finds a Standard Model Higgs and nothing else.

Others addressed the same issue, with [Lisa Randall]() writing:

> In my specific field of particle physics, everyone is worried. I don't say that lightly. I've been to two conferences within the last week where the future was a major topic of discussion and I'm at another one where it's on the agenda.

Her specific concern is motivated by her interest in large extra-dimensional theories, for which no evidence has shown up so far at the LHC. If the extra jump by a factor of 6.5/4 in energy that will arrive in 2015 after repairs still shows nothing, this may be the end of the line for such theories for a very long time. The prospects for a higher energy machine are problematic in terms of technology, as well as the political will to pay for them. The overselling of this that went on for many years pre-LHC won't make it any easier to re-use these theories as an argument for building a new machine.

[Amanda Gefter]() sees no reason to worry. Particle theorists will just move to making progress without experiment, through studying paradoxes of the current theory, with her final example for optimism the recent debate over the "firewall paradox".

[Carlo Rovelli's contribution]() explains one problem with this: humans are very good at convincing themselves they have found some wonderful explanation of something (e.g. some resolution of a paradox, like the supposed SUSY solution to the hierarchy problem), when reality actually involves something quite a bit more subtle and unexpected:

> A number of my colleagues in theoretical physics have spent their life studying a possible symmetry of nature called "supersymmetry". Experiments in laboratories like Geneva's CERN seem now to be pointing more towards the absence than the presence of this symmetry. I have seen lost stares in the eyes of some colleagues: "Could it be?", how dare Nature not confirm to our imagination?

By the way, when I was in Paris last week I picked up a copy of Rovelli's wonderful short book that has just come out in France [Et si le temps n'existait pas?](). It begins with a personal history of how he got into science, from a background in the 1970s disillusion following the flowering of radical ideas in the 1960, a story I found quite interesting, since I'm of the same generation as him. There's also the story of how some of the ideas of loop quantum gravity developed, and some speculative material about time. Definitely worth looking for if you read French and are interested in these topics.

Comments

1. **Bernhard**
   January 14, 2013

   "the "Nightmare Scenario" that HEP is facing if the LHC finds a Standard Model Higgs and nothing else."

   Well, the current Higgs diphoton rate is not really supporting this scenario, quite the contrary. This should keep people busy at least for some years.

2. **Pi**
   January 14, 2013

   Hello Prof. Woit,

   Nima has published two papers with the second one on SUSY and the first one on scattering amplitudes. As a general audience, I'd like to hear some explanation and your comments about these two papers.

   Best

3. **Peter Woit**
   January 14, 2013

   Pi,

   In both cases, it's probably worth making it clear that Arkani-Hamed has co-authors.

   I'm far from expert enough to comment intelligently about the amplitudes paper (except that the short section on relations to mathematics is rather wild). At some point soon I'll probably write more about the latest status of SUSY, and the second paper you mention is part of that story.

4. **Bob Jones**
   January 14, 2013

   Rovelli's argument is totally bizarre. He criticizes supersymmetry for being too speculative, when in fact it is one of the most conservative ideas about BSM physics. Supersymmetry is not in the same category as the multiverse, nor is it an a priori bad idea that should have been abandoned long ago, as Rovelli implies. It is a very general idea that addresses a range of problems, and it is an important part of quantum field theory regardless of whether it provides a successful framework for BSM physics.

   The most ironic thing is that Rovelli is one of the leading proponents of loop quantum gravity. Most of his argument applies pretty well to his own field…

5. **Bob Jones**
   January 14, 2013

   Peter, I don't want to lead the discussion off topic, but I'm curious to know why you say the relation of Arkani-Hamed's work to mathematics is "wild".

6. **Peter Woit**
   January 14, 2013

Bob Jones,

To be more explicit, I was referring to section 15.4 of the paper, for which I think the adjective “wild” is pretty appropriate. Again, calling this “Arkani-Hamed’s work” is doing his collaborators a huge disservice. In the case of section 15.4 especially, which pretty clearly was written by the mathematicians in the collaboration (Goncharov and Postnikov). Please though to all, if you want to find a place to discuss this paper, you need to find one moderated by someone more expert in the topic than me.

About Rovelli, I think his point was exactly that the least speculative of these kinds of ideas, weak-scale SUSY, is turning out to have nothing to do with reality, giving a good lesson in why one should be skeptical of imaginative speculations of theorists. Yes, the lesson also applies to LQG.

7. **Geoff**
January 14, 2013

If anyone is taking bets on where the necessary input for the way forward is going to come from, can I put my money on observational cosmology?

8. **Peter Woit**
January 14, 2013

Geoff,

You can put your money there, but people have been making that bet (that something learned from cosmology would tell us how to go beyond the standard model) for more than 30 years now, and so far it has been a losing one.

9. **Geoff**
January 14, 2013

Thanks for the reality check. It seemed a slightly better and more obvious choice than my second guess which was looking at different systems that occur far away from equilibrium.

10. **chris**
January 15, 2013

“In my specific field of particle physics, everyone is worried. I don’t say that lightly.”

it is interesting how perspective can distort reasoning even for the most emminent of scientists that should have quite a keen sense of how not to fool themselves.

i am in hep theory and i am not worried in the slightest. neither are any of my colleagues. that might be connected to the fact that all of us never believed susy or string theory to be of any use for understanding the weak scale in the first place. so accordingly, we did not indulge in building spectacular models that get killed now by experimental evidence.

quite on the contrary from being worried, i have the sincere hope that department hiring committees will resume to hire based on contributions to physics on not on how well one person can jump on the latest fad that is fashionable but rather very much unlikely in the grand perspective of things.

how preposterous it is for a scientist to be disgruntled by what nature chooses to be. we are supposed to find out, not to satisfy our vanity. the “SM only” results of the LHC are quite healthy to the field and let us not forget that the Higgs (as boring as it might seem to some – i am specifically disregarding the gamma-gamma excess here as this is most probably a systematics issue) is the first fundamental spin-0 we have found – a true prediction not to be sneezed at.

a bit of humbleness would serve us all well

11. **Simon**
January 15, 2013

Bernard
The results from ATLAS and CMS are consistent with a SM Higgs boson.

12. **Bernhard**
January 15, 2013

Simon,

Yes, they are consistent. However, according to ATLAS the diphoton rate is about 80% the SM prediction. The interesting thing is that the excess grew with luminosity, but of course as chris points out there is still plenty of room to blame this on systematics. I am being optimistic and believing in ATLAS rather than in CMS.

13. **laboussoleestmonpays**
January 15, 2013

I wonder if theoretical physicists need studying speculations like the firewall paradox or need developping a heuristic firewall to deal with “wild” speculations …

14. **Jack**
January 15, 2013

Interesting discussion. I left theoretical physics 30 years ago when Mike Green (now the Lucasian professor) successfully convinced me there were no useful ideas out there. Of course his actual intention was to convince me to join him in String theory research, but the idea that since we had no best fit theory (I was in agreement that SUSY on it’s own looked unconvincing), then the next best option was to provide so many degrees of freedom that somewhere in the resulting vast solution space would be an answer, was enough to make me realise that no one had anything useful to say. Seems like it’s pretty much the same situation, no change.

I do disagree with your comment that 30 years of cosmology research hasn’t shown what’s beyond SM – on the contrary, the only actual experimental evidence we have at all beyond SM is from cosmology as far as I can tell.

15. **Shantanu**
January 15, 2013

Jack, I completely disagree with you that
“the only actual experimental evidence we have at all beyond SM is from cosmology as far as I can tell”, even though that seems to be the current folklore.
from astronomical observations alone. there is not one shred of evidence that cold dark

matter has anything do with WIMPs, SUSY or beyond standard model particle physics
or even with standard model of particle physics.
(the only argument given is WIMP miracle which has been overblown and IMO it is as likely or unlikely as Titus' Bode's law)
Regarding dark energy, it may well be consequence of us living in an inhomogenous universe or a breakdown of classical GR.

The only other evidence you may be considering is inflation. In 80's people were optimistic
that inflation is connected with GUTs and the like. However GUT based models of inflation are ruled out

16. **physicsphile**
January 15, 2013

Shantanu,

From cosmology we get that only about 5% of the Universe is baryonic. That means new physics or "beyond standard model" physics is needed to explain what the other 95% is. Admittedly it could be modified general relativity but as far as I understand, people usually mean the "standard model" to include general relativity.

17. **Peter Woit**
January 15, 2013

physicsphile,

Dark matter is the most promising possibility for a connection between observational cosmology and the SM, and a huge amount of effort for many years has gone into exploring this. The bottom line though is that this has yet to lead to anything. Even if dark matter is due to some new particle not in the SM (an axion, a WIMP, something else), the constraints that cosmology provides on the properties of this particle aren't enough to either allow definitive experimental tests, or such that they point to a convincing extension of the SM. The SUSY WIMP scenario is the most developed of such things, but it doesn't seem to be working out.

18. **Jack**
January 15, 2013

The SM plus GR does not explain the observed properties of the universe (galactic rotational discrepancy, etc). They do explain every single experiment we have ever done on earth and near space (i.e. to the solar system edge).

Internal inconsistencies (renormalisation, etc) and ugliness and lack of integration between SM+GR is NOT a valid experimental reason for SM+GR to need modification – the universe's laws could be ugly and inconsistent. The only actual experimental evidence we can detect that is not explained by SM+GR is that obtained by observations of the universe beyond our solar system. Sadly.

19. **Peter Woit**
January 15, 2013

I think that's enough about cosmology, which is pretty much off-topic.

20. **Shantanu**
January 15, 2013

physicsphile, DM could very well be a primordial black hole (which is perfectly consistent with all data), in which case its nothing to do with particle physics, and
is consistent with GR. Also it could be an artifact of backreaction (see 0809.1183)
or some similar misunderstood physics.
But anyhow the main strawman I wanted to destroy which you will hear in almost every
conference is that dark matter is evidence for Weak scale SUSY or any beyond SM
theory which predicts a stable massive particle with electroweak interactions.
There is no evidence for astronomical observations that the cold dark matter is WIMP

21. **SpearMarktheSecond**
January 15, 2013

It took many years for neutrino mixing/mass to be experimentally proven beyond all doubt… until the early 1990's and SAGE, the evidence was thought to be as poor as that right now for WIMP dark matter (from DAMA/LIBRA, Cogent, ATIC, etc).

Not that the WIMP evidence is convincing or right, but the point is: if you give up doing experiments, you are guaranteed to discover nothing interesting. The neutrino guys never gave up. And the dark matter searchers must never give up either.

The current ratio of dark to luminous matter is evidence that the dark matter has weak interactions with luminous matter. It is not an airtight case, but it is interesting enough to pursue experimentally.

BTW, the LHC has really interesting and constraining results on light WIMPs, via missing energy. No signal, but very interesting constraints.

22. **Yatima**
January 15, 2013

> the universe's laws could be ugly and inconsistent.

They may be ugly but we better hope they are consistent. Actually being able to get 1 = 2 (even if you have to jump through a few hoops for this) is very bad, economic mainstream-level bad.

23. **Geoff**
January 15, 2013

Sorry if my cosmology comment derailed the conversation. Part of what I had in mind was that if large classes of models predict a negative value for a cosmological constant in stark contrast to the observed value at least cosmology provides a sanity check unavailable elsewhere (and this has been within the past 15 years as opposed to 30).

If somehow we could travel back in time to 1961 and try and get unstuck, I'm not entirely sure anyone would consider it obvious to ask a guy working for the phone company. New ideas on how to move forward seem to come from unexpected places utilizing unexpected analogies.

24. **Pol**
January 15, 2013

How is the hep-th job market doing? Looks like pheno modelers are doing fine..

25. **gstoessl**
January 16, 2013

Are sterile neutrinos as dark matter candidates already ruled out ?
The most extreme scenario could then be: SM + 4th neutrino + GR and
nothing else.

26. **Shantanu**
January 16, 2013

gstoessl ,
For most generic parameters, sterile neutrino satisfies what astrophysicists call
“warm dark matter” (WDM). From fits to cosmological data, WDM constitutes a very small fraction of the matter/density budget.
Having said that, since we have not detected a sterile neutrino or know its mass etc, its entirely possible to cook up sterile neutrinos with non-standard properties so that they could be CDM candidate in which case you are right.
Again astrophysical observations are completely agnostic to nature of CDM.

27. **David Nataf**
January 16, 2013

Astrophysics and Cosmology have taught us that:

– There is dark energy, and it has a specific density. We will soon find out how it evolves with redshift.
– There is dark matter, and its properties are actually quite well constrained, i.e. it cannot be a light particle, hence “WIMPs”, where “M” stands for “Massive”.
– Neutrinos have masses. That comes from observations of the sun and the original SM had massless neutrinos. Actually, I think it was cosmology originally that taught that there were at most 7 neutrino species, which was a surprise at the time.
– The GZK effect is true, a probe of particle physics at 10^20 eV.

In the near-future we’ll have more constraints on dark matter, we’ll know to what extent dark energy evolves and what its equation of state parameter is, more work will be done on the lithium problem, there will be more evidence for (or against) inflation, we’ll directly measure gravitational waves in the labs, we’re approaching tests of gravity at high curvature scales, etc. Currently, cosmological constraints suggest a “4th” neutrino species at 2-sigma significance, and we’ll know more about that soon as well.

Some of you need to pay more attention.

28. **srp**
January 16, 2013

Call me crazy, but as an outsider who can only follow things dimly, it seems to me that stuff like

http://www.annualreviews.org/doi/abs/10.1146/annurev-nucl-102711-094949

makes a pretty strong case that the SM is not at all worked out yet and that there are some huge, important unsolved problems in understanding existing accelerator data. There are even hints that multiple anomalies are pointing to some common basic conceptual shifts.

I guess one could say that all this stuff is still not “beyond” the SM, but so what? There are 400% anomalies against current understanding and they get bigger (instead of the expected smaller) with collision energy. Or one could say that these are just problems in calculating the predictions of the theory rather than with the theory itself, but a) how do you know? and b) if so, isn’t doing those calculations a primary job for theorists?

Perhaps there are some anthropological factors that would explain what is or is not considered a big deal to worry about in physics. But even in a “softer” field like finance, where predictions are by their nature much less precise, if it is thought that x is supposed to equal y but empirically x = 4y, where x and y are basic observables, people tend to get exercised about it.

29. **Yatima**
January 17, 2013

The above paper is obtained at lower rates than post-bailout rent-seeking ones at the DOE:

Puzzles in Hadronic Physics and Novel Quantum Chromodynamics Phenomenology

30. **fuzzy**
January 17, 2013

Hi Peter,

I believe that in the last 20-30 years, we had a lot of speculations in theoretical high energy physics, but not many frank, critical discussions.

Surely, a big part of our society wants to hear from the physicists bombastic ideas, amazing scenarios, in a words, they should run the show; and, by contrast, we have much less requests of exercising critical sense.

However, it is important to recall that all of us, scientists included, are called to decide whether we want “to exchange a walk on part in the war for a lead role in a cage”. This is what should primarily worry us, in my view.

The same view is expressed in http://arXiv.org/pdf/1206.1466.pdf in somewhat more formal terms.

31. **Peter Erwin**
January 17, 2013

I’ll confess to being a bit nonplussed by the final paragraph of your Edge contribution, where you seem to think that the current problems of particle physics are somehow going to infect the rest of science. ("Will intellectual progress become just a memory, with an important aspect of human civilization increasingly characterized by an unfamiliar and disturbing stasis?") I can see no evidence for this in any other field of science.

32. **D.G. Perkin**
January 17, 2013

Yatima: Thanks for the link. This seems a useful reminder that there are still problems in HEP, even though it does not tackle the electroweak radiative corrections which (IMHO) seem more serious, unless I've missed some work published recently.

SRP and others: the Standard Model is still quite healthy, despite points referred to above. Like the Copenhagen Interpretation of Quantum Mechanics, it keeps taking the flack from its detractors and continues to generate results in accordance with experiment.

Regards,

D.G. Perkin.

33. **Peter Woit**
January 17, 2013

Peter Erwin,

Well, it's a "worry" about what might happen that was being asked for, not an already serious problem…

As Lisa Randall notes, within particle physics "everyone is worried". Whether this infects other fields depends a lot on how particle physicists deal with the problem. One particular form of the worry is whether pseudo-science (e.g. the string theory anthropic landscape) will become the dominant paradigm in the historically important field of fundamental physical theory. If this happens and fundamental physics changes from an ongoing successful example of how humans can understand reality to a dismal example of what is wrong with human behavior, there may be larger implications.

Perhaps I should be more optimistic and not worry. we'll see.

34. **Peter Shor**
January 17, 2013

My hope is that Alain Connes is actually onto something with his connection of non-commutative geometry to the Standard Model. However, physicists seem universally either to ignore this or to dismiss it.

35. **cormac**
January 17, 2013

Speaking from the perspective of someone who teaches an introductory course in the history of particle physics, I think there is more to the disappointment at lack of evidence for SUSY than arrogance or irritation that our theories don't match reality (so far).
The idea of super gauge symmetry provided a way around the famous no-go theorems of the 1960s; when theoreticians encountered major problems in extending the unification program to include the strong and gravitational interactions, SUSY suggested a possible escape route. So much so that, as I understand it, it is difficult to see how the fundamental forces can ever be described in a unified framework without some version of this fundamental symmetry. So lack of evidence for SUSY is a little worrying as it could imply that some interactions are unified but not others…which seems strange and also at variance with our favourite cosmological pictures. That said, there are many different versions of SUSY and it's early days yet…

36. **emile**
January 17, 2013

David Nataf:

You wrote that Dark Matter cannot be light. That is not correct. Axions for instance could be very light (and address the Stron CP problem).

37. **Tmark48**
January 17, 2013

My my, reading those "apocalyptic" reactions from physicists just makes me think they are nothing but drama queens. HEP is littered with unresolved problems, inside the standard model and outside the SM. If multidimensional theories are out, pick another problem. Isn't that what a theoretical physicist is supposed to do ? Or have we arrived at a situation were overspecialization leads to stagnation ? You study 20 years to have the instruments and skills to tackle one problem, and beyond that ? Nothing ? Now this would be catastrophic.
Me, I'd like to see theoretical physicists get another go at axiomatic quantum field theory or something equivalent like that. A theory that from the get-go negates infinities. A proper physical theory where you don't have to deal with renormalization and other arcane techniques to get rid of things that shouldn't even be in the theory to begin with.
I think designing a finite quantum field theory is a much more interesting proposition than chasing strings, d-branes and other exotic structures with no link whatsoever to down to earth experimental physics.

38. **Low Math, Meekly Interacting**
January 17, 2013

I feel there's some reason to worry over the prospect of loss of "Big Science" in HEP. This branch of physics, to many, represents an ideal few other disciplines can rival, and an exemplar of "pure" research. Can anyone think of a more impractical scientific discovery in the past thirty years which has attracted so much attention as the Higgs boson? I do fear a world in which that discovery may be the end of new discoveries in fundamental physics for a very long time. Without this exemplar, or any obvious path to pursue it, will science as a whole veer more and more toward the "practical"? Will science, as a whole, lose the tradition of curiosity for its own sake needed to sustain it?

39. **A.J.**
January 17, 2013

A proper physical theory where you don't have to deal with renormalization and other arcane techniques to get rid of things that shouldn't even be in the theory to begin with.

This is one of those scurrilous rumors that just won't die. The modern formulation of quantum field theory — the one Wilson et al got off the ground in the 70s — is free of unphysical infinities. The textbook presentations, unfortunately, are littered with them.

40. **Peter Woit**
January 17, 2013

Please, no more about renormalization. It's off topic, and blog comments here about it are not unlikely to enlighten anyone about anything.

41. **ker**
January 17, 2013

Peter,

For all your criticism of string theory, you are clearly a product of the 70s and 80s culture in which somehow particle theory was the 'fundamental' area of physics and the intellectual backbone/heavyweight of the field. As someone who has spent equal time on your side of the fence and on the other side in condensed matter, soft matter etc in the last 10 years, I can tell you that the culture of particle theory today is to first order irrelevant to the rest of physics and science.

It is a very isolated narrow field with little intellectual heft today even within physics departments. Other physicists work on as many interesting novel ideas & systems in a year as string theorists work on in a decade – and these physicists know it.

The days of Gell-mann & hep-th towering over physics and science culturally are long dead.. I am sure Peter knows this in his head but his worry about the culture of hep-th affecting the rest of science shows some remnants of Peter's upbringing. Trust me, other scientists don't give a damn..

42. **Peter Woit**
January 18, 2013

Thanks ker,

I think you're right, as far as some physics departments go, and someday even the IAS may hire a non-particle theorist (although the time-frame of particle physics dominance goes back to the 50s and 60s, before my time, and it's not as weak now as you claim).

Non-physicists though often encounter physics through curiosity about "what is the world made of?", "what are these fundamental physical laws that govern this?", as well as through taking courses where they learn the standard historical narrative. From this point of view, particle physics and cosmology are likely to always seem like central topics (and to always get a lot of press), so degeneration of research in these areas is going to look to outsiders like degeneration at a core location of modern science.

43. **MathPhys**
January 18, 2013

Some of us find exact solutions in statistical mechanics and quantum field theory deeper and more fundamental than theoretical high energy physics as it currently stands. A typical talk on current high energy theory sounds as theoretically ad hoc as a talk on civil engineering.

The best parts of modern string theory (topological strings and AdS/CFT) and Yang-Mills theories (non-perturbative dualities and exact solutions) are essentially new applications and extensions of ideas from the theory of integrable models.

44. **David Nataf**
January 18, 2013

Emile,

I'm pretty sure axions are not consistent with growth of structure and galaxy rotation curves.

Light particles don;t gravitationally settle into halos, they travel at relativistic speeds and are spread evenly across the universe.

However, there could still be axions, and they could in principle be inferred astrophysically, for example as a cooling mechanism for white dwarfes.

45. **P**
January 18, 2013

@chris: the worry isn't that our theories aren't working. The worry is that if new physics doesn't show up at this scale the governments won't fund expensive new experiments to probe beyond the standard model. I'm also a high energy physicist, and many particle physicists I know, even ones who don't like string theory, are very concerned about this possibility.

If nature tells us something else is responsible for stabilizing the hierarchy than the theories we've come up so far – great! Nature is telling us something. But the concern is that we won't learn anything really new at the LHC and funding for high energy experiment will screech to a halt.

@ker:

Physicists of your type have many physical systems to study, and there are many more of you than there are string theorists (it's not even close), so it's not surprising that you come across more physical systems. High energy physicists are, by definition, interested in one physical system, though they may apply their "novel ideas" (in the sense of abstract theoretical ides) to many physical systems.

Which bring me to my main point, to correct somewhere where you're off. Your statement about novel ideas is absurd, assuming by that you mean some more abstract ideas that may or may not be immediately applicable to already-known-to-exist real world physical systems. Regardless of the eventual fate of string theory's ability to describe the one *system* high energy physicists are (by definition) interested in,
nearly all abstract conceptual breakthroughs in the last thirty years in gravity, quantum field theory, or string theory have been *made by string theorists* or people who at one point called themselves string theorists. In this sense, nearly all of the "intellectual heft" to use your phrase is coming out of theoretical high energy physics.

In my experience at top 20 U.S. institutions in physics, between giving seminars at many of them and researching as a member of a number of them, the reason "particle theory today is to first order irrelevant to the rest of physics and science" is because the average condensed matter theorists lacks the theoretical backbone to understand what we are talking about. The very best do, absolutely, I agree with you, but it's just downright offensive and incorrect to make your claim in the way you have.

46. **Peter Woit**
January 18, 2013

P,

One of the big reasons that many physics departments are now treating particle theory as irrelevant is the incredibly arrogant behavior and attitude of theorists like yourself. Instead of showing some humility and admitting that things have not gone well in recent years, too many string theorists think that it's a good idea to go on about how brilliant they are, how wonderful their "conceptual breakthroughs" are, and how the problem is just that non-string theorists are ignorant and stupid (i.e. lack "theoretical backbone to understand what we are talking about"). If you want to know why virtually no string theorists are getting jobs in the US, this has a lot to do with it.

47. **P**
January 18, 2013

Peter,

Apologies for the tone of the previous post, I am a confident competent theorist, not an arrogant one. Sometimes this comes out the wrong way when I find someone's arguments silly, incorrect and damaging, or offensive.

High energy physicists acknowledge some difficulties faced in using one of their theories (strings) to uniquely address issues in TeV scale physics. You and I have discussed this many times.

However, hiring in physics departments should be based on quality of work and scientific though, either conceptual and abstract or applying known ideas to a new system (or ideally new ideas to a new system). You yourself made the argument that it is made based on hurt feelings and perceived arrogance, and unfortunately this is sometimes true. High energy physicists readily acknowledge when real conceptual breakthroughs come from people in other fields (e.g. Kitaev, Wen (though formerly a string theorist), C. Kane, others, etc.), but when high energy physicists stress their many conceptual breakthroughs in the last 30 years, we are calling a spade a spade, not being arrogant. This is scientific endeavor; we should be honest about progress and it is a shame when good ideas and confidence in them are perceived as arrogance, particularly when this affects hiring decisions. Hiring of scientists should be based primarily on the quality of their ideas, not their sometimes bad attitudes.

48. **Peter Woit**
January 18, 2013

P,

Arrogance by itself isn't the issue, if physics departments didn't hire anyone arrogant, they'd be a lot smaller. What is the issue is that people don't want colleagues who are both arrogant and delusional, convinced that their work is highly successful and important (when it isn't), and that everyone around them is just too dumb to see this.

49. **Shantanu**
January 18, 2013

David you are wrong. axions are perfectly consistent with a vanilla CDM.
axion is a non-thermal relic so its perfectly fine. note that something as heavy as a WIMPzilla (worked on by Rocky Kolb et al) could also be a vanilla CDM.
again astrophysical observations alone provide no guidance for the mass or the interaction
cross-sections.

50. **chris**
January 18, 2013

P,

"The worry is that if new physics doesn't show up at this scale the governments won't fund expensive new experiments to probe beyond the standard model."

and they are right. i myself do not see the need of a multi-billion-$ collider to extend our energy range by a factor of 5 when there is no compelling argument that new physics should show up there.

in such a situation the money is probably better spent elsewhere. where? well, i currently don't know, but people will have ideas i am sure.

what i perceive as the real problem here is the same problem that infests us at the individual level: the success-metric driven system that science is slowly turning into makes many of us think that the ultimate goal of science is to divert ever increasing streams of external funding into our direction. this is just plain wrong.

if we have learned all that we can reasonably hope to learn through current accelerator technique, then let's be happy that we learned it and turn to something else. and if a thousand people have invested 3 decades of their lifes into this particular topic that turns out to be a dead end then it is a dead end still. no amount of money will ever convince nature to change its laws so as to make them accessible to us.

now please don't get me wrong – i am not arguing against a next collider. i actually think that a linear collider "Higgs factory" would be well worth building at least. but i seriously dislike the gut reaction of many physicists that lament the decreased chances of future funding now that the SM is confirmed as if it was the ultimate goal of physics to finesse out as much tax money as possible.

51. **Peter Woit**
January 18, 2013

chris,

I think a crucial question is the magnitude of the cost of going to higher energy. Can this be done within the current size of the CERN budget? For instance the idea of a higher energy LHC (HE-LHC) in the same tunnel might be one that could be funded without significantly increasing the CERN budget (to be clear, I don't know if this is true), especially since it takes a long time to build these things, spreading the cost out over many years.

Without some specific important new target to justify a higher energy machine, I think it's going to be very hard to make the case for lots more money for such a thing (except maybe for the Japanese, who may have good financial reasons to print a lot more money…). On the other hand, once the LHC has done what it can, do you just start shutting down large parts of CERN and firing most of the staff there, or do you pursue a viable way to investigate higher energies, even given a large probability you're not going to find something exciting?

52. **Thomas Larsson**
January 18, 2013

That a science comes to a halt when it reaches its boundaries is neither strange nor unprecedented. The obvious example is of course geography. Few modern geographers strive to become a new Columbus or James Cook, and those who do are hardly taken seriously.

In fact, we are now seeing a prediction of John Horgan pan out. After the end of science, scientists will do boring things, but they will never admit that it is boring.

53. **Tmark48**
January 18, 2013

> Thomas Larsson said : "In fact, we are now seeing a prediction of John Horgan pan out. After the end of science, scientists will do boring things, but they will never admit that it is boring."

–
Didn't historians witness the end of history when the Soviet Union collapsed and the old world order went into pieces ? Seriously, I don't think that confirming the SM will be the end of science. It will make HEP less relevant but scientific research will go on. Investing in other branches of physics. It's a natural cycle I think, scary for some but necessary.

54. **Bernhard**
January 18, 2013

What we need in HEP is a real breakthrough in experimental technology to search for new physics. If accelerators become impractical we have to find a cheaper way to do TeV collisions. The only thing we had guaranteed with the LHC was the Higgs or something else, we should not be too surprised or upset about "just" finding the Higgs. I think experimentalists need to be "blamed" as well for the lack of imagination. The LHC was a brilliant project and a formidable experimental achievement but I hardly see people discussing the problem of how could we invest in promoting solutions to NOT need accelerators (at least huge ones) in the first place. This kind of breakthrough might be decades or a century in the future but might be also closer than we think. But while theorists have been trying all possible things (including some things that can hardly be called science, but anyway), experiments follow the same basic logic of Lawrence, just got a lot bigger (OK, shoot me me for the oversimplification here if you want). We need fresh new ideas on how to do this differently, and we should seriously start promoting this as a challenge for the most brilliant young experimentalists.

55. **srp**
January 18, 2013

Did you notice the "move along, nothing to see here" non-response by DC Perkin? The linked paper had mainstream particle physicists showing that the hadron part of the SM is definitely NOT "passing all the tests." It is systematically failing them in interesting, not-close-to-the-observational-noise ways at accessible experimental energies. Or maybe the theory "properly understood" would pass them, but the theory is now wrongly understood, in the sense of physicists having an incorrect picture of how its assumptions relate to observable phenomena, which would also seem to be a pretty important problem for high-energy theorists to work on.

I understand that QCD is a difficult jungle through which to hack, but isn't that a made-to-order challenge for HEP?

56. **StrangeRep**
January 18, 2013

Hi Peter,

Thanks to your blog article I started reading some of the other non-physics Edge contributions. Did you read the one by John Tooby? I.e.,

"Unfriendly Physics, Monsters From The Id, And Self-Organizing Collective
Delusions".

This line near the end:

"we need to design our next generation scientific institutions to be more
resistant to self-organizing collective delusions, "

seems appropriate, :-), though I have no idea how to do it. 🙁

57. **Miguel**
January 21, 2013

> Amanda Gefter sees no reason to worry. Particle theorists will just move to making progress without experiment, through studying paradoxes of the current theory, with her final example for optimism the recent debate over the "firewall paradox".

Please, no. Theory was "ahead of experiment" for about 40 years (since 1973) and look what that brought us. While theory was though to be ahead it was actually off on a tangent. And then another tangent. And another….

58. **Miguel**
January 21, 2013

P:

> However, hiring in physics departments should be based on quality of work and scientific though, either conceptual and abstract or applying known ideas to a new system (or ideally new ideas to a new system).

Hiring and research funding is now largely based on bean counters weighing the number of citations by impact factors. That is the real reason why Peter Woit is right to worry about progress in science slowing down. Maybe this is only apparent as the signal to noise ratio goes down as the amount of drivel published to pad CVs grows, and the rate of actual advancement of science somewhere remains steady or growing…

59. **P**
January 22, 2013

Hi Miguel,

No one is going to argue with you on this point. CV padding is not science.

Regarding your notion of tangent, this isn't the right viewpoint. It seems your definition of tangent applies to any abstract concept that isn't directly applied to an experimentally observed system, because that is what a lot of the last 40 years has been, since the standard model works so well. It seems like to you essentially any progress in formal theory is a tangent.

And there is really no arguing with string theory when it comes to progress in formal theory. Yes – you can argue that it's not good for phenomenology, though as an expert I can say nearly every argument I've seen on this blog is either wrong on some important points or missing important developments from the last ten years. But formal theory – particle physics aside – it has led us to see deep explanations of dualities in field theory, the AdS/CFT correspondence, mirror symmetry, deep properties of scattering amplitudes that Nima argues in a recent paper may apply to N=1 and N=0 theories, etc etc etc. There are many more. These are not tangents or "delusions", to use Peter's phrase.

But more importantly, coming back to the point of this article: we should be very concerned about Higgs + nothing. Not because "it's not what we wanted" scientifically – we must be fine with whatever effective theory nature hands us – but because it could signal the end of the reductionism approach to experimental particle physics (if new colliders aren't built). And this would be very sad for humanity, I think.

For the record, I am very happy that some of the best universities are hiring pure particle theorists the last few years. This is the time to do it, if there ever was one, and there are many excellent new papers on hep-ph. Over the next five to ten years there will be a swing back in the other direction, however. These things are cyclical.

Cheers,
P

CERN Briefing Book

January 18, 2013
Categories: Experimental HEP News

This year the US and European HEP communities are engaging in exercises designed to put together plans for the future. In the US it's Snowmass 2013, leading up to a big meeting in Minneapolis this summer. This past week has seen preliminary meetings at Irvine to discuss future prospects for experimental study of SUSY and other BSM ideas, and at Princeton for discussion of future prospects for study of the Higgs.

Over in Europe, there is a plan to update the 2006 European strategy for particle physics, This will officially take place in May/June, based on a document to be finalized by the CERN Council in March. Next week in Erice there will be a meeting to draft this document. To prepare for this, there was an open symposium last September, leading to the preparation of a briefing book, now available here.

The briefing book is a very interesting 220 page document covering in up-to-date detail the current experimental situation and future prospects, for all areas of HEP. One big issue is the Higgs: now that its mass is known, what can be learned about it using some new machine (a "Higgs factory") beyond what can be learned from the LHC? As far as prospects for a new, higher energy machine, the document describes the possibilities, but no decision about such a thing is likely to be made until after results become available from seeing the LHC run at 13 TeV starting in 2015.

Comments

1. **Markk**
   January 18, 2013

   I have a question about the goals. Are these more technology plans or experimental plans? It seems like until results at higher energies are analysed, the scientific direction may not be known, but we could be looking at what technologies would be needed in different cases.

   For example I have read about these linear burst (for lack of a better term) accelerators that somehow get energy injected in a short time. Is that a possibility? Is just a bigger type of current system the only bet? It seems to me like we may be in a period where research into enabling experimental technology is more important to look at.

2. **Peter Woit**
   January 18, 2013

   Markk,

   The technological issues are a huge part of the discussion, they're what determine what the possibilities are. One chapter of the briefing book devoted specifically to accelerator technology, and the question of which areas of such R and D to fund is a big one being considered.

3. **Brendan**
   January 18, 2013

   Booklet also seems to be taking a stand on credit that is not aligned with the previous 50 years of particle physics theory and history…p. 151 Chapter 7, Particle Physics Theory

   The theoretical foundations for such a discovery were first laid down, almost fifty years ago, by three theorists working in Europe: Englert, Brout and Higgs.

   Not sure who wrote the chapter (for sure European) but leaving out GHK is interesting and political – certainly contrary to history and American Physical Society.

4. **Friend**
   January 18, 2013

   I'm curious to know if there is any plan to accelerate the particles with lasers, or perhaps they already do. Thanks.

5. **Peter Woit**
   January 18, 2013

   Friend,

   See pages 169-170 of the briefing book:

   "This technology is not yet ready for a proposal for a high energy accelerator."

6. **srp**
   January 20, 2013

   The briefing book is an interesting window into how the world looks to the experimental particle physicist. The public is usually exposed only to views of the world presented by theorists. The differences are telling.

   For example, in the hadron physics section there's a lot of discussion of how much empirical work continues to be needed to fill in the picture of how the proton works. Lots of collisions to measure one-dimensional parton distributions are prescribed, and on the cutting edge it's suggested that it might be cool to find out how everything fits together in two or three dimensions. OK, then, but could we stop hearing about how the existing theory is so darn perfect that we have nothing to work on?

   I don't think that the average citizen who reads popular science articles realizes that the existing theories, models, and data are insufficient to explain or predict the quantitative properties of the proton and its structure. The CERN briefing even has a throwaway paragraph about how the spin of the proton isn't close to being derivable from measured spin components of the quarks and gluons. Oh. Shouldn't we be a little bit curious about that?

   Here's a safety tip for physicists who want public money for continued experimental HEP research: Don't shoot yourselves in the foot by exaggerating the level of understanding already achieved by theory. And don't kid yourself that the public will be more enthralled by far-out speculative stuff than by near-to-hand puzzles about things they've heard of and think they partly understand. "There are big gaps in our understanding of how the proton is constituted" might actually be an easier sell than "We think there are a bunch of new particles we can make at higher energy that would cancel out some of the nasty parts of our equations for the particles we can already see." Of course, people in physics would actually have to care intensely about how the proton works to say it with a straight face, and unfortunately I'm not as sure as I used to be that that is the case.

7. **Peter Woit**
   January 20, 2013

   OK srp, that's now the third comment insisting on the importance of studying poorly understood aspects of QCD. You've made your point, enough.

The Anatomy of a Scientific Gossip

January 23, 2013
Categories: Uncategorized

The University of Birmingham has put out a press release today about new research by their computer scientists, on the topic of the spread of gossip about the Higgs via Twitter. This is all based on an arXiv paper, The Anatomy of a Scientific Gossip, and has been picked up by New Scientist, Phys.org, and Aidan Randle-Conde.

Since I've been designated as one of the Best Physics Gossips on this topic:

> If the Higgs boson was a dead celebrity, Woit would be your TMZ — first to the scene, first to break it, and have it be right.

I think I should perhaps comment on what this research actually shows. From what I can tell, it just provides evidence that Twitter is a worthless swamp full of people who have no idea what they are doing "re-tweeting" stale information to each other. Getting their information from tweets, according to these researchers things began with

> **Period I:** Before the announcement on 2nd July, there were some rumors about the discovery of a Higgs-like boson at Tevatron;

and went on from there. They start looking at the data only from July 1 on.

Looking back at what actually happened, I started posting about the coming LHC results on June 17 (the Tevatron results were a side-show). On June 18th, Matt Strassler had the story, accusing me of ruining the CMS and ATLAS blind analyses, for top-secret reasons that could not be revealed. June 19th saw a New York Times story about this with a link to my blog entry and by June 20th Sean Carroll and Jennifer Ouellette were writing about #HiggsRumors being a "Trending Topic" on Twitter.

I suppose it's true that a couple weeks later there were about a million tweets about this, but why would you conceivably want to look at any of them? While I was writing this blog posting, an incoming e-mail from Twitter popped up on my screen.

> **We've missed you on Twitter!**
>
> So much is happening right now on Twitter, and building a great timeline is the way to really enjoy the service. Get to Twitter and start building a timeline that reflects you and your interests, you'll see how quickly Twitter becomes an invaluable part of your life.

I don't think so…

Update: At his blog, Matt explains that he wasn't accusing me of anything. It was CMS and ATLAS physicists who, by telling me me about the results after unblinding, were guilty of ruining the blinded analyses for still top-secret reasons.

Comments

1. **Stephen Brooks**
   January 23, 2013

   The tweets aren't the content, they're usually links to the content. I see Twitter like a personalised newswire: you follow people and sources that tend to flag up the interesting news. You'd not want to read 100 Higgs tweets, you'd follow the link to the CERN webcast, article or blog that just came out.

2. **twit**
   January 23, 2013

   You could nominate it for an IgNobel prize in the category of "Useless Research Spawned by the Higgs Boson".

3. **Chris Oakley**
   January 23, 2013

   Twitter is for twits, by definition.

4. **srp**
   January 23, 2013

   The unkind might equate Twitter to the U.S. CB radio phenomenon of the 1970s, only with hipsters instead of truckers getting the ball rolling.

5. **P**
   January 23, 2013

   Peter,

   "first to the scene, first to break it, and have it be right."

   In my experience, this was definitely true. The experimenters (Jester, Dorigo, etc) tended to be more tight-lipped, and I have always reading your blog on the hep-ex news. Keep up the rumor posting, as they come along!

   P

6. **Peter Woit**
   January 23, 2013

   Thanks P,

   Actually, Jester is a theorist, not an experimentalist, and an excellent source of reliable gossip about the Higgs and other experimental news. I may have done a bit better than him on the Higgs, but he's got far better sources and much better knowledge of what is going on in CMB and dark matter-related news (see his recent postings).

7. **Xezlec**
   January 24, 2013

A worthless swamp if you consider informing the public worthless. The fact that that "stale" information was new enough to them that they felt compelled to repeat it shows that those tweets were useful to them. Twitter works just like word-of-mouth, except without as much distortion at every stage, so you may as well say that talking to people in person is worthless.

8. **David Nataf**
   January 24, 2013

   Xezlec,

   Have you ever used more than 140 characters when talking to people in person?

9. **twitter**
   January 24, 2013

   Twitter has done nothing to help human kind. The brilliant people working there could have been doing something useful instead. It is a shame.

10. **Robert Rehbock**
    January 24, 2013

    The capacity for anyone to publish and republish anything true or falseby essentially anonymous means can be both a blessing and a curse.
    I do not agree though with Strassler in either his original post or the subsequent exchanges. Unlike exposure of means of calculation or the setup of the experiment that could influence others behaviors, the data cannot be changed once the group gathered it. All that can by the other group be learned is that their results did or not agree with completed observations and work.
    as tosecrets – a secret is something known to one person. something known to two or more can be at best confidential. One may have little confidence that anything known by many can be kept off the Internet.

11. **tulpoeid**
    January 27, 2013

    I personally think another phenomenon is a lot more noteworthy and maybe research-worthy, from a social perspective; the fact that ~15k people all over the world knew about something that was red-hot press material, nobody was making them keep their mouths shut, but they nevertheless went on to do so for months only out of respect for their own and their colleagues' work.
    Is this fact ever going to be properly acknowledged?

Short Book Reviews

January 24, 2013
Categories: Book Reviews

There's now a fairly long list of books that I've found worthwhile recently and wanted to write about here, making it unlikely I'll have time to write in detail about them. Instead, here are some short reviews:

- More than seven years ago I wrote very critically here about Leonard Susskind's The Cosmic Landscape. That book struck me as embodying the worst aspects of where string theory has ended up, promoting to the public in a high-profile way a dangerously pseudo-scientific excuse for string theory's failure. Debate about the anthropic landscape has now been going on for nearly a decade, with mixed results. This ideology still has its believers and gets taken seriously, but I think it's fair to say that interest has dwindled as it has become clear that no one has a serious idea about how to use it to make any kind of scientific prediction. For both proponents and opponents, it's now old news, hard to get interested in talking about, especially since the lack of any evidence (pro or con, now or forever) seems guaranteed.

  Luckily for all of us, Susskind has moved on to much more promising topics. He has a new popular book out which is quite good, entitled The Theoretical Minimum. It's basically a textbook on classical mechanics, written at a level appropriate for someone who has had a calculus class, but not necessarily any more physics or mathematics than that. The style is breezy and colloquial, with lots of nice explanations of some of the basic concepts of physics. It's wonderful to see Poisson brackets appearing and nicely explained in a popular book destined to be displayed at bookstores everywhere.

  The book is based on one of several series of lectures given by Susskind as part of Stanford University's Continuing Studies program, all of which are available on video at YouTube (see here for a list). The writing of the book is a joint effort of Susskind and George Hrabovsky, who started the project of turning Susskind's lectures into book form.

- While selling popular books with equations in them is a new concept in the US, it's not so unusual in France. When last in Paris I picked up a copy in a non-scientific bookstore of Cédric Villani's Théorème Vivant, which includes equations I can't even follow. It's basically a fascinating journal he kept during 2008-2011, focused on a problem he was working on during this period with his collaborator Clément Mouhot. It provides a good picture of what it's like to be a top-class analyst working on a difficult problem. During this period, Villani was very much aware that he might be a candidate for a Fields Medal, which provided some motivation for him to push forward. If you want to know what it's like to really want a Fields Medal, to work hard to get it and succeed, this is the book for you.

  A large part of this work took place during a year when Villani was holed up at the Institute in Princeton, and this is described in detail. Difficult working conditions included lack of access to good bread or cheese, a major reason Villani turned down efforts by Princeton to keep him there and returned to France, where he is now Director of the Institut Henri Poincaré in Paris. He also maintains a blog here where you can keep up with his activities.

- Steven Weinberg's Lectures on Quantum Mechanics is based on graduate-level quantum mechanics courses he has taught over the years. It covers concisely and well most of the standard topics that are make up a quantum mechanics course at this level (this is definitely not a beginning QM book). It does differ from most QM books though in providing a high-level and serious discussion of the question of interpretations of quantum mechanics, a topic about which Weinberg has thought deeply. After explaining carefully the issues, he ends up with:

  > My own conclusion (not universally shared) is that today there is no interpretation of quantum mechanics that does not have serious flaws, and that we ought to take seriously the possibility of finding some more satisfactory other theory, to which quantum mechanics is merely a good approximation

  I fear I'm with those who don't share this conclusion, but his arguments are well-worth paying attention to. For someone else who has thought deeply about all this, and come to conclusions closer to my own less well-considered ones, see this recent blog entry by John Preskill (don't miss the discussion in the comments).

  The book ends with a modern but very short chapter on entanglement, Bell inequalities and quantum computation.

- I've recently gotten a copy of a wonderful new quantum field theory textbook, Anthony Duncan's The Conceptual Framework of Quantum Field Theory. It's a long, fat book, packed with material that doesn't appear in other QFT books. Most modern QFT books stay focused on the goal of writing down the Standard Model and giving the details of how to do perturbative calculations in the theory. Duncan instead devotes most of the book to a careful investigation of the basic issues raised when one works with a theory of quantized fields and tries to understand exactly how such objects are connected to the particle states and their scattering that we see in the real world.

  Besides the close attention to thorny conceptual problems normally glossed over, Duncan also gives a long discussion of the early history of the subject, a time in which the conceptual problems were being thought about by the leading figures in the field. Probably every one who has learned quantum field theory in one way or another could benefit by going through this book and picking up some insight into all the questions that were ignored in whatever other book they learned the subject from.

- Finally, for those already fluent in quantum mechanics and quantum field theory, there is Mikhail Shifman's Advanced Topics in Quantum Field Theory, published last year. It concentrates on methods for understanding the non-perturbative behavior of QFTs, especially gauge theories. A major topic is semi-classical methods and the art of extracting non-perturbative information about the QFT from interesting solutions to the classical equations of motions (e.g. instantons and solitons). The latter part of the book focuses on supersymmetric theories, where supersymmetry can be used to get further insight into the non-perturbative behavior. In recent years, much of the research interest in SUSY has moved away from the idea of using it for Beyond Standard Model physics (a trend likely to accelerate with the failure of SUSY to show up at the LHC), and towards thinking of it as a tool for studying QFTs. Shifman's book gives a good introduction to the basic examples of how this works.

Update: Lev Okun sent me a copy of his ABC of Physics: A very brief guide. It's a remarkable document, managing to cover all of fundamental physics in about 120 pages, from the simplest topics in high school physics to the Higgs and superstring theory (the latter treated with appropriate skepticism). If you want an overview of the subject that is as short as possible, this is for you.

Comments

1. **Bernhard**
   January 24, 2013

   "we ought to take seriously the possibility of finding some more satisfactory other theory, to which quantum mechanics is merely a good approximation"

   Interesting to see this coming from Weinberg. It seems to contradict a younger Weinberg who wrote "Dreams of a Final Theory". I remember one of the points he made in that book was that QM was here to stay, and not an approximation of anything more fundamental. Apparently, he changed his mind.

2. **lev**
   January 25, 2013

   The place of the higgs particle in the framework of the Standard Model of Elementary Particles is described in the book "ABC of Physics: A Very Brief Guide" by Lev

Okun.
See Amazon.com for Editorial Reviews by Michael E. Peskin (SLAC National Accelerator Laboratory) and Robert P. Crease (Stony Brook University, Physics World) and Customer Review by traveller2. The book was published by World Scientific on March 27 2012

3. **Douglas Natelson**
   January 25, 2013

   Thanks for these reviews – you're providing a real service (though my damn reading list never seems to shrink).

4. **Shantanu**
   January 25, 2013

   Peter , any comments from the higgs workshop at Edinburgh?

5. **Peter Woit**
   January 25, 2013

   Shantanu,

   Nothing really new there. More news about the Higgs should come in a month or so, once the experiments have results ready for announcement at Moriond in early March.

   I suppose I could write about SUSY, but thought it better to give that a rest for a while…

6. **Spencer Tracy Jr.**
   January 25, 2013

   Although I don't agree with a lot of Susskind's theories – I met him 2 years ago in NYC after his panel discussion at the World Science Fest and found hime to be very friendly and very generous with his time. I have also enjoyed several of his youtube lectures on GR and Higgs.

7. **Kavanna**
   January 25, 2013

   Susskind is very friendly, no matter what you think of the landscape and the anthropic principle.
   Should have published those classical mechanics notes from his class! When I was his student at Stanford, he was an idiosyncratic teacher, and you could not expect any hand-holding. Not only were c and h-bar set to unity, but dimensionless factors too: 2, 1/2, pi, i, etc. We called these supernatural units.

   One hopes that Hrabovsky has parsed the lectures into a form easier to digest.

8. **Yatima**
   January 25, 2013

   But i is already unity, and how can π be unity? That doesn't even make sense…

9. **1=2=i=pi**
   January 26, 2013

   When did the supernatural ever make sense?

10. **MathPhys**
    January 26, 2013

    "lack of access to good bread or cheese"

    hehehehe best reason one can think of to go back to France.

11. **tulpoeid**
    January 27, 2013

    I'm sincerely interested in your conclusions on QM interpretation, could you post a link to relevant entries? (Of course the Preskill link is not bad either.) In any case I'm delighted to finally see someone as large as Weinberg not sticking to many worlds and other funny stories.

12. **Peter Morgan**
    January 27, 2013

    I second your recommendation of the Anthony Duncan.

13. **Harry**
    January 27, 2013

    About Villani's book, to be completely fair, books with such-high level equations are not that common here in France ("Théorème Vivant" must be quite unique in this category).
    Also, personnally I thought the bread-and-cheese argument was some kind of joke, but maybe he was serious about that after all..

14. **Peter Woit**
    January 27, 2013

    tulpoeid,

    About my personal views I don't think I can do better than the link to Preskill, who does a much better job than I can of explaining this point of view. In the online notes for my QM class one can find some other references about this.

    Harry,

    I think Villani's comment was partly tongue in cheek, but also partly serious. There's a big difference between living in Paris or another French city, and living in a rather isolated American suburb like Princeton. The bread and cheese problem there is real, but this also stands in for lots of other things one misses by living in a place like Princeton.

15. **David Metzler**
    January 29, 2013

    The link to Preskill eventually led me to Fermilab's Holometer. I've also seen a similar proposal using the LIGO equipment. I can't tell how likely that is to pan out… any thoughts?

16. **Peter Woit**
    January 29, 2013

    David,

    I don't know about the LIGO proposal, but for something about the holometer, see here
    http://www.math.columbia.edu/~woit/wordpress/?p=4572

This Week's Finds

January 26, 2013
Categories: Uncategorized

Twenty years ago this past week, John Baez posted the first of his "This Week's Finds in Mathematical Physics" to the sci.physics newsgroups, inaugurating internet blogging about Mathematical Physics, many years before anyone even knew what a blog was. For his first posting, try looking at
http://math.ucr.edu/home/baez/twf_ascii/week1
and for all the rest of them see
http://math.ucr.edu/home/baez/TWF.html

There's a huge amount of interesting material in John's TWF postings, and the amount of effort that he has put into providing detailed, clear explanations on all sorts of topics is kind of staggering. While I often try to emulate what John has done (and "This Week's Hype" of course is a sort of homage, one he may not appreciate...), I feel I'm doing well if I can manage to put together a few sentences of comments about a "Find", with John's much more useful detailed expository work something beyond my capabilities.

For a "Find" from this past week in mathematical physics, I can recommend Hermann Nicolai's "Quantum Gravity: the view from particle physics" (arXiv:1301.5481) a write-up of his lecture this past summer at a conference in Prague. He makes a point about quantum gravity that I very much agree with: the problem with the subject is not so much that of finding a consistent quantum gravity, but of finding one that fits together with the SM and tells us something new that we can check. He writes:

> Being exposed to many talks from the different 'quantum gravity camps' I am invariably struck by the success stories I keep hearing, and the implicit or explicit claims that 'we are almost there'. I, for one, would much prefer to hear once in a while that something does not work, and to see some indications of inconsistencies that might enable us to discriminate between a rapidly growing number of diverging ideas on quantum gravity . If, however, the plethora of theory ambiguities were to stay with us I would conclude that our search for an ultimate explanation, and with it the search for quantum gravity, may come to an ignominious end (like in Breughel's painting).

and

> To conclude let me restate my main worry. In one form or another the existing approaches to quantum gravity suffer from a very large number of ambiguities, so far preventing any kind of prediction with which the theory will stand or fall. Even at the risk of sounding polemical, I would put this ambiguity at 10^500 (or even more) – in any case a number too large to cut down for any conceivable kind of experimental or observational advance.

Included in his talk are various more specific comments about these issues, well worth pondering. If I were John Baez, I'd have the energy to describe them in detail and explain clearly exactly what is going on, but for this I fear someone will have to get John more interested in quantum gravity again...

Update: I should mention other tributes to TWF here, here, and here.

Comments

1. **E**
   January 26, 2013

   What? I can't really read font.

2. **johnmcAllison**
   January 26, 2013

   John Baez, Chris Hillman and Dr Kevin Brown were the three main figures from the 1990s on sci.math that I fondly remember.

   Dr Kevin Brown still hosts Math Pages http://mathpages.com/home/index.htm

   whereas Chris Hillman mysteriously deleted his Relativity on the Net page in 2007.

3. **Franco**
   January 27, 2013

   Any model of quantum gravity can be tested only against one fact: the entropy of black holes. A good friend who works in quantum gravity once summarized the situation in a simple way: there are zillions of models that reproduce the entropy of black holes and gravity, but there is no model that explains the other interactions.

   It is very unlikely, therefore, that a good theory of everything will appear through quantum gravity research.

4. **Giotis**
   January 27, 2013

   I think Nikolai is too pessimistic and on the other hand too demanding.
   A suitable candidate for a theory of evereverything (as a working project) should

   1. be able to reproduce in principle the theoretical content of the low energy effective world i.e. GR+QFT

   2. incoproprate natuarally all the ingridients needed for the derivation of SM as we know it (Fields, gauge groups etc).

   3. be able to treat Gravity quantum mechanically

   4. exhibit mathematical and theoretical consistency

   5. be consistent with current experimental data

   String theory (and String theory only BTW) fulfills the above criteria and so the theory should be taken seriously as a base of research for a unified theory.
   At some point of development the theory should be able to offer theoretical solution to known problems of GR+SM e.g. singularities , EW scale stabilization, fate of

spacetime at planck scale, resolution of black hole information paradox, dark matter candidate, the CC problem etc

String theory has made considerable progress answering some of these questions.

Finally it would be great if the theory could make defintive testable, predictions at low energies but we don't know if this is possible even for the correct theory.

Thus all in all it looks good for String theory in my opinion.

5. **Bob Jones**
   January 27, 2013

   "Any model of quantum gravity can be tested only against one fact: the entropy of black holes."

   No, a theory of quantum gravity definitely cannot be tested using black holes because we will probably never be able to measure the entropy or temperature of a black hole. There are, however, other ways in which we could potentially observe quantum gravitational effects. For example, it is conceivable that quantum gravitational effects in the early universe could lead to testable predictions about the structure of the present universe. In addition, many people believe that the strong and electroweak interactions will be unified at a length scale which is only a few orders of magnitude larger than the Planck scale. Thus, it is possible that quantum gravity could play an important role in the unification of the other forces.

   "there are zillions of models that reproduce the entropy of black holes and gravity"

   Not really. The only models that successfully reproduce the semiclassical result for black hole entropy are models based on the holographic principle, including string theory. In other approaches, like loop quantum gravity, the situation is not at all satisfactory because the theory has a free parameter (the Immirzi parameter) which needs to be adjusted to a certain value in order to get the correct result. In fact, this is why string theory is such an important tool for studying quantum gravity. It provides a concrete realization of the holographic principle and a paradigm for doing microscopic calculations of black hole entropy.

6. **Peter Woit**
   January 27, 2013

   Enough with the tedious hype about string theory and how it will someday magically be testable. I wrote about Nicolai's talk because it's clear he's given up on such nonsense and is trying to get beyond it, which is interesting. How about reading what he has to say and thinking about it instead of repeating BS?

   The argument over black hole entropy calculations wasn't interesting when it was news, and there are probably now students here at the university who weren't even born when these calculations were done. Enough.

7. **Bob Jones**
   January 27, 2013

   Peter,

   I'm not sure if you're talking to me, but just to be clear, I am not suggesting that string theory will become "magically testable" in the near future. I did mention that quantum gravity could play a role in the unification of the forces and that this could lead to testable predictions from quantum gravity, but it sounds like you would agree with me about that.

8. **Shantanu**
   January 28, 2013

   anyone know what happend to chris hillman? is he in acadamia He had such mastery over GR ?

9. **Jeff M**
   January 28, 2013

   Well, after the Byrds, and The Flying Burrito Brothers, he bounced around and is currently touring with the Desert Rose band… 🙂

10. **JG**
    January 28, 2013

    Chris Hillman got upset about the way the web was developing (too many cranks), posted negative opinions about wikipedia and the like (he had initially contributed many articles), and decided to delete his site and go offline. But you can still access his old relativity site (hosted by John Baez) on the internet archive here

    He contributed to physicsforums until the end of 2007, posted comments on some math related blogs (including this one) in 2008 and then seems to have disappeared completely?

11. **Igor Khavkine**
    January 28, 2013

    Nicolai's article doesn't harbor any surprises. It certainly captures the current attitude of particle theorists, who seem to consider quantum gravity (QG) as some kind of panacea, or merely a synonym for what is currently unknown. Unfortunately, the state of knowledge reflected therein is most often of particle physics folklore, rather than the technical state of the art. One could nit pick at any number "issues" addressed by Nicolai as either requiring QG for their resulution or providing a clue as to how QG should be and in turn argue that they are not necessarily problems at all or have little to do with gravity.

    There is one particularly opaque and unfortunately inaccurate statement at the end of section 6 on Anomalies. He correctly points out that anomalies are a serious worry in quantization, especially for gauge theories. This is followed by a remark about the possible anomalies occurring in the diffeomorphism algebra in 2d theories (incidentally, of which the string worldsheet theory is an example). Unfortunately, that remark is followed up by another one, namely that we do not have a classification of diffeomorphism algebra anomalies in higher dimensions, which is actually incorrect. The Belgian group of Henneaux, Barnich and Brandt worked out in the mid-to-late 90's that, in in most dimensions including 4d, the SM+GR does not have any new anomalies compared to just the SM. Similar information can also be found in volume 2 of Weinberg's QFT treatise.

    Having been in the audience, I drew attention to this point in the question period after Nicolai's talk. However, my remark does not seem to have had much impact.

12. **DrDave**
    January 28, 2013

    Nor sure if this is the painting he is referring to, but fits the bill http://en.wikipedia.org/wiki/The_Triumph_of_Death

13. **Yatima**
    January 29, 2013

    How about The Tower Of Babel. This image was used in Carlo Rovelli's book or maybe Laurent Nottale's, not sure.

14. **Perry**
    January 29, 2013

    The font was a nice touch

    Alt.physics.woit.

15. **Izzy**
    January 30, 2013

    I think it's Breugel's "The Fall of Icarus", the subject of a famous poem by Auden.

16. **Raizonator**
    February 2, 2013

    "He makes a point about quantum gravity that I very much agree with: the problem with the subject is not so much that of finding a consistent quantum gravity, but of finding one that fits together with the SM and tells us something new that we can check."
    Exactly, that I think is what is often overlooked: Quantum gravity is not primarily the unification of q.m. & gravity BUT the SM + gravity, the former bringing in a lot of interesting geometry.
    I just watched this video, where this is motivated very nicely
    http://www.youtube.com/watch?v=j8-7nOed_aE&list=PLHX6aNQ5-1N-ZIpkJ0OVOaqyAMOfDZI1v&index=2

17. **John Baez**
    February 19, 2013

    Thanks! For a second I thought that font was the result of some error.

    Chris Hillman began his internet career as a relentless scourge of crackpots, but then became increasingly scared of them, probably due to threats he received. He then tried to expunge every trace of himself, for example demanding that I remove his page *Relativity on the World-Wide Web* from my website.

    He doesn't have an academic career, and when I last checked he was unemployed and ill. He originally had some connection to the math department at the University of Washington, and had an email account there. Later he lost that. More recently all communications I've received from have been via pseudonymous email accounts.

    One moral is that if you plan to spend a lot of time debunking crackpots, you should expect some of them to eventually spend a lot of time attacking you. So, think a bit about whether you have the stomach for this. I decided a while ago that there are better things to do.

    Bob Jones wrote:

    > In other approaches, like loop quantum gravity, the situation is not at all satisfactory because the theory has a free parameter (the Immirzi parameter) which needs to be adjusted to a certain value in order to get the correct result.

    That was certainly true of the old calculations I was involved with, and I agree that this was a frustrating situation. But anyone who is interested should look at the more recent papers by Eugenio Bianchi, especially Entropy of non-extremal black holes from loop gravity.

19. **Mitchell Porter**
    February 19, 2013

    "anyone who is interested should look at the more recent papers by Eugenio Bianchi"

    John, what about the criticism that Bianchi isn't even counting black hole microstates, he's just reproducing Hawking's semiclassical calculation? Hossenfelder, Motl, and others all say this.

Arthur Wightman 1922-2013

January 30, 2013
Categories: Obituaries

I just heard today that mathematical physicist Arthur Wightman passed away earlier this month, at the age of 90. Wightman was one of the leading figures in the field of rigorous quantum field theory, the effort to try and make precise sense of the often heuristic methods used by physicists when they deal with quantum fields. He was a well-liked and very respected professor at Princeton during the years 1979-84 that I was a graduate student there, but unfortunately I don't think I ever made an effort to talk to him, to my loss. The university has something about him here, the department here.

Wightman is most well-known for the "Wightman Axioms", which are an attempt to formalize the fundamental assumptions of locality and transformation under space-time symmetries that any sensible quantum field theory should satisfy. His 1964 book with Raymond Streater, PCT, Spin, Statistics and All That, explains these axioms and shows how they lead to some well-known properties of quantum field theories such as PCT invariance and the Spin-Statistics relation. When this work was being done during the 1950s and early 60s, quantum field theory was considered something that couldn't possibly be fundamental. All sorts of discoveries about strong interaction physics were being made, and it seemed clear that these did not fit into the quantum field theory framework (this only changed in 1973 with asymptotic freedom and QCD). In any case, problems with infinities of various sorts plagued any attempt to come up with a completely consistent way of discussing interacting quantum fields, providing yet another reason for skepticism.

Wightman was one of a small group of mathematical physicists who reacted to this situation by trying to come to grips with the question of exactly what a quantum field theory was, in an attempt to find both the implications of the concept and its limitations. After the early 60s, attention moved from the axioms and their implications to the question of "constructive quantum field theory": could one explicitly construct something that satisfied the axioms? Examples were found in 2 and 3 space-time dimensions, but unless I'm missing something, to this day there is no rigorous construction of an interacting QFT in 4 space-time dimensions. There is every reason to believe that Yang-Mills theory, constructed with a lattice cut-off, has a sensible continuum limit that would provide such an example, but this remains to be shown (and there's a one million dollar prize if you can do this).

Thinking back to the early 1980s and my days as a graduate student, it's clear what some of the reasons were why I didn't spend time going to talk to Wightman. With the triumph of the Standard Model, attention had turned to questions about quantum gravity, as well as questions about the non-perturbative behavior of QCD. I certainly spent some time trying to read and understand the Streater-Wightman volume, but its emphasis on the role of the Poincaré group meant it had little to say about QFT in curved space-time, much less how to think about quantized general relativity. Gauge theories in general did not seem to fit into the Streater-Wightman framework, with the tricky issue of how to handle gauge symmetry something their methods could not address. For non-perturbative QCD, we had new semi-classical computation methods, and I was happily programming computers do numerical simulations of Yang-Mills theory. Why pay attention to the difficult analysis needed to say anything rigorous about quantum fields, when the path integral method seemed to indicate one could just put them on a computer and have the computer tell you the answer?

In later years I became much more sensitive to the fact that quantum fields can't just be understood by a Monte-Carlo calculation, as well as the importance of some of the questions that Streater and Wightman were addressing. As particle theory continues to suffer deeply from the fact that the SM QFT is just too good, anything that can be done to better understand the subtleties of QFT may be worthwhile. It remains true that gauge theories require new methods way beyond what is in Streater-Wightman, but looking back at the book I see it as largely devoted to understanding the role of space-time symmetries in the structure of the theory. The importance of such understanding of how symmetries govern QFT may be a lesson still not completely absorbed, with gauge symmetries and diffeomorphism symmetries part of a story extending Streater and Wightman to the Standard Model, in a way that we have yet to understand.

Comments

1. **P**
   January 31, 2013

   Hi Peter,

   I'm not sure about what precise definitions of "rigorous" would make mathematicians happy, but in discussions over the last few years it seems they don't have as much of an issue with the recent works on supersymmetric localization, and this includes work in d=4. The reason, if I understand, is that they usually take issue with the measure in the path integral, citing that the space of all possible field configurations isn't well defined, but that in some cases supersymmetric will localize the set of contributing field configurations to a nice well-defined space.

   Of course, one could take issue with the fact that the theories are rather formal, but at least there is some progress in some examples.

   Any thoughts on how localization fits into your / other definitions of rigorous?

   Cheers,
   P

2. **A.J.**
   January 31, 2013

   Peter,

   This is sad news. Another giant I'll never meet.

   P,
   The problem isn't that the space of fields isn't well-defined. Finding the space of fields for a given model is the easy bit; it basically has to be the space of linear functionals on the space of sources which the classical fields couple to. Most of these linear functionals are distributions rather than continuous fields, but the space is perfectly well-defined. And in fact, the distributions are necessary: without them, you won't get the right short-distance singularities in the OPE.

   The problem is, first, that it's not easy to show that the path integral measure exists on this space of distributions, and, second, that it's hard to show that the dressed observables are really integrable with respect to the path integral measure. (The latter question is really what the Yang-Mills millenium prize is about: Confinement means that many of the observables from the classical theory _aren't_ integrable; the ones that remain generate a Hilbert space with a mass gap in the Hamiltonian.)

   Supersymmetric localization says that — for some (but not most!) observables — the path integral over the big space of fields reduces to an integral over a finite dimensional subspace. This will someday be a wonderful theorem, but it's not true for enough observables to count as a definition of the measure on the big space.

3. **Peter Woit**
   January 31, 2013

P,

A.J. does a good job of explaining the problem. If you just want a rigorous construction of not QCD, but something like a TQFT, where in principle we have an independent characterization of what all the observables are, in a much more tractable framework, you can get a rigorous 4d theory by just making that framework your definition.

I think the formal application of localization to path integrals is a fantastic idea. Perhaps the best hope for getting rigorous 4d QFTs is to evade the problems A. J. explains by not trying to get a rigorous version of an arbitrary QFT, but reformulating the definition of a QFT to be something for which localization works automatically. Right now though, as far as I know this won't buy one any physically interesting QFTs. One speculation I'm fond of is that if you better understood the representation theory of certain infinite-dim groups, you could reformulate certain QFTs in terms of such representation theory, and get a rigorous definition of an interesting theory that way. Well, it works in quantum mechanics, where you can do the harmonic oscillator that way….

4. **Peter Orland**
January 31, 2013

Though I am not really a pessimist, I am a little wary of focussing exclusively on axiomatic methods to study field theories. These methods seem to be most successful when we understand aspects of theories by other means. I'd be happy to be proved wrong about this.

I would be surprised if localization works for theories with asymptotic freedom. Most of these theories seem rather special. I'm not an expert though.

Most of the theories where the Wightman axioms are proved (using constructive field theory) are super-renormalizable. That means a simple subtraction makes it possible to remove the cut-off. So in a way, constructive methods are most powerful for theories where we can already control renormalization. There is a claim that planar phi^3 in six dimensions is "constructable", but I have not tried to check this. I think there is good reason to be optimistic in 1+1 dimensions where we have a lot of exact information; getting to more dimensions is a long way off.

I also don't expect that the mass gap/confinement problem will first be understood via axiomatic or constructive field theory (though methods borrowed from these subjects, say lattice constructive field theory methods, might be useful).

5. **Peter Orland**
January 31, 2013

But don't get me wrong… I am a big fan of Streater and Wightman and many of Wightman's papers.

6. **deconstructed**
February 1, 2013

Maybe I can offer some opinions (and even some facts):

A.J.: as there are no complex measures, YM doesn't have a Euclidean measure. That does of course not mean, that the Standard Model can't be constructed mathematically.

Peter Orland: The people working on making the SM – as used to calculate predictions for experiments – mathematical is a set of measure zero. The problem is not, that there are some people looking at SM-physics "non-rigorously". The problem is that there are no people doing it rigorously. It certainly will be hard to learn anything "non-perturbatively", if we don't even have constructed the theory we want to know something about.

All: Constructive QFT imho is the strife to construct the SM – again as used for predictions – in a mathematically sound manner. And it shouldn't matter what methods will in the end to success (if that occurs). But in the moment mathematical physics doesn't seem to be set up to achieve this goal, as it is divided into analysis people doing Schrodinger and maybe Dirac operators and algebraists having fun with TQFT. From my point of view it seems unlikely that either one tradition alone will be able to achieve above mentioned goal, which is of course an extremely hard one.

Peter: I am curious about that idea you mentioned regarding "representation theory of certain infinite-dim groups". Can you point me to any sources? Sorry if this bores other people in here.

Anyway, RIP Arthur Wightman and thanks for setting the goal.

7. **A.J.**
February 1, 2013

deconstructed: I'm sorry, but I don't quite understand what you mean by "as there are no complex measures, YM doesn't have a Euclidean measure". Can you clarify?

8. **deconstructed**
February 1, 2013

A.J.: The generating functional for YM is not real-valued, which is a condition of Minlos' theorem, which in turn gives necessary and sufficient conditions for the existence of measures over locally convex spaces.

(Minlos' theorem is the analog of Bochner's theorem for probability measures. Check out Gelfand's Generalized Functions, Volume IV, I think. Or Bourbaki's Integration)

There are also no complex-valued measures on the real numbers.

Sorry that I was a little cryptic there, but I can already hear Grandmaster P booming: "There are plenty a places to discuss measures. Enough."

9. **Peter Woit**
February 1, 2013

deconstructed,

I don't know much about technical issues with measures, but in the case of pure Yang-Mills I believe you should be able to understand the problem as one of showing that an appropriately constructed limit of the theory regularized as some version of lattice gauge theory should exist and have desired properties. I think the point Peter Orland is making is one that I agree with: if you don't have a good physical understanding of the infrared behavior of these theories (and we don't…), no analytical technique is going to solve the problem.

As an example of what I meant by using rep theory of infinite dim groups, consider the Wess-Zumino-Witten model, a 1+1 dim QFT. If you try and naively discretize that and control its continuum limit you will encounter all sorts of problems. On the other hand, the behavior of the theory is largely determined by knowing about the representation theory of a loop group.

10. **Peter Orland**
February 1, 2013

deconstructed:

I have some sympathy with your views, but I am not convinced that your statement, "It certainly will be hard to learn anything "non-perturbatively", if we don't even have constructed the theory we want to know something about," is entirely true.

I suppose it could be so, but precedent suggests not. There are some physical phenomena (in classical mechanics or statistical mechanics) where proving theorems really settled physical questions, so you could be right. The field theories we have solved, however, were first solved by less rigorous methods more familiar to theoretical physicists.

There is a long list of field-theory models (the Lee model, integrable theories, QED with monopoles) which were well understood (by which I mean some observables were calculated) without rigorous methods. Rigorous tools were applied, only afterwards, to a small subset of these models. The only field-theoretic model I can think of which was solved first by constructive methods was Nelson's. Nelson introduced it at the start of the constructive field theory program (it's a model of non-relativistic quantum particles, interacting with a relativistic scalar field).

I am a fan of constructive FT, because it gives a lot of insight (as in phi^4), but its successes in seem to be for models we already had some control over.

11. **deconstructed**
February 1, 2013

First of all I don't think that we have to, or even should, start with lattice gauge theory. Don't get me wrong, if you are able to continue the work of Bałaban and prove results, that would be a gigantic sucess. From a conceptual point of view, however, lattice theories have the distinct disadvantage, that you have to redo the proof for every observable you investigate. I digress.

My point is, that from the outset it should not matter where we start, as long as the starting point is mathematically sound.

The term "good physical understanding" is key here imho. If it's meant to be "knowlege gleand from calculating Feynman diagrams", I agree – we don't have a lot of that.

But we do have Bałaban's work, which all but proves the existence of the YM partition function in the lattice framework. And as such it does have a lot of information not only on the ultraviolet behaviour but also on the infrared behaviour of YM.

Anyway, we have to find an approximation of SM where we can control the infrared behaviour. So we should try a few. Except for the ones we already know don't work, obviously. Your WZW example is just one of many indicators, showing that there are a very large amount of bad approximations.

Also, there are a lot of interacting theories in 2d, where groups don't help you at all. Hence what I said before, that we should throw everything in the ring we have, everything from algebra to analysis, groups to spaces.

Regarding the "rep theory of infinite dim groups" thing: where you being ironic when you said it worked for the harmonic oscillator in QM? If not, can you point me to a document I can read to understand this? I would like to understand the very basic idea you have.

Greetings!

12. **Peter Orland**
February 1, 2013

To add to what Peter W. said about Witten-Wess-Zumino models…

Much the same can be said about other 1+1-dimensional theories. We know the
S matrix and some off-shell information exactly. I think that most people working on these expect that these results will eventually lead to a rigorous definition. This is done without the benefit of a functional measure or a Lagrangian.

13. **deconstructed**
February 1, 2013

Peter Orland: Your post came, while I was answering Peter's. I shall gather my wits and reply to yours asap.

14. **A.J.**
February 1, 2013

deconstructed:

Yes, I know what Minlos' theorem says. I gave a class on it once, for whatever that's worth…

And I don't think there's anything wrong with talking about constructive field theory in a post memorializing Arthur Wightman. So if you'll allow me to pester you a bit more… I still don't quite know what you're trying to convey to me with your comment, and I'd be happy to learn. In particular, in lattice SU(2) Yang-Mills, everything physically relevant looks real-valued to me. The Wilson action is real, and the Haar measure on gauge fields is real, so the lattice path integral measure is real. The observables should all be generated from characters of products of holonomies, and the characters of SU(2) are real valued. (Forgive the restriction to SU(2). I thought it best to get concrete.) So it looks to me like the relevant generating functional is also real-valued.

So what precisely about my comment are you objecting to?

15. **A.J.**
February 1, 2013

As a side comment: I doubt the Standard Model can be constructed mathematically. The Higgs sector is going to cause trouble.

16. **deconstructed**
February 1, 2013

Well I didn't say it would happen that constructive theory is faster than any heuristic approach, Mr Peter Orland. I'm just saying, that it will get harder and harder to glean information about the complete theory without having the full theory. Do you contest, that perturbative calculations about QCD – strongly interacting as it is – are getting harder by the loop?

But that's not even the issue. Even if you could calculate more and more diagrams, we're not even sure that our theory is approximated anymore by the stuff we calculate. (I think recent quark gluon plasma observations at the LHC indicate that the strong interactions do in fact cause deviations from the calculations, if you don't get goose bumps from some minor conceptual issues as long as the "predictions" fit.)

Can you have predictions out of a theory, that has no mathematical basis(, yet)?

17. **Peter Orland**
February 1, 2013

Hi deconstructed,

No, I can't do any of the things you ask. I am just saying that QFT is a complicated problem and we need to view it from with many different angles. Usually insight comes first, then theorems. Constructive FT is usually better for the latter, which I agree is important. Balaban's stuff is great (though I can't make the Polish "w" on my keyboard), but so are other ideas.

We can't just be hammers (and hit nails) or screwdrivers (and provide OJ+vodka). We have to able to do everything.

Regards,
P.O.

18. **KP**
February 1, 2013

Since 'rigorous' vs 'non-rigorous' methods are being discussed, it seems the right place to ask the following:

How can we trust 'non-rigorous' methods that have little mathematical justification while dealing with QFTs that have no observational support? That is, I can see that all our non-rigorous QFT methods can be justified for the SM because it fits with experimental data. But, is there any justification to using the same methods for things like SuperYM?

What if, the SM is a very special case where the non-rigorous methods just happen to give the same answer as the hypothetical rigorous formulation of QFT?

19. **deconstructed**
February 1, 2013

I can certainly see why some fields move faster than others.

A.J.: You'll have to excuse my very brief comment at the beginning. Our discrepancy shows how differently we think, even if we both seem to both come from the mathematical physics community.

What I meant was, that starting from the classical Yang-Mills differential equations (or density), when you build a "time-zero-algebra" in order to go to Euclidean space and quantize (Osterwalder-Schrader reconstruction) the "measure" you encounter will not from the outset be real-valued. At this stage you're not even allowed to use gauge invariance, because that's what you want to prove for your quantized theory. Of course as soon you have constructed the whole theory you should be able to find a "section" through your solution space aka predictions, where everything you're interested in is real (although that doesn't ensure the existence of the measure, as you know).

Of course, starting from an approximation which is already obviously supporting a measure will have certain advantages. But other approximations not supporting a measure might have other advantages.

While writing this it ocurrs to me, that calculations for the LHC are probably done using lattice gauge theory. Maybe I should reevaluate my starting point.

20. **deconstructed**
February 1, 2013

KP: All your questions are excellent.

21. **A.J.**
February 1, 2013

@KP: Which non-rigorous methods do you have in mind?

22. **KP**
February 1, 2013

@AJ
For the sake of being concrete, how about path integrals? If I am not mistaken, it is not really clear that the "measure" on the space of field configurations even exists in a mathematically rigorous sense.

In any case, the Wick 'rotation' used to define the partition function is only valid in stationary spacetimes. So, we know at least one situation in which the path integral is ill-defined but QFT supposedly exists.

23. **A.J.**
February 1, 2013

@deconstructed: Thank you for the comments. It's educational to see other perspectives.

Regarding LHC, from what I recall, it's a mix. The highest energy processes can be treated perturbatively, but as you get away from the beam collision point, you need numerical simulation to understand what's going on.

24. **Igor Khavkine**
February 1, 2013

Speaking of 'rigor' in QFT. I want to make a technical remark that may seem like a triviality, but I think is important for the perception of the mathematical foundations of QFT.

It is of course true that physicists often use heuristic mathematical manipulations in their calculations. And just as Peter Orland has pointed out, these calculations are replete with insights that are then routinely turned into completely rigorous proofs by mathematical physicists and mathematicians (it is also not excluded that the same person could wear more than one of these hats). So there is no particular lack of rigor in the mathematical treatment of QFT. And there are examples where I think rigorous methods do correct erroneous thinking that was guided by more naive heuristic methods.

What is true is that these rigorous proofs do not necessarily establish the exact results that we would want. Namely, the best physical predictions that we can get out of the Standard Model (though fully rigorous) are not numbers but rather formal power series in the theory's coupling constants. It really doesn't matter whether people use path integrals (whose mathematical foundations are "shaky") to arrive at these answers, because by now there do exist fully rigorous (though somewhat different) methods that are known to give equivalent results.

What is missing is not rigor but 'strictness' (using 'strict' as the opposite of 'formal'). By that, I mean that we are not currently able (with a few low dimensional exceptions) to replace the above mentioned formal power series by actual functions, whose asymptotics these series represent. And until we do, as already brought up by deconstructed and KP, we do not have reliable estimates on the errors that we get by truncating the asymptotic power series. That is, until then, we do not have reliable error bars around our theoretical predictions.

This lack of 'strictness' is the real problem with the foundations of QFT. Unfortunately, I think it is rather hard to predict at the moment whether it will be solved by a satisfactory construction of field-theoretic path integrals or by some other means. I think it would pay not to be dogmatic on this point.

25. **A.J.**
February 1, 2013

KP:

I think the best answer I can give is that it's a good idea to use methods that have been tried in more than one experimentally tested physical model, that it's safer to use methods which make sense in regularized approximations, and that it's safest to use methods which have been shown to work in rigorous examples.

The path integral is one of these. It works in QED, QCD, the Standard Model, and probably dozens of low energy approximations to these, like the Skyrme model. It's grounded in lattice path integrals which arise by repeatedly inserting resolutions of the identity into correlation functions, which is about as mathematically kosher as it gets. The continuum limit of these lattice approximations has been constructed rigorously in a number of low-dimensional examples, and in these examples, everything works pretty much as the physicists think it should. This gives me some confidence that what works for Standard Model calculations also works for SO(99) gauge fields with Dirac fermions in some weird representation.

26. **Thomas**
February 1, 2013

I am a little confused by this discussion. There are no people working on rigorous methods for the standard model (SM), because we do not expect that the SM can be rigorously defined (because of the Higgs sector and the U(1) gauge group). We believe that QCD can be rigorously defined, and we expect that chiral gauge theories can be defined as well. We think that in the case of QCD we already have a construction (as a limit, via euclidean lattice gauge theory), but of course there is no proof that the limit exists. I am not quite sure what the consensus is regarding chiral fermions.

There are a number of non-perturbative results in 4d that have been proven using physicist's methods (not as many as we would like, obviously), for example the Seiberg-Witten result for the low energy effective action of N=2 SUSY YM, and proving these results is an obvious goal for more rigorous methods.

27. **Alexander Dynin**
February 1, 2013

Dear Professor Woit,

The heyday of constructive QFT during 1970's stopped short before 4
dimensions with a general supposition of triviality for scalar fields.

The Clay institute problem looks as Jaffe's attempt to revive it for Yang-Mills fields.

Unfortunately, even modified Wightman axioms (see, e.g., Chapter 10 of Bogoliubov, N. N., Logunov. A. A., Oksak, A. I., and Todorov, I. T., "General Principles of Quantum Field Thory, Kluwer, 1990) are in a serious conflict with the simplest cases of Gupta-Bleuler theory of quantum electromagnetic fields, as well as commonly used local renormalizable gauges (see, e.g. Strocci, F., S., "Selected Topics of the General properties of Quantum Field Theory", World Scientific, 1993.)

There was a vivid discussion among W. Heisenberg, P. Jordan, and W. Pauli of the corresponding "Volterra mathematics" for possible applications to functional Shroedinger operators.

This approach has been realized in my solution of Yang-Mills Millennium problem (the latest version "Mass gap in quantum energy spectrum of relativistic Yang-Mills fields", arXiv:1205.3187).

The paper abstract:

A non-perturbative and mathematically rigorous quantum Yang-Mills theory on 4-dimensional Minkowski spacetime is set up in the framework of a complex nuclear Kree-Gelfand triple. It involves an infinite-dimensional symbolic calculus of operators with variational derivatives and a new kind of infinite-dimensional ellipticity.

In the temporal gauge and Schwinger first order formalism classical Yang-Mills equations become a semilinear hyperbolic system for which the general Cauchy problem (with no restriction at space infinity) is equivalent to one with a family of periodic initial data. Yang-Mills quartic self-interaction and the simplicity of a compact gauge Lie group imply that the energy spectrum of the anti-normal quantization of Yang-Mills energy functional of periodic initial data is a sequence of non-negative eigenvalues converging to infinity and, by caveat, has a mass gap at the spectral bottom. Furthermore, the energy spectrum (including the mass gap) is self-similar relative to an infrared cutoff: it is inversely proportional to the initial data period.

According to Wikipedia, "Since 2009, Alexander Dynin claims to have proved the Yang- Mills Millennium Problem. Nevertheless, the physics community seems to be turning a deaf ear to him,
apparently because they feel incompetent to assess his unorthodox mathematical methods."

Regards,

Alexander Dynin

Professor of Mathematics,
Ohio State University

28. **Nakanishi**
February 2, 2013

Dear Professor Dynin:

Although I do not know whether or not Wightman functions are definable in your theory, I would like to note that there are serious mathematical difficulties in formulating gauge theories in axial-type (i.e., axial, light-cone and temporal) gauge in the Wightman-like formalism. For a review, please see
N. Nakanishi, Critical Review of the Theory of Quantum Electrodynamics, in T. Kinoshita (ed.), Quantum Electrodynamics (World Scientific, 1990).

29. **KP**
February 2, 2013

@AJ

I agree with your view that using the tools we already have is a good idea. At the same time, I feel that finding a more rigorous formulation is also warranted.

@Thomas
Do you mean to say that if the SM is the correct theory excluding gravity (as the LHC results seem to indicate thus far), then we will be stuck with a 'correct' physical theory that can not be hoped to be made mathematically rigorous? Or am I understanding this wrong?

30. **deconstructed**
February 2, 2013

Thomas: Just because "we believe", or rather, just because there are heuristic calculations suggesting, that the SM is not a mathematical theory, that doesn't mean nobody should work on settling the question. I want to know whether it exists or not and I hope I'm not alone with that wish.

31. **John Baez**
February 2, 2013

P wrote: "I'm not sure about what precise definitions of "rigorous" would make mathematicians happy…"

The definition is pretty simple. In a "rigorous" approach to a subject, you start by laying out a set of axioms and rules for deduction. Then everything else you derive using those. Ideally you also show they're consistent: that is, it's impossible to derive a contradiction. In practice, you often try to show they're relatively consistent: any contradiction would lead to a contradiction in some widely accepted set of axioms, like ZFC.

It's easy to make small chunks of quantum field theory rigorous, just by precisely stating the rules used. The hard part is that quantum field theory as practiced by physicists uses many different bunches of rules, and it's hard to precisely state them all, much less show they're consistent or organize them into something elegant.

Nonetheless this has been successfully done in a bunch of cases, and there's been a lot of progress now that more mathematicians are getting interested in quantum field theory.

32. **Thomas**
February 2, 2013

@KP

Yes, but we know that gravity exists (and presumably dark matter).

@deconstructed
I think it is not correct to dismiss the existing work on triviality of ϕ^4 and $U(1)$ gauge theory as mere heuristics. Having said that, I think it would still be valuable to provide a lattice definition of the complete standard model, and then show that this theory is indeed just QCD plus free fields.

33. **Peter Orland**
February 2, 2013

Thomas,

I think what deconstructed means is that triviality of phi^4 in four dimensions is not proved. The papers of Froehlich and of Aizenmann proved it is trivial in more than four dimensions, but not in exactly four.

34. **Abdelmalek Abdesselam**
February 4, 2013

Just a small correction to what Peter Orland said above. The methods of constructive QFT are not limited to super-renormalizable theories. For instance massive Gross-Neveu in 2d which is only asymptotically free in the UV has been given at least three different rigorous constructions: by Gawedzki-Kupiainen, Feldman-Magnen-Rivasseau-Seneor and finally more recently by Disertori-Rivasseau. What is needed is that running couplings remain small in the range of scales under consideration. Super-renormalizability is not essential.

35. **Peter Orland**
February 4, 2013

Dr. Abdesselam,

Actually, what I said was that constructive methods appear to be limited to theories for which renormalization can already be controlled. I did not say only super renormalizable theories could be understood this. The Gross-Neveu model, for example, can be studied with 1/n expansions, which gives a very good picture of its behavior in any dimension (even in more than 2D).

36. **Abdelmalek Abdesselam**
February 4, 2013

Dr Orland,

Sure. “renormalization can already be controlled” means heuristically and of course this precedes the corresponding constructive result which proves that the renormalization of the model can be controlled rigorously and nonperturbatively. By the latter I mean “not simply in the sense of formal power series” which is weaker than what physicists might understand by nonperturbative, i.e., pertaining to strong coupling phenomena for instance.

37. **Chris Austin**
February 6, 2013

Arthur Wightman seems also to have been deeply involved in early work on BHPZ renormalization, even if he apparently didn’t publish on it at the time, (although he later co-edited a book on renormalization with G. Velo). Klaus Hepp’s fundamental paper contains a very substantial acknowledgement to Wightman.

38. **Chris Austin**
February 6, 2013

Sorry, I meant BPHZ.

Short Items

February 3, 2013
Categories: Uncategorized

- Resonaances has an excellent posting about the latest WMAP9 CMB measurements, and the value N_{eff} for the number of implied light degrees of freedom. When the WMAP numbers were released late last year, they quoted

  N_{eff}=3.89+/-.67, 3.26+/-.35, 2.83+/-.38

  for the results of fits to their data and others (see section 4.3.2). Jester described this as "like finding a lump of coal under the Christmas tree": the value N_{eff}=3 implies no new light degrees of freedom beyond the known 3 light neutrinos. A rumor soon appeared on his blog that this result was in error and would be corrected.
  The corrected version is now out, with new results

  N_{eff}=3.89+/-.67, 3.84+/-.40, 3.55+/-.49

  and a note about the correction: "slight correction to Neff for case with BAO."
  which seems reasonable if you regard the difference between finding no unknown degrees of freedom and discovering a new unknown one as "slight".

- Martin Perl has an interesting blog entry entitled What Me Worry About The Future of High Energy Physics? He describes his views about the problems facing HEP, what he thinks of the Fundamental Physics Prize, and some comments on the history of physics (as well as some kind words about this blog).
- On the Beauty front, you can watch a video of Enrico Bombieri's lecture at the IAS on Beauty in Mathematics. On February 15 in Boston the big AAAS annual meeting will include a session on Is Beauty Truth? Mathematics in Physics from Dirac to the Higgs Boson and Beyond.
- viXra log has a posting about video released by CMS of the session on June 15th where their convincing evidence for the Higgs in gamma-gamma decays was first unveiled to the larger collaboration. It was at this point that most of the 3000 or so physicists in CMS knew for sure they had a Higgs discovery. One can speculate about what the graph of number of people in the world aware of this would look like as a function of time, but I'm sure by June 17th when I first heard about it, it was already much more than 3000, and growing exponentially.

  This was about three weeks before the public announcement on July 4. Of course now what we all want to know is what the full 2012 CMS dataset says about gamma-gamma, and whether it agrees with the SM or not. The general assumption is that this will be made public at the March 2-9 conference in Moriond. So, based on the timetable last time, one can guess that within the next week or two such results will be disclosed to the full CMS collaboration.

- As every year, one can follow the latest trend in US particle theory hiring at the tenure track level here. Lubos Motl describes the current situation as one of hep-th being subjected to terrorism, I guess by hep-ph.

Comments

1. **Sesh**
   February 4, 2013

   You can hardly say the CMB measurements together with the BAO have "discovered" an unknown degree of freedom. Neff of 3.046 is inconsistent with the data by at most 2 sigma. That's not much evidence on which to base any sort of claim for discovery, so WMAP are quite right not to do so. Especially given all the other parameters that could be varied, and the fact that ACT and SPT appear not to be very consistent with each other, and that some of the BAO data looks a little fishy too.

2. **Yatima**
   February 4, 2013

   > Lubos Motl describes the current situation as one of hep-th being subjected to terrorism, I guess by hep-ph.

   Send in the hep-drones for Great Justice!

   Seriously though, no mention of the Proton Size Discrepancy?

3. **Kavanna**
   February 4, 2013

   But according to Lubos, everything is terrorism — or at least, dangerous post-modern nihilism — especially opposition to the Holy and Beautiful Theory of Extended One-Dimensional Thingies.

   Looks like Neff = 4 is not impossible, BTW. It's a new "slight" degree of freedom!

4. **S**
   February 4, 2013

   Speaking of beauty, I'm curious about your reaction to this article, which mentions you. It seems to me that it somewhat mischaracterizes your position.

   http://chronicle.com/article/When-Beauty-Is-Not-Truth/136803/

   I've understood you more to think that people are doing the wrong theorizing, not that theorizing is dead (and similarly, that string theory is inelegant, not that elegant is useless). But perhaps I'm wrong.

5. **Peter Woit**
   February 4, 2013

   S.,

   About the Orrell book: I think it's a well done history of the "beauty" issue in physics, and right now this is a big issue because a lot of people are interpreting the failure of string theory and supersymmetry as a failure of the idea that you should pursue such beauty. I definitely disagree with Orrell's conclusions, but he represents a view which I think is going to be getting more traction.

I talked to the Chronicle writer who wrote the review, and I think he decided not to quote me because my point of view complicates the issue and it's complicated enough to explain to a general readership already. So, he added me in with Gleiser and Orrell as claiming the "predictive power of theorizing in physics waning", which in some sense is true, although my reasons for thinking this are rather different than those of Gleiser and Orrell (crudely, I'd say that the problem is a sociological one of people pursuing failed ideas, claiming them to be beautiful even if they aren't).

6. **chris**
February 5, 2013

i'd rather guess by nucl-th…

7. **P**
February 5, 2013

@ Chris:

I think most of these people are hep-ph.

It's interesting to note that, while most of the jobs are going to ph people, there still aren't that many jobs! At top U.S. institutions over the last five years, for example, I'd estimate there have at most been O(10-20) ph hires. Who, in the LHC era, can blame the community for wanting to hire at least 10-20 excellent young professors to carry model building into the next generation? This will saturate in the next few years and the hires will swing back towards formal theory a bit.

8. **Brathmore**
February 7, 2013

From Dr. Perl's blog about the Fundamental Physics award: "The time scale for physics progress is a century not a decade. There are no decade scale solutions to worries about the rate of progress of fundamental physics knowledge."

This raises the question of how long one must wait for experimental validation before one rejects a theory. I am sympathetic to remarks that string theory has been a three decade long rabbit hole in a quest for a unified theory. But what makes three decades special, if the "time scale for progress…is a century…" as Dr. Perl suggests? Does one wait only a year (no), a decade (no), a few decades (?), a century (?), or even longer to abandon a theory? How do you decide? I suspect that up until this point in modern physics, theories with no experimental support were eventually replaced by theories that did garner such support – thereby rendering the question moot, since a clear alternative **with** support existed. But today, such a trajectory may not occur, since as Dr. Perl points out, it is becoming increasingly difficult to even build machines capable of testing theories at the scale where we want to answer the TOE questions.

In short, if no TOE rival to string theory emerges with experimental support, then how does one decide how long to give string theory before calling it quits? If an elegant theory exists without experimental support or falsification, should it be abandoned when no alternative exists to replace it?

If data falsifies string theory (and I am not competent to evaluate this question), then by all means let us abandon the falsified theory. But, if I understand some of the arguments in this forum correctly, the gripe against string theory is less that it has been falsified, than that it cannot be falsified – a bold claim indeed, given that (i) unforeseeable progress in technology could occur in the future conducive to such testing; or (ii) unforeseeable progress in string theory could occur giving rise to testable claims.

Speaking as an outsider, I wonder out loud if one of the dilemmas faced by string theorists is that, even if they were to acknowledge string theory's failings, they still believe it to be far more promising than any other TOE in existence (or that they can conjure themselves). Until that changes, they have no other TOE to work on, and will therefore stick with strings.

9. **reject**
February 7, 2013

Actually a theory is abandoned rather than rejected, and that happens when an alternative comes along which does a better job of explaining things. So it was with the luminiferous aether; it was abandoned when Einstein produced the theory of relativity, but there was no explicit `rejection' of the aether theory *per se*. So also with the phlogiston theory of earlier years. It was eventually abandoned because other theories could do a better job. When it was claimed that phlogiston must have negative mass, people just lost interest in it. But there is no real time scale for these events (changes of paradigm?). String theory will likely persist until something else comes along which does a better job of explaining things. There is no time scale for that.

10. **chiz**
February 7, 2013

Gleiser's comment in the Chronicle article that RH amino acids don't occur in nature is technically false, they do occur – even in humans – although they certainly aren't common. His claim about the beauty inherent in asymmetry – and the example he gives – also seems wrong. Personally, I'm sympathetic to the notion that beauty and truth are highly correlated but I'm not sure why this issue is brought up in connection with the standard model or any extension of it since the standard model has always struck me as rather ugly. Are there really people who think that CKM mixing is elegant? It looks, to me, like an ugly kludge. And using singlets for RH states but doublets for LH states also strikes me as profoundly ugly. I don't really understand how Gleiser – or anyone else – could regard that as an elegant or beautiful piece of mathematics.

February 8, 2013

Peter, OT
Link to Arkani-Hamed talk at STSCI (about 80 minutes long)
https://webcast.stsci.edu/webcast/detail.xhtml?talkid=3398&parent=1

12. **M**
February 8, 2013

Does somebody know if this paper
http://arxiv.org/pdf/1302.1617v1.pdf
means that Planck will announce a non flat universe with OmegaK ≈ 10^-3?

13. **Toni**
February 8, 2013

Peter,

if all experiments confirm the standard model (with a Higgs and nonzero neutrino masses), then the arguments from the hep-th community stating that the standard model is incomplete must be wrong.

It looks as if 30 years of a so-called “incomplete standard model” are coming to an end. Would it be possible to have an overview of all these arguments and to check them one by one?

It seems very bizarre to me that for 30 years a complete physics community has been convinced that the standard model is incomplete or even wrong, but that this conviction now turns out to be mistaken. What have they been telling to students for the past 30 years, and why? Where are the mistakes? Why have they been made?

14. **Peter Woit**
February 8, 2013

Toni,

There are solid arguments that in principle the SM is incomplete (no quantum gravity, bad short distance behavior of scalar and U(1) gauge fields, a large number of parameters whose origin is mysterious, perhaps dark matter, if it is not astrophysical in origin). But the arguments that the SM is incomplete at the TeV scale have always been quite weak and highly speculative. I hope that the news from the LHC will have the effect of causing people to rethink some things often claimed to be strong arguments, but which really aren’t. First amongst these is the “hierarchy” or “fine-tuning” problem (which I’ve often gotten into arguments with people about here, not interested in repeating now…)

Unfortunately, so far what I’ve been seeing from prominent theorists is no desire to re-examine their assumptions, but instead things like “maybe X that is needed to complete the SM is at a little higher mass than we thought, let’s wait for 2015-6 before doing anything”, or “OK, if there is no X, then we give up on science and go for anthropics as the explanation”.

15. **Toni**
February 9, 2013

Peter,

thank you. The distinction between “incomplete at TeV scale” and “incomplete at Planck scale” is a good one.

Then the present experiments can be summarized by saying that the standard model is (probably) complete at the TeV scale.

At the Planck scale, quantum gravity and parameter explanation must kick in. Yes, dark matter is still open – if it is an issue at all – and even the short distance behavior might be a non-issue. Even certain Czech bloggers admit that the Planck length is the smallest physical distance.

So we could arrive at the situation that only two issues are open: quantum gravity, which we will probably never confirm experimentally, and the parameter calculations.

If that is true, our beloved “theory of everything” will be extremely narrow in scope. In practice, it will only explain the parameters! Are we all prepared to live with such a “basic” TOE? It will not fascinate, not excite passions, not change our world view, not produce new technologies, and not provide any power.

Could the TOE really be a footnote at the end of textbooks on the standard model? Are we all prepared for this anti-climax?

16. **Mitchell Porter**
February 9, 2013

“Are we all prepared for this anti-climax?”

The progress of physics has to end one day, either in the discovery of the final truth, or in coming up against barriers to knowledge that we cannot surpass.

It could also come to a fake conclusion for a while, where a certain set of barriers are treated as unsurpassable even though they are not, and so the philosophical culture of physics might settle into vague affirmations of a favored cosmology, such as one already sees among some proponents of a “landscape multiverse”, and John-Horgan-esque musings about the limits of knowledge.

However, I do not expect to see that really happen, not in a big way. Of course certain opinion leaders and their followers may settle for such opinions. But in the big bad world outside narrow schools of thought, the situation is still discord, confusion, clash of ideas, a trickle of genuine empirical discovery, and enormous new vistas of thought still waiting to be explored.

If we actually had a theoretical framework that could predict all the parameters of the standard model, that would be an intellectual revolution that wouldn’t just stay within physics. The cultural impact would be as big as relativity. So if you want to understand how having a true theory of everything would feel, consider the cultural significance of relativity.

We don’t go around talking about relativity every day, but it’s hardly a technical curiosity buried at the ends of textbooks either. Relativity is one of the fixtures of modern intellectual culture. It’s a beloved and challenging set of ideas for people who like science – and a constant spur to the invention of crackpot alternatives for people who don’t like it – and the source of new philosophies like the idea of a “block universe” – as well as a reference point in cultural discussions.

Human culture is diverse, contradictory, always reconfiguring itself, contains a thousand elements, and changes in response to an ever-changing world. The place of a verified final theory in human culture would not remain fixed, but it would be a very heavy presence in a number of areas of thought and life.

17. **Sesh**
February 10, 2013

M: It’s possible of course, but I don’t see why you should especially think that. As far as I can tell, Marc Kamionkowski is not on the Planck team and Phil Bull definitely is not, so they shouldn’t have any special insight into what Planck are seeing – the confidentiality restrictions on this data are pretty tight (until March).

18. **tulpoeid**
February 10, 2013

There we go again about CMS collaborators eager to spill out “secrets”….. When will the lack of actual spilling be properly acknowledged as an unusual, for humankind’s standards, demonstration of respect for one’s work and for one’s colleagues’ work?

Do you want a more pragmatic point? Here it is. What will anyone* on earth gain by the “secret” given away a few days before its announcement? The only thing you’ll manage will be to spoil the end.

* Not talking about the bloggers who will host the giveaway of course.

Existence of Kähler-Einstein Metrics

February 7, 2013
Categories: Uncategorized

An important recent development in geometry has been the announcement of two claimed proofs of a long-standing conjecture about the existence of Kähler-Einstein metrics. Simon Donaldson is talking about this at MIT this week (see here and here), and the last in a series of his papers with Xiuxiong Chen and Song Sun giving details of their proof appeared on the arXiv earlier this week, see here. For the earlier papers in the series, see here and here, as well as the original announcement of the proof in outline here. Gang Tian also has a preprint with a proof, see here. As usual in mathematics, one might want to wait for these preprints to be refereed by experts before being sure that a proof is in hand.

Given any manifold, there's an infinity of ways of putting a metric on it. A major theme in modern geometry and topology has been the pursuit of the idea that in many cases there may be a unique "best" choice for such a metric. The proof of the Poincaré Conjecture involved just this sort of idea, showing that starting with any metric on a simply-connected three-manifold one could deform it in a specific way to end up with certain special possibilities that could be completely analyzed.

For Kähler manifolds, the big open question of this kind has been that of whether one can find a unique metric that is both Kähler and Einstein (thus "Kähler-Einstein"). For negative first Chern class this was shown by Aubin and Yau, and for zero first Chern class by Yau in his proof of the Calabi conjecture (these are the "Calabi-Yau" manifolds). For positive Chern class there are counter-examples, but the conjecture has long been that Kähler manifolds satisfying an appropriate notion of "stability" will have such a unique Kähler-Einstein metric, and it is this conjecture that apparently has now been proven.

The details of this are far beyond my expertise, so I refer you to the papers quoted above, as well as some expository articles about the problem by Donaldson and Tian, as well as a series of blog posts (here, here, and here) by Terry Tao based on lectures by Yau.

Comments

1. **not even right**
   February 8, 2013

   so, does this have any hope of selecting manifolds from the landscape?

2. **arnold**
   February 8, 2013

   Hi,

   This is certainly not the right place to ask this question so i'm sorry but I don't really know where else to ask. Do you know if there is going to be an eilenberg lecture this semester and if yes about what it will be ?

   Regards,
   Arnold

3. **Bobito**
   February 8, 2013

   There's not much doubt that the result is correct. Donaldson, Chen, Tian are among the biggest experts on the problem, the ones who proposed the path to solve it, the one who laid the groundwork for solving it. Moreover it was sort of expected they (or some student) would solve it.

4. **Peter Woit**
   February 8, 2013

   not even right,

   No. This has long been suspected to be true and does not help with that problem.

   Arnold,

   No Eilenberg lectures at Columbia this semester. That program funds visiting lecturers, but not necessarily two per year, just one this year (Klainerman, who lectured in the fall). Wait till this fall…

5. **anon**
   February 9, 2013

Quick Links

February 17, 2013
Categories: Uncategorized

Posting has been light recently, partly since I've been working on writing up notes for my course (more about that soon), but largely because there hasn't been a lot of news to write about in the math-physics world. The LHC shutdown yesterday, with the latest online machine status report now saying:

> No beam for a while. Access required. time estimate: ~2 years

It will take about that long to replace magnet interconnections and do other work required to get the LHC working at an energy close to the design energy of 7 TeV/beam (seems likely they'll be trying for 6.5 TeV/beam).

Results from the full 2012 data set for the Higgs are likely to be released soon, at Moriond in early March. Not much in the way of rumors available about this, which may have something to do with no surprises in the data. I hear there will also be, as expected, yet more stringent limits on SUSY reported.

For a US-centric series of reports on HEP and future plans, see talks here at a meeting this week at Fermilab.

On the cosmology front, there should be big news next month with Planck finally reporting results on March 21 (see here), to be followed by a conference dedicated to the results a couple weeks later.

No matter how cosmology is doing as a science, the Templeton Foundation is doing its part to promote its non-scientific aspects, with major funding for projects designed to promote and institutionalize the subject of "Philosophy of Cosmology". Just before the Planck data release, DAMTP will host a Templeton-funded conference on "Infinities and Cosmology", which will include two lectures by Michael Douglas on "Can we test the string theory landscape?". Templeton is also funding a three-week summer institute in Santa Cruz to "promote understanding and research" on topics like "reasons for believing in a multi-verse, anthropic arguments, the metaphysics of laws and chance, why anything at all exists." If you want to spend three weeks this summer among the redwoods discussing such topics, and collect a check for $2500 from Templeton, apply now.

Sometimes I make fun of pseudo-scientific research favored by some Northern California physicists by speculating about the role of marijuana in their research efforts. On a much more serious note, Southern California's John Schwarz and his wife Patricia have been involved in admirable efforts to change US policy against investigating medical uses of marijuana, with Schwarz writing an editorial here last year, and speaking at a conference in DC next week.

For more evidence of how ideas about string theory have worked their way into US general cultural life, a couple people have pointed me to Adam Gopnik's piece about Galileo in last week's New Yorker, which contains the following:

> Contemporary historians of science have a tendency to deprecate the originality of the so-called scientific revolution, and to stress, instead, its continuities with medieval astrology and alchemy. And they have a point. It wasn't that one day people were doing astrology in Europe and then there was this revolution and everyone started doing astronomy. Newton practiced alchemy; Galileo drew up all those horoscopes. But if you can't tell the difference in tone and temperament between Galileo's sound and that of what went before, then you can't tell the difference between chalk and cheese. The difference is apparent if you compare what astrologers actually did and what the new astronomers were doing. "The Arch-Conjuror of England" (Yale), Glyn Parry's entertaining new biography of Galileo's contemporary the English magician and astrologer John Dee, shows that Dee was, in his own odd way, an honest man and a true intellectual. He races from Prague to Paris, holding conferences with other astrologers and publishing papers, consulting with allies and insulting rivals. He wasn't a fraud. His life has all the look and sound of a fully respectable intellectual activity, rather like, one feels uneasily, the life of a string theorist today.

Comments

1. **srp**
   February 17, 2013

   Pet peeve with articles like Gopnik's: They are so caught up in the battle of Reason against Faith that they fixate on the Copernican issue (where Galileo's contribution was as much polemical as substantive) and never consider Galileo's best justification for caving in to the Inquisition: He was about to revolutionize science with his work on kinematics, and death would have prevented him.

2. **leaning tower**
   February 17, 2013

   I've climbed up the Leaning Tower of Pisa. There is a sign at the bottom which says "Please do not drop objects off of this tower."

3. **tmp**
   February 17, 2013

   Templeton has money and it can fund anything it likes. The Church of Galileo's day also had plenty of money (and power). But the Copernican system won out anyway, eventually. Galileo could see the moons of Jupiter, the phases of Venus and the shadows of mountains on the Moon. Obviously others saw these things too (eventually) . Experimental data was ultimately the key to the success of the \`new science'. So it is with string theory today: endless theorizing will neither prove nor disprove any \`world view'. But \`big science' data is expensive and hard to acquire. So Templeton and suchlike will be around for a while.

4. **lun**
   February 17, 2013

   While the LHC is down for two years, RHIC risks being definitively shut down.

   I would say this is big news, both for experimental reasons (it is the last accelerator of truly international significance remaining in the US) and for theoretical reasons (discussions of applicability of string theory to the matter RHIC produced featured quite prominently on this blog and "string wars" in general)

5. **norhic**
   February 17, 2013

   DOE wants to build FRIB (Facility for Rare Isotope Beams) at MSU = Michigan State University, also there is BNL/RHIC and JLAB/CEBAF. Both BNL ad CEBAF have been trying for years to host the EIC = electron-ion collider, a sort of mini-HERA. But DOE does not have enough money to fund all these facilities. Big science costs big money.

Organizations like Templeton can fund conferences, but I doubt Templeton could pay for RHIC operations year after year.

6. **Surendra**
February 17, 2013

Moriond = Englert Nobel Campaign. ULB Physics lead is heading the conference.
https://indico.in2p3.fr/internalPage.py?pageId=0&confId=7411

Last year the same conference leads tried to name the Boson the "BEH Boson" even as BE had no boson in their 1964 paper.
http://www.newscientist.com/article/dn21604-what-to-call-the-particle-formerly-known-as-higgs.html

Peter Higgs' campaign was January 9th – 11th in Edinburgh for Higgs Institute opening. Led by his handlers and John Ellis.
http://higgs.ph.ed.ac.uk/workshops/higgs-symposium

Tom Kibble's campaign (and to lesser extent GHK) is on March 13th at Imperial College for TK's 80th birthday. Weinberg is heading over for this.
http://plato.tp.ph.ic.ac.uk/conferences/Kibble80/index.html

7. **GB**
February 17, 2013

Doesn't anyone spare a thought for Jeffrey Goldstone for a Nobel?

8. **Surendra**
February 17, 2013

Goldstone needs a better campaign manager 🙂 MIT won't stoop to that.

However, one can't help but think his snub already occurred in 2008 as he should have won with Nambu. Of course Cabibbo should have won with K and M that year also. So the 2008 Nobel could have been a couple different prizes and split across a couple years.

Hopefully the committee gets more creative on the Higgs issue.

9. **Peter woit**
February 17, 2013

Enough hijacking of the comment section of this posting for Higgs Nobel discussion. Unless of course you have inside information about what the Nobel committee is doing about this, in which case that would be news, please share….

10. **steve newman**
February 17, 2013

speaking of the cosmology front-
there was big news last month -http://news.nationalgeographic.com/news/2013/01/130111-quasar-biggest-thing-universe-science-space-evolution/

but no one seems to be talking about it.

a mainstream group of astronomers has discovered the largest cosmological
structure ever seen. Large enough to defy the cosmological principal that the
'standard model of cosmology' is based on. They published in Monthly Notes of the Astronomical Society.

The discussion of this, so far, non existent.

11. **cormac**
February 18, 2013

Many thanks for those links Peter, I wish I had remembered Moriond in time.
Re Cambridge conference on the philosophy of cosmology, I disagree; I think it looks very interesting. I don't think DAMTP, or individuals like John Barrow and George Ellis would participate in something shoddy. Such conferences seem to me to be a worthwhile effort to consider the philosophical aspect of modern problems in physics

12. **Peter Woit**
February 18, 2013

Cormac,

I have no doubt that the DAMTP conference will discuss the multiverse at the highest level possible. But I think it's worth noting that conventional sources of funding for science typically would not fund this kind of conference, that the funding is coming from an organization which has its own agenda. That agenda is not to promote good science but to get as much attention as possible for certain kinds of pseudo-science which support their world-view.

13. **Shantanu**
February 18, 2013

Peter, this is probably OT, but what ddid you think of Arkani Hamed talk at stsci?
Thanks

14. **Henry Bolden**
February 18, 2013

Some big announcement about dark matter from Sam Ting at MIT is coming soon according to this article in the Globe and Mail (a Toronto newspaper):

http://www.theglobeandmail.com/technology/science/mit-physicists-experiment-pulls-dark-matter-into-the-spotlight/article8783097/

Anyone here know what the "big news" is supposed to be?

15. **Peter Woit**

February 18, 2013

Shantanu,

I don't think there's anything new there. For a more extended version of the same thing, see Arkani-Hamed's series of lectures at the IAS a couple years ago at

http://video.ias.edu/taxonomy/term/4

For those interested, Shantanu is referring to the talk here

https://webcast.stsci.edu/webcast/detail.xhtml?talkid=3398

16. **uair01**
February 18, 2013

Interesting to see John Dee mentioned in this context. I always felt that his experiments with angel communication and his analysis of the Enochian language somehow feel like early modern science. The endevour was based in magical thinking but the methods were revolutionary and – in their way – rational.

I like your analogue with modern string theorists. Angelic language indeed!

BTW, this is a great book on this subject:
Renaissance curiosa : John Dee's conversations with angels, Girolamo Cardano's horoscope of Christ, Johannes Trithemius and cryptography, George Dalgarno's Universal language
Shumaker, Wayne / Center for Medieval and Early Renaissance Studies / 1982

February 19, 2013

More details on Ting's press conference here. A paper is being submitted to a high energy physics journal in a couple of weeks. He doesn't yet have sufficient data to report the entire energy range AMS can pick up, in a statistically meaningful way. He may, possibly, have evidence that the spectrum is dropping off at some energy in a way consistent with a theory of dark matter. Or, possibly, he may not.

18. **chiz^2**
February 19, 2013

In other words, let's have a press conference to drum up publicity, maybe to procure more funding, maybe to establish a timestamp for later use for priority claims ~ "I told you so." But when it comes to specifics, it's just a set of vague statements. Maybe Ting has evidence of "something" maybe he does not. But let's hold a press conf anyway. Not the Ting of the J particle anymore. But I don't really blame Ting for doing this (and I don't blame string theory either). That's modern physics (or should I say fiziks?).

19. **Hamish**
February 19, 2013

Good luck with the lecture notes…you will have a hard time topping this debut by a Columbia colleague!

http://gawker.com/5985130/half+naked-ivy-league-prof-opens-quantum-physics-course-with-911-footage-hitler-puppet+smashing-ninja

20. **Peter Woit**
February 19, 2013

chiz^2,
This story is based on the AAAS conference, a huge yearly event partly designed to get the press to come hear about ongoing science research, so kind of like a huge press conference. The timing wasn't chosen by Ting. He's famous for not running a tight ship and not releasing results until absolutely certain. It's not implausible that he just wasn't quite ready this week.

21. **Kavanna**
February 19, 2013

It's nice to see that the reality of string theory is spreading further into the educated lay public. It's a terrible bust, like the post-bubble economy. Much has been squandered on researching dead-ends while ignoring serious scientific questions.

The obsession of Reason versus Faith mars a lot of the coverage of string theory and related issues. In late medieval and Renaissance times, these categories were not anywhere near as sharply distinct as they are today. Applying that kind of thinking to understanding these thinkers and their times (NOT just the theories that survived later scientific scrutiny) is completely out of place.

The irony is that string theory fits all the definitions of a faith-based pseudo-science, with a thin veneer of rationalizing with the Standard Model to make it look plausible.

OTOH, what the Templeton people are promoting seems fine. They're stimulating thought and debate, not including or excluding anyone on non-scientific criteria, and so on. (Only the question of "why is there anything at all?" lies entirely outside science.) With the rise of modern cosmology and the issues surrounding quantum measurement, which seems to require a thermodynamic selectivity — related to life and consciousness, but not requiring them — a lot of old questions included in the pre-modern Aristotelian physics — questions of intentionality and teleology — once again become legitimate scientific questions. Our answers and means of arriving at those answers will, of course, be quite different from 500 years ago.

SUSY and Quantum Mechanics

February 19, 2013
Categories: Favorite Old Posts, Uncategorized

You may have read somewhere today that Columbia professor strips down to underwear in bizarre lesson to help baffled students learn quantum mechanics (first-hand sources here and here). That wasn't me, but I have been talking to my class for the last couple weeks about quantizing fermionic variables, and some simple quantum mechanical examples of supersymmetry. Notes on the supersymmetry stuff are here, earlier notes on the fermionic version of quantization and what it has to do with Clifford algebras and spinors are on this page.

These notes are not quite finished, mainly because I've been trying to sort through the hairy issue of sign conventions that comes up when you start dealing with a Hermitian inner product on anti-commuting variables, something you need to do to get unitary representations. There's a detailed treatise on the subject by Deligne and Freed, who are very smart and sensible, but I'd like to understand this better. The choices they make end up leading to odd self-adjoint operators having eigenvalues proportional to a square root of i, which is consistent, but not exactly intuitively clear. The best source for finding details of the mathematics used in SUSY is probably the IAS volume that Deligne/Freed is part of. The first part includes valiant efforts by Bernstein, Deligne, Freed, and Morgan to get the mathematics right, including the signs (they say "Writing this has been an absolute cauchemar de signes!"). One sign they get wrong is a typo on page 91 (equation 4.4.5).

The parallel stories of bosonic and fermionic oscillators are among the deepest things in theoretical physics, and involve just spectacularly intricate and deep mathematical ideas (symplectic geometry, rotation and spin groups, Heisenberg groups, the metaplectic representation, Clifford algebras and Weyl algebras, spinors, etc., etc…). I hope the course notes I've been writing give a little insight into this and the way Lie groups, Lie algebras, and their representations are involved. Generically, "supersymmetry" refers to generalizing the notion of a Lie algebra to include odd generators, and thus get a "super" Lie algebra, sometimes acting in an interesting way that mixes even and odd variables. In the notes I describe two very simple examples, showing how one gets a "square root" of the Hamiltonian operator.

There are all sorts of interesting structures one can get by looking for supersymmetrical versions of QFT, and the IAS volume describes a lot of them. One wonderful example is the N=2 susy gauge theory that gives a TQFT with observables four-manifold invariants. This is an unphysical theory, but tantalizingly close to physical theories. It involves a "twisting" mixing the space-time and internal symmetries which might be the sort of thing needed to avoid the problem of the kind of "superpartners" that is deadly for SUSY extensions of the standard model.

Perhaps the most compelling example though is the way the fact that the Dirac operator is a square root of the Laplacian can be thought of as an example of SUSY. This is one of the deepest ideas in mathematics, something whose implications I suspect we still don't completely understand.

   February 19, 2013

   Hi Peter,

   Nice post – I'm curious to look at the notes.

   I'm confused by one of your paragraphs, though. You're right to point out the importance of SUSY gauge theories in studying interesting mathematical quantities – including the Donaldson-Thomas invariants you presumably had in mind, but also many other quantities.

   I was wondering if you could elaborate on

   "It involves a "twisting" mixing the space-time and internal symmetries which might be the sort of thing needed to avoid the problem of the kind of "superpartners" that is deadly for SUSY extensions of the standard model."

   As I see it, one can argue (as you do, but I disagree with) that the hierarchy problem is not a problem and that SUSY is not well motivated. One can also argue that we won't see superpartners at the LHC. Was this the kind of "problem" you meant? There is no theoretical problem with superpartners in BSM models, and in particular the soft masses could be at a high scale and they could completely decouple from low energy physics. There is no theoretical problem, so I'm just very curious what you had in mind!

   Moreover, whatever the problem is, how you do expect the topological twist to help with the problem?

   Thanks,
   P

2. **Peter woit**
   February 19, 2013

   P,
   The basic problem with SUSY extensions of the SM is that in them SUSY doesn't mix any degrees of freedom you know about. Instead it takes each degree of freedom you know about and mixes it with a new unobserved one (the superpartner) that you have to postulate, and then start jumping through hoops in order to make unobservable. This new "symmetry" one has introduced is trivial on the world as we know it.

   The reason I mention the Dirac operator and the N=2 TQFT case is that in these cases there is a supersymmetry, but it does something more interesting than taking bosons to fermions with spin changing by 1/2. In the Dirac operator case, the Z2 grading is that of even/odd spinors: the SUSY operator (Dirac operator itself) takes left-handed spinors to right-handed spinors and vice versa (this is just QM though, not QFT). In the N=2 TQFT case (Witten's first 1988 TQFT) the twisting basically turns this into a theory of differential forms, and the SUSY is like a deRham differential taking even to odd forms and vice-versa. Because of this though, this theory violates spin statistics and is non-physical.

   I'm certainly not claiming I have an intelligible idea of how to construct a physical QFT that avoids the standard usage of SUSY, just pointing out that there are examples of theories where it does something different than the usual problematic thing.

3. **Bob Jones**
   February 19, 2013

   "You're right to point out the importance of SUSY gauge theories in studying interesting mathematical quantities – including the Donaldson-Thomas invariants you presumably had in mind"

Did you mean to say Donaldson invariants? Donaldson-Thomas theory is really a topic in enumerative algebraic geometry rather than topology.

4. **P**
February 19, 2013

Hi Peter,

Very good! Thanks for explaining what you mean. I agree with you that this is something very important to emphasize to the outside community: SUSY is a theoretical framework that may or may not have relevance for particle physics, but like any truly deep theoretical structure it has implications for other fields. The mathematical impact of SUSY gauge theories and string is immense: from uncovering mirror symmetry, to the Donaldson-Thomas invariants you mentioned, to recent work on 3d-3d correspondence, 2d-4d correspondence, exact partition functions, and their relevance for three-manifolds, GW and GV invariants, etc. It's really amazing that QFT has anything to say about mathematics that mathematicians didn't already known, and this is certainly true of some SUSY QFT's. Also, thanks for pointing out the relevance of the deRham complex – I haven't looked at that paper in awhile.

On the other issue: since you don't like strings or BSM SUSY for the hierarchy problem, it surely seems like these new degrees of freedom are pointless. But for those of us that do, mixing known degrees of freedom with unknown degrees of freedom is the whole point. e.g. this is what allows for the non-renormalization of the Higgs mass (or any scalar mass) above the scale of supersymmetry breaking. Once one is building SUSY models BSM, the values of the soft masses are model dependent. Some models are killed; others are not. This isn't jumping through hoops, it's just the normal death that any set of models goes through as experimental bounds get better. Perhaps people start studying new models over time based on bounds, but that model was always there in theory space, regardless of whether people studied it! 🙂

Cheers,
P

5. **Peter Woit**
February 19, 2013

P and Bob Jones,

I was referring to Donaldson, not Donaldson-Thomas. Specifically Witten's 1988 paper
"Topological quantum field theory",
http://projecteuclid.org/euclid.cmp/1104161738
this paper takes N=2 susy on a four-manifold and uses the twisting trick to get a TQFT with Donaldson invariants as observables. Many mathematicians were not so impressed by this because it didn't seem to tell them anything new about Donaldson invariants. They had to eat their hats a few year later when the Seiberg-Witten paper about this same theory came along.

While mirror symmetry and QFT arguments telling one new things about algebraic geometry are all well and good, what's remarkable is that this is a simple 4d QFT with gauge fields, fermions, scalars, looking very close to the kind of theory that describes the real world. It doesn't deserve to be forgotten…

6. **P**
February 19, 2013

Certainly SUSY QFT has importance consequences for enumerative algebraic geometry, also. I'm forgot the exact context of SW theory and four-manifolds, though. It's D and not DT?

"While mirror symmetry and QFT arguments telling one new things about algebraic geometry are all well and good, what's remarkable is that this is a simple 4d QFT with gauge fields, fermions, scalars, looking very close to the kind of theory that describes the real world. It doesn't deserve to be forgotten…"

True, but remember that though N=2 theories can come close to being realistic in a certain sense that you just mentioned, the absence of chiral matter is fatal. In this sense N=1 theories have a shot, and N=2 theories do not.

Also, I read a little too quickly and though you were talking about the magnificence of the standard model for a second – another model that also doesn't deserve to be forgotten 🙂

7. **Lowell**
February 20, 2013

Gee, there is a long discussion in my book "Quantum Field Theory" Sec. 2.4 about
Fermonic variables, Grassmann numbers, and such.

Is there anything wrong with this exposition?

Lowell Brown

8. **Peter Woit**
February 20, 2013

Lowell,

Thanks for writing. Your book is on my shelf, and I've been consulting it, maybe more so this semester as I cover some QFT.

You give a very good discussion of coherent states for fermions and the fermionic path integral, but in my course I'm not covering this (for lack of time), sticking to the Hamiltonian formalism (which you don't emphasize). What I'm trying to explain is the fermionic analog of Poisson brackets, quantization, and how this quantization gives you unitary representations of the symmetry groups of the situation. In the fermionic case things the part that's not straightforward is unitarity, you have ghosts to worry about.

9. **D.R. Bocancea**
February 20, 2013

Peter,

"This new "symmetry" one has introduced is trivial on the world as we know it."
There is a name, or a paper , for this ..?

Dan

10. **Peter Woit**
February 20, 2013

D.R. Bocancea,

In SUSY extensions of the standard model, the SUSY symmetry generator act by taking known state to unknown superpartners. Restrict to the states we know, this is the zero operator, so the states are invariant.

11. **chris**
February 20, 2013

Lowell,

no, that is perfectly fine, but you might once again go over your proof of a massless particle having half-integer spin 🙂

12. **Shantanu**
February 20, 2013

Peter, something OT.
but could (or someone elsE)you help me decipher this press release
http://www.reuters.com/article/2013/02/18/us-space-higgs-idUSBRE91H0RR20130218
how is higgs boson related to fate of the universe?
Thanks

13. **Nick M.**
February 20, 2013

Hi ***Shantanu***,

You might want to check out this recently published New Scientist article, written by *supersymmetry evangelist* Lisa Grossman :), that talks precisely about this issue with many helpful links to other news articles (most notably the BBC News and NBC News) as well as having links to other original technical papers and letters. For example, see this paper published in "Physics Letters B" from this past August, which talks about the relationship between the Higgs boson and top quark masses as it relates to vacuum stability, and this letter in "Letters to Nature" from August of 1982, which talks about vacuum stability in a more general sense.

— Nick M.

14. **Peter Woit**
February 20, 2013

Shantanu,

This is based upon assuming we completely understand the effective Higgs potential at currently accessible energies and then extrapolating up to GUT energies, assuming no new relevant physics. The fact that the Higgs mass is such that the quartic term in the Higgs is getting very small at such high energies is intriguing, but I wouldn't describe any such metastability result as a reliable calculation.

15. **M Uppal**
February 20, 2013

Dr. Woit, may I ask that you please teach this class again next year? At the very least you'll have one student enrolled 🙂

16. **P**
February 21, 2013

Peter and Shantanu,

It's important to differentiate between an unstable vacuum and a metastable vacuum. The story about extrapolating up to GUT scale and the quartic coupling becoming zero would cause our vacuum to become *unstable*. This is in contrast with the possibility that there is another vacuum and we tunnel to it out of a metastable vacuum. Talk of bubble universes and the like (as here) is the later case.

In any case, Peter is absolutely right that this calculation makes huge assumptions not only about the Higgs potential and couplings, but also about the absence of other scalar fields. The latter completely changes the story, and from everything we know about cosmology and particle physics (let alone semi-speculative top-down approaches), the Higgs is almost certainly not the only scalar field in nature.

Cheers,
P

17. **Peter Woit**
February 21, 2013

M. Uppal,

I won't be teaching this next year, but anyone reading through the notes who has any questions is encouraged to come by my office, I'm usually there….

18. **Nick M.**
February 21, 2013

p>Thanks, ***Peter***, for the clarifying comment. One often gets the feeling, when reading through the calculations that are presented in these papers, that a plethora of assumptions, both explicit and tacit, are required in order for the conclusions to hold up. Indeed, from the BBC News article that I have a link to in my comment above, the caveat is "If we use all the *physics we know now*, and you do this straightforward calculation – it's bad news." If I have any further questions or comments regarding the vacuum stability issue, I will direct them to the thread that you recently just started on this topic, i.e., Higgs News.

— Nick M.

P.S.: I, too, along with ***M. Uppal***, wish you were going to offer the QM class (the one that you just taught) next semester. Unfortunately, it would be a bit of a morning walk from the Los Angeles area, where I currently live, to Columbia University in N.Y..

Higgs News

February 21, 2013
Categories: Experimental HEP News

Official announcements won't come out until the Moriond conference first week of March, but reliable rumors are starting to trickle out about what the Higgs news will be. ATLAS will report (based on about 21 fb^{-1} of 8 TeV data + the 2011 7 TeV data) that the gamma-gamma excess has gone down slightly (from 1.8 to 1.65 times the SM value). Still about 1.5 standard deviations high, but this isn't encouraging if you want something that disagrees with the SM.

At the AAAS 2013 meeting in Boston this past week, a press conference was held to update the media on the Higgs. What the media got from the press conference was the news that the Higgs may spell doom, unless supersymmetry saves us. This isn't just doom for HEP physics research, it's doom for the entire universe:

> "At some point, billions of years from now, it's all going to be wiped out…. The universe wants to be in a different state, so eventually to realise that, a little bubble of what you might think of as an alternate universe will appear somewhere, and it will spread out and destroy us," Lykken said at AAAS.

This is based on a renormalization group calculation extrapolating the Higgs effective potential to its value at energies many many orders of magnitude above LHC energies. To believe the result you have to believe that there is no new physics and we completely understand everything exactly up to scales like the GUT or Planck scale. Fan of the SM that I am, that's too much for even me to swallow as plausible.

If you are being kept awake by the Higgs metastability issue, you'll want to know the Higgs mass as accurately as possible. The rumor from ATLAS is that the difference in best fit masses between the gamma-gamma and ZZ channels has narrowed, with gamma-gamma moving up slightly to 126.8 GeV, ZZ quite a bit, to 124.3 GeV.

Comments

1. **mass**
   February 21, 2013

   Knowing the Higgs mass as accurately as possible will require a lepton collider, either e+e- ILC or a muon collider, or both. Hadron machines can do search and discovery, and they can access states which lepton colliders cannot directly produce, but high precision spectroscopy requires lepton colliders.

2. **Mitchell Porter**
   February 21, 2013

   "that's too much for even me to swallow as plausible"

   Shaposhnikov and Wetterich managed to *predict* the Higgs mass in 2009, based on the assumption of a grand desert, and some Planck-scale boundary conditions. Doesn't that count for something?

3. **Peter Woit**
   February 21, 2013

   Mitchell Porter,

   That the boundary condition of the quartic Higgs coupling going to zero gives the right Higgs mass definitely counts as at least intriguing, if not more. That doesn't though imply enough understanding of what is going on at those energy scales to believe the metastability calculation. It also doesn't imply that it's a good idea for a theorist sharing a press conference about the Higgs with two LHC experimenters to start jabbering about the annihilation of the universe, ensuring that's the story the press covers…

4. **Curlo**
   February 21, 2013

   In order to understand the significance of the new measurement, we need to know not only its central value but also its uncertainty. One would expect the uncertainty to go down with more data. How did you compute the 1.5 sigma excess you report ?

5. **ohwilleke**
   February 21, 2013

   Shaposhnikov and Wetterich are assuming asymptotic safety (i.e. subtle hypothetical new physics justified on quantum gravity grounds), which from a practical nuts and bolts perspective is just another way of saying the the running of the coupling constants and masses with energy scale is slightly different from a Standard Model beta function decrees, at many, many orders of magnitude above anything that could ever be recreated physically, based on a handful of low energy data points empirically in a model that acknowledges that it does not consider quantum gravity in any respect.

   Generically, any high energy scale tweak to one or more of the beta functions of the Standard Model is going to have the same potential to resolve the metastability issue, and given the closeness of the Standard Model result to true stability, the nudge need only be every so slight.

6. **srp**
   February 21, 2013

   I'm slightly puzzled by this stance. Normally, our host doesn't like going BSM without evidence and argues that there hasn't been any evidence turned up yet for anything BSM. Here, from what I can discern, the calculation at issue is "radically conservative" in the sense that it takes the SM as gospel truth and extrapolates it as far as possible. That sounds like exactly the sort of exercise you'd want to do with a theory you were pretty confident about. I mean, extending quantum mechanics to black holes is a pretty big reach beyond existing data, but that activity doesn't seem to have gotten similar flak around here, presumably because people are very confident about QM. What am I missing?

7. **Peter Woit**
   February 21, 2013

   Curlo,

   The uncertainty has gone down, but so has the deviation from the SM value. At least that's the rumor….

8. **P**
February 22, 2013

Peter,

Any word on the ATLAS "Twin Peaks"?

Thanks for the updates.

Excited for Moriond,
P

9. **Peter Woit**
February 22, 2013

P,

See the last paragraph of the posting…

10. **Pi**
February 22, 2013

Dear Peter,
You said you'd write about the new Arkani-Hamed et al paper on supersymmetry. I hope you haven't forgotten.
Thanks a lot for your updates.

Best,
Pi

11. **Thomas Larsson**
February 22, 2013

If gamma-gamma excess has gone down from 1.8 to 1.65 times the SM value, it means that the excess in the new data set is considerably lower, right? Isn't that what you would except from a statistical fluke?

12. **MathPhys**
February 22, 2013

Pi, Nima doesn't have a new paper on supersymmetry, does he? Or do you many the paper with many other people on the Grassmannian in scattering amplitudes?

13. **Pi**
February 22, 2013

MathPhys,
Here it is: http://arxiv.org/abs/arXiv:1212.6971
Simply Unnatural Supersymmetry.
Meanwhile, you might find this interesting: https://twitter.com/grahamfarmelo/status/304313270511214592

14. **Paolo**
February 24, 2013

Peter,

do the rumors imply that the option that the Higgs was just a statistical fluke is gone forever? After all, the bump is very small compared to the background. My colleagues say, behind closed doors, that even if the Higgs were a statistical fluke, human nature would prevent from admitting it. This is because of the French and Italian concept of "honour", they say.

But is the data strong enough now for a Nobel prize? Until now, the number of events was extremely small, and there easily could be some selection bias. You once mentioned in your blog that "half of ATLAS was sleeping with half of CMS"…

15. **Yatima**
February 24, 2013

> This is because of the French and Italian concept of "honour", they say.

What!

1) This is not a collaboration by French and Italian research groups only.
2) We are not talking about Imperial Japan, Prussia Gone Bad or US politicians. We are talking about responsible people able and willing to check their ideas and data against an actually existing oracle over long timescales.
3) The fact that the FTL neutrino results were thoroughly verified and ultimately retracted empirically proves this bizarro idea wrong.

16. **Peter Woit**
February 24, 2013

Paolo,

The evidence for the Higgs is overwhelming. There are large, well-defined peaks undeniably visible in two different channels, at the two different experiments. Any one of these four peaks would be quite convincing evidence that something is there, seeing four independent ones at close to the same mass removes any possible doubt. It may have even gotten to the point that the experiments will stop reporting combined statistical significance numbers for their Higgs results, since the number would be something large and uninteresting.

As Yatima points out, whatever the problem caused by the honorable French and Italians, there are plenty of dishonorable Americans and others to make up for it. As for confirmation bias and bed partners, the phenomenon of people taking delight in the prospect of proving that their nearest and dearest is wrong, and they are right, is not exactly unknown….

The State of SUSY

February 27, 2013
Categories: Uncategorized

Results putting new limits on SUSY based on the entire first run of the LHC are starting to emerge (see for example this from CMS) with more likely at Moriond next week. Since one is dealing with a theory with a large number of parameters, these are hard to characterize in a simple way. One thing to focus on is the limits on gluinos, since just about every popular version of SUSY says these should be about the easiest thing for the LHC to see. Very roughly, the Tevatron was able to set typical limits of about 300 GeV on such things, and the LHC at 8 TeV (4 times the Tevatron) is now giving limits around 4 times higher, 1.2 TeV. This is not likely to change much for the next few years until after the LHC comes back at 13 TeV in 2015. One can with some confidence predict that the gluino mass limit will then go up to about (13/8)*1.2 TeV or around 2 TeV, maybe a bit more in years after that with a high-luminosity LHC. Farther out in time, the next machine under discussion that could raise the limit is the HE-LHC, at 32 TeV, giving limits around 5 TeV. The time scale for this though is something like 2030-40, even assuming such a project ever were to get funded. I suspect the right characterization of that project might be "not in my lifetime".

There is a new paper out claiming to see evidence of a gluino in the data around 1000-1100 GeV. The same authors (see here), have been claiming to see such gluinos since the early LHC data, first at around 7-800 GeV, with a mass getting higher with each round of new data and higher mass limits.

Few are likely to pay attention to this, but what is getting taken much more seriously is the case that Nima Arkani-Hamed has been vigorously making recently (see for example his talk at the Higgs Symposium). Arkani-Hamed is now by far the most influential theorist in this area, with slides from his latest talks often appearing in many other people's presentations, functioning as the embodiment of the conventional wisdom of the field. He also is the only phenomenologist with a $3 million Fundamental Physics prize, awarded for his work on models that have had great influence, although zero success experimentally.

One of these, split supersymmetry, is what he is now promoting as the explanation for the negative LHC results. In this model, which he developed with Savas Dimopoulos back in 2004, the main argument for SUSY, the hierarchy argument, gets abandoned in favor of anthropics. The Higgs mass and the electroweak scale are what they are not because of SUSY, but because otherwise physics would be different and we wouldn't be here. Once one abandons the hierarchy argument, the remaining arguments for SUSY are extremely weak (I'll try and explain these in more detail in a separate posting), but for some reason Arkani-Hamed still thinks the idea is worth promoting and that vindication for his $3 million may yet be had.

Split SUSY works by moving all scalar superpartners up to unobservably high energies, but a few particles including the gluino are supposed to be at potentially observable masses. Back in 2004, Arkani-Hamed and Dimopoulos were hopeful about the possibilities for the LHC seeing a split SUSY gluino, writing:

> However, at peak luminosity of 30 fb^{-1} per year, the LHC may well be a gluino factory producing roughly a gluino per second(for m_g ~ 300 GeV).

These hopes have now been dashed, and at the Higgs symposium talk, illustrative spectra show gluino masses at 2.1 and 2.3 TeV (this may just be because that's about the limit of what the LHC could see). Arkani-Hamed and co-authors have a recent paper out discussing Simply Unnatural Supersymmetry, i.e. "the simplest picture of the the world arising from fine-tuned supersymmetric theories". Here calculations are done for gluino masses ranging from 1.5 to 15 TeV, and the story is that we'll have to be lucky to get any experimental evidence for this model. They end with:

> If Nature has indeed chosen the path of un-natural simplicity, we will have to hope that she will be kind enough to let us discover this by giving us a spectrum with electroweak-inos lighter than ~ 300 GeV or gluinos lighter than ~ 3 TeV.

So, the current state of the conventional wisdom about SUSY from its most influential proponent is pretty much the following. It's still the thing to try and sell to the public as the best bet for the future of physics, but the hierarchy argument is gone, and at a fundamental level it's anthropics, the landscape and the multiverse. He's pretty much given up hope of ever getting any experimental evidence for this, other than the outside possibility of maybe the gluino mass being just low enough to be visible in rare LHC events late in the decade.

The interesting question about all this I think is a sociological one: will this untestable and rather ugly theory based on anthropic reasoning become widely seen as the "best hope" for fundamental particle theory? In a post-LHC world where mankind has abandoned the high-energy frontier, will the conventional wisdom of the textbooks be that SUSY and those gluinos must be there, but unfortunately happen to be just out of reach?

Update: For a survey article that just came out this evening, which tries to show that the main argument for SUSY (the hierarchy problem) is not quite dead yet, see here.

Update: New Scientist has a special section this week about "Crunch time for physics" (unfortunately mostly behind a paywall). On SUSY, Frank Wilczek is still a believer, based on the renormalization group calculation he was a co-author of back in 1981. If no SUSY turns up at the next LHC run though, even he will throw in the towel:

> I cannot believe this success is an accident. But in science faith is a means, not an end. Supersymmetry predicts new particles, with characteristic properties, that will come into view as the LHC operates at higher energy and intensity. The theory will soon undergo a trial by fire. It will yield gold – or go up in smoke.

He has a bet with Garrett Lisi that superparticles will be detected by July 8, 2015.

Comments

1. **Pi**
   February 27, 2013

   Peter,
   Many thanks for posting this.
   I don't think, if SUSY doesn't show up at the LHC, physicist can easily persuade governments to build another gigantic collider. 2030-2040 is too optimistic I think.
   So what will HEP theorists do 1)if SUSY doesn't show up 2) in the meantime for another collider?

2. **Mitchell Porter**
   February 27, 2013

   The structure and the parameters of the standard model will still need explaining. And if anyone ever manages to hit on the right explanation, presumably it will predict the next decimal place in the parameters. So experiment won't be completely dead, even if there's nothing beyond the Higgs.

3. **John**
   February 27, 2013

   HEP theorists will be fine. Maybe you're wondering about phenomenologists? They'll just keep doing what they've been doing for the past decade or so, up to and including the LHC period. Invent various random scenarios of zero value. The only thing the LHC did was confirm what we already pretty much knew. Actually it did two things. It also artificially boosted the number of pheno hires, for a "just in case something shows up we need many monkeys to figure it out" scenario.

Since the LHC taught us nothing new, I'm not sure why we should be so eager to build yet another one. There's plenty of other stuff do anyway. Also things like dark matter detectors are much cheaper and there are actually better motivations behind those. We actually expect dark matter, which we know nothing about. We aren't however expecting anything at the LHC, it's all just "spray and pray".

4. **M. Wang**
February 28, 2013

It had been known since before the Great Depression that, in aggregate, stock analysts' predictions produce negative risk-adjusted returns, but thousands of people still make it a living to this day, some being paid 7-digit salaries. It is even considered a serious offense to discuss their track records in industry gatherings.

By the 1990's, solid statistics had proven beyond doubts that mutual fund managers as a whole added negative values after fees, but the industry continued to grow. It now manages assets well in excess of the US GDP.

As of last month, the latest statistics on hedge funds also showed a negative overall return after fees in aggregate. Yet, your university may have to cut hiring further next year because its endowment fund loses a few more billions in various hedge funds.

The point of my long-winded examples is that, in a complex society, there is plenty of room for BS-artists to prosper as a group or even industry. My bet is that the likes of Brian Greene and Lisa Randall will continue to sell plenty of books, be invited to guest-star in TV shows and give inspirational speeches to young students in science. Of course, the dark matter may come to rescue HEP from ignominious heat death, but what if it doesn't? Is there any reason why dark matter has to be WIMP? Does a WIMP have to have a signal measurable within the next 20 years? What if nothing shows up?

5. **Umesh**
February 28, 2013

Why do you have to keep trashing genuine attempts at explaining nature in a rather negative and totally un-constructive fashion?

6. **Shantanu**
February 28, 2013

Peter (or others), is there any current serious attempt to link SUSY models to neutrino masses/mixings etc? Way back in 1998 when first non-0 evidence for neutrino mass was found, P. Ramond claimed its evidence for low energy SUSY.

7. **Yatima**
February 28, 2013

@John

"The only thing the LHC did was confirm what we already pretty much knew."

Woah I must have missed that part. It's good to know that we already "pretty much know" everything without even looking for it. Maybe your excellency will just spell out what else we already know and don't actually need to check?

8. **Thomas Larsson**
February 28, 2013

Theorem [Larsson 2007]
Supersymmetry will not be discovered at the LHC.

Proof: String theory predicts supersymmetry (Witten 1984-2002). String theory predictions are always wrong. Hence supersymmetry does not exist, and will in particular not be found at the LHC. QED.

Corollary
Lubos Motl will lose his experimental-susy-by-2006 bet.

9. **Tmark48**
February 28, 2013

Oh boy oh boy, from hierarchy to anthropic justifications.
SUSY is going from bad to worse. Unbelievable, simply unbelievable.

10. **Eric**
February 28, 2013

Actually, it's very possible that supersymmetry solves the hierarchy problem with an acceptable amount of fine-tuning even if the gluino, sleptons, and squarks all have multi-TeV masses, and consquently cannot be observed at the LHC. In the context of minimal supergravity, there is a region of parameter space on the hyperbolic branch called the focus point. Spectra which lie on the focus point have low fine-tuning which is fairly insensitive to the scalar masses. For these spectra, it is easy to have the correct Higgs mass and a dark matter relic density which satisfies the WMAP limits. Since the scalar masses for these spectra are heavy it may not be possible to observe them at the LHC. However, the direct dark matter detection cross sections are within reach, so this is where supersymmetry may be found even if there is no chance of finding it at the LHC. A linear collider should be able to study the neutralinos and charginos for these spectra. I would suggest reading the review article of Jonathan Feng which is out on hep-ph today rather than misrepresenting the situation.

11. **Peter Woit**
February 28, 2013

Eric,

I did link to the Feng article and encourage people to read it who want to see the state of attempts to find still viable "natural" SUSY models. Arkani-Hamed makes it clear that he now sees these things as too complicated and contrived to be plausible, which is why he's promoting the idea that split SUSY is the best hope. You should argue the with him the question of whether "focus-point" models are plausible, he's not even mentioning them as worth discussing…

12. **Noah Smith**

February 28, 2013

So my question is…What's up with Arkani-Hamed? Does he really believe the stuff he's selling here, or is he just trying to stay in business for another decade?

13. **Peter Woit**
February 28, 2013

Noah Smith,

The interesting thing about Arkani-Hamed is that for quite a few years now, most of his research work has been in a completely different direction than BSM physics like SUSY. Instead he's studying new ideas for a very different formalism for computing scattering amplitudes (the"positive Grassmanian") and hopefully reformulating QFT in a dramatic way. His talks about BSM SUSY tend to focus on the issue of "What are the only remaining conceivable forms of SUSY that are viable?", not on whether BSM SUSY is a good idea or not.

Why he (and a lot of other prominent theorists, at the IAS and elsewhere) have decided to keep promoting this as it becomes an ever more obvious failure is a good question, with the only answer I see that they feel that they and some of their colleagues have a lot invested in it. My impression is that most theorists have long ago given up on BSM SUSY as hopeless (see for instance the HEP phenomenologist bloggers like Jester and Matt Strassler). Why it continues to get so much positive attention is somewhat of a mystery. Arkani-Hamed would do the field a huge service if the next time he were asked to discuss SUSY and BSM physics he were to give a talk explaining why it's no longer a plausible idea, and instead start promoting fundamental mathematical physics work of the sort he's now himself doing.

14. **King Ray**
February 28, 2013

If you read Thomas Kuhn's The Structure of Scientific Revolutions, you will recognize that we are in a stale period between paradigms. The SUSY/String Theory paradigm has not panned out after nearly 40 years of effort.
I believe that if you have a theory, you should either be able to test it experimentally, e.g., the bending of light predicted by General Relativity, or have it be able to explain a previously unexplained fact or phenomenon, e.g., the precession of the perihelion of Mercury. Otherwise you are not using the scientific method (where you test your theories), and you are going to be led astray by false aestheticisms. I heard that Feynman suggested that if superstring theory were the theory of everything, why couldn't string theorists predict the mass of the electron?

15. **Eric**
February 28, 2013

Peter,
Arkani-Hamed hardly represents the majority view of phenomenologist who work on supersymmetric models. His is actually a fairly extreme position which you are using as a straw-man. The bottom line from my own analysis is that the superpartners can easily have masses greater than 5 TeV and the hierarchy problem can still be solved with only minor fine-tuning. If you were more of a scientist and less of a propagandist, you would know this. At any rate, pay attention to the next update from the dark matter direct detection experiments.

16. **Peter Woit**
February 28, 2013

OK Eric, interesting to hear that the majority of phenomenologists see Arkani-Hamed as an extremist (and a propagandist too I guess since you're characterizing me that way when I'm just quoting him..). Also interesting to hear that SUSY proponents are now looking for vindication from dark matter direct detection, not the LHC.

King Ray,

I agree that what we're seeing is the collapse of a paradigm. The problem is that the new paradigm being heavily sold is multiverse mania. Not a pretty situation. Interestingly, string theory has kind of dropped off the map as irrelevant, since it says zero about anything testable, at the LHC or elsewhere (and that's the problem, that it predicts nothing at all, not that it doesn't predict the electron mass).

17. **Shantanu**
February 28, 2013

Eric,
To turn it around, if dark matter experiments see nothing, would you be willing to change your opinion and agree that SUSY is dead?
Shantanu

18. **Bob Jones**
February 28, 2013

"He also is the only phenomenologist with a $3 million Fundamental Physics prize, awarded for his work on models that have had great influence, although zero success experimentally."

The prize was also awarded for his very interesting work on scattering amplitudes.

"string theory has kind of dropped off the map as irrelevant"

This statement is just delusional. If you look at the new hep-th submissions on arXiv, you will see that about half the articles are string theory articles. As long as string theorists are coming up with interesting results, string theory is not going to go away.

19. **Bob**
February 28, 2013

Breaking news: phenomenologist gives talk about particle physics at particle conference! Woit misunderstands phenomenologist and gives a rant about the end of physics.

20. **King Ray**
February 28, 2013

Bob,

"hep-th submissions on arXiv"? How about "confirmed predictions at the LHC"?

21. **Anonymous**

February 28, 2013

@King Ray

The idea is that SUSY does (or at least, did) explain a previously unexplained phenomenon, namely the unnaturally low electroweak scale, in a very plausible way. Nowadays, criticisms of SUSY are that its explanation has become inconsistent with data, or at least that the continuing interest in SUSY is not reflecting the present absence of direct detection when in the most plausible models we should have seen something already.

22. **Mitchell Porter**
February 28, 2013

The conventional reasons for believing in supersymmetry, known to me, are hierarchy problem, gauge coupling unification, dark matter, and (for theorists) string theory.

But you don't need the full supersymmetric spectrum to obtain dark matter or gauge coupling unification. So if anthropic finetuning were to become the new paradigm for explaining the Higgs mass, presumably that would weaken supersymmetry's popularity in the long term. It could end up being regarded as a Planck-scale phenomenon only.

23. **Bob**
February 28, 2013

This is wrong. The only indication we ever had that susy is right is its prediction of gauge coupling unification. This fact has not been undone by the current data, no matter how much ppl might kick and scream about it. Let's also remember that every other proposal for new physics at the weak scale is clearly dead. Susy is the only remaining idea that hasn't been totally killed yet, though low energy susy is a bit injured, while high energy susy is still fine.

24. **Bob Jones**
February 28, 2013

King Ray,

Most of the string theory articles submitted to arXiv are about applications of the AdS/CFT correspondence, and while they do not make BSM predictions, some of them do make contact with experimentally testable phenomena in nuclear and condensed matter physics.

So far, the only prediction of new physics which has been confirmed at the LHC was the prediction of the Higgs boson. Besides Higgs et al, nobody has made a successful prediction, so I don't think it makes sense to criticize string theory specifically for not making LHC predictions.

25. **Peter Woit**
February 28, 2013

Bob Jones,

It's not "his" work on scattering amplitudes, he's only one of quite a few people who have worked on this. If there was going to be a $3 million award for advances in scattering amplitudes, it would be going to other people.

The reference to string theory "dropping off the map" was about BSM physics and the LHC. I think the consensus is now quite clear that string theory is irrelevant to the LHC, as well as any other conceivable experiment. You virtually never anymore see what used to be the usual nonsense in the press about "predictions of string theory", as string theorists have mostly given up putting out such press releases.

"Bob",
Perhaps you could consider explaining just what it is that I don't understand here.

"The only indication we ever had that susy is right is its prediction of gauge coupling unification."

So, that whole hierarchy thing, no one ever really meant those arguments for susy? And the WIMP miracle, that's not serious either? The only argument for SUSY is that if you believe in a desert up to the LHC, and you believe in GUTs (for which there is zero evidence) then you get a number coming out right to 10-20%? That's all that SUSY has ever had going for it? Wow…

26. **onymous**
February 28, 2013

I'll probably regret wading into physics blog comments again, but:

I thought the idea that the focus point scenario can lead to low fine-tuning even with multi-TeV scalars had been unceremoniously buried many years ago. It seems to require a really odd set of assumptions to be believed (for instance, you're allowed to ask how sensitive the theory is to varying a universal scalar mass, but not to varying the top Yukawa or varying scalar masses in a nonuniversal way). I'm not really sure why it's being resurrected. If you really think you understand the set of top-down theories that could be realized in nature well enough to make this argument, more power to you, but the argument is often repeated without all the necessary caveats.

It's my belief that all models of natural SUSY suck. (I worked on one myself, and it sucks too.) Direct SUSY limits are mildly troubling, but the elephant in the room is the Higgs mass, which just obliterated almost all sensible models of natural SUSY. The contortions people go through to save a bit of fine-tuning just seem absurd to me. Complicating your theory to save fine-tuning isn't really winning. I think it is important and interesting that the LHC rule out these scenarios, but none of them are remotely plausible. Maybe if you posit compositeness right around the corner or something extreme like that you can find some room to live, but it seems unlikely that Nature is that kind of Rube Goldberg machine.

It's a really, really unpopular opinion in the hep-ph community, but I think what Nima says is exactly right: the only plausible-looking incarnation of SUSY we have left is the "semi-split" scenario with scalars at 100 or 1000 TeV. It's still a hell of a lot more natural than the Standard Model alone, and it gives gauge coupling unification, so I wouldn't bet against it. This is not your grand-advisor's SUSY scenario, though, and the community should be more honest about that.

The Opera neutrino anomaly basically wiped out any illusions I had left that the hep-ph community as a whole was serious and intellectually honest.

27. **Bob Jones**
March 1, 2013

"It's not 'his' work on scattering amplitudes"

No, it's certainly not his exclusively, but he has played a leading role in recent work on scattering amplitudes, and this is acknowledged in the prize citation.

"You virtually never anymore see what used to be the usual nonsense in the press about 'predictions of string theory'"

Yeah, but press releases are not an accurate indicator of what's happening in a field. The fact that journalists are not talking about "predictions of string theory" does not mean that string theory dropped off the map. String theory is still a very important direction in current research, and regarding LHC predictions, the situation for string theory has not changed recently.

28. **chris**
March 1, 2013

i would pity the poor susy phenomenologists for the miserable state they are in: having to defend an obviously obsolete theory. i would pity them had they not all the best-paying and most prestigeous faculty positions.

for the greater good of physics one can only hope that their failure will at one point be publicly recognized as complete and they will be ridiculed out of their preposterous ideas. i fear that nothing else will stop this madness.

29. **Anonyrat**
March 1, 2013

So Arkani-Hamed won $3 million for work done in the last two years? That is the conclusion it seems one must draw if one looks at the top-cites for 2010:
http://www.slac.stanford.edu/spires/topcites/2010/annual.shtml

(I can't find a more recent topcites.)

30. **prepo**
March 1, 2013

Sir Joseph Larmor is remembered today for Larmor precession and his formula for the radiation by a nonrelativistic accelerating charge, yet in his day his most famous work was his Adams Prize essay "Aether and Matter". You can still buy it of you wish
http://www.amazon.com/Aether-matter-Joseph-Larmor/dp/B00385WM14

Larmor was appointed to the Lucasian chair of mathematics. He retired in 1932 and was succeeded by Dirac. Nobody laughed Larmor out of his preposterous ideas.

31. **Anonyrat**
March 1, 2013

Ah, here is the INSPIRES 2011 annual list:
http://inspirehep.net/info/hep/stats/topcites/2011/annual.html
and the 2011 all-time list:
http://inspirehep.net/info/hep/stats/topcites/2011/alltime.html

Still no indication.

32. **Anonyrat**
March 1, 2013

Larmor's 1900 essay "Aether and Matter" is available online here:
http://archive.org/details/aetherandmatter01larmgoog

Wiki says:
".Larmor opposed Albert Einstein's theory of relativity (though he supported it for a short time). Larmor rejected both the curvature of space and the special theory of relativity, to the extent that he claimed that an absolute time was essential to astronomy (Larmor 1924, 1927)."

So I guess prepo's point is borne out.

33. **Peter Woit**
March 1, 2013

Anonyrat,

Arkani- Hamed's http://arxiv.org/abs/hep-ph/9803315 (with Dimopoulos) has about 4500 citations, making it one of the most influential and heavily cited HEP papers of all time. On the all-time top-cites list you give, it is number 7, led only by Weinberg's 67 paper, Kobayashi-Maskawa since everyone doing flavor physics quotes that, the 3 early papers on AdS/CFT that everyone quotes, and Randall-Sundrum. It's the first thing mentioned in his Milner prize citation. The other remarkable thing about it is that no one ever seriously believed this kind of model was plausible, and LHC results quickly ruled it out at accessible energies. I suppose you could claim that maybe it will show up at higher energies, but I don't know of anyone who would bet on that, even given very advantageous odds.

All IAS HEP professors got Milner prizes, and Arkani-Hamed got his IAS professorship around the time he started working on amplitudes. Put differently, if he had never worked on amplitudes, he'd still be an IAS professor, and surely also a Milner prize winner…

34. **Anonyrat**
March 1, 2013

Thanks for clearing that up. I thought Bob Jones has written that Arkani-Hamed's $3 million prize was for his work on scattering amplitudes, and since A-H's most cited paper was on extra dimensions, and none of his scattering amplitude work upto 2011 was cited any where close to that, I was quite puzzled.

35. **Thomas Larsson**
March 1, 2013

Regarding Wilczek, recall what he wrote in his Future Summary back in 2001 (p 20):

"5.5. Produce the New Particles!
Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, **there must be several accessible to the LHC**"

36. **new particles**

March 1, 2013

Let's not get carried away about the failure of new particles to appear at LHC energies. With all of the euphoria of the success of QED renormalization in the post-WW2 years, *nobody* predicted the appearance of the V-particles (later called strange particles). In later years, after the discovery of charm, *nobody* said there would be a third generation of quarks, and there would be a new family of narrow resonances at approx 10 GeV. By 1975 the Standard Model was in place, but the Upsilon was discovered in 1977. The SM didn't predict the (b,t) generation. Although once the b was found, the top was immediately claimed to exist, but no theorist could quantify its mass. Gordy Kane's calculation notwithstanding, no theorist (from 1960s to 2000s) could quantify the mass of the Higgs either. There isn't really any quantitative non-SUSY (or non-string) prediction of what the next generation of BSM particles will be, nor what their mass scale will be. (I suppose there is the axion …)

37. **Philip Gibbs**
March 1, 2013

new particles, the third generation was predicted in 1973 by Makoto Kobayashi and Toshihide Maskawa to account for observed CP violations. I think you are right that nobody predicted strangeness though, or even muons.

38. **Philip Gibbs**
March 1, 2013

New Scientist also has a quick interview with Milner this week.

39. **new particles**
March 1, 2013

Aha. The appearance of the Upsilon at approx 10 GeV was a surprise, though. Nobody knew the mass scale of the third generation quarks. This was very clearly demonstrated by the top quark. Once the b was found, nobody doubted the t would exist. But nobody had the faintest idea of its mass. A whole string of machines (PEP, PETRA, TRISTAN, LEP … others?) all failed to produce the top. Eventually the Tevatron did, but there was no *a priori* proof that the design energy of the Tevatron (as a collider) would be sufficient to produce the top. As for the muon, that is a classic. It took many years to demonstrate that the muon was NOT the Yukawa particle, and to find that there were in fact two particles, the pion and the muon. And as Isidor Rabi famously said, when the muon was recognized to be a lepton, "Who ordered that?" Nobody expected a heavier version of the electron to exist.

SUSY may be getting more and more constrained in parameter space, but for the most part nobody has ever had any really good idea of the mass scale and properties of the next generation of particles.

40. **Mitchell Porter**
March 1, 2013

"new particles" said

"Gordy Kane's calculation notwithstanding, no theorist (from 1960s to 2000s) could quantify the mass of the Higgs either"

Shaposhnikov and Wetterich obtained it http://arxiv.org/abs/0912.0208 … by assuming a desert between the weak scale and the Planck scale, and by assuming that the Higgs quartic coupling goes to zero at the Planck scale.

Also, to be fair, Dharwadker and Khachatryan http://arxiv.org/abs/0912.5189 managed to predict it … in a crackpot paper which issued in the formula "Higgs mass equals half the sum of W+, W-, and Z masses".

41. **new particles**
March 1, 2013

Good! So tell us all the mass of the nearest BSM particles, and their symmetries and interactions! There's no need to post items about the lack of observation of SUSY!

42. **Pi**
March 2, 2013

Is there any chance that the LHC tell us at least if there's such thing as unnatural SUSY that Arkani-Hmaed et al are talking about?

43. **Peter Woit**
March 2, 2013

Pi,

According to the authors of the paper whose final part I quoted, the answer is "only if we're lucky".

44. **Cliff**
March 2, 2013

"Once one abandons the hierarchy argument, the remaining arguments for SUSY are extremely weak"

Thats simply not true. Naturalness is a *rough* guide to finding the correct description, but it is *not* an inconsistency! By contrast, any of your attempts to describe the quantum field theory together with general relativity without using SUSY go 'Glub, glub, glub' right to the bottom of the sea. There is just no way to argue that the aesthetic criterion of naturalness (as useful as it may be in many cases) is more important that mathematical consistency.

From what I understand about F-SU(5), it is confined to a distinct window of parameter space and can be definitively ruled out at the LHC. I think its pretty awesome that a totally falsifiable model is putting forward explanations for the vacuum energy problem and other things. It looks kind of unfair to me that you've reduced it to a cheap punchline that supports your own eternally pessimistic viewpoint. The F-SU(5) explanation for why most SUSY searches have come up empty seems worth taking seriously: the cuts on missing transverse energy are too high, and the production of superpartners may be very soft.

Decrying the "conventional wisdom" of using supersymmetry as a fundamental principle for unification isn't actually going to help advance the field in any way. Especially as long as SUSY remains the only mathematically viable principle to put the 'big picture' together. But if SUSY turns out not to be a feature of the low-energy world, that may be that. As you've implied, there may unfortunately be an end to what we can see. That's not some grand crisis, that would just be life. But I remain somewhat more optimistic at this point.

45. **Peter Woit**
March 2, 2013

Cliff,

I don't think it's me who has reduced F-SU(5) to a "cheap punchline", but rather those who think it is a good idea to put out a new paper every few months about their latest "predictions" and how they are seeing (or smelling…) evidence for this theory in the data, just to have this conclusively falsified days or weeks later by new data (leading to another paper…). Maybe in 2016 or so these authors will stop smelling things and write a paper acknowledging that the idea is wrong. I'll believe that when I see it.

As for a "grand crisis" caused by failure to find SUSY, my point of view is rather that not finding SUSY at the LHC might finally start causing people to give up on a bad idea (SUSY extensions of the SM like the MSSM) and working on something more promising. So, not a "grand crisis", but an opportunity, one that some prominent theorists are digging in their heels trying to stop from arriving.

46. **Garrett**
March 2, 2013

The gauge coupling unification result from SUSY is impressive, but this can happen more economically by just adding a handfull of Higgs multiplets.

47. **King Ray**
March 2, 2013

Mitchell,

Thanks for the link to the Shaposhnikov and Wetterich paper. In their closing statements they say

"Detecting the Higgs scalar with mass around 126 GeV at the LHC could give a strong hint for the absence of new physics influencing the running of the SM couplings between the Fermi and Planck/unification scales."

This is very interesting, and may not bode well for BSM physics. It is intriguing that a prediction of the Higgs mass might arise from SM and gravitational considerations. It will be curious to see how well their prediction matches the final Higgs mass.

48. **Bob**
March 3, 2013

" . . . my point of view is rather that not finding SUSY at the LHC might finally start causing people to give up on a bad idea (SUSY extensions of the SM like the MSSM) and working on something more promising."

What looks more promising these days?

49. **Toni**
March 3, 2013

The susy experts all speak and dream of coupling constant unification. But there is no good reason why these should unify. This is a wish, a hope, a dream. Grand unification, even as an approximation has no basis. As long as we suspect that the dream is true, we will not get susy in the waste basket – where it belongs.

50. **Peter Woit**
March 3, 2013

Bob,

Pretty much anything. Arkani-Hamed himself is working on amplitudes. There's a huge amount about the non-perturbative behavior of quantum field theories that we don't understand.

No, there isn't some obviously better idea about BSM physics that everyone should work on instead of SUSY. But if people can't think of something more worthwhile to spend their time on than a failed idea that has already received a huge amount of attention, maybe they should be in a different business.

51. **Toni**
March 3, 2013

Bob,

the most promising would be an idea that keeps the standard model intact and just explains its parameters. Such an idea would have the advantage to agree with experiments. Alas, the idea itself is still hidden in the clouds.

52. **Cliff**
March 3, 2013

Peter: About F-SU(5), I don't understand why it matters if they write a paper in 2016 saying they were wrong. Nobody has to bother reading what they see or smell in the data because they predict that new particles will be discovered by the LHC! Again I just fail to see what is so terrible about them describing that the best fit for some superpartner mass has increased. They've just released a new paper because there are new searches that will soon be published that they want to compare their model to. You seem certain that they are behaving dishonestly but you don't seem to want to make that case based on any actual details of their claims.

My bigger beef is that you're conflating SUSY as a high-energy principle with SUSY as a feature of sub-TeV scale physics. Obviously it would have been nice if these two things went together, but there is no justification at all for saying the absence of SUSY at a scale of 1 TeV implies that its not a useful (or necessary) principle for high energies.

The best ideas for what lies beyond the next bend haven't actually changed much. Its obviously understandable why that fact is frustrating, but that seems like the inevitable implication of the logic here. Ingenius and totally unexpected insights are welcome of course, but until/unless they get here, not much has changed.

53. **Peter Woit**
March 3, 2013

Cliff,

I don't believe the F-SU(5) people are dishonest, but assume that they actually believe that SUSY will appear in the next release of data. However, if you keep publishing papers with such claims that don't have much to back them up, and always turn out to be wrong, at some point your credibility goes to zero, which I think is the case for them right now.

That SUSY was supposed to explain the hierarchy problem, and so appear before 1 TeV, was probably its most heavily advertised feature and best argument for paying attention to it. The failure of this seems to me worth noting and has major implications for the whole idea. Post that failure you can try and claim that SUSY is a wonderful idea, that adding huge numbers of unseen degrees of freedom with huge numbers of new parameters, in a way that explains nothing about observable physics, is something that people should take seriously as our best idea about how to move forward in fundamental physics. I don't think though that many people are ever going to buy this.

54. **dark**
March 4, 2013

"No, there isn't some obviously better idea about BSM physics that everyone should work on instead of SUSY. But if people can't think of something more worthwhile to spend their time on than a failed idea that has already received a huge amount of attention, maybe they should be in a different business."

PW How would a discovery of dark matter in the coming years from various research groups affect your scientific judgment on the plausibility of SUSY?

(and for SUSY advocates like Eric, how would the failure to detect DM in increasingly sensitive and sophistic experiments affect SUSY)

55. **Eric**
March 4, 2013

Dark,

The bottom line is this: There is a good chance that the scalar quarks and leptons are too heavy to produce a signal at the LHC. However, even in this case supersymmetry can still solve the gauge hierarchy problem. Furthermore, it can do so without requiring much fine-tuning (the little hierarchy problem) for certain regions of the parameter space. Most of the superpartner spectra which fall into this category produce a relic neutralino density which is at or below the WMAP constraint. In addition, the proton-neutralino cross sections for direct detection are just at the point where they are within reach of experiment. Thus, it is quite possible that dark matter will be discovered in the near future and this would lend additional support for supersymmetry, even if no signal is seen at the LHC. On the other hand, if dark matter is not directly detected, there is always the possibility of R-parity violation or simply that the neutralino only provides a small fraction of the dark matter density.

56. **dark**
March 4, 2013

Eric
thanks for the reply. I understand that not finding SUSY at LHC can be explained away, and "R-parity violation or simply that the neutralino only provides a small fraction of the dark matter density"

what if they don't find any dark matter – neutralino – or otherwise, at all?

57. **chris**
March 5, 2013

Thus, it is quite possible that [*next big experiment will measure something*] in the near future and this would lend additional support for supersymmetry, even if no signal is seen at [*last big experiment that failed to produce anything about SUSY*]. On the other hand, if [* next big experiment will give no signal*], there is always the possibility of [* next level of complication moves SUSY out of reach once more *].

58. **punter**
March 5, 2013

Most of that New Scientist section is accessible through free registration for the next ten days.

59. **Kavanna**
March 18, 2013

There is a strong, general argument for SUSY, based on the Coleman-Mandula theorem. It's the one general type of symmetry that combines "internal" and "spacetime" symmetries allowing a natural combination of particle physics and gravity.

But that's a very general argument. It says nothing about implementation. The attraction for phenomenology has always been the power of SUSY's opposite-sign cancellations across many areas (loops, cosmological constant). These arguments all rely on perturbation theory, a shaky starting point that assumes everything's weakly coupled in the regimes we're talking about.

60. **Kavanna**
March 18, 2013

Thus, the argument here is, in large part, not about supersymmetry, but about the validity and limitations of perturbation theory. If the crucial physics is strongly coupled, a different approach is needed.

61. **CLAUDIE**
March 27, 2013

Dear Peter Woit,

I am a student of philosophy and will humbly admit I got half way through your article – and felt sad that I could understand so little. I do however understand the basic concept of SUSY and would adore an answer in 'layman's terms' what you feel the future is for SUSY ?

I would be so very grateful,

(Ask me anything about Eastern Philosophy — but Physics, I struggle, but read on anyway because it fascinates me 🙂

Claudie

62. **Peter Woit**
March 27, 2013

Claudie,

In layman's terms, SUSY (as in superpartners for the standard model particles) is an idea that has gotten a huge amount of attention, despite not explaining much of anything. If the arguments for it were true, it should have been seen before the LHC. Now that it is being conclusively experimentally ruled out at LHC energies, the idea is basically dead, although it is going to take some people quite a while to admit this (they're now saying "wait til 2015!", and I doubt they'll even give up then when results come in at the highest possible LHC energies).

63. **CLAUDIE**
March 29, 2013

Dear Peter Woit,

Thank you kindly for your concise & considerate answer. I guess I have a vested interest in SUSY because it embodies some of what is predicted or at least theorised about by verdict philosophy – which is my filed of expertise. Also being a teacher and humanitarian – I had hoped for a theory of wholeness & unity — to open up a new discourse, whereby children can be taught to nurture the earth and nature in general, as a component of their own essence. I probably sound like a tree hugger (and undeniably I am 🙂

Kind Regards,

Claudie

Quick Links

March 3, 2013
Categories: Uncategorized

This should be a month with quite a bit of experimental news, including

- Latest Higgs news from the LHC experiments here on Wednesday.
- Release of data from AMS-02 was advertised as "two to three weeks away" back on February 17.
- Planck data release on March 21.

A couple weeks ago, Arianna Borrelli of the Epistemology of the LHC project gave a talk at CERN (slides here). It includes some interesting data from surveys of HEP physicists in September 2011 and September 2012.

The Simons Foundation website keeps having some of the best writing on math and physics around. Natalie Wolchover has an excellent story about a complex subject, that of the role of computers in proof. The also have an essay by Barry Mazur about another complicated related subject, the nature of evidence in mathematics.

Finally, if you want to watch a very good introduction to D-modules, see video from David Ben-Zvi at MSRI here and here.

Update: Edward Witten will be speaking here in New York this evening (Monday March 4) at Hunter College, for more information see here. Unfortunately I have other plans and will have to miss this.

Comments

   March 3, 2013

   What happened with Moriond? they dont put the slides

2. **M**
   March 3, 2013

   The new results from LHC, Planck and AMS are important but there will not be any surprise, only confirmations of previous experiments and reduction of uncertainties

3. **Peter Woit**
   March 3, 2013

   jihn,
   Their website says slides will be posted only after the session is over (next Saturday), presumably here
   https://indico.in2p3.fr/conferenceOtherViews.py?view=standard&confId=7411

4. **srp**
   March 3, 2013

   The findings quoted below by Borrelli's group look very consistent with Lakatos's "Methodology of Scientific Research Programs." You have the "hard core" theoretical preconceptions that are not tested (e.g. SUSY), the "protective belt" of disposable models that mediate between the data and the hard core, and the use of overall judgments about the expanding or contracting nature of what the scientific research program can satisfyingly explain to decide amongst them.

   "these results do not support the traditional pictures of physicists comparing and
   preferring models/theories according to some criteria
   – models are rather regarded as exploratory tools for research than as serious
   candidates to a theory of new physics. Yet the general approaches (SUSY, extra
   dimensions…) are taken seriously ("theoretical cores" Borrelli 2012)
   – LHC results did not change much the pattern of (rather feeble) abstract
   preferences, but seem to have further eroded the belief in individual models –
   yet interestingly SUSY is somehow slightly, relatively better off (Sept. 2012!)"

5. **Yatima**
   March 4, 2013

   The article about using computers for proving theorems (and possibly for sniffing out or discovering theorems) is indeed interesting.

   Still, after 30 years of discussion there is still existential Angst about the usefulness or the fruitfulness of using symbolic manipulation by machine to break through problems … damn!

   After all, we know that proving theorems is not exactly in P (so the program needs to be very astute to make progress unaided) and that Hilbert's program is unattainable as such so there will always be fine-tuning and possibly unprovable theorems to make life interesting (though for some reason, one encounters these very rarely in practice). Humans won't be out of a job! At least until full AI that is demonstrably not unhinged has been mastered.

   Doubts about a proof done by machine ("by steam", if one so will), though it may never go away, can ultimately be brought down to an adequate level. I am sure most people will take "three independent programs have found proofs that are, unfortunately, too large or obscure to be checked by brain – let's start from there" over "no proof exists". And even then, the search of possibly nonexistent but elegant ("highly compressible"?) proofs can go on.

   Conversely, are there any proofs that were found to be wrong long after they had become "common knowledge"?

   Physicists seem to go for it instead of wallow in doubt here. Does this come with the territory?

6. **Urs Schreiber**
March 4, 2013

For quantum field theory the interesting aspect of the "univalent foundations" mentioned in Wolchover's article is that it has the *gauge principle* built right into the foundations of mathematics. Moreover, a good chunk of Lagrangian, local (pre-)quantum field theory has a natural and fairly immediate axiomatization in univalent foundations: http://ncatlab.org/schreiber/files/QFTinCohesiveHoTT.pdf .

7. **Sakura-chan**
March 4, 2013

Peter, you can call him Ed.

8. **anonymous**
March 4, 2013

"Conversely, are there any proofs that were found to be wrong long after they had become 'common knowledge'?"

One item of common knowledge that comes to mind would be the status of the classification of finite simple groups. My copy of Dummit & Foote from 2004 states, "The classification of finite simple groups…. was completed in 1980…" In fact it was completed in 2004. See for example Wikipedia for discussion.

9. **Jeffrey M**
March 4, 2013

I'm not sure I would count the classification of finite simple groups as a "proof" exactly. More of a framework I would say, which of course involves many proofs. In any case it's not like it was wrong in 1980 exactly, it just wasn't quite finished. Off the top of my head and assuming "long" means long, I can't think of anything really. There are plenty of published proofs which are later discovered to be wrong, but usually it's pretty quick. In my field there was a "result" of McKean showing that eigenvalues of the Laplacian on Riemann surfaces are >= 1/4, but Randol came up with counterexamples 2 years later. There are plenty of other things like that around.

10. **Sesh**
March 5, 2013

It looks like the big announcements and data releases from Planck might end up clashing with the announcement of the new Pope, which will probably divert public attention. I wonder if positive media coverage is important enough for them to reschedule?

11. **malfatti**
March 5, 2013

Read this about how the erroneous solution of the Malfatti problem survived for more than a century.
http://www.cut-the-knot.org/Curriculum/Geometry/Malfatti.shtml

12. **Peter Shor**
March 5, 2013

Ironically, the paper "The Four-Colour Theorem Solved, Again" linked to above does not reference the paper where the four-colour theorem **was** solved again.

Higgs Update

March 6, 2013
Categories: Experimental HEP News

Updated results about the Higgs are being reported at Moriond today, slides available here. The organizers have given the talks titles with "BEH Boson" replacing the usual "Higgs Boson" (to promote Englert's shot at a Nobel), but the speakers have mostly ignored this, titling their slides with the usual "Higgs" or maybe "Standard Model Scalar". Some more details are starting to appear at the CMS site here, presumably ATLAS will soon update their site here.

The only surprise so far is that the CMS results for the gamma-gamma channel are not ready yet. Philip Gibbs has very good coverage of the latest news here, including this about CMS:

> Rumour puts the CMS diphoton excess at 1.0 +- 0.2, to be shown at Moriond QCD next week perhaps.

As mentioned here a couple weeks ago, the size of the ATLAS excess in that channel has gone down since last year, now at 1.65 +/- 0.24(stat) +/- 0.21(syst) (where 1.0 is the SM prediction). If you believe Philip's rumor, the combined ATLAS + CMS result for the gamma-gamma channel would be 1.32, consistent with the SM prediction at the level of 1-2 sigma.

In the ZZ channel, CMS reports a cross-section relative to SM of .91 +/- 0.27, ATLAS 1.7 +/- 0.5. Combining them gives 1.30, again quite consistent with the SM. For the WW channel, CMS has .76 +/- 0.21, ATLAS 1.5 +/- .6, averaging out to 1.13, again very much consistent with the SM. For channels with bottom quarks, CMS has 1.3 +/- .6 and for channels with taus CMS has 1.1 +/-.4, ATLAS says the expected signal is still to small in these channels for them to say much.

Some more talks this afternoon may give a bit more detail.

All in all, the story is that this is looking very much like a garden variety SM Higgs, which is discouraging for hopes of hints about how to get beyond the Standard Model. The experiments will continue working on improving their analyses of this data, but it seems unlikely that the picture will change much. There's going to be a long drought now until we see significantly better data for these numbers. Probably not until 2016 until the LHC has been operating long enough to produce significant luminosity at higher energy.

The New York Times yesterday put out a wonderful special issue of its Science Times section, devoted to an excellent long article by Dennis Overbye telling the story of the Higgs discovery from the point of view of the ATLAS and CMS scientists (and emphasizing their rivalry). Highly recommended reading. The article does credit a certain blog with being the venue where a mistaken early Higgs claim was leaked (I'm sorry to hear that that ruined some people's vacations), although the fact the the actual Higgs discovery news broke somewhere else than in the Times doesn't get mentioned…

Professor Matt Strassler has a posting about the Times article, explaining how it shows that other particle physics bloggers were wrong to think that the 3 sigma signals reported by ATLAS and CMS back in late 2011 were strong evidence that the Higgs had been found, and that he had been right to be skeptical.

Update: New ATLAS results are here. Do not miss the extremely cool animated gifs of the evolution of the Higgs signal as data accumulated.

Update: Valuable commentary at Resonaances.

Comments

1. **john McAllison**
   March 6, 2013

   "There's going to be a long drought now until we see significantly better data for these numbers"

   Tut tut, Peter, you're so ungrateful that it's 2013 with probably the greatest discovery of the past few decades in the bag. I'm sure the 25\fb of data will keep people busy for the next two years. If anything, they must be ecstatic they have this amount of data compared to 2011 when they were hoping for 1\fb over the year.

2. **Peter Woit**
   March 6, 2013

   John McAllison,

   The drought comment was just about these very specific Higgs branching ratio numbers, which I think it is going to be hard to dramatically improve on without a lot more data. There are many, many other things to look for in the LHC data which I'm sure will keep people quite busy, and hopefully will turn up something unexpected.

3. **King Ray**
   March 6, 2013

   Peter,

   Thanks very much for the link to the NYT Higgs piece. I liked the analogy of the Higgs field to snow, with massless particles flying above it like birds (see the Higgs drawings by Nigel Holmes).

   I thought the ending of the article was pretty neat; Prof. Higgs has a good sense of humor:

   When she showed the Atlas 5-sigma result, the audience exploded again. The applause seemed to go on forever. It had been left to Dr. Heuer to declare officially that a new particle had been discovered.

   "I think we have it," he said. The cheers began again. Dr. Higgs was seen wiping away tears.

   The morning dissolved into pandemonium and Champagne, in the CERN auditorium and in labs, classrooms, conference rooms and living rooms in every time zone in which humans wondered about their universe. Dr. Wu waded through the crowd. She hugged Dr. Higgs.

   "I've been looking for you my whole life," she said.

   "Well," he replied, "now you have found me."

4. **Nick M.**

March 6, 2013

Hi ***Peter***,

The link that you have given for the “slides available here” section of your post — that is, the first link — seems to have a ‘security certificate error’ as reported by the three different browsers that I used to try to go there; i.e., IE, Firefox, and Chrome. I decided to throw caution to the wind and go all the way there anyway, and indeed they are the slide portion of the presentations at Moriond in PDF format. I think that they may be the slides that accompany these WebCasts as given at Moriond today on the Higgs.

By the way, Thanks for compiling this Higgs update,
— Nick

5. **Nick M.**
   March 6, 2013

   Peter,

   Sorry for all the worry about ‘certificate error’, as the certificate issuer for this site, the French based CNRS2-Standard, seems to not be well recognized by the current crop of U.S. based browsers. Anyway, there doesn’t seem to be any real security rick involved with this site, despite all the browser warning hullabaloo.

   — Nick

6. **Shantanu**
   March 6, 2013

   Peter and others,
   pre-snowmass meeting going on at slac.
   You can listen to the audio of the cosmic frontiers part of it.

7. **Peter Woit**
   March 7, 2013

   Shantanu is referring to this ongoing workshop which looks like it includes quite a few interesting talks:
   https://indico.fnal.gov/conferenceDisplay.py?ovw=True&confId=6199

8. **Nick M.**
   March 7, 2013

   Peter,

   New Scientist just released the article “Rumour points to a completely boring Higgs boson” where they quote ‘yours truly’ just after the section heading “Garden variety”.

   — Nick

9. **Peter Woit**
   March 7, 2013

   Nick M.,

   Thanks. Good to see that someone else is being quoted as the source of rumors this time, not me…

10. **chiz**
    March 7, 2013

    Meanwhile AP are reporting that if the particle isn’t a Higgs then there is only one other thing it could be – a graviton. Cool. Gravity is now a short range force. That will be a boon to the space-launch people. I better go and nail everything down.

American Journal of Modern Physics

March 7, 2013
Categories: Uncategorized

This morning an e-mail came in from the "Science Publishing Group", a call for "Editorial Board Members, Reviewers and Paper" for their open access journals, advertised as

> **Full peer review**: All manuscripts submitted to our journals undergo double blind peer review.
> **Fast publication**: Fast peer review process of papers within approximately one month of submission.

This included a special deal on the "Article Processing Charge": \$70 or \$120 before May 15. I've been highly suspicious of all "author pays" open access schemes in math or physics, so I decided to check into what this one was. When I went to their web-site and looked at their list of journals, the first on the list that looked like it would have material in it I would know something about was the American Journal of Modern Physics. The first paper that showed up on the journal web-page was MSSM Neutral Higgs Production Cross Section Via Gluon Fusion and Bottom Quark Fusion at NNLO in QCD by Tetiana Obikhod, so I took a quick look at it.

It looked perfectly competent, but oddly it wasn't on the arXiv, and the only papers by that author on the arXiv appeared to be some papers on F-theory and D-branes from 1997-98. A little bit of investigation quickly showed that much of the paper was plagiarized from elsewhere, including at least a 2003 paper by Harlander and Kilgore, Higgs boson production in bottom quark fusion at next-to-next-to-leading order and a 2011 paper by Bagnaschi et al. Higgs production via gluon fusion in the POWHEG approach in the SM and in the MSSM (neither of which are listed in the references).

For instance, the AJMP paper introduction has

> In the Standard Model the gluon fusion process is the dominant Higgs production mechanism at the LHC. The total cross section receives very large next-to-leading order (NLO) QCD corrections, which were first computed in . Later calculations retained the exact dependence on the masses of the top and bottom quarks running in the loops. The next-to-next-to-leading order (NNLO) QCD corrections are also large, and have been computed in . The role of electroweak (EW) corrections has been discussed in . The impact of mixed QCD-EW corrections has been discussed in . The residual uncertainty on the total cross section depends on the uncomputed higher-order QCD effects and on the uncertainties that affect the parton distribution functions (PDF) of the proton .

while Bagnaschi et al. has

> In the Standard Model (SM) the gluon fusion process is the dominant Higgs production mechanism both at the Tevatron and at the LHC. The total cross section receives very large next-to-leading order (NLO) QCD corrections, which were first computed in ref. in the so-called heavy-quark effective theory (HQET), i.e. including only the top-quark contributions in the limit mt → ∞. Later calculations retained the exact dependence on the masses of the top and bottom quarks running in the loops. The next-to-next-to-leading order (NNLO) QCD corrections are also large, and have been computed in the HQET in ref. . The finite-top-mass effects at NNLO QCD have been studied in ref. and found to be small. The resummation to all orders of soft gluon radiation has been studied in refs. . Leading third-order (NNNLO) QCD terms have been discussed in ref. . The role of electroweak (EW) corrections has been discussed in refs. . The impact of mixed QCD-EW corrections has been discussed in ref. . The residual uncertainty on the total cross section depends mainly on the uncomputed higher-order QCD effects and on the uncertainties that affect the parton distribution functions (PDF) of the proton .

In the body of the AJMP paper, for example starting at the bottom of page 3 with

> The subprocesses to be evaluated at the partonic level are given as following…

the following material in the paper including the equations is an edited version of Harlander and Kilgore, starting at their page 4 with

> The subprocesses to be evaluated at the partonic level are given as following…

As far as I can tell without spending more time on it, the author did run some kind of package to calculate something (the plots in the paper aren't in the older papers), and then wrote the surrounding paper largely by plagiarizing the other two papers. There's a good reason this one isn't on the arXiv: they now run an automated system which would have immediately identified the plagiarism problem.

It's possible that I just got unlucky, that there was a problem only with the first of the papers I looked at, but this seems unlikely. I realize that this is a very obvious case of a journal with extremely low standards, run to make money off of the increasingly popular "author pays" model of financing journals, but I'm hoping that those that are trying to move high-quality journals to this model are seriously thinking through the issues involved. Just this month in the AMS Notices, there is discussion of a proposal to move two of the AMS journals in that direction. Yes, this is very different than AJMP, but there's an argument to be made about the "author pays" model that it is best avoided, since it's a good idea to keep academic and vanity publishing strictly separate endeavors.

Comments

1. **jinb**
   March 7, 2013

   The sad thing is the plagiarist will still probably get a job from people who aren't in a position to evaluate the work and just see the all-important "published in …" stamp.

2. **Marty**
   March 7, 2013

   You wrote "It's possible that I just got unlucky, that there was a problem only with the first of the papers I looked at, but this seems unlikely."

   I looked at the *second* of the papers, "Raleigh waves…" by Rajneesh Kakar and Shikha Kakar. This is also cut and paste from other sources (without citation) as far as I can tell. Parts are also duplicated in the article by the same authors in "Journal of Chemical, Biological and Physical Sciences"

   Among many other instances (found by google searches), compare "We consider Oxyz Cartesian co-ordinate system with o being any point on the free surface, here we consider the free surface and interface of granular layer resting on nonhomogeneous granular half space bounded by two planes of different material given by z = 0 and z = H respectively. Also it is assumed that oz being normal to half space and Rayleigh wave propagation in the positive direction of xaxis. Here it is also assumed that at a great distance from centre of disturbance, the wave propagation is two dimensional and is polarized in xz-plane." in AJMP to:

   "We consider oxyz cartesian co-ordinate system with o being any point on the free surface, here we consider the free surface and interface of granular layer resting on non-homogeneous granular half space bounded by two planes of different material given by z = 0 and z = H respectively. Also it is assumed that oz being normal to half space and Rayleigh wave propagation in the positive direction of x-axis." in Sethi-Gupta-Gupta, "Propogation of Surface Waves in non-Homogeneous, Magneto Granular

Medium under the Influence of Gravity & Initial Compression", also compare to "Int. J. of Appl. Math and Mech. 6 (20): 50-65, 2010

3. **Matt Leifer**
   March 7, 2013

   Picking on scam journals published by predatory open access publishers does not discredit the author-pays model. It is a bit like saying that all conferences where you have to pay a registration fee must be bad just because you got some spam emails from scam conferences. The truth is there are crappy journals in the closed access world as well (Chaos, Solitons and Fractals anyone?), but everyone knows what the good journals are and ignores the rest. Why wouldn't we do the same with open access journals? Why don't you look at some of the reputable journals that adopt an author pays model, e.g. the New Journal of Physics or Physical Review X?

4. **srp**
   March 7, 2013

   Matt:

   Good points. The community of readers and citers will sort it all out.

   One could even argue that since the balance of attention scarcity these days falls on inundated readers who have access to the arXiv, it makes little sense for readers to pay for more articles. Maybe readers should pay people who can tell them which articles not to bother reading–"anti-publishing."

   But after the last go-around on this subject it appears that it will take an extremely powerful lance blow to unseat our host from his hobby-horse.

5. **Peter Woit**
   March 7, 2013

   Matt,

   I don't doubt that it's possible to have high-quality author pays journals in fields where that has been part of the culture of the field. Even so though, it seems to me that anyone running such a journal should be worrying about the problem of the financial incentives of the organization being driven by the equation "more accepted papers=more income". As well as the fact that they're in a business now being invaded by hordes of scam artists.

   In fields that I know about (math and HEP physics), there is no culture of high quality author pays journals (at least not that I'm aware of). Anyone starting such a thing has to explain how they're going to deal not only with the misaligned incentive problem, but also the problem of getting people who can publish in excellent journals for free to pay instead.

   srp,

   "Maybe readers should pay people who can tell them which articles not to bother reading–"anti-publishing.""

   Excellent idea, I'm a pro at this. Will contact some VCs with my business plan right away…

6. **chiz**
   March 7, 2013

   Playing Devil's advocate for a moment – Obikhod is Ukrainian. Maybe, possibly, perhaps, she isn't a fluent or confident English speaker, and just took sentences from other papers in lieu of struggling to write them herself.

7. **Peter Woit**
   March 7, 2013

   chiz,

   That sort of thing is fairly common, especially in introductory material, and you could try to excuse the borrowings from Bagnaschi et al. that way. In this paper though, large chunks, including lots of equations, are later in the paper taken from Harlander and Kilgore. The equation plagiarism is hard to excuse as a language problem.

   Funny, I just got another promotional e-mail from "Science Publishing Group" a few minutes ago.

8. **Brian Dolan**
   March 8, 2013

   It seems to me that it is inevitable that this kind of thing will happen with the so-called "open access" system. With the old "reader pays" system the journals had to maintain standards to make money, no-one will pay to read articles in a poor quality journal. But with the open access model, the more papers the journal publishes the more money they make and the quality becomes completely irrelevant. It might be argued that they must still maintain standards or no-one will want to publish in them, but that is manifestly wrong — as jinb says in an earlier comment "the plagiarist will still probably get a job from people who aren't in a position to evaluate the work". There are more people than ever desperate to publish to further their careers and the journals will have no problem getting articles from all an sundry (mostly paid for by public funds …).

9. **Alex**
   March 8, 2013

   I would venture a guess that opening an "author pays" high energy physics journal is the perfect recipe for going broke and getting ridiculed. I don't know a single high energy theorist who would be willing to pay any significant amount of money for being allowed to submit an article to any particular journal. The fact that said journal will be known as "the vanity journal" will make it even worse. We referee for free, which is a way of paying journals, but that is a different thing.

10. **Judith McGovern**
    March 8, 2013

    You might be interested to know that the UK government has announced its intention to move towards a requirement for all papers resulting from research-council funded work to be published in "gold open access" journals – ie those which make all papers freely available immediately, and hence inevitably are author-pays. (Other forms of open access such as putting the text on ArXiv are "green" rather than "gold".) There has even been a significant sum of money made available to finance page charges initially.
    http://www.rcuk.ac.uk/research/Pages/outputs.aspx
    The reasonably prestigious IoP journals (eg J Phys G) are therefore moving to allow this model.

Many of those working in areas where self-archiving has been the norm see little benefit in the new system, and worry about being required to get approval from someone in the University in order to publish….

11. **Rhys Davies**
March 8, 2013

@Judith McGovern:
This was discussed at the STFC "Town Meeting", at the end of the theory meeting at Durham, just before Christmas. STFC dish out the majority of high-energy/fundamental physics funding in the UK, and they are well aware of the strong 'green' open-access culture in the field, arising from the universal use of the arXiv. The impression I got was that they are trying very hard to convince the higher-ups that this is sufficient.

Your link contains a document, last updated just two days ago, which includes the following clauses:

"RCUK recognises a journal as being compliant with this policy if:
…
The journal consents to deposit of the final Accepted Manuscript in any repository, without restriction on non-commercial re-use and within a defined period."

and

"While RCUK recognises that many researchers derive value from sharing early versions of papers (for example, by using the arXiv pre-print archive), RCUK will consider only versions 'as accepted for publication' when assessing compliance with its policy."

So at this stage, it sounds like nothing much should change, as long as authors remember to update their arXiv submission to the version which is accepted for publication.

12. **Peter Woit**
March 8, 2013

Thanks Judith and Rhys,

That's exactly the sort of thing I'm worried about. In HEP/Math, the only "open access" problem is things not being on the arXiv. Misguided attempts to solve the supposed problem that don't recognize may lead to a worse situation and new problems.

13. **Low Math, Meekly Interacting**
March 8, 2013

I hope I'm not annoying anyone by chiming in, but I find the discussion fascinating. For better or for worse, I think open-access is going to be new paradigm relatively soon, so if it has major and insurmountable flaws, it will impact all scientific disciplines. My own attitude is the current paradigm in the life sciences is so flawed anyhow (in both industry and academia) that we may as well at least try something different. But physics and mathematics has the arXiv ingrained in the culture, which appears to render traditional publications almost redundant EXCEPT for the very important fact that if one wants a career, they need peer-reviewed papers on their CV. So, how do you have a career that requires the Gold Standard of peer review when the customary suppliers of that standard are no longer economically viable? If perverse incentives render open-access journals an intrinsically-flawed model, whither the tradition of peer review?

14. **Bernhard**
March 8, 2013

It is really worrying to hear that JP G is embarking on this. I was fist thinking that this whole thing was a bit of exaggeration because I always thought these journals would anyway never be taken seriously due to low impact factor. But if JP G is planning this big mistake, then one wonders what is next. It is annoying to lose the option of a good journal like the JP G, but if they adopt this model I think many people (me included) will just avoid publishing there.

15. **Felipe Zaldivar**
March 8, 2013

Just in case someone has some doubts on the quality of the journals of the "Science Publishing Group", prompted by Peter's post and curiosity I looked at one of its "math" journals, "Pure and Applied Mathematics Journal", which has already two volumes, each one with one issue. In the 2012 volume there are two papers. One, with the title "Galois Groups of Polynomials and the Construction of Finite Fields" caught my attention and I took a look at it. Well, I shouldn't have done this. I know, you know, and I think everybody knows what this so-called open access predators are doing. The paper (for lack of any other name) is a list, with no particular order, of elementary results from the usual undergraduate algebra course. However, the exercises (one may believe it could be an assignment) listed at the end are quality are not even on the level of a bad, very bad, undergraduate student! If you feel curious you may look at the "paper" at the link below:

http://article.sciencepublishinggroup.com/pdf/10.11648.j.pamj.20120101.12.pdf

16. **S**
March 8, 2013

As others have said, you can't generalize author-pays as a whole by a few bad apples. Otherwise I could point to the various spam emails I get every day, and conclude that the entire internet outside of big corporate walled gardens has nothing of value.

You mentioned the AMS plan to try author pays with a couple journals. As I understand, the PAMS is so inundated with submissions that editors have actually been given limits on how many papers they're allowed to accept. This creates perverse incentives in a different direction. Suddenly it becomes extremely difficult to get published in a journal like PAMS if you don't have close connections with an editor there. This exacerbates the problem of mathematical insulationism, where the high-tier journals tend to publish exclusively work in flavor-of-the-year fields and anything out of the ordinary is toxic.

The only way to completely avoid perverse incentives altogether is to use a model like the Electronic Journal of Combinatorics: no author fees and no limits on how many articles can be accepted. (It's 2013, why is the AMS still limiting journals based on how many sheets of paper a physical volume can hold?)

17. **Jon Lennox**
March 9, 2013

In all non-broken cases, "author pays" is really "funder pays", right? The assumption is that everyone doing research in these fields has a research grant.

So it seems to me that you could get the incentives a lot better, without changing the ultimate flow of money, if the funding agencies funded the journals directly. That way, the journals' incentive would be to put out the best journal they could (so their grants get renewed) rather than to publish as many papers as possible.

It would also be a lot fairer to researchers without funding.

18. **tomate**
March 9, 2013

I am a fresh researcher in statistical physics. I will tell an episode about open access – and maybe ask for an advice on publishing.

Some months ago I received an invitation to write an article for a special issue of a journal (new institutional email account just activated). Since I had some publishable material on that very subject, I decided to roll up my sleeves and started writing. Was I naive! I didn't realize that the "invitation" was for a pay-per-publish journal (my fault of course! I didn't read all details of their email, but who would think that you have to pay when invited our for dinner?). I got my work ready, formatted according to the journal's Latex style, and finally, when I submitted it, I was asked to pay.

I got mad. I vigorously protested, and this eventually led to something: It might be that my paper is accepted even without fee. In the meanwhile, I realized that the "special issue" is just a strategy to get money from a closed self-citing community. Whilst my paper is the due quality for a research paper (that I believe), I noticed that these special issues are filled up with old review material. I wonder how refereeing is being conducted there…

So, on the one hand, I don't want to be misguided for a member of such a cummunity, and I don't like people to think that I pay for publishing (even if I don't). On the other hand, this work is ready, and you all know how much a pa**-**-***-*ss is to format it for another journal (admitting that the subject is interesting enough for any otherjournal).

19. **Peter Woit**
March 9, 2013

tomate,

Thanks for writing. That story shows clearly one of the big problems with journals like this: they sometimes get authors to send them good articles, by one means or another. Their whole business model is based upon trying to make themselves hard to distinguish from more reputable journals, by any means they can. People who think these scams are not a major problem because they can just easily be ignored are underestimating the ingenuity and goals of those running these operations.

20. **Peter Woit**
March 9, 2013

Jon,

Thanks for the comment. What you're suggesting I think is kind of what the international funding agencies in HEP are planning to do with SCOAP^3. This does deal to some extent with the incentives problem, especially if the threat of being defunded is real (although now the incentive for the publisher is still to drive down quality and publish as many papers as possible, taking the journal right up to the line where it would get defunded, but not over it). The main argument against it in that case is that instead of getting rid of the expensive journal publishers like Elsevier, it entrenches them permanently, supplanting university budget money they were in danger of losing with more stable government money.

This is an international consortium with possibly stable funding. If it were a US funded operation, you might worry about having your scientific literature shut off when budgets are cut or sequestered.

21. **srp**
March 9, 2013

Online dating scams occasionally snare a Paul Frampton. Author-pays publishing scams occasionally snare a naive researcher or steal a couple of minutes from a reader. Peer review allows all kinds of bad behavior by reviewers sabotaging their rivals and promoting their friends. Occasionally the existence of life insurance motivates a murder (this was actually a major objection to life insurance when it was an innovation.)

Institutions must be judged on the balance of their effects.

22. **Low Math, Meekly Interacting**
March 10, 2013

srp nails it. I'd say the institution of peer review, as it exists today, is in need of a serious overhaul, if for no other reason than it cannot cope with the current level of scientific misconduct (though there are plenty of other reasons). In some disciplines, this problem is obviously a lot more troublesome than in others, but fragmentation of scientific standards between disciplines seems pretty untenable to me. So we have a new paradigm emerging, which is to realign the payment structure so as to make research publications freely accessible to all. This has enormous implications, as it disrupts the business model of the customary "gatekeepers" of research publication, with attendant effects on the "gold standard" of peer review.

I certainly acknowledge the dangers inherent in the author-pays model, but the status quo is being stretched beyond its limits, and the completely free model of a preprint archive kinda looks like the Wild West, even with the system of sponsorship, and even the author of this blog has suffered injustice at the hands of that system.

So is there something better in the works? Science is a human enterprise, and it's entirely subject to human failings. I'm not optimistic we're all going to become Vulcans, so ways of coping with the human condition are needed. What saves the enterprise and helps insure its supremacy is its competitive (and even adversarial) nature and the fact that the competition is settled by observation of the Real World (however you like to define that). It would seem to me, at minimum, that making the fruits of scientists' labors as freely and openly available as possible does the most to foster scrutiny of and challenge to scientific claims, and open access does at least aspire to go some way towards achieving that goal. It likely has problems. We already have problems. Is some weighing of relative problems (both known and conjectured) justified as we attempt to change the publication system?

23. **Jon Lennox**
March 10, 2013

Peter: Is the incentive to publish lots of mediocre papers (keeping your journal just good enough) any different for funder-pays than it is for traditional subscriber-pays? I think the factor that's kept the mediocre paper count down in the past was the space limitations implicit in physical publishing — once you've gone to an electronic format, that's out the window, regardless of how the money's flowing.

Also, if you're in a funder-pays environment, is there really a problem with entrenchment of publishers like Elsevier? If they're doing a enough job to keep their grants going, and the journals are open-access, I don't think there's anything intrinsically wrong with them being big. (I guess you might run into a regulatory capture problem, where they get their grants renewed due to lobbying rather than quality, or the like.)

24. **Brian Dolan**
March 11, 2013

As one of the 13,000 people who have signed Tim Gower's "Cost of Knowledge" petition against Elsevier's practices (http://thecostofknowledge.com), I would be very unhappy to seem then being given money directly out of the tax-payer's pocket.

"Low Math, Meekly Interacting" above gets to the kernel of the problem, that the current system relies on peer reviewed publications to assess grant applications, job and promotion applications, so we cannot do without it. But it doesn't have to cost the Earth.
We (i.e. active researchers) already do all the research, we type and typeset the articles, we act as editors and we do the refereeing. So what do we need the journals for?

Let me throw out the following idea for discussion. At least in physics, with the archive, we can completely eliminate the journals: all we need to do is set up editorial panels for various sub-disciplines ourselves and, when someone submits a paper they indicate whether or not they want it to be refereed for "publication". We go through the usual refereeing process and, if it is accepted, it appears in the archive listings as "published" (maybe put a little asterisk beside, to indicate "published"). This would completely equivalent what the journals do at the moment, and would cost almost nothing. Of course we would have to persuade the funding agencies that this is "Gold Standard".

The only problem I can see with this proposal is that there would then be only one place to send articles and, if it's rejected, there is no second option — no other "journal" to send it to.

25. **Bob Levine**
March 11, 2013

Brian—

I like your idea and have always thought that something like this should be the model. But doesn't its viability depend on persuading departmental P & T committees that this new 'gold standard' is also a new 'blue ribbon' outlet? The cooperation of academe (not just at the departmental level but through all the levels of admin review) would seem essential for the success of this approach, and I don't know what the level of resistance to it would be on the part of senior established scientists in physics, let alone other fields which don't have something like arxiv, with its semi-'established' status. The problem is not just one of publication format; the whole culture of the university meritocracy seems to be part of the issue.

26. **Jeff McGowan**
March 11, 2013

I think Brian Dolan has a very interesting idea. In math anyway there's already a partial refereeing process for arxiv, since anything interesting will get read by many people, and if there's a problem they'll let the author(s) know, and it usually gets pulled. Of course you can't force someone to pull it that I know of, and some things probably don't get read my many, if any, people, so they slip through the cracks. I think journals have historically served 3 purposes. First of course, they make things accessible. That's is not an issue now. Second, the refereeing process kept things legit. That's still an issue, but as Brian points out we're doing that anyway now for free, so why not just do it for arxiv? Third, they sorted things quality wise – if I see a paper in JDG or GAFA or Transactions or whatever, I know it's got to be interesting in some way. This relates to what Brian said about the problem with arxiv and making it a refereed source is that you have only one venue. Maybe the way around this is to have a stable of referees, have everything read by say 3 of them, and have them not only check the validity of the paper but also grade it. That way papers which would be in Annals and papers for Proceedings (or lower) could all be published, as long as they were correct, essentially it would be like having many journals, and you submit to all at once, the referees decide which one to publish in.

27. **Yuichiro Fujiwara**
March 11, 2013

Peter,

You say:

That story shows clearly one of the big problems with journals like this: they sometimes get authors to send them good articles, by one means or another. Their whole business model is based upon trying to make themselves hard to distinguish from more reputable journals, by any means they can.

I would have agreed with you if his story were about how the journal tricked him into sending a good research paper through a dishonest means. But as far as I can tell from his comment, it seems to be due to his own lack of a due diligence. He himself says he didn't carefully read the email from the journal. He doesn't seem to have researched the journal and/or publisher before submission either.

Do you think it is a problem for a new journal to attract good papers through acceptable means in order to become indistinguishable from other reputable journals? If the journal dishonestly hid the fee or put it in tiny fine print, I see a problem. If you were talking about spamming researchers' mail boxes, I would understand to an extent. But if it is just that the author was careless, what he descried may not clearly show a big problem in academic publishing.

I don't think you would say it is a problem that reputable journals want to publish good papers. Why shouldn't struggling journals wish for good papers then? If they become indistinguishable from already established journals because of their effort in attracting good papers, it's just they're already one of them at least in terms of quality.

I understand that a certain open access model may make some journals want to publish papers *regardless of their quality*. I agree that this can be a problem. But I don't think being open access makes it unacceptable for a journal to want to publish good papers. It's only a problem if they want bad papers.

Now, if a journal dishonestly tricks researchers so they get good papers, it's certainly a problem. But it's a terrible thing regardless of publishing model. I don't think open access models particularly encourage such dishonest conduct more strongly than other models. I don't think the comment you're responding to clearly suggests that it was a dishonest trick either. If anything, I tend to think that his tone of writing makes it difficult to guess exactly what happened.

28. **Peter Woit**
March 11, 2013

Jon,

You're right that electronic format does remove a traditional brake on journals lowering their standards. Still though, there is a difference between any model where they get paid per article and one where the amount they are paid is determined by other factors.

Much of the debate about Elsevier in recent years has been of the order of "how can we get rid of them: they're costing our community a lot of money way out of proportion to the value they provide". Before having granting agencies directly funding Elsevier, I think that issue should be addressed: are they worth it?

Yuichiro Fujiwara,

I think you're blaming the victim here. Yes, victims of scams wouldn't be victims if they did a better job of figuring things out before getting scammed.

Obviously reputable journals should want to publish good papers, having scam artists who manage to publish good papers is a problem though. Publishing outfits like this one are not just in the business of getting paid by plagiarists and incompetents to do vanity publishing for them, but are engaged in a serious effort to mislead people and make them think they are something they are not (a legitimate operation with real standards), and are sometimes successful. They're doing this because they can make money off an author-pays model. I'm just pointing out that before the math and HEP communities abandon their traditional practices and move to author-pays, they should keep in mind that this model is already leading to a huge scam-publishing problem.

29. **Yuichiro Fujiwara**
March 11, 2013

Peter,

I don't think I'm blaming "the victim of a scam." I'm saying that we don't know if he is actually a victim or if it was a scam in the first place.

He only told his side of the story anonymously in a not extremely professional tone on the internet without giving any concrete evidence that backs up his claim when he can clearly do so by, for example, giving the link(s) to said special issue and/or post what you seem to believe is a dishonest email to "trick" him into submitting a good paper. I tend to take an angry, anonymous, one-sided story without supporting evidence cum grano salis, especially when the unhappy person didn't give the link to *openly available* evidence.

Of course, the journal in question may in fact be of extremely low quality or even part of a scam you describe, although I can't agree that it is clear from his comment that this was the case. Even then, I am having a hard time convincing myself he is a "victim" who shouldn't be blamed. Perhaps, it is the norm in statistical physics, but I find it very careless to submit your own work you are pride of to a journal you know nothing about. It is not that "victims of scams wouldn't be victims if they did a better job of figuring things out before getting scammed." You are supposed to make sure you know what the journal is like before you submit your own work.

I would have sympathized with him if it were a sophisticated scam such as listing famous researchers on the editorial board without permission and uploading good quality papers from established journals as if they were originally published in the scam journal. But in my opinion, it doesn't count as getting scammed if you publish in a low quality journal because you didn't check what it's like before submission.

Also, I can't agree with your argument that a certain open access model is *leading* to scam-publishing problem. I don't think it is the direct cause. Would you tell your university's administrators that they should keep in mind that the "student-pay" model of university education is leading to a huge scam diploma-mill problem? They scam naive students because they can make money off of them. But I don't know if we should be wary of the student-pay model or if universities should rethink their business model because of the existence of diploma mills.

I agree that we should know there are academic publishing scams out there. And I understand that making it easy to start a new journal also makes it easy to start a publishing scam. But if you were pointing this out, I fail to see how the comment you were replying to "clearly shows" it.

The Professor, the Bikini Model and the Suitcase Full of Trouble

March 8, 2013
Categories: Uncategorized

Fresh off its great long article about the Higgs, the New York Times is devoting a similar amount of space to the other big mind-blowing high energy physics story of the past year or two, Paul Frampton and his adventures in South America. This coming weekend's New York Times Magazine has a feature article on The Professor, the Bikini Model and the Suitcase Full of Trouble, which covers the whole amazing story well.

Comments

1. **Bee**
   March 8, 2013

   Well, after that article he'll probably be drowned in marriage proposals…

2. **Mark**
   March 8, 2013

   Peter is Paul Frampton respected in the physics community? I couldn't tell if he was all hype and ego or contributed in a meaningful way to HEP.

3. **Phil**
   March 8, 2013

   Wow, what a story. i feel sorry for Frampton and hope others will read his story and learn from it!

4. **Marc Sher**
   March 8, 2013

   Mark—

   Paul Frampton has made major contributions to HEP. A paper I wrote with him in 2001 just hit 250 citations — he has 271 published papers with 7000 citations. So he has always been considered a solid physicist (and has a remarkable high number of PRLs).

   However, the community was surprised by his talk a couple of years ago comparing himself to Newton — it raised some eyebrows and had some concerned about his health (he is 68). And his last few papers have been a bit odd.

   I don't know what happened in South America. I suspect he knew more than he's letting on (but not as much as the authorities think). When he returns a year from this May, we should all give him the benefit of the doubt and hope he can get back into physics.

5. **Z**
   March 8, 2013

   I'm surprised no one has mentioned an autism-spectrum disorder like Aspergers. But I don't know anything about Frampton besides what I've read — however, what seems to really define him is his blinding ego.

   HEP theory in the last 30 years seems to be centered around egos, their pet theories and respect in the community. It's been 30 years since the W/Z discoveries. If you define "meaningful contribution" in HEP theory as something beyond the standard model and GR that is experimentally confirmed, almost no one has made any such contribution. I'm no sociologist, but if the community's respect is the only criterion for being a good theorist, then this environment seems ripe for creating potentially detrimental egos.

6. **john McAllison**
   March 8, 2013

   @Mark, yes I was thinking exactly the same about Paul Frampton – no denying his stellar academic record, but what about his creative contributions to the physics community?

   This is where Microsoft Academic comes in handy:
   http://academic.research.microsoft.com/Author/12899234/paul-h-frampton
   385 publication, 286 citations.

   Now let's compare this to Ed Witten:
   http://academic.research.microsoft.com/Author/2582335/edward-witten
   398 publications, 41,013 citations (yes, it really does say 41,013)

   Is it fair to say that roughly, Paul Frampton's contributions to physics are possibly 1/20th those of Ed Witten's?

7. **Marc Sher**
   March 8, 2013

   John McAllison—Microsoft Academic is garbage. Frampton has 6900+ citations. Look at http://inspirehep.net/search?ln=en&p=f+a+frampton%2C+p&of=hcs&action_search=Search for a listing of all 6900, if you wish.

8. **Curlo**
   March 8, 2013

   The ratio of the citations that McAllison quotes from Microsoft Academic is closer to 150 than to 20. However, the ratio of the Spires citations that Marc defends is roughly 14 (100,000 of Witten compared to 7,000 of Frampton), so close to 20, indeed ! The number of published work is almost the same (268 published works compared to 252).

9. **john McAllison**

March 8, 2013

Mark Sher, OK:

http://inspirehep.net/search?ln=en&ln=en&p=witten%2C+edward&of=hcs&sf=&so=d&rm=&rg=25&sc=0

Edward Witten has around 100,000 citations, H-index 143, compared to Paul's H-index of 43. For further comparison, Stephen Weinberg has an H-index of 94.

So based upon this, I think it's fair to say that Paul Frampton is/was a world class physicist, but not necessarily in the division of current/past top world class physicists.

10. **bw**
March 8, 2013

The tone and title of this article unfortunately plays up the stereotype of physicists as bright, but socially inept. That this is written for the general public for this Sunday Times Magazine section makes it worse. 408 on-line comments already posted to the NY Times as of this Friday night (9:17 p.m. EST) before the article even appears in print on Sunday means this will be a highly popular article. And many of the comments snicker at highly intelligent people who can't function in the real world.

11. **Leopold Bloom**
March 8, 2013

It's deeply shameful that so many in the physics community have rallied around this criminal. Seems that it's ok to commit a serious crime if you are a physicist.
And for those who really believe that he didn't know about the cocaine: I'm not even going to try to sell you a bridge; I reserve that for the merely gullible, not for people with mental disabilities.

12. **CPV**
March 9, 2013

"The tone and title of this article unfortunately plays up the stereotype of physicists as bright, but socially inept."

Hmm…have you actually met any physicists…especially good theoretical physicists?

13. **SC**
March 9, 2013

but you've got to look at how much of an advance each paper was, too, so 1/20th might be an overestimate

14. **Shantanu**
March 9, 2013

Btw this maybe controversial pov, but don't think large citations necessary means
a good paper. For example, Randall-Sundrum model has lots of citations even though there is a single shred of evidence that it is right.

15. **imho**
March 9, 2013

I fully believe that we all should support our fellow Physics brothers and sisters… BUT Frampton was very likely trying to smuggle cocaine into Europe, how many young kids were going to die over his activities? Granted he was lonely and he probably did it for some imagined life with a bikini model, but we as a community need to have higher standards.

Were this some urban teenager from the barrio bring drugs into one of our communities we would feel differently. I say leave him in prison… Actions have consequences.

16. **Marcus**
March 9, 2013

Leopold Bloom:
For in the same way you judge others, you will be judged, and with the measure you use, it will be measured to you. (Matthew 7:2)

17. **Thomas**
March 9, 2013

Marcus:

Do you mean to apply the same dictum to what we say about every (ex-)inmate of Devoto prison who seems guilty?

18. **Jonathan**
March 9, 2013

It is quite clear from the article that he's guilty. His sentence (a year or two of house arrest after a short stint in prison) is pretty light given the crime. It is kind of sad that a serious physicist would get caught up in this, but do keep in mind the effect of addiction and that he was trying to contribute to this problem solely out of self-interest. I think people should stop rallying around him, but at the same time I think once he gets out of jail he should be treated as before, since he did do his time.

I wonder if UNC will fire him due to his having committed this kind of crime. I guess they'll have to make a decision on this at some point.

19. **Roger**
March 9, 2013

The article would have been improved with some pictures of the bikini model.
http://www.dailymail.co.uk/news/article-2183861/Denise-Milani-Bikini-model-terrified-drugs-gang-used-honeytrap-science-professor.html

20. **gs**
March 9, 2013

Not to incite an off-topic discussion of the Drug War, but to put my reaction into context:

Having only known the rudiments of this situation and being a strong opponent of the "War on Drugs", I had been giving Frampton the benefit of the doubt. However, if the article is correct, I'd find him guilty.

21. **Peter Woit**
March 9, 2013

Please, the "War on Drugs" is definitely off-topic, thanks. If you want to discuss that, a posting about Frampton on Slashdot has just appeared, see

http://yro.slashdot.org/story/13/03/09/186229/the-manti-teo-of-physics

22. **gs**
March 9, 2013

Apparently Frampton knew what he was doing. Apparently he was doing it for money and other personal gain, not as an act of idealism or civil disobedience.

Apparently this is not an Aaron Swartz scenario.

23. **Paul Frampton**
March 9, 2013

If I may chime in as the subject of this discussion, I wish to state categorically that I am not, and have never been, an intentional smuggler of illegal substances. When I checked in a bag belonging to somebody else, which admittedly showed bad judgement, at Ezeiza airport in Buenos Aires, Argentina, on January 23, 2012 I had no knowledge or suspicion whatsoever that the bag contained any illegal material hidden within it.

24. **Peter Woit**
March 9, 2013

Thanks Paul.

(Yes, that comment was posted from Buenos Aires).

This may be a good time to close off this thread, since the discussion has kind of degenerated, with Slashdot a better place for this. I'll take the liberty of ending with my own comment that, while reading the Times magazine story made it hard not to come up with one's own conjectures about what really happened, I also realized that they were probably not worth much. Any news story like that one presents a very small selection of edited information, giving one the misimpression that one knows more than one does about what happened.

Things to Follow This Week

March 12, 2013
Categories: Experimental HEP News

If you want to keep up on the latest in HEP news, here's what you should be following this week:

- Neutrino Telescopes is happening in Venice this year, and I noticed that there's a very active blog for the conference, with a wealth of detailed postings about the talks. At first I was very impressed that such a large group of well-informed and energetic bloggers had been organized to cover this, then realized that it's actually just the indefatigable Tommaso Dorigo at work. He's doing a great job covering what is going on at the conference, and if as is looking all too possible, the LHC finds no new physics besides the Higgs, neutrino experiments may be where attention focuses in the future as the best hope for this.
- In Aspen this week there's a conference called Higgs Quo Vadis, on the current state of knowledge about the Higgs. Look for talks on Friday by Lisa Randall, Nima Arkani-Hamed and Nati Seiberg about what it all means.
- A second workshop at Moriond is going on this week. Will CMS finally release its gamma-gamma results there?
- If not at Moriond or Aspen, maybe at that LHCC meeting tomorrow?
- To keep up with the state of the LHC machine itself and plans for the future, the LHC Machine Advisory Committee is meeting later this week.

Update: One more. The HEPAP committee met this week, slides here.

   March 12, 2013

   the link for "Higgs Quo vadis" does not work…

2. **Peter Woit**
   March 12, 2013

   Thanks n, fixed.

3. **Svennor**
   March 13, 2013

   Hi Peter,

   There's also a nice paper on N=4 SYM scattering amplitudes @ finite couplings (all multiplicity/all loop) which seems like a big deal . I guess that's worth mentioning 🙂

   http://arxiv.org/pdf/1303.1396.pdf

   Best

4. **Len**
   March 14, 2013

   The other thing to watch this week was Kibble's 80 birthday celebration.

   http://plato.tp.ph.ic.ac.uk/conferences/Kibble80/

   Event was attended by Weinberg, Lars Brink (head of Nobel Committee), Guralnik, Close, and others.

   Pretty blatant Nobel campaigning by Imperial College to get Kibble on the ticket and using his somewhat minor 1967 paper as justification to be include over rest of his GHK team.

   Told the head table for dinner included Weinberg, Lars Brink, and Kibble with Frank Close giving after dinner talk to promote this 1967 paper. Weinberg also made some interesting comments in his talk about Israel.

   Wasn't sure the Nobel Committee went to campaigns like this but I guess that is the world we now live in. IC pushing hard to ensure the Americans (and CERN) gets overlooked in October.

5. **Peter Woit**
   March 14, 2013

   Len,

   Thanks. Interesting that Weinberg is attending an Imperial College event. Back in 2007 he publicly withdrew from one honoring Salam to protest what he saw as British anti-Semitism.

6. **Len**
   March 14, 2013

   Peter,

   I did not remember that 2007 event well but here is an article in the Guardian on that issue. Of course made a bit more interesting given Weinberg is an atheist.

   http://www.guardian.co.uk/education/2007/may/24/highereducation.uk1

   Lars Brink was also at a private dinner with Kibble and Weinberg Tuesday evening. No word on what type of dish was served to Lars.

   I have heard of physicists being invited to Stockholm for lectures to indicate they are likely candidates but not where the Nobel chair visits the candidate's campaign. I think Salam gave a lecture in Stockholm before his ’79 Nobel and Higgs was there in October of 2010.

More about Nothing

March 13, 2013
Categories: Multiverse Mania

It seems that last year's philosopher-physicist fight over nothingness (if you missed this, you can read about it starting here) is flaring up again. Recall that it all started with a David Albert New York Times review of Lawrence Krauss's latest book as "pale, small, silly, nerdy", moved on from there to Krauss characterizing Albert as "moronic", after which many others joined in. The New York Times today is reporting that Albert has been disinvited from participating in a debate over nothingness at the American Museum of Natural History here in New York, possibly because of Krauss's attitude that "If it were up to me, I wouldn't choose to spend time on stage with him".

The event in question is this year's Isaac Asimov Memorial Debate, on the topic of The Existence of Nothing. Tickets to the main theater and simulcasts in other rooms are sold out, but you can watch the debate online live here. It will feature Krauss, J. Richard Gott, Eva Silverstein and Charles Seife, with Jim Holt replacing David Albert.

Earlier this week the Simons Center at Stony Brook hosted another big public event promoting the latest deep-thinking from theoretical physicists. On Monday Andrei Linde gave a talk on "Universe or Multiverse?". Besides the usual pseudo-science, there were some things I hadn't seen before. Linde argues that one should replace the "pessimist's":

> If each part of the multiverse is so large, we will never see its other parts, so it is impossible to prove that we live in the multiverse.

with the "optimist's":

> If each part of the multiverse is so large, we will never see its other parts, so it is impossible to disprove that we live in the multiverse.

and goes on to argue that multiverse theory is more basic than universe theory because it is more general. At a more technical talk the next day he showed an implementation of this new way to do science, arguing for a new class of supergravity inflation models where "we can have any desirable values of n_s and r". Somehow also, the ability to get any r you want is great since "A discovery or non-discovery of tensor modes would be a crucial test for string theory and SUSY phenomenology". I'm not sure how you reconcile measuring r as a "crucial test", and having a theory that gives any value of r you want, but maybe I'm missing something.

Linde ends with another innovation. You see, the multiverse doesn't just explain why physics is the way it is, it also explains why mathematics is the way it is:

> Physicists can live only in those parts of the multiverse where mathematics is efficient and the universe is comprehensible.

I guess I should just be thankful that I don't live in one of those parts of the universe where mathematics is inefficient.

Update: More about the Albert disinvite story here.

Comments

   March 13, 2013

   I can't believe people are being paid for such frivolous pursuits when we still have not settled how many angles can dance on a pin.

2. **Avattoir**
   March 13, 2013

   'The New York Times today is reporting that Albert has been disinvited from participating in a debate over nothingness at the American Museum of Natural History here in New York, possibly because of Krauss's attitude that "If it were up to me, I wouldn't choose to spend time on stage with him".'

   Is it? The way I read the NYT piece was Albert was disinvited (uninvited) because the organizer, Neil de Grasse Tyson, became concerned that the nature of the dispute between Albert and Krausse reasonably threatened to eat up the 'science' orientation he, Tyson, wants for the talks.

   The NYT piece does voice the first concern, but as voiced by Albert, not the reporter.

   Off this, I'm sympathetic with Tyson: http://bloggingheads.tv/videos/1728

   Where Albert's contribution would have been better placed than Krauss' (to say nothing of Richard Dawkins): http://preposterousuniverse.com/naturalism2012/

3. **Peter Woit**
   March 13, 2013

   Avattoir,

   I have no inside information about what really happened here. I'll comment though that if you're the organizer of a thing like this, it's extremely unusual to disinvite one of your panelists because you've decided that maybe they weren't such a great idea. One of very few things that can cause organizers to have to take this kind of step is when they have one participant in essence saying "it's him or me".

   Note that this event is a debate, every year they try and get a panel with some conflict (in the past the string wars have been a topic). This one was planned after the Krauss/Albert thing happened, seemingly specifically to exploit this philosopher/physicist conflict.

4. **Avattoir**
   March 13, 2013

   I respect that you're familiar with and closer to whatever's going on, but it's still not what the NYT is reporting.

   Accepting that historically this event has been debate-oriented, IF IT WERE ME in Tyson's position, having watched that discussion between Albert and Carroll (and the other; there's two on bloggingheadstv), and having read Krauss' book, I'd be concerned, first, that Krauss seems way out of his weight class, and second, with the reception such a 'debate' would get from the sort of audience likely to attend.

   Mine is more of an Ocham's Razor take: that Tyson determined he's more interested in discussion around any controversies in Krauss' construct on the science than he is with producing something like the, um, far more nuanced consensus reached in the Naturalism conference.

5. **Peter Woit**
March 13, 2013

Avattoir,

The NYT is reporting that Albert believes he was disinvited because of Krauss's insistence, and is quoting Krauss to the effect that he does not want to get on stage with Albert. I don't think Albert is being paranoid…

6. **Christian Takacs**
March 13, 2013

"Physicists can live only in those parts of the multiverse where mathematics is efficient and the universe is comprehensible."

I wasn't aware that logic, causation, and arithmatic were strictly localized phenomena. Silly me. Occams razor trumps the simplistic truisms of SAP or WAP any day of the week, or "If things were different, they would be different" valid statement, but completely useless. It is far more likely that Professor Linde's argument is incomprehensible, rather than the rest of the cosmos.

7. **friend**
March 13, 2013

Logic, proof, and argumentation can only be applied to propositions. If there exists nothing to describe with a proposition, then you cannot apply logic and reason to it. You can't prove there once was nothing that gave rise to something.

8. **Chris Oakley**
March 14, 2013

Wait – so people are paying for tickets to see a debate about nothing? Why not just subscribe to the BBC Parliament sattelite channel?

9. **Mr MonoPole**
March 14, 2013

"Physicists can live only in those parts of the multiverse where mathematics is efficient and the universe is comprehensible."

It likely means, that there are (likely) some Universes where 2+2=5

We do not live in such a Universe, so our Mathematics is efficient and comprehensible.

10. **former mathematician**
March 14, 2013

re localized mathematics.

Recall Greg Egan's short story "Dark Integers." It hypothesizes the radically anti-Platonic view that arithmetic theorems are untrue until and if they are exhibited by configurations of particles.

11. **Guillaume**
March 14, 2013

> "Physicists can live only in those parts of the multiverse where mathematics is efficient and the universe is comprehensible." (Andrei Linde, 2013)

I prefer the original:

> "I'm what you would call a teleological, existential atheist. I believe that there's an intelligence to the universe, with the exception of certain parts of New Jersey." (Woody Allen, in Sleeper [1973])

12. **Gary**
March 14, 2013

Responding to ZZZ: I'd like to announce that the question of how many angels can dance on the head of a pin has been answered. (Happy PI day to all 8)

13. **Tom**
March 14, 2013

Regarding the physics-philosophy kerfuffle:

I think the biggest cultural difference between the two sides is the philosopher's insistence in rigor in argument. To be sure, not all philosophers hold themselves to this standard (nor, perhaps, even most within certain subfields, like Continental Philosophy), but it remains the methodological touchstone of our profession.

That is simply not the case in physics. A lot of very shoddy thinking goes on with you guys. Your unfounded devotion to string theory is an excellent example.

I was not a big fan of the tone of Dr. Albert's initial review, but I think the content was right on. The fact that physicists take it almost as a matter of faith that there is no god really irritates us. Now, I'm an atheist, and so are most of my colleagues. Maybe 20% of philosophers believe in a god. But practically none of us think that the existence of god is a TRIVIAL issue or one that can be solved simply by obtaining more facts or (even worse) that we recently obtained enough facts to settle the issue.

14. **Peter Woit**
March 14, 2013

Tom,

"unfounded devotion to string theory" is very much a minority position among working physicists, probably much more of a minority than your estimate of the 20% of philosophers believing in God. In particular, Krauss is a well-known critic of string theory.

On the "nothingness" debate, I'd guess most physicists find it an embarrassment and if the question of what to do about the AMNH debate were up to them would disinvite both Albert and Krauss and cancel the whole thing. I'd hope that most philosophers feel the same way, not that "their side" in this idiocy is the right one.

15. **nasren**
March 14, 2013

Second Tom's view. Albert's criticism of Krauss was right on the money — even if the tone left a sour taste in the mouth. Krauss's response was unbelievably childish, and this disinviting nonsense smacks of the same kind of behaviour.

16. **tt**
March 14, 2013

you'ld be closer to Pi on 3/14/15

17. **jim**
March 15, 2013

Yes. Krauss was the one making weak philosophical arguments and selling them to the media as science. Albert only pointed that out. Then Krauss commits the ad hominem fallacy. What an embarrassment.

18. **Gabriel**
March 15, 2013

> Physicists can live only in those parts of the multiverse where mathematics is efficient and the universe is comprehensible.

To read him more charitably, I think this means not that abstract mathematics varies from universe to universe with regards to some sort of intrinsic efficiency, but that physics varies from universe to universe in such a way that the efficiency with which it can be expressed mathematically also varies.

But I'm not going to watch the lecture to find out if that first impression is the correct interpretation in context.

19. **Kavanna**
March 18, 2013

Multiverse lunacy 🙂

The debate over nothing is a disgrace. Physicists should be keeping as far as possible from such misuse of philosophy and pseudo-theological mumbo-jumbo.

20. **DrDave**
March 18, 2013

From King Lear: "Nothing will come of nothing"

21. **tt**
March 18, 2013

"Nothing from nothing leaves nothing" — Billy Preston

22. **Anon**
March 21, 2013

Is mathematics efficient and is the universe comprehensible? Linde is begging the question.

23. **nabil**
March 22, 2013

I don't like the idea of the existence of huge number of universes which people use to explain anything they don't understand . It's very easy to say that the physical constants are the way they are because we are in a part of spacetime that happens to have these values .I think this is not the way nature is designed .

24. **veskebjorn**
March 25, 2013

@tt: You'd be much closer to pi on 3/14/16–at least in our peculiar version of Euclidean geometry. Elsewhere in the infinite variety and delights of the multiverse, pi might be a different number, a circle might be impossible, or numbers might be useless in trying to describe local reality. But then, the idea that physics requires “efficient” mathematics and a “comprehensible” universe is itself absurd. Humans have been making physical sense of and accurate predictions about our universe for millennia without the aid of mathematical notation, whilst being certain that variously irrational, more-or-less potent, divine entities existed and were subject to no laws. Math seems to have come a long way, but some of the wilder-eyed physicists who promote unfalsifiable fantasies don’t seem to have progressed much beyond Genesis.

The CMS data on the Higgs in the gamma-gamma channel has been released this morning, see [slides from a talk at Moriond]. Basically the excess over the SM prediction seen in this channel in earlier data is gone, with CMS reporting ratios to the SM predicted value of .78 +/- .27 using one sort of analysis, 1.11 +/- .31 using another, so, naively averaging, say .95. ATLAS sees 1.65, so a naive combination would give 1.3, only about one sigma high, very consistent with the SM.

Amusingly, the better than 4 sigma signal CMS was advertising last summer in this channel that was part of the case for the discovery announcement has largely vanished in the new 8 TeV data. With one analysis method, they see only a 2 sigma signal in the 8 TeV data. If they had been working with this new, larger and better, data set instead of the older, smaller 7 TeV data set, the Higgs discovery claims might not have been possible last summer. Of course, the CMS + ATLAS combined gamma-gamma results are very strong evidence for a Higgs signal, and the ZZ results are overwhelming, so the existence of a new particle is not in doubt. This is actually what you expect if a SM Higgs is there: you should get reversion to the mean and disappearance of the earlier too large observed excesses.

CERN has a press release out today which is getting a log of attention, headlined
[New results indicate that particle discovered at CERN is a Higgs boson]. This emphasizes results about the spin, but the new gamma-gamma results are what is significant, as they remove the one anomaly that was getting a lot of attention from theorists hoping for some kind of violation of SM behavior.

1. **behghk**
   March 14, 2013

   CERN does not call it a Brout-Englert-Higgs-Guralnik-Hagen-Kibble-pleaseaddmynametothelist-(Anderson hey what about me?) boson?

2. **King Ray**
   March 14, 2013

   Success has a thousand fathers but failure is an orphan.

3. **dark**
   March 14, 2013

   To anyone –
   what are the scientific ramifications of finding a *single* higgs boson (and no SUSY @ LHC) with SM only properties @125-6 GEV to the likelihood of SUSY, MSSM, GUT SUSY-GUT? I was of the understanding that they predicted multiple higgs bosons., and therefore, finding 1 and only 1 decreases the likelihood of SUSY or GUT.

4. **Eric**
   March 14, 2013

   Dark,

   The additional Higgs bosons predicted in the MSSM can have large masses such that they would not have been observed at the LHC. This is also true of all other scalars in the MSSM.

5. **dark**
   March 14, 2013

   eric ok thanks,

   but in those class of models are those “too large for LHC energies” masses “natural” and “well-motivated” or simply epicycles?

   I thought natural well motivated MSSM prefer a very light Higgs 110GEV?

6. **jinb**
   March 14, 2013

   Scalars are more naturally heavy than they are light, the only expectation for them to be light being the hierarchy problem, but otherwise if you relax that assumption it’s not arbitrary. Quite the opposite, it would be arbitrary to have them light, which is the guiding principle behind nima’s split susy model. Just abandon TeV scale hierarchy problem and see what’s the most natural thing for susy to do.

   SUSY does prefer a light Higgs relative to the Z mass, and 125 GeV certainly is light.

7. **paddy**
   March 14, 2013

   And just what is the “most natural” unnatural thing for susy to do? kinda like a word game eh?

8. **Thomas Larsson**
   March 14, 2013

   That the Higgs mass seems to sit exactly at the border of SM consistency is interesting, and reminds me of a similar phenomenon in another part of physics. In the 1940s Lars Onsager proved some inequalities that critical exponents must obey for consistency. Twenty years later people found that these inequalities were in fact identities, i.e. critical exponents are on the border of being inconsistent. The underlying reason for this is scale symmetry.

   Extrapolating this observation to the SM, the fact that Higgs seems to be borderline inconsistent could indicate that some symmetry principle is at work. There is of course no secret what I believe that this symmetry principle might be.

9. **A**
   March 15, 2013

"but in those class of models are those "too large for LHC energies" masses "natural" and "well-motivated" or simply epicycles?"

I wouldn't call them epicycles because you don't have to add anything to the model to obtain them, but the higher you raise the remaining SUSY masses, the more finely tuned is the smallness of the electroweak scale relative to those SUSY masses.

10. **Allan Rosenberg**
March 15, 2013

According to the Washington Post, the conclusion "helps solve one of the most fundamental riddles of the universe: how the Big Bang created something out of nothing 13.7 billion years ago." http://www.washingtonpost.com/world/europe/physicists-say-they-are-now-confident-they-have-discovered-the-long-sought-higgs-boson/2013/03/14/0ffa6562-8c90-11e2-adca-74ab31da3399_story.html Let all of the people who say HEP experimentation is a waste of resources chew on that!

11. **bang**
March 15, 2013

It does help, in its own way. Take away the Higgs, the quarks and leptons, the (nonabelian) gauge bosons, the photons … and what do you have? No photons, ergo no blackbody radiation, ergo no CMB, ergo … how will you even be able to say the Universe came from a Big Bang?

12. **emile**
March 16, 2013

I've found recently that many people (even a few in HEP) confuse the Higgs boson of the SM with the particle predicted by Higgs. Back then, there was no SM, and no weak neutral boson. The prediction involved a scalar field that coupled to W bosons to give them their mass. I'm glad that CERN is now making the point that this is a Higgs boson: there is a particle beyond a reasonable doubt, it couples to weak bosons, and spin measurements are compatible with a spin 0+ particle and the alternatives are disfavoured (at ~95% CL or greater).

@bang: could you expand a bit on cosmology without EWSB? so we would have no photon but we would have four massless bosons, including the "B". So what would replace the CMB? matter-anti-matter particles would annihilate to what? There would be a background radiation of Bs? I had not thought of this before…

13. **Michael Brown**
March 16, 2013

@emile Recently read this physics stackexchange question on the standard model without EWSB. I found Ron Maimon's answer in that thread to be interesting and well worth reading.

Note that QCD still gives a mass to the weak gauge bosons (though much smaller than their actual masses due to the Higgs), and nuclear physics is very different. I'd love to know if anyone has any scholarly references about this.

14. **Alex**
March 16, 2013

"I'd love to know if anyone has any scholarly references about this."

Yes, for example Robert Shrock and Chris Quigg made quite an effort exploring this scenario explicitely here:

http://arxiv.org/pdf/0901.3958

15. **bang**
March 16, 2013

@emile: Back up a step and set aside EWSB. Go back much further, to the days before QM and Relativity. Go back to the 19th century. Scientists in the 19th century (geologists etc) had come to realize that the Solar System was at least hundreds of millions of years old. Scientists also knew enough physics to realize that the Sun was a ball of mainly hydrogen gas, and its approximate size and its radiated power. They also knew from chemistry that chemical hydrogen burning to water could not provide eneough energy to sustain the Sun's radiated power for such a long time. So the source of the Sun's energy was a puzzle which 19th century physicists knew they could not explain with the physics of the day.

My point is *they knew that they did not know*. They knew that there was new physics `out there.'

And they were correct. We know today that thermonuclear fusion is the source of the Sun's energy. It is a form of energy unknown in the 19th century. It required both QM and Relativity to answer the puzzle of the source of the Sun's energy.

So, my point is that the Higgs, etc. *do* help to increase our understanding of fundamental processes, the interaction of matter and radiation, and this does help, in its own way, to understand the physical processes of the Big Bang. Don't jump ahead so quickly to EWSB.

16. **Flakmeister**
March 18, 2013

With regards to the the earlier modest excess over the SM in the di-photon channel one needs to appeal to the old adage "discoveries are always made on an upward fluctuation"….

I do have to admit that "No-lose theorem" for a TeV scale collider is starting to look like the lowest possible payoff was in the offing… Too bad, even though I was never a fan of low energy SUSY, but, discovering would have enabled a return to the Golden Age of Particle Physics, i.e. when everyone with pulse could find something new, but unlike the 60s, one could actually calculate quantities….

Given the slim prospects and likely timeline for the next collider, perhaps it is just as well that it was a SM higgs and that was "all she wrote"….

Request for Advice

My main method for keeping track of new information on the web has for many years now been RSS, with Google Reader for a while the main tool for this. Google yesterday announced that they're shutting this down, with as far as I can tell the reason being that RSS doesn't fit into their plan for world domination. So, like everyone else, I need to figure out how to change over to something new. For "what do I do now to keep track of other web-sites?", there are hundreds of such discussions I can follow (Feedly seems to be getting the most attention), although I'd be interested to hear from anyone who is very knowledgeable about this. If it doesn't run across multiple machines with different operating systems, I'm not very interested. If it only runs on mobile devices, forget it, although being able to run it that way would be a plus.

More importantly though, I'd like to ask for advice from my readers about how they keep track of new blog postings here and what could be done to make that easier. Extra points for links to how to implement solutions using a standalone WordPress installation. Note that I'm not trying to find ways to drive lots of new traffic here, more interested in making life easier for the generally well-informed readers I already have.

So far in life I've pretty much completely avoided knowing anything about social media and how they work, so advice on that front would be appreciated. About all I know now is that there is some way to set up twitter to provide announcements of blog postings, and that looks like one of the first things I might try. If there's some way to do this kind of thing without festooning one's site with other people's logos and stuff about "likes", that would be great.

Update: Looks like RSS is still the most useful for people. I have however set up a "notevenwrong" twitter account, and just installed a wordpress plugin that should add something there when a post is published or updated. Let's see if it works…

Comments

1. **David Woodruff**
   March 15, 2013

   I'm in the same boat, since I follow a large number of blogs including yours with Reader. I am still in denial about Reader going away! There is a change.org petition that has already attracted quite a lot of attention (http://www.change.org/petitions/google-keep-google-reader-running)–maybe google will have mercy on us and keep it going.

2. **Matt**
   March 15, 2013

   I for one am anxious to see what people post here for solutions. I'm at a total loss for what to do. The whole point of Google reader is that I can keep everything synced to my Google account and don't have to deal with all sorts of accounts all over the place.

3. **Kasuha**
   March 15, 2013

   I don't know if this will be helpful but anyway…

   List of alternatives:
   https://docs.google.com/spreadsheet/ccc?key=0ApTo6f5Yj1iJdFRfWmhUVjV0WkktTjJhUUE4dGR5WUE#gid=0

   A petition to keep it running:
   https://www.change.org/petitions/google-keep-google-reader-running

4. **Hypnos**
   March 15, 2013

   I use a standalone RSS reader to keep track of various feeds, including that for your blog; I have never used Google Reader, and don't understand why its termination is such a big deal.

5. **Deane**
   March 15, 2013

   I'm in the same bind. Will watch the comments to se what's recommended.

6. **Filip**
   March 15, 2013

   Apart from Feedly that I don't like that much, I will try The Old Reader (currently waiting my subscriptions to be imported from Google, as there are now too many new users jumping in). It seems that it is an option the most similar to Google Reader, and you can use your Google account with it. Of course, it is Web based, so any machine is good for it.
   Cheers

7. **Peter Woit**
   March 15, 2013

   Hypnos,

   I used several standalone RSS readers before Reader. The problems with them typically were that they didn't sync between multiple computers (e.g., home, work, mobile), that they were buggy, and didn't behave well when dealing with large numbers of feeds, or with the content of some kinds of feeds.

8. **fraac**
   March 15, 2013

   I don't really know how this works, or why they would want it to suddenly not work, but I'm *assuming* that the 'click to subscribe' button in my Chrome address bar will still be there and allow me to subscribe to RSS feeds using a different but similar Google service.

9. **Markk**
March 15, 2013

I am in the same boat. I track blogs with Google Reader. I will be looking for some Web based system to replace it. I am surprised that the number of people using it is dropping. I guess people that have a list of blogs to follow is now small? Has the readership dropped off? People must be using something.

Hypnos, the advantage Google Reader gave me was that I could read entries at lunch at work, the go home and pick up right where I left off on a different computer, then go on a trip and use my nook, and everything was all the same everywhere and every change went everywhere.

10. **jensph**
March 15, 2013

The Old Reader looks like an great alternative (I've missed not having Reader comments since Google launched Google+), assuming they launch mobile versions that cache content.

I've been trying out Feedly. It looks pretty, but I'm not sure if I'll be able to navigate as efficiently.

Also Digg is promising to build an option.

11. **Martin**
March 15, 2013

I just switched to newsblur.com and am finding it a very adequate replacement for google reader. They even helpfully connect to your google account when you signup and import your feeds for you with no fuss.

Their service is under a bit of stress at the moment (as I believe a lot of the alternate reader services are at present) but I suspect that will dissipate over the coming days.

The service is a paid subscription if you have more than 64 sites, but the cost is less than a cup of coffee a month ($2 monthly). Paying has the benefit that you are no longer the product but a paying customer. Services that you pay for a product tend to pull the rug from under your feet less quickly than ones where you are the product.

12. **Kirill**
March 15, 2013

I use RSS reader in desktop Opera browser because of easy search, filters and integration with e-mail client, but because Opera has questional future and it has not any synchronisation I wanted to move to Google Reader in the past.

13. **KP**
March 15, 2013

I have recently switched to Feedly from Reader, and I really like it so far. The good people at Feedly have introduced a very easy way to migrate all of your feeds from Google Reader before it shuts down.

It installs as a browser app for Chrome and Firefox (haven't looked at other browsers) and also as a mobile app on iOS and Android. Also, it works on Linux which is a good thing.

I have been following NEW on Reader for the past few years and now Feedly for the past few days. You do have a link to your RSS feed in the site's Meta section which is what is needed to follow this site. In any case, modern feed readers are smart enough to figure out the feed even if you only give them the URL of the site. (That is how I did it on both Reader and Feedly.) So to me it seems that you really don't have to set up anything more.

Cheers

— KP

14. **Fred P**
March 15, 2013

Personally, I just visit this site; I was unaware that you had an RSS feed – nor am I likely to use it now that I know.

As for Google Reader, I'd never heard of it. For data-intensive cases, or sources where I want to make certain that I don't miss any content, I use RSS. Otherwise, I surf when I'm interested. This means, of course, that sites I travel to less frequently I forget about – but I consider that a feature, not a defect.

15. **Boaz**
March 15, 2013

I also use Google reader RSS reader to find out about new posts for your blog.
I'll probably try out some of the other readers, which I've gotten lazy and forgotten how to use. I also use Twitter sometimes and a lot of blogs I follow make announcements of new posts there. Here's a Twitter based voting system where people are suggesting different RSS readers.
Feedly is #1, Bloglovin is #2…
Thanks for your informative blog which has been a staple of my internet reading over the years.

16. **Hypnos**
March 15, 2013

Thanks for the explanation — the issue is here is not that an app was discontinued, but a *platform*. As you hinted at, this is precisely the risk with cloud services and why I don't use them. Since I need a laptop for work anyway, I just have everything set up on that including my RSS reader.

Good luck!

17. **Heikki Arponen**
March 15, 2013

There's still time until july. I bet there will be plenty of decent alternatives by then, some of which may not be free.

18. **Suzanne L**

March 15, 2013

You could take a look at rss2email (http://www.allthingsrss.com/rss2email/). It's a python program that fetch news from your RSS feeds and redirect them to your mailbox (as text or html message, whatever you prefer; one mail per new entry). You should be able to run it on every system that runs python. You just run it, say once a day, from one arbitrary computer (but allways from the same, to avoid getting duplicates), and then you can access and archive the news of the day from any device from which you can access your mailbox.
If you have an account on some server that is connected to the internet all the time (like a university server), maybe you can have a script running periodically on that server that do the job automatically.
This is what I use to follow websites, including this blog, since I find it very convenient to get everything (my mails, news, arXiv feeds…) from just one program (my mail viewer). Combining it with mail filtering is best…

19. **X**
March 15, 2013

I started kicking Feedly around and was not impressed. My use pattern for gReader is to leave it open all the time with a list on the left panel of all feeds with unread stories. When I have time, I click on a feed and read some stories from it. I can abandon the page at any time and come back later to find if new stories have appeared in any feed.

When I tried the same thing in Feedly, trying to read one feed moved me into some kind of sub-page showing a fraction of my feeds (both read and unread (Why do I want to look at feeds I already finished reading?)). Apparently, they expect me to mouseover and click around some tabs to see what's updated. The whole point of a feed reader is to save me the time I was spending clicking around a hundred bookmarks. For me, unusable.

It also seems to want to put big pictures all over the place. I'm not reading a lot of picture books online, so I just get swaths of whitespace next to all my items.

20. **Wally**
March 15, 2013

WordPress has a reader. You can subscribe to and read Blogger and WordPress blogs. Good enough for basic purposes.

21. **JohnB**
March 15, 2013

RSSOWl is very good, but as you say, it has issues with certain feeds, and can not sync between machines (it used to use Google Reader for this); the problem with certain feeds is longstanding and I'm not sure it will be fixed (a pity as great program otherwise), but the authors will be looking at alternative sync systems, possibly using the future Feedly sync API at some stage.

So yes, very good program, just the devs aren't as active at updating it as they should be:
http://www.rssowl.org

22. **ohwilleke**
March 15, 2013

FWIW, a lot of us geezers just click through a bunch of links in a blogroll every two or three days, no RSS feed or google reader services required.

23. **Peter Woit**
March 15, 2013

All: I've set up a twitter account "notevenwrong" for people to follow that will notify about new postings, for those not using RSS for this purpose. I'm not now planning to put anything else there.

fraac,

Google has also just removed that functionality from Chrome, see here
http://techcrunch.com/2013/03/15/google-kills-rss/
Evidently that was an interface to Google Reader, but could be configured to work with other RSS readers.

It looks like this is not just a decision to stop developing a particular piece of software, but a general declaration of war on RSS, removing RSS support from all Google products. The most convincing explanation I've seen for this is that Google has always had a problem with people getting content via RSS, since this typically bypasses their advertising and other tracking embedded in web-pages.

24. **JJG**
March 15, 2013

Netvibes (http://www.netvibes.com/) is pretty good for aggregating a pile of RSS feeds, rather like the old Google homepage — I switched to it after that closed that down. It seems everything of Google's that I've ever used has been closed down, so I avoid them now so as to not jinx other users (I never used Reader, that's not my fault).

25. **Chandan Dalawat**
March 15, 2013

Google wants you to join Google+.

26. **yoshi**
March 16, 2013

Yep, I recommend netvibes since I use it everyday

27. **Bee**
March 16, 2013

I'm another one of these people who use Google reader to sort their news. I'll probably migrate to feedly, it has an iPhone app, which is handy because I presently pipe the Google reader into Newsify, which probably won't work anymore. I've tried netvibes, but it seems terribly cluttered and I don't really have the patience for this.

28. **Peter Woit**

March 16, 2013

Chandan Dalawat,

As far as I can tell, Google+ just doesn't do what I need at all, with no way to keep track of new material on blogs and other internet sites (except Google+ sites). One of the main things it does is provide people a way to link to internet material they find interesting and want to share, but I'm guessing the way people are finding such material is typically via Google Reader (or some other RSS reader).

29. **Vytautas Jakutis**
March 16, 2013

Digg is building a reader.

I personally connect with ssh from various computers to my remote home server and use Newsbeuter.

30. **paddy**
March 16, 2013

Peter,
Not helpful and perhaps a bit snarky, but I use NEW to tell me when something interesting is happening. Thank You.

31. **Peter Woit**
March 16, 2013

paddy,
Not really helpful to me, but much appreciated. Thank you.

32. **David Appell**
March 17, 2013

I use a standalone RSS reader, Bloglines, but have Blogtrottr email me new blog entries for blogs I really want to keep up with (including this one).

33. **Suzanna E**
March 17, 2013

I am a scientist in the epidemiology field. To be honest to get my news updates in my field, I subscribe to email alerts from all the scientific journals of interest – i select updates on news plus Table of Contents. I find this approach extemely useful.

34. **Shuhao Cao**
March 17, 2013

I pretty much track all my scientific reading in Google reader. Especially there is a nice feature in reader called "sort by magic", where it gathers your reading statistics and chooses what you like to read. Twitter? I don't know. Though RSS sounds so yesterday and web 2.0'ish, it is still my main source of getting information, learning new things other than my research area. Guess I'll just switch to another feed reader. BTW: saw a petition in the reply. The idea of petition sounds pointless to me, for Google dropping support for RSS must be a long term plan, and reader would never come back.

35. **Kevin**
March 17, 2013

I have used RSS since the first version of NetNewsWire. Then they added Google Reader syncing, which I adopted (without ever visiting Google Reader itself). Through the years I have come to rely entirely on RSS feeds, synced with Google Reader, but viewed on any of a dozen Mac, iPhone and iPad apps. I can check journal articles on my phone while I wait for my coffee, and when I get to my office, a different program on my desktop already knows I read those titles/abstracts. It is the most efficient workflow for keeping up to date with journals and blogs. These programs also integrate Instapaper perfectly, so I have a hierarchy of "favorites". I have no idea what to do without Google Reader for syncing, but I hope someone figures it out.

Given that not once in close to 10 years have I actually visited the Google Reader web interface, I'm not too surprised that Google killed it. The have by far the most unappealing user experience imaginable (except Google itself), so they should stick to running a huge database and let real designers do the front end. Worse, my university adopted Google for everything (including our email!), so we are forced to use those soulless UIs. Fortunately, there are many capable programs that sync with Google Calendars and other Google databases.

36. **Stephen Crowley**
March 18, 2013

Sage is an excellent RSS reader plugin for Firefox. https://addons.mozilla.org/en-us/firefox/addon/sage/

37. **Ossicle**
March 18, 2013

I almost literally don't understand a word of this, but perhaps someone here will find it interesting. A techie friend posted to Facebook:

"This looks like a thing to mention.

Basically: here's where you vote to tell Bitnami that they should support "Tiny Tiny RSS". If they *do* support ttRSS, the upshot will be either a tarball or an RPM or a VMWare image or an Amazon Cloud image (usually "all of the above") that you deploy and, bampf, you're running your very own replacement for Google Reader."

And he linked to this:

http://bitnami.org/product/tiny-tiny-rss

-O

38. **Peter Woit**
March 18, 2013

Ossicle,
I’ve looked at that. The idea is that you run your own version of what Google is running, on your own webserver. Not useful if you don’t have your own webserver to use for this purpose. I’m still curious though if any one using it can comment on whether it has performance or bug problems (can you really do this kind of thing without Google’s massive server farm, or without a staff of people to maintain the software?).

39. **Gerald Loeffler**
March 18, 2013

just wanted to stress how very **sub-optimal Twitter** is compared to RSS/Atom: only with RSS/Atom does the reader get a guarantee (or as close to a guarantee as is possible with currently available technologies) that he/she doesn’t miss any pieces of information published by an information source. With Twitter it takes an inordinate amount of effort (and is decidedly non-standard) to not **lose pieces of information** published when the reader was offline.

40. **Bob**
March 18, 2013

I spent an hour or so going through the popular alternatives to Google Reader and settled on NetVibes, because with a little configuring it was the most similar to Google Reader. Switch from “widgets” view to “reader” view to get a Google Reader-like interface. Then delete all the default feeds and import your personal feeds. (You only have to do these things once.)

Other readers I tried:

Feedly: The interface is too different from Google Reader for me. It requires multiple clicks to do things I am used to doing in one click.

NewsBlur: Almost like Google Reader but with separate window panes for story titles and expanded stories. I don’t like the extra window pane.

The Old Reader: From what I can tell, stories can’t be read in the reader, you’d have to keep leaving the reader and going to the external webpage.

41. **Rien**
March 19, 2013

I read this and all other blogs almost exclusively through RSS, mostly with Google Reader on my phone and with Gruml on my Mac. I usually only click through if I want to read comments. (Or comment, which I almost never do, but I usually read most of your posts.)

The Google Reader app is by far the best RSS reader I’ve tried, unfortunately. Before I stopped using Firefox I used Sage, which is quite good.

42. **Leonardo**
April 3, 2013

With some customization, the use of Feedly can become very similar yo Google Reader. First time I tried Feedly, I felt a little bit awkward and thought that it wouldn’t work, but later, as I customized it, and found out the next-previous buttons are j-k (counterpart of GReader was n-p which makes something else in Feedly), now I am pretty comfortable with Feedly. But the fact that it is in the form of an add-on bothers me a little, I would prefer a standalone webpage with its own login, etc. But I am not sure whether this is really important or not.

Busy Week

March 16, 2013
Categories: Uncategorized

There should be lots of breaking news this upcoming week, sometimes with real-time webcasts for those that want to follow along:

- Planck data release on Thursday the 21st. Media briefing in Paris will be at 10am local time, see here. In the US, NASA will host a press conference at 11am EDT, see here.

  The night before here in New York at 7:30 pm (watch here) two journalists and three leading cosmology theorists will be discussing the emergence of the universe or multiverse from nothing. Perhaps someone will ask them what this theoretical work implies in terms of predictions for the new results to come out the next day.

- On March 20th at noon in Norway, the winner of the 2013 Abel Prize in Mathematics will be announced here. This is a prize of about $1 million, set up in 2002 to be an equivalent of a Nobel prize in mathematics. They seem to like to give this one to people from the Courant Institute here in New York.
- I'm wondering what's up with the Templeton Prize, a $1.66 million dollar prize normally awarded each year in March. Haven't seen any announcements, but perhaps this will also happen this week.
- Finally, there's Yuri Milner's Fundamental Physics Prize, which at $3 million makes everyone else look like pikers. Last December, the news was that the award would be announced at a ceremony at CERN on March 20. Candidates for the prize are a group of three condensed matter physicists, string theorist Joe Polchinski of UCSB, and string theorist Alexander Polyakov of Princeton. With the decision being made by a group of previous winners largely consisting of string theorists from Princeton, if I had to guess the winner, I'd go with the string theorist from Princeton. Coincidentally or not, Polyakov is scheduled to give the String Theory Seminar at CERN on March 20, on the topic of Sensitive, unstable and turbulent vacua.

Update: The Fundamental Physics Prize announcement will be Wednesday at 8pm, live webcast here. The IAS faculty will be there in force, with TH String Theory Seminars scheduled for Arkani-Hamed and Witten on Tuesday, Seiberg on Thursday.

Update: The Templeton Prize will be announce April 4, see here.

1. **Deane**
   March 16, 2013

   It seems unlikely that they would award it to anyone from Courant this year, since the committee met and made their decision *at* Courant. It would look really funny if they picked someone from Courant. Of course, it's already amazing that they've already chosen three from Courant. And, if you ask me, Louis Nirenberg easily deserves one.

2. **Peter Woit**
   March 16, 2013

   Deane,

   I think you're probably right. On the other hand, while it would look kind of funny for a group of Princeton string theorists to award the prize to a Princeton string theorist, I'm not betting against that…

3. **Pi**
   March 16, 2013

   I hope John Conway gets the Abel for this year.
   And also I found this recent article in guardian about SUSY interesting:
   http://www.guardian.co.uk/science/life-and-physics/2013/mar/14/supersymmetry-spell?CMP=twt_fd

4. **hu**
   March 16, 2013

   What happened with AMS-02 results? Haven't heard anything since the announcement back in February.

5. **anon.**
   March 17, 2013

   string theorist Alexander Polyakov

   Surely Polyakov is, by any measure, one of the great quantum field theorists–or for that matter, theoretical physicists–of the last 50 years, even disregarding his work on string theory.

   March 18, 2013

   I also have been patiently awaiting AMS-02 results

8. **Peter Woit**

March 18, 2013

Seth Thatcher,

Well, the news this weekend from AMS-02 on twitter, see

https://twitter.com/AMSISS/status/313110134593318914

is that they really want to get to 3000 followers on twitter. Maybe that's what they're waiting for on the data release….

9. **DR**
March 19, 2013

the fundamental physics prize really should change its name to "the math in physics prize". Since when a theorist with all works contradicted by the experiments can win a "physics" prize? Also, N=2 is not physics, how come it gets a physics prize???

10. **Peter Woit**
March 19, 2013

DR,

This isn't a "math in physics prize", most of the laureates (and all of the candidates this year) have not done important mathematics or mathematical physics (Kontsevich and Witten are the ones who really have). The prize is for "fundamental physics", not mathematics.

God to Award Prizes for God Particle

March 19, 2013
Categories: Uncategorized

In more news about the Fundamental Physics Prize awards planned for tomorrow evening at CERN, it turns out that God himself (AKA Morgan Freeman) will be giving out the awards, as well as hosting a TV show about this the same evening.

Physicists have often claimed to be upset by the "God particle" business, but it looks like CERN and the Fundamental Physics Prize people may be now embracing the idea. Leon Lederman is the one originally responsible for the terminology, supposedly because his publishers twisted his arm into using The God Particle as the title of his 1993 book about the Higgs. Evidently they've twisted his arm again, with Beyond the God Particle set to appear in October.

Both Sean Carroll and Matt Strassler are upset about a CBS News report, which contains some scientifically inaccurate hype that they're blaming on Michio Kaku. It's unclear to me why, after 20 years of over-the-top hype about string theory and extra dimensions from Kaku (going back for instance to here), they're all of a sudden up in arms about this now. Whatever the reason though, I very much agree with Matt's

> Doesn't the taxpaying public deserve the truth? Isn't the truth already exciting enough? And what will the public think of science if, in this information era, the promulgation of falsehoods and near-falsehoods on national media is unanswered by complaints from other scientists?

and think it's great that he and Sean are now turning their attention to this problem.

Update: It's definitely gang up on Michio Kaku day in the blogosphere, with PZ Myers and Chad Orzel chiming in. Still a mystery to me why this is happening today, since Kaku has been responsible for far more outrageous stuff continuously for over 20 years.

Update: Philip Gibbs comes in on Kaku's side here.

1. **Jon Orloff**
   March 19, 2013

   I have always thought that the term "God Particle" was a mistake. In the first place it sounded as if high energy physicists were using it as a gimmick to get taxpayers to pony up for bigger accelerators (who wouldn't pay for a bigger machine to find God?). In the second place it induced (induces) cringing and leaves a bad taste in one's mouth..

2. **Nex**
   March 19, 2013

   Same old problem, I remember reading about Feynman criticizing the "eightfold way" theory name cause of people taking it literally as a connection between physics and buddhism. The "god particle" term seems way more problematic still.

3. **gott**
   March 19, 2013

   Actually, Leon Lederman wanted to call the Higgs the `Goddamn particle' because it was so difficult to find, but the editors objected to that and changed the name to the `God particle'. So *that* was the arm-twisting of Leon Lederman by the editors. As for the new book `Beyond the God Particle' I've not heard of it till now and I have no idea what arm-twisting if any took place.

4. **Hypnos**
   March 19, 2013

   > It's unclear to me why, after 20 years of over-the-top hype about string theory and extra dimensions from Kaku (going back for instance to here), they're all of a sudden up in arms about this now.

   Because the Higgs actually exists?

5. **Flakmeister**
   March 19, 2013

   @Gott,
   yep, thats the version of the story that I heard…. And having had some interactions with Leon, it does seem plausible….

   And something tells me that cursing that damn particle is not over…

6. **cormac**
   March 19, 2013

   I like Nex's 'god particle' with a small g, I must admit I've been using this for a while. I find it a reasonable compromise, gets bums on seats while not pretending to deities etc…in the many talks I have given, I have yet to meet a member of the public who thinks it has anything to do with religion

7. **Yatima**
   March 19, 2013

   > "Still a mystery to me why this is happening today"

   Just another black swan event.

8. **Jens**
   March 19, 2013

   If Higgs Particle = God Particle, shouldn't Higgs be God rather than Morgan Freeman?

9. **notHiggs**
March 19, 2013

@Jens: Nope. Or at least I expect that will the chorus of protest from Brout, Englert, Guralnik, Hagen, Kibble, and never mind that one of them's dead, since we're talking about God here. Are those squawks from Anderson I hear in the background?

10. **David Metzler**
March 19, 2013

Your headline would make The Onion proud. Nicely put.

11. **lev**
March 19, 2013

Why not call this particle simply "higgs"?

12. **yuk**
March 19, 2013

By the same logic, let's call the electron a `dirac' (or `jj' or even better a `faraday' … how about 'faraday and dirac' = `fad'?), and the pion a `yuk'.

13. **lev**
March 20, 2013

to yuk:
there is no time reversal in history. Do you agree that higgs is simpler than Higgs Boson and less blasphemous than god?

14. **yuk**
March 20, 2013

Not really. I'd be perfectly happy with 'brussels brout'.

15. **lev**
March 20, 2013

How many physicists would be perfectly happy with your choice?

16. **yuk**
March 20, 2013

Picky, picky … how about 'qibble' ? (to be pronounced 'kibble'?)

17. **Johnny**
March 20, 2013

"God particle" is a mistake because God does not exist but the particle does!

18. **poisson**
March 20, 2013

Je n'avais pas besoin de cette hypothese?

19. **paddy**
March 20, 2013

yuk,
While we are renaming particles..how about not muon but…(drum roll please)…the "whoorderedthaton"?

20. **yuk**
March 20, 2013

@paddy: Very good! I completely missed that, but it deserves first prize!

21. **speakertoanimals**
March 21, 2013

Couldn't agree more with your comments about Kaku: he's been an embarrassment for two decades now. Maybe some of the folk are upset (now) bc he's being quoted instead of THEM?

Joe Lykken: No SUSY, No Naturalness Problem

March 19, 2013
Categories: Uncategorized

Conventional wisdom in the particle theory for about 30 years has been that the Standard Model has a huge "hierarchy" or "naturalness" problem, the solution to which is supposed to appear at the LHC via SUSY or some other new BSM physics. With no SUSY or other BSM physics appearing at the LHC, this conventional wisdom is now moving towards claims that fundamental physics has been shown by the LHC to be "unnatural", with parameters that are environmental, artifacts of our position in the multiverse generated by the anthropic landscape of string theory. For an example of this, see Seiberg's [Now What?] talk at [Aspen] (Arkani-Hamed also spoke, with presumably a similar point of view, although the talk is not available).

It seems to me that a much more logical conclusion to draw would be that the LHC has just shown that the hierarchy/naturalness argument was mistaken. I've never understood why people found it convincing, and have often argued about this here on the blog. From the "hierarchy" angle, the problem is why the ratio of the electroweak-breaking scale to the GUT or Planck scale is such a small number, but we don't actually have any evidence for GUT physics or for quantum gravitational physics, so no good reason to be sure that such high scales are relevant to anything or the cause of a hierarchy problem. From the "naturalness" side, while the theory is renormalizable, one can worry about the sensitivity to high energies of its cutoff dependence, but it's unclear to me why one should be that concerned about this. More worrisome is that the Higgs sector introduces most of the undetermined parameters of the SM, a much more serious defect of the standard theory.

Today at a workshop on [The First Three Years of the LHC], Joe Lykken gave a talk on [Higgs without Supersymmetry], in which he argues that there is no naturalness problem or need for supersymmetry, and makes a specific suggestion about how to think about the high energy behavior of the Higgs. He starts off with:

> is there a Higgs naturalness problem?
>
> •For decades the HEP community has asserted that naturalness is the central issue
> •Simply put, we have assumed that either EWSB is natural, in which case we need to explain why, or that it is fine-tuned, in which case we also need to explain why
> •I will argue that this is a false dichotomy,and that LHC results are hinting at a third path

then explains the standard dogma about quadratic sensitivity to the cutoff. He argues that the solution to this problem lies in properly understanding the scaling behavior of the Higgs, following ideas that go back at least to W. Bardeen in 1995 (see [here]). The fact that the renormalization group flow of the quartic term in the Higgs potential takes it to zero at high energies is interpreted as a suggestion that the right UV boundary condition is that the Higgs potential vanish. From there Lykken goes on to discuss more specific ideas, which may lead to observable new physics at LHC scales.

These aren't really new ideas, but I think Lykken is drawing the right lesson from the LHC results: the naturalness argument for SUSY has now been shown to have been misguided, and it's time not to give up and adopt the pseudo-science of anthropics, but instead to question the dogmas that have dominated the subject for decades.

Comments

1. **Flakmeister**
   March 19, 2013

   Link for Lykken's talk is a duplicate of Seiberg's….

2. **Peter Woit**
   March 19, 2013

   Flakmeister,

   Works fine for me??

3. **Mean and Anomalous**
   March 19, 2013

   The Lykken link works fine for me as well. Also, Peter, you wrote:

   '…for SUSY has now been show to have been misguided…', you meant to write '…shown…'

4. **Peter Woit**
   March 19, 2013

   Mean and Anomalous,

   Thanks, fixed.

5. **Flakmeister**
   March 19, 2013

   Thx.. my bad (too many tabs flying around)….

   Don't be so hard on TeV scale SUSY…. it always struck me as a jobs program for experimentalists and theorists… Hell, at LEP2, one search analysis could give you 5 easy papers…. SUSY did have the benefit of providing testable predictions (even though you knew there was a lot of wiggle room)

6. **Frank Quednau**
   March 19, 2013

   As an outsider to this world, I had to look up on naturalness – indeed it seems strange to me that lack of naturalness should hint at anything. The universe seems to show structures at many different scales of Spacetime, how should a model representing such a universe exhibit "naturalness" as defined in wikipedia?

7. **Peter Woit**
   March 19, 2013

   Frank,

The scales of various observed physics have some explanation in terms of our understanding of the astrophysics/physics (except I guess the size of the universe, the time back to the big bang is just an historical fact).

Very roughly, the idea of naturalness is that if even if you don't know how to compute something, you expect it to be "naturally" of order 1 in the appropriate units. If it's exponentially smaller, there should be some reason. People try and apply this to particle physics at scales such that we don't have experimental evidence.

Then the question arises as to why the Higgs mass (or W, or Z, etc) is so small in units of the GUT or Planck scale. The answer may just be that there is no GUT scale and the Planck scale is irrelevant. The SUSY explanation is that fermionic superpartners 0f the Higgs have zero masses (before SUSY breaking), and this keeps the Higgs small small. You then expect the SUSY breaking scale to be what determines the mass. Thus the problem arising now, since the LHC has shown that the SUSY breaking scale must be quite a bit higher than the electroweak breaking scale.

This argument is made in various forms at the beginning of just about every review paper or talk on SUSY, and I'm just giving a crude version of it. Best I not go on about the details, but look for a more detailed version that might be readable.

8. **lun**
March 19, 2013

Some of your collegues might have shown the string landscape is in fact falsifiable, by, erm… falsifying it
http://arxiv.org/abs/1303.4428.pdf

9. **Peter Woit**
March 19, 2013

lun,
As they say in the abstract "if our results prove applicable to string theory…"

But please, that's really off-topic, and I think the Lykken talk is a much more interesting subject.

10. **N. Nakanishi**
March 19, 2013

The non-existence of SUSY in Nature is quite natural; I have expected this result since thirty years ago. Because there is no Nambu-Goldstone fermion, one must go to supergravity in order to make use of super-Higgs mechanism. However, I showed that the supergravity cannot be a fundamental theory. In my review paper of the manifestly covariant canonical formalism of quantum gravity published in 1983 (Publ. RIMS 19, 1095), I emphasized "It is not the right way to extend the Lorentz invariance of elementary particle physics at the level of determining the fundamental Lagrangian density." (p.1125) The reason for this claim essentially arises from the fact that there is no spinor (linear) representation of general coordinate invariance. For more details, see my recent paper entitled "Space-time structure in the ultimate theory" (Intern. J. Mod. Phys. D 20 (2011) 253; DOI: 10.1142/S0218271811018809).

11. **Peter Woit**
March 19, 2013

N. Nakanishi,

Please, this has nothing to do with Lykken's talk about the Higgs which is the topic of this posting.

12. **Flakmeister**
March 19, 2013

Yes, the Lykken talk is interesting, dove tailed very nicely with Strumia's Moriond presentation. I am not a theorist but I do remember being struck by Bardeen's infrared fixed point stuff in the early-mid '90s. Glad to see that yet another old dog might be taught a new trick or at the very least get a few more walks around the park….

I took a gander at the Moriond talks and I was somewhat taken aback by the clearly palpable tone of the theory summary talk, given with a proverbial almost stiff upper lip in the face of what clearly may be the death knell of the HEP as an experimental science…. Ironically from its own astounding success…

I was also tremendously impressed by the quality of the experimental results from the LHC. It is clear that there are still truly excellent young people entering the field, I only hope that they find the oppurtunities they deserve….

13. **Thomas**
March 20, 2013

Peter,

Lykken states that his ideas will lead to dark matter discoveries. While it is great to eliminate one dream world (susy) he makes the mistake to introduce another (dark matter). Why is it not possible to stop with these silly games? After all, we only need an explanation for the SM parameters – not more not less.

14. **tulpoeid**
March 20, 2013

Kudos. Please keep your efforts at dispelling quantum theology – I wish it wasn't necessary but this has been on for so longer than anyone anticipated. And worse, the matter at stake is not just absence of falsifiability anymore.

15. **Peter Woit**
March 20, 2013

Thomas,

I'm not convinced by Lykken's dark matter model, but it's quite reasonable for him and others to pursue such ideas. A long shot, but at least not flogging a dead idea as in SUSY models.

16. **dark**
March 20, 2013

"It seems to me that a much more logical conclusion to draw would be that the LHC has just shown that the hierarchy/naturalness argument was mistaken. I've never understood why people found it convincing, and have often argued about this here on the blog. From the "hierarchy" angle, the problem is why the ratio of the electroweak-breaking scale to the GUT or Planck scale is such a small number, but we don't actually have any evidence for GUT physics or for quantum gravitational physics, so no good reason to be sure that such high scales are relevant to anything or the cause of a hierarchy problem."

are there any theoretical, observational or experimental ramifications if your position is physically correct i.e there is no GUT or planck scale in nature?

17. **Peter Woit**
March 20, 2013

dark,

I think the question to ask is whether there is any evidence for a GUT scale, or that the Planck scale has something to do with particle physics. A huge effort has gone on for decades trying to find such a thing, come up empty so far.

18. **dark**
March 20, 2013

Peter Woit

if there is no GUT scale, does this mean there is no "unification" of 3 of the 4 forces? if there is no planck scale, does this mean there is no QG?

19. **Peter Woit**
March 20, 2013

dark,

There may be some sort of "unification" of the SM forces (e.g. something that explains their relative coupling constants, and why SU(3), SU(2), U(1)). But there's no evidence for the specific proposal of putting these groups into a larger group like SU(5) or SO(1o) and then introducing some new Higgs fields to break the symmetry back down. This has never been the most compelling idea. Not only does it not solve the problems introduced by the Higgs, it adds a whole new set of them with new problems (including the hierarchy problem).

We really know nothing about quantum gravity, including whether the Planck scale is even the correct scale at which its effects become important.

20. **Eric**
March 20, 2013

Peter,

Perhaps I'm missing something, but is it really the case that the loop corrections to the Higgs mass are only a problem if there is a new physics at the GUT or Planck scale? The questions seems to me to be, what is the appropriate cutoff scale for these loop corrections? You seem to be arguing that the cutoff for these loop corrections should be the EW scale without requiring any new physics at this scale. Is it not true that the appropriate cutoff should be the next highest scale at which new physics appears? Even in the case that there were not new physics at the GUT or Planck scales, then wouldn't the corrections to the Higgs mass be expected to be infinite?

21. **dark**
March 20, 2013

"There may be some sort of "unification" of the SM forces (e.g. something that explains their relative coupling constants, and why SU(3), SU(2), U(1)). But there's no evidence for the specific proposal of putting these groups into a larger group like SU(5) or SO(1o) and then introducing some new Higgs fields to break the symmetry back down. This has never been the most compelling idea. Not only does it not solve the problems introduced by the Higgs, it adds a whole new set of them with new problems (including the hierarchy problem)."

Isn't SO(10) embedded the whole string theory TOE research program? If you don't think SO(10) broken by new Higgs field then in what sense is there any reason to expect stringy unification?

"We really know nothing about quantum gravity, including whether the Planck scale is even the correct scale at which its effects become important."

you have this link
"For an example of this, see Seiberg's Now What? talk at Aspen (Arkani-Hamed also spoke, with presumably a similar point of view, although the talk is not available)."

in Seiberg's article he confidently claims QG is well known thanks solely to string theory do you agree?

22. **King Ray**
March 20, 2013

One thing about GUTs is the large number of extra gauge bosons that are introduced. The Standard Model has 12 gauge bosons–8 gluons, the W+, the W-, the Z and the photon. If we go to SU(5), then we have 5^2-1=24 gauge bosons, double the number in the SM. SO(10) has 10*(10-1)/2=45 gauge bosons, nearly 4 times the number in the SM; SO(10) could also exist by itself as the gauge symmetry of nature without string theory, just as a GUT–all the quarks and leptons plus a sterile neutrino of a single family fit into its 16 rep. String theory once considered a gauge group of E8xE8; each E8 would have 248 gauge bosons, for a total of 496. Going from the SM to a large GUT is like generalizing a small town into New York City or Tokyo, almost literally. It seems a large price to pay to explain a handful of parameters. You have to introduce lots of extra Higgs fields to break everything down to the SM. It seems that the SM is simpler than a large GUT theory. Just out of curiosity, I once computed all the subalgebras of just one E8 using Dynkin diagram technology–it was amazing what was in there.

Also, if the strong and electroweak gauge symmetries arise for totally different reasons, there might be no reason that they should unify.

23. **dark**
March 20, 2013

@kingray

wouldn't those extra gauge bosons show up as new forces?

Also, if the strong and electroweak gauge symmetries arise for totally different reasons, there might be no reason that they should unify.

that's what ive wondered about – one of the arguments for SUSY is gauge coupling.

24. **King Ray**
March 20, 2013

dark, yes if you had a large GUT, the SM would be the tip of the iceberg. It would be a huge extrapolation. Where unification has worked before, it was more of a case of interpolation–Maxwell just added a term to the eponymous equations, Weinberg et al just added enough to get U(2).

25. **King Ray**
March 21, 2013

dark, if everything fit in one simple GUT group, then technically there would only be one force, with lots of gauge bosons. One force seems to be associated with each gauge group: SU(3) is the strong force, SU(2)xU(1) the electroweak force, and SL(2,C) is the gravitational force. Sometimes the electroweak force is split into the electromagnetic and weak forces, but they are tangled.

26. **Alex**
March 21, 2013

Hi,

I find these ideas quite compelling, and I have long thought that introducing a cutoff regulator might be the unnatural thing to do if there are no new high scale particles coupling to the higgs. However, that idea is not new at all, and I think you make it look too much like it had been unknown or suppressed by the SUSY inquisition somehow, while the truth is that people are working on it all the time.

However, I don't see how this (now also Lykken's) idea – that the right boundary conditions for the higgs potential are such that it should vanish somewhere, are any more experimentally testable or any less pseudoscientific than superstring theory, which at least establishes a framework to accomodate the other known particles and forces.

27. **BB**
March 21, 2013

Lykken seems to misunderstand the basics of QFT and RG.
M_ Planck (at last) provides a cutoff to his theory, and thus the relevant operators such as H^2 gets turned on with a coefficient of the size M_planck to some positive power.
In other words, the CFT is badly broken by gravity and cannot thus be invoked as a solution of the hierarchy problem unless some new separate symmetry forbids the relevant deformations. Take for instance QCD: it is natural because the dangerous strongly relevant operators, such as the quark masses, can be forbidden by the chiral symmetry, while the gauge interactions are only marginally relevant and give you the desired hierarchy via dimensional transmutation. SuSy and RS are other examples where gravity enters only through irrelevant deformations.

28. **Alex**
March 21, 2013

"Lykken seems to misunderstand the basics of QFT and RG.
M_ Planck (at last) provides a cutoff to his theory, and thus the relevant operators such as H^2 gets turned on with a coefficient of the size M_planck to some positive power."

Obviously, he must try to avoid this via some kind of asymptotic safety scenario. Do you think this is impossible? If so, it certainly isn't a "basic QFT" argument which says so.

29. **BB**
March 21, 2013

@ Alex,

If the CFT is exact (e.g. unbroken by gravity which becomes part of it) then it is not clear how to actually have any flow in the IR in the first place. Moreover, while the Higgs potential seems almost reaching a fixed point in the deep UV, the yukawas are not and they keep running spoiling the picture. Not to mention that the Higgs quartic is actually becoming negative below the Planck scale. About the ERG methods that people use to promote asymptotic safety scenario, it doesn't seems well suited for theories like gravity or YM where the operators that get omitted by the truncation of the effective action contain more and more derivatives.

30. **Alex**
March 21, 2013

BB,

The fact that a heavy top quark makes the quartic coupling go negative too early would indeed be a problem for the asymtotically safe gravity scenario I guess.

As far as the running of the Yukawas etc is concerned, yes, in DREG in the SM the quartic rises again due to the gauge couplings – also, not all gauge groups are asyptotically free.

Shaposhnikov and Wetterich argue that in their RG scheme, the combined running of SM+Gravity exhibits a modified Yukawa and gauge running. What the impact of the truncation is I am not competent at all, but I would hope that people at least have checked different ones to see what the impact is.

31. **dark**
March 21, 2013

@Also, if the strong and electroweak gauge symmetries arise for totally different reasons, there might be no reason that they should unify.

are there any theories that explore this? what would be the experimental predictions from this?

32. **Anon**
March 21, 2013

I never quite got the naturalness argument's reliance on the assumption that some arbitrary ratios be of order 1. Aren't there, in a suitable measure-theoretic sense, infinitely "more" large numbers than numbers of order one for nature to choose from, if nature is going to choose parameters randomly?

33. **Peter Woit**
March 21, 2013

Anon,

Only in the multiverse-mania world where if we don't know how to calculate something we can never understand it, so it's equally likely to be any number would your argument apply. More conventionally, the standard idea is that there are fundamental structural reasons why the numbers we calculate have roughly certain values. Even if you can't calculate things exactly, if you have a good understanding of what governs the result of the calculation, you expect to be able to do an order of magnitude estimate.

34. **Alex**
March 21, 2013

dark,

Type II Superstring Models with separate brane stacks for the sm gauge groups dont involve unification.

Predictions are hard… No proton decay maybe 🙂

35. **dark**
March 21, 2013

@ Alex says:

thx.

wouldn't the simplest model though be "the strong and electroweak gauge symmetries arise for totally different reasons, there might be no reason that they should unify" + 4D QFT + GR no SUSY + DM is sterile neutrino ?

36. **Mitchell Porter**
March 21, 2013

There is some discussion here of Lykken's talk… So far, I am confused about how all these things are supposed to relate: (1) the argument from DimReg that the SM is technically natural after all, (2) the idea that the SM is tuned to metastability by special UV boundary conditions, and (3) the use of radiative EWSB in a Higgs-portal model. Are they logically disconnected but thematically similar, or are there supposed to be logical connections?

37. **BB**
March 22, 2013

@ Mitchell Porter,

well, (1) is simply (very very) wrong. The hierarchy/naturalness problem has nothing to do with divergences and the regulator. The hierarchy problem is about the stability of hierarchically separated physical scales. BTW, even dim. reg. generates relevant dangerous operators via its finite mass terms.
(3) would be very important in order to generate an hierarchy (via dimensonal transmutation like in QCD) of scales but only if one can forbid the relevant deformations with a separate symmetry. Otherwise is simply plain tuning.

38. **Alex**
March 22, 2013

BB,

"The hierarchy problem is about the stability of hierarchically separated physical scales."

Surely the people proposing this scenario will agree that heavy particles coupling to the Higgs will immediately constitute a new high scale also in DREG, which will make a light higgs unnatural. That's just ordinary matching and running in DREG. They seem to disagree that the Planck scale counts as such a high scale in this scheme. In that sense DREG is important and crucially connected to the EW naturalness problem because it makes it possible to regulate QFT without having to introduce a huge scale invariance violation via a planck scale cutoff.

"BTW, even dim. reg. generates relevant dangerous operators via its finite mass terms."

May I ask what exactly are you alluding to here?

39. **BB**
March 23, 2013

Alex,

Above I was,alluding to the finite terms which are still quadratically sensitive to any new physics scale.

Even assuming that no fundamental scale, not even Planck, breaks the CFT in the UV, I don't think there is anything deep in dimreg. As there is nothing deep in dimreg for gauge theories, it just makes the calculations easier. Moreover, one could work with another arbitrary regulator and add a conformal compensator to the cutoff scale, rendering it as practical as the dimreg one.

40. **ohwilleke**
March 28, 2013

The really compelling argument that Lykken makes is that an ultraviolet boundary condition of zero for one or more quantities including Higgs boson mass or couplings that runs with energy scale can set the mass scale for the Standard Model at some suitable UV boundary. This argument is similar in form to the SUSY argument that the GUT scale is set by the point at which the running of the coupling constants cause them to converge (a scale that conveniently coincides with the energy scale when the patterns of CMB variation that we observe arose). SUSY proponents have made much of the fact that the running SM coupling constants don't converge at a single point, but a very subtle tweak to their running near their UV convergence chalked up to quantum gravity effects, for example, can easily resolve this issue which is essentially precisely what was done in the asymptotic safety based prediction of the Higgs boson mass.

The conclusion that the hierarchy problem is principally a problem of our flawed understanding of where fermion and boson masses in the SM come from, likewise makes sense. If some unknown mechanism drives the relative fundamental particle masses of the Standard Model, then the absolute masses flow naturally from any boundary condition for any particle mass, Higgs or otherwise, that can fix the mass scale of fundamental particle masses generally. Surely, the one thing almost everyone believes intuitively is that the many experimentally measured constants of the SM have some deeper relationship to each other. As much as anything we need "Within the Standard

Model" (WSM) theories at this point that motivate the why's of the moving parts in it, as much as we need "Beyond the Standard Model" (BSM) theories that give rise to "new physics." The only place empirical evidence is telling us that we need "new physics" is in the gravitational/cosmology sector.

Thus, the particularly SM extension that Lykken explores in his talk isn't terribly compelling. But, the notion that minimal modifications of the SM are the way to go, rather than one creating heaps of new particles and forces a la SUSY, is a good one. A better minimal SM modification than the one he discusses, for example, which still meets the test of adding particle/force content only to the extent absolutely necessary is the one discussed in "Gravitational origin of the weak interaction's chirality" by Stephon Alexander, Antonino Marciano, Lee Smolin (Submitted on 20 Dec 2012) http://arxiv.org/abs/1212.5246 which fits the dark matter sector and gravity into the same degrees of freedom as the electroweak SU(2)*U(1) sector, with electroweak constituting the left handed and gravity constituting the right handed counterparts of each other, leading to a "massless graviton coupled to an SU(2) triplet of chirally coupled Yang-Mills fields. . . . [with] a Dirac fermion [that] expresses itself as a chiral neutrino paired with a scalar field with the quantum numbers of the Higgs." In other words, in addition to a graviton and its intricate gravitational fields, it gives rise to a singlet sterile neutrino dark matter particle and a simple scalar inflaton and/or dark energy field.

41. **Mitchell Porter**
March 28, 2013

What does it mean for a Dirac fermion to "express itself" as a "chiral neutrino paired with a scalar field"??

Abel Prize to Pierre Deligne

March 20, 2013
Categories: Uncategorized

Just woke up to see that [this year's Abel Prize] has gone to algebraic geometer and number theorist Pierre Deligne, who is one of the truly great figures in 20th century mathematics. Deligne first became well-known for his proof of the Weil Conjectures in the 1970s, and has had a long and and very fruitful career since then, much of it spent at the Institute in Princeton. While working mainly in a part of mathematics far from physics, he also has had a long history of interactions with physicists, participating in the IAS year-long program on QFT, and most recently getting involved in current research on amplitudes. An excellent choice, congratulations to him!.

Update: See Tim Gowers's blog for more, including his talk presenting Deligne's work.

Comments

1. **cims conf**
   March 20, 2013

   The Courant Institute is hosting a one-day conf tomorrow for the Abel Prize.
   http://cims.nyu.edu/webapps/content/special/Abel_in_NY

   Courant's three Abel laureates will speak. Will you go?

2. **Peter Woit**
   March 20, 2013

   cims conf,

   That was a few weeks ago (Feb. 21, not March 21). Didn't hear about it until the day after. This week is Spring Break and everyone (except me…) has left town.

3. **El-Coco**
   March 20, 2013

   I was pretty surprised (as I am every year) that Terry Tao didn't win.

4. **Peter Woit**
   March 20, 2013

   El-coco,

   You have to realize that this prize was only started in 2002. In some sense they're now in the process of working their way through the list of all the great figures of 20th century mathematics who are still alive. It's now (intentionally I think) kind of an opposite of the Fields Medal, which was designed to reward and encourage young people still early in their careers.

   Looking at the list, no one younger than mid-sixties has gotten the Abel. If Tao remains in good health, I'd predict he'll sooner or later get the prize, but it may take a while…

5. **opp**
   March 20, 2013

   Jean Pierre Serre (2003), Michael Atiyah (2004), John Griggs Thompson (2008), John Milnor (2010) and now Pierre Deligne (2013) are all Fields Medalists, so one hypothesizes that the Abel is to encourage FM winners to keep working and not goof off in their old age?

6. **Peter Woit**
   March 20, 2013

   opp,

   This kind of gives some good data on what fraction of great mathematicians get the Fields Medal (5/13). Reasons for not getting the Fields Medal include doing ones best work when not young and having the misfortune to be of around the same age as several other great mathematicians (so missing out on the Field during the typical narrow time-window people are good candidates for it).

7. **jin**
   March 20, 2013

   Who got 2013 fundamental physics prize?

8. **tg**
   March 20, 2013

   Technically it's Tim Gowers. So it's Gowers' blog not Gower's blog.

9. **Peter Woit**
   March 20, 2013

   jin,
   Announcement coming up soon, see
   http://webcast.web.cern.ch/webcast/play.php?event=241643

   tg,

   Thanks, fixed.

10. **anon**
March 20, 2013

If you go to the blog, you will find that it is (correctly) Gowers's blog.

11. **MathPhys**
March 20, 2013

Deligne deserves *two* Abel prizes. One for his mathematics and one for his character. Very well deserved.

12. **Bob Jones**
March 20, 2013

"Deligne deserves two Abel prizes. One for his mathematics and one for his character."

Grothendieck would disagree with you.

13. **Ray**
March 20, 2013

@Peter It's funny how the year long course on QFT & Strings simply becomes course on QFT for you.

14. **Peter Woit**
March 21, 2013

anon,
OK, fixed the fix.

Ray,
http://www.math.ias.edu/qft
"A program in Quantum Field Theory for mathematicians was held at the Institute for Advanced study during the academic year 1996-97."

15. **Ray**
March 21, 2013

The AMS published book is called "Quantum Fields and Strings: A Course For Mathematicians". Let's not forget Eric d'Hoker's celebrated string theory course was a part of the year-long program as well.

16. **Bob Jones**
March 21, 2013

Gaitsgory's notes in that volume are very nice too.

17. **Peter Woit**
March 21, 2013

Bob Jones,

That may be a minority opinion… I don't think I've previously heard of anyone being able to understand Gaitsgory's notes. It's amusing that your and Ray's comments came in next to each other. I forget who I heard this from, and it's probably 2nd or 3rd hand and not accurate, but someone told me that Gaitsgory was originally the one writing up notes for d'Hoker's lectures. This led to a problem though when the lecturer himself could not understand the notes of his own lectures, so decided he had to write up his own. Again, take that story with a grain of salt, but still…

18. **Bob Jones**
March 21, 2013

To be honest, I should admit that I also find Gaitsgory's notes very hard to understand. But the topic of chiral algebras is something that I find very interesting, and I've spent a lot of time reading that section.

Fundamental Physics Prize to Polyakov

March 20, 2013
Categories: Uncategorized

As I predicted a few days ago, the string theorists in Princeton have made their choice for the $3 million dollar Fundamental Physics Prize: another Princeton string theorist, Alexander Polyakov. Evidently there's no official announcement, so Matt Strassler has retracted his original posting about this, now calling it an "unsubstantiated rumor", but someone at the ceremony e-mailed me with the news, so it is substantiated.

Earlier today I did watch the first part of the awards ceremony, although I had to leave to do something else before the Polyakov announcement. It was quite remarkable, designed to look very much like an Oscar ceremony, with Morgan Freeman as master of ceremonies, and the Laureates getting a big trophy to take home, as well as the $3 million check. The program was largely a string theory hype-fest, with the description of the accomplishments of the Laureates making no distinction at all between what was purely speculative and what wasn't. Viewers of the part I saw would have no idea that string theory is not tested, settled science.

Polyakov was one of the leading figures during the 1970s and early 1980s in the effort to understand the non-perturbative behavior of QFTs, especially the question of how confinement in QCD works. By the early 1980s, one of the most promising ideas about this was to try and find a string theory dual for QCD (and I spent quite a bit of time reading papers by Polyakov and collaborators about string theory and possible relations of it to gauge theory). As far as I can tell, Polyakov was never much of an enthusiast for 10d string theory unification, but kept arguing that what was interesting about string theory was the possible dual relationship to gauge theory, a point of view that has become the dominant one in recent years with the rise of AdS/CFT (which Polyakov played a role in).

For more about Polyakov's work, the best source is the man himself. He has written some wonderful articles about this history and the evolution of his thinking, see for instance here, here and here.

Anyway, congratulations to Polyakov, a great physicist who now won't be impoverished compared to his colleagues. Perhaps in future years the scope of the Fundamental Physics Prize can be widened, with string theorists at Harvard and Santa Barbara sharing in the loot.

Update: Here's a picture of Polyakov and the trophy you get with the $3 million. The money will provide him with "more freedom and opportunity to pursue future accomplishment."

Update: The official announcement is here.

Update: Nature has a report about the awards ceremony, as Internet billionaire throws lavish soiree for physicists.

Comments

1. **ketchup**
   March 20, 2013

   It sure is ironic that Matt Strassler posted an unsubstantiated rumor. I hope he did not subvert the scientific process of the awarding of the Fundamental Physics Prize.

2. **Bob Jones**
   March 20, 2013

   "The program was largely a string theory hype-fest, with the description of the accomplishments of the Laureates making no distinction at all between what was purely speculative and what wasn't. Viewers of the part I saw would have no idea that string theory is not tested, settled science."

   None of these prizes have been awarded specifically for work on the more speculative aspects of string theory. The accomplishments of all the FPP laureates are well established.

3. **Peter Woit**
   March 20, 2013

   Bob Jones,

   Did you watch the awards ceremony that I was describing?

4. **Bob Jones**
   March 20, 2013

   Peter,

   Yes, and I have to say that all the lights and goofy music made me cringe. I wish they would tone it down and hire someone more serious for their master of ceremonies. I think it's embarrassing to honor all these great scientists in such a silly way.

   As for their discussion of string theory, I'm not worried that the public will get the wrong impression of the subject. They did mention a couple of speculative topics in the ceremony, but most of what they were talking about were important and well established results of mathematical physics. I think it's great if the prize generates more widespread appreciation of this sort of work. In my experience, most laypeople are already rather suspicious of string theory, and they tend to under-appreciate its value as a tool in the study of quantum field theory and quantum gravity.

5. **Bob Jones**
   March 20, 2013

   Also, I'm not sure how much you watched, but most of the awards ceremony was about the discovery of the Higgs boson. They even got Charlie Rose to interview the experimentalists via Skype.

6. **MathPhys**
   March 21, 2013

   Is that photo of Polyakov with the trophy photoshopped? He looks ridiculous in that tux.

7. **Jin**

March 21, 2013

Where is planck mission announcement? A similar result?

8. **Abraham Smith**
   March 21, 2013

   All your jeering aside, that is a great-looking trophy. I assume it's meant to be a Hopf fibration?

   I also wonder what economists would think about a prize so large, which, unlike the Fields Medal and Wolf prize, could allow someone to retire early. Physics politics aside, would such a prize act as a motivation/inspiration, or will it cause mid-career experts to become less productive? (By comparison, the Abel prize is approximately 1 M$, but it so far is only for people who are already "well-settled" in their careers and lives. The Nobel is usually split several ways.)

9. **Bernhad**
   March 21, 2013

   Jin,

   watch it live here: http://spaceinvideos.esa.int/esalive

10. **jin**
    March 21, 2013

    Thanks, I finally found it. It is Simon White not Pavel Kroupa. It is unfair.

11. **Peter Woit**
    March 21, 2013

    Abraham Smith,

    Here's the official description:

    "All of the 2012 and 2013 Fundamental Physics Prize Foundation winners participated in the Ceremony and also received the special award trophy, a work of art created by Danish-Icelandic artist Olafur Eliasson.

    The Fundamental Physics Prize trophy is a silver sphere with a coiled vortex inside. The form is, in fact, a toroid, or doughnut shape, resulting from two sets of intertwining three-dimensional spirals. Found in nature, these spirals are seen in animal horns, nautilus shells, whirlpools, and even galaxies and black holes.

    The award is made of silver, an artistically significant material for a physics prize, as silver materialized from exploding stars."

12. **Cynthia Reid**
    March 21, 2013

    Bash the ceremony as you may (perhaps because you weren't invited?), it was refreshing and encouraging to see money, effort and recognition put into something beneficial in the sciences for a change, rather than sports and entertainment. Seeing physicists paying respect to the evening and the Foundation by honoring the black tie dress code was memorable. They ALL looked great.

13. **Cynthia Reid**
    March 21, 2013

    OK, that was snide and I apologize. But it was great to see physicists finally get some mainstream public recognition.

14. **Peter Woit**
    March 21, 2013

    Cynthia Reid,

    Just to be clear, I'm critical of the endless overhyping of string theory and the damage that has done to the subject, with a flood of $3 million checks and this kind of hype-filled production not helping the matter at all. I've no problem with the award to the LHC experimentalists, that's great.

    As for the ceremony, what I saw of it wasn't my kind of thing, so I wouldn't have enjoyed it even if invited (and some of those laureates up on stage didn't look like they were having a good time…) But I'm glad if others enjoyed it.

15. **Bernhard**
    March 21, 2013

    Peter,

    It is very unfortunate this is a stringy prize, blamed on the fact the committee chosen by Milner was simply too narrow. But, with the criteria being personal achievement in the field rather than being right about anything (which is the criteria the facto) , Polyakov more than meets it. With the same criteria for the experimentalists it is extremely hard to say the same. I think Polyakov deserves, in this respect, way way more than them.

16. **N.**
    March 21, 2013

    Circus Incredible.

17. **Peter Woit**
    March 21, 2013

    Bernhard,

    My impression was that for the experimental rewards, it was supposed to be clear that these were not really awards for personal achievement, but awards to one person meant to symbolize a larger group. I'd hope the awardees spent a lot of time at the ceremony acknowledging that. What happened to the supposed plans that these awardees had to distribute the money somehow to younger people who could use it? Are those going ahead, or are they going to just keep the money?

18. **Bernhard**
March 22, 2013

Peter,

This might be the underlying idea, but it is not what it is being explicitly said on the prize´s "awarded for" and therefore not the idea the general public is getting.

In any case, about what they will do with the cash, I don´t know. Last time I checked only Fabiola Gianotti explicitly said she wanted to "set up a fund with her share of the prize to support young physicists in the Atlas group". Incandela said something more vague about " find a way to put this to good use for the benefit of all who made this possible", but this was when the prize was announced and I did not hear about it anymore since then. I guess now that they have the money we should wait a few months to see what happens. The other spokespersons by the way, did not make the same claim, as far as I know.

19. **Yatima**
March 23, 2013

Somewhat earlier, Abraham Smith said:

> I also wonder what economists would think about a prize so large

Well, real economists (a set not fully compatible with the set of of clowns writing economics columns in the NYT) would just STFU because there is nothing to be said about this at all except that someone spends money on something that he evidently thinks is worth spending the money on. Taxpayers are apparently not involved, so no spending of other people's money either. Any further development is up to the receiver of the donation. Human Action? Hell yeah.

20. **Peter Woit**
March 23, 2013

Yatima,

Please, ideological discussions about economics are one of the few things stupider than discussions of the multiverse. No more, ever.

Yuri Milner has decided that he doesn't like the way capitalism has been working in this area, and so has decided to change the structure of rewards in physics research. He has every right to do this, those with less money have every right to either applaud or criticize his decision.

Planck Results

March 21, 2013
Categories: Uncategorized

The long awaited CMB results from the Planck satellite are now out, see here. A NASA press conference is about to start here.

You really should be reading about this somewhere else, from a much better informed blogger, someone expert in cosmology, which I very much am not. My non-expert impression is that, as rumored, the results are quite vanilla: 3.3 +/- .3 light neutrinos, so no evidence for a fourth neutrino, no significant non-gaussianity. No cosmic strings, see here, which has

> conclusion that there is at present no evidence for cosmic strings in the Planck nominal mission data.

In recent years multiverse mania has involved lots of claims to see evidence of other universes in earlier CMB data. Nothing about this in the Planck announcements I've seen, presumably they looked and didn't find anything, or maybe thought it wasn't even worth looking…

I'll try and make a list of informed commentary that I find, and keep a list here. Suggestions for additions are welcome.

Richard Easther live-blogged the announcement here.
Sesh Nadathur has comments here.
Ethan Siegel has a posting with background here.
The word from Resonaances is here.

Comments

1. **Ehud Schreiber**
   March 21, 2013

   A crucial quote from Easther's blog: "… there is no use of polarization data — this is being worked on, but it will make a big difference when it becomes available."

2. **Sesh**
   March 21, 2013

   Yes, there's not much in the data for particle physicists to get excited about, though there are a few interesting little anomalies, including the fact that the best-fit Hubble parameter value is getting further away from the one that is measured by the Hubble Space Telescope team.

3. **Peter Woit**
   March 21, 2013

   Thanks Sesh,
   Added a link to your blog to suggested reading about this.

4. **Filip**
   March 21, 2013

   I follow this blog and there is a nice story about the new findings (including a nice introduction on the matter, good for non experts like me).

5. **ohwilleke**
   March 21, 2013

   The result I read in paper sixteen was Neff=3.30 +/- 0.27 v. Neff 3.046 for the three Standard Model neutrinos. So, their result is a little less than one sigma from the Standard Model value. A four neutrino model would have an Neff of a bit more than 4.05, which is about three sigma from the measured value which is roughly a 99% exclusion and is a confirmation of the Standard Model.

   Planck also combines data from multiple sources puts a cap on the sum of three neutrino masses in a three Standard Model neutrino scenario of 0.24 eV (at 95% CI) with a best fit value of 0.06 eV. The floor from non-astronomy experiments is 0.06 eV in a normal neutrino mass hierachy (based on the difference between mass one and mass two, and between mass two and mass three which are both known to about two significant digits) and 0.1 eV in an inverted neutrino mass hierachy. In a normal neutrino mass hierarchy, this puts the mass of the electron neutrino at between 0 and 0.06 eV, with the low end preferred (I personally expect that an electron neutrino is significantly less than the mass difference between the first and second neutrino type of about 0.006 eV).

   Note that a particle that is in the hundreds or thousands of eVs would not count towards Neff because it is not light enough to be relativistic at 380,000 years after the Big Bang. So, it really only rules out a light sterile neutrino, rather than a heavy one. The LSND and MiniBooNE reactor anomalies have hinted at a possible fourth generation sterile-ish neutrino of about 1.3 eV +/- about 30%, so the Planck people did a study on the sum of mass limits if there were a disfavored four and not just three relativistic species and came up with a cap on sterile neutrino mass in that scenario of about 0.5 eV +/- 0.1 eV, which is about 2.5 sigma away from the value of the LSND/MiniBooNE anomaly estimates considering the combined uncertainties.

   LEP ruled out a fourth species of fertile neutrino of under 45 GeV, and I wouldn't be going out on a limb to say without actually doing the calculations that a fertile neutrino of 45 GeV to 63 GeV, if it existed, would have wildly thrown off all of the Higgs boson decay cross-sections observed (since a decay to a 45 GeV to 63 GeV neutrino-antineutrino pair from a 125.7 GeV Higgs boson would have been a strongly favored decay path if it existed) and is in fact therefore excluded by the lastest round of LHC data. The LEP data already excluded fertile neutrinos in the 6 GeV to 20 GeV mass range where there are contradictory direct dark matter detection experiment results at different experiments.

   But, a particle that we would normally call a sterile neutrino for other purposes in the Warm Dark Matter mass range of KeV or the Cold Dark Matter mass range of GeV to hundreds of GeV, or anything in between (including any of the possible direct dark matter detection signals or anything that would generate the Fermi line at 130 GeV), would not be a relativistic particle within the meaning of Neff which only counts particles that would move at relativistic speed given their masses at the relevant time.

6. **fuzzy**
   March 21, 2013

   Oh gosh, there is no evidence for sterile neutrinos! But … so many theorists have speculated on this possibility in the recent years, that at this point it is really necessary to ask oneself: What should we think of them?

Do you think that their job is anyway justified, like that of a lousy actor? They have been unlucky, as a poker gambler could be? Or, they tried to do something legitimate, as a lawyer who tries an ambiguous cause? Or, rather, we should say that they haven't been able to understand the nature, they failed their goal of scientists, and misled other colleagues?

What I think is evident, but I do not believe that their failure will leave any track in their record. Rather, their useless work will have served to increment the list of people who cited them: thus, in good company, they will be ready to do a new mistake. That's how the circus works!

7. **Peter Woit**
March 21, 2013

fuzzy,

You're rather harsh…. I rather think that one should feel the pain of those engaged in trying to find a viable theory that goes beyond the SM, since that has so far been impossible. It may be that the neutrino sector is our only hope left to see non-SM physics (i.e non SM with neutrino masses).

8. **useless**
March 21, 2013

Why is their work useless? It is easy to forget now that, back in the 1920s, to explain the continuous energy spectrum of beta decay electrons, Bohr, Kramers and Slater were willing to say energy is not conserved in individual decays, only statistically overall. Bohr was willing to consider that the electrostatic potential was not 1/r but 1/r^{some other power}. As for nuclei such as alpha particles, to explain the charge/mass ratio, Rutherford and many others believed in nuclear electrons.

9. **fuzzy**
March 21, 2013

Dear Pete, searching for theories is an important activity, sure, but one thing is to do this by sticking to good principles, one thing is to follow fashions. I know there are serious scientists who are trying their best, but also too many people working as such, that rather of being engaged in searching for a theory, are busy in searching an opportunity of publishing, citations, prestige and such. I also feel that neutrino physics is a promising avenue, first of all because there are useful measurements, but this does not mean that anything connected to neutrinos is a valid starting point. A good theorist (working in neutrino physics or elsewhere) should be able to know the difference between what is valid and what is of little value somewhat in advance, I feel.

Dear "useless" (dear colleague 🙂 thanks for the relevant feedback. In my view, one thing is to speak of solid experimental fact, another thing is to exaggerate the relevance of facts not fully assessed and partially contradictory among them. We knew that this type of sterile neutrinos that are being discussed were a muddy hypothesis, even without the Planck satellite (though it was possible to select the facts that one wanted to consider). Moreover, I remember that "not even wrong" is a sentence of a guy who was very prudent in publishing his ideas, including those on continuous beta spectrum, that have superseded the wrong hypotheses of Bohr. I think we should rather strive toward Pauli, Schrodinger, Feynman rather than exercising our unchained imagination or to show our talent in producing sexy names or forcing experimentalists to do some more measurement.

10. **Sesh**
March 22, 2013

I think the reason Richard Easther quoted Neff as 3.2 +/- 0.2 was because that was what Efstathiou said in the first media briefing. I don't know why that was – either both Easther and I misheard, or maybe Efstathiou just misremembered the numbers.

Incidentally, if combined with recent measurements of the deuterium fraction by Pettini and Cooke, the Planck constraint on Neff is even tighter: 3.02 +/- 0.27. I'm not sure how much these deuterium measurements are trusted though.

11. **physics_dude**
March 22, 2013

I'm a little confused, Peter. I've read about two anomalies that cannot be explained by the standard cosmological theory — anomalies that were first detected by WMAP, and have been detected again by PLANCK. Yet, both you and Jester dismiss it. How come?

12. **Peter Woit**
March 22, 2013

physics_dude,

I'm no expert, so relying on others. Jester and most of the other experts I've read about this don't seem to find these anomalies to be of great significance, and their arguments for why seem to me compelling. But, for more details, you need to ask them.

13. **Low Math, Meekly Interacting**
March 22, 2013

Perhaps I'm wrong, but my understanding now is that even if one could come up with a reasonably compelling explanation for the anomalies, their nature makes it impossible to rule out their being a statistical fluke…unless we can start observing other "universes".

I'm a bit chagrinned to learn that the Planck data are quite literally as good as it will likely get when it comes to observations of the CMB. That would seem to bode rather poorly for the prospect of getting greater cosmological insights to BSM physics any time soon.

14. **ohwilleke**
March 22, 2013

"I'm a bit chagrinned to learn that the Planck data are quite literally as good as it will likely get when it comes to observations of the CMB. That would seem to bode rather poorly for the prospect of getting greater cosmological insights to BSM physics any time soon."

We at least have weeks or months to absorb this round before the polarization data becomes available. This data, among other things places meaningful bounds on quantum gravity theories.

Also, while our observations of the CMB won't necessarily get all that much better, data from other sources should make it possible in combination with Planck data to leverage more out of it. For example, if we can determine the neutrino masses and hierarchy independently of Planck, this allows us to very finely constrain the properties of anything other than the three known active neutrinos that shows up in Neff.

Similarly, if we used extra solar system deep space probes to make paralax distance measurements of unparalleled accuracy, we could discern if any part of the estimate of the cosmological constant and Hubble parameters corrected for by Planck and attributed to factors like uncertainties in red shift measurements for Standard candle Ia's in fact has any possible other source.

15. **Alessandro Melchiorri**
March 22, 2013

A sterile neutrino is perfectly consistent with the Planck data.
If you actually look at the real numbers here: http://www.sciops.esa.int/SYS/WIKI/uploads/Planck_Public_PLA/3/32/Grid_limit95.pdf
you see that Planck alone gives Neff=4.5\pm1.4 at 95% c.l., while Planck+HST
3.7\pm0.5 at 95% c.l..
In few words is just when you combine with ACT data (the highL dataset) that you get a lower number.
The Planck collaboration preferred to be conservative and has put 3.3\pm 0.3 at 68% c.l. in the abstract, but there is plenty of space for a fourth sterile neutrino (that does not necessary gives you 4.05 ! it depends on how and when it decouples from the primordial plasma !) and it is actually suggested if you combine with HST. The value of the Hubble constant from CMB is indeed model independent and if leave the neutrino number as free you get a very good agreement with HST.

16. **Alessandro Melchiorri**
March 22, 2013

sorry I meant model dependent ! 🙂

17. **Richard**
March 23, 2013

> while our observations of the CMB won't necessarily get all that much better

I've read that a couple places, but I'm unclear on its meaning.

Is is that angular resolution and spectral resolution are at physical limits? If so, are these limits those of any detectors or are we talking cosmological fuzzing so detector physical limits are irrelevant? Are Earth orbit and launch-feasible detector size any constraint?

(I know the argument that accelerated expansion will leave our galaxy alone in a black universe, but in the meantime?)

Pointers appreciated. It's something of a novelty to be in possession of the best possible data.

18. **Sesh**
March 23, 2013

Richard,

For the temperature anisotropies, the limiting factor is cosmological. The process of recombination, which is what makes the universe transparent to photons, is not instantaneous. As a result, photon diffusion washes out anisotropies on small scales, which is what causes the exponential damping of the higher peaks in the power spectrum (this is called Silk damping or diffusion damping).

So getting better angular resolution doesn't help – at even smaller scales there essentially aren't any anisotropies there to measure. (Of course, this is a relative statement: if you could build a reference blackbody with an order of magnitude better temperature stability and put it into orbit, you could measure smaller temperature differences.)

In terms of polarisation measurements though, Planck isn't quite at the achievable limit. Here there are other experiments planned. And one could also measure distortions of the blackbody spectrum of the CMB, which provide a different probe of inflation, and for which the best experimental constraints available still come from COBE/FIRAS.

19. **Shantanu**
March 23, 2013

Peter one thing to note, although I maybe wrong on the finer details,
limit on energy scale of inflation is around the GUT value, so another
blow to GUT.

20. **David Nataf**
March 24, 2013

Observations of the CMB could very much improve with future experiments by better removal of background.

We are in the Galaxy, and as such an important souce of microwaves are …. the Galaxy… as well as background Galaxies giving sources everywhere.

Planck has to remove all of this:
http://2.bp.blogspot.com/_mazRoHLuLl0/TDIRdC2JvrI/AAAAAAAAAaw/Y8EIr8cUlco/s1600/plcmb.jpg

Before they can give a CMB map, which is extremely hard, and is not done perfectly at this point. They also need to account for the fact that foreground galaxy clusters lead to lensing of the CMB photons, as well as the Sunyaev Zeldovich effect, for which you will find separate papers already out, and countless more in the future.

There is a lot more work to do in CMB science.

21. **Low Math, Meekly Interacting**
March 24, 2013

Thanks for clarifying perspectives, David & Sesh!

22. **paddy**
March 24, 2013

Thanks to Peter, Sesh, David, and all the knowledgeable commentators' for their blather and links to even more blather. And note…blather is NOT meant as a derogatory term.

23. **Shantanu**
April 2, 2013

FYI: Planck symposium webcast live

http://www.sciops.esa.int/index.php?project=PLANCK&page=47_ESLAB

24. **Gian-Luca**
April 7, 2013

Peter,

do the new results from the Planck satellite shed any light on whether the cosmological constant decreases with time? You discussed this topic in some of your previous blog posts. The issue would be of interest to many!

Gian-Luca

25. **Peter Woit**
April 7, 2013

Gian-Luca,

Not sure what you're referring to, I'm not very well-informed about whether there's evidence for a time-varying CC. I don't see any reason Planck would have results about this, and haven't heard anything about it. If they did have such results, I assume they would be well-publicized.

The Existence of Nothing

March 22, 2013
Categories: Multiverse Mania

The sold-out "debate" held Wednesday night here in New York is now available for viewing online, see here. I just watched most of it, and one of many things I couldn't figure out is what if any propositions were being debated. Lots and lots of the usual multiverse mania, and endless flights of speculative fancy and empty, meaningless argumentation. I'd guess this left much of the audience thinking there's not much difference between what well-known scientists do and what stoned college students do when they're talking late at night. Amongst all this, a few topics stood out as completely missing:

- Any significant discussion of what our best theories really say about the vacuum. There are all sorts of interesting things you could say about the vacuum of the Standard Model QFT, but no one seemed interested in this topic.
- Any legitimate connection to experimental test. The Planck results to be released the next day were referred to by Eva Silverstein, who claimed that CMB observations could test the sort of thing she was talking about. In actuality, there seems to be zero prospect that Planck or any other such observations will test the speculative ideas about string cosmology she was referring to.
- Any indication that the multiverse and string theory are not settled science that all physicists now agree on. The problems with this picture of the world went completely unmentioned as far as I could tell.
- Any mention of the disinvited David Albert.

Comments

1. **P**
   March 22, 2013

   "In actuality, there seems to be zero prospect that Planck or any other such observations will test the speculative ideas about string cosmology she was referring to."

   This isn't true. Like anything, it is model dependent, but there are string cosmology models which predict a large scalar to tensor ratio, e.g. axion monodromy. I believe the predictions for r in these models are large enough that they could be ruled out by Planck.

2. **Peter Woit**
   March 22, 2013

   P,

   I don't doubt that you can come up with "string cosmology" models that "predict" just about anything imaginable. People are free to do this and go on stage and tell the public about how this is an inspirational example of science in action, but I think this is quite misleading.

3. **P**
   March 22, 2013

   Peter,

   This is precisely how model building – in QFT or in string theory – works; there are many choices, and indeed a wide variety of things can be predicted (though not "anything imaginable", as you say). This is true in both particle physics and cosmology.

   Inflation needs a scalar field, and certain types of scalar fields appear in string theory. In considering one as a candidate inflaton, predictions are made and these models can be ruled out as experiments become more precise. This could be true of axion monodromy at Planck. Such ideas are perfectly honest and are how science / model building works, in both QFT and string theory.

   Cheers,
   P

4. **pred**
   March 22, 2013

   I suppose the key criterion with the notion of 'predictions' is *falsifiable* tests. What falsifiable statements do the predictions (e.g. of string cosmology) make?

5. **Peter Woit**
   March 22, 2013

   pred,

   The question of whether string theory satisfies the criterion to be science has been debated endlessly here (and elsewhere). If you look into this, you'll see that falsifiability by itself cannot be such a criterion. For a trivial example analogous to P's axion monodromy, I can tell you that I have a (rather complicated…) model of the early universe, which predicts that Steven Hawking's initials will be visible in the polarization data inside the large cold spot that Planck has found. This is a testable prediction (which will be falsified next year…), but if I were to spend my time coming up with a detailed model designed to do this and studying it, you might sensibly consider what I'm doing to not be science.

6. **pred**
   March 22, 2013

   I saw the SH initials (was it the WMAP data?). Most 'predictions' are actually retrofits to data, i.e. you tell me the answer and I'll demonstrate why my theory fits the facts perfectly. It gets embarrassing if the facts change, because someone discovered a calibration error etc., but most retrofit theories are able to backtrack on things like that. There has to be more than one falsifiable *pre*diction, and they all have to come from the same model (no fiddling with endless adjustable parameters).

7. **Peter Woit**
   March 22, 2013

   pred,

The SH was found in WMAP I think.

Yes, typically people try and justify their models by fitting them to facts. The problem I'm describing is a bit different though. The question of whether something is science has to do with whether it is giving non-trivial, reliable information about the physical world. Being able to make accurate falsifiable predictions is one characteristic of successful science. But my point is that just because you make a falsifiable prediction, that doesn't by itself mean you are doing science. Astrologers make falsifiable predictions all the time…

8. **Paul Wraight**
   March 22, 2013

   I thought Luke Barnes comments in his blog http://letterstonature.wordpress.com/2013/02/18/why-science-cannot-explain-why-anything-exists/ conveyed a lot of sense.

9. **Z**
   March 22, 2013

   I wish they had discussed the question of if Mathematics exists and the notion of logical consistency (do axioms exist? What about incompleteness theorems?), since presumably, any deep fundamental theory must ultimately arise from some mathematical structure Some of these issues go back to Plato's time, but I think they still have relevance to these musings.

10. **cormac**
    March 22, 2013

    There was a series of seminars on the results in Cambridge today. Very impressive; it's now SWH, by the way!

11. **cormac**
    March 23, 2013

    Sorry, that was a bit obscure. What I mean is this: in relation to the comments above on the initials SH being imprinted on the cosmic microwave background, as measured by WMAP, Paul Shellard joked at a seminar yesterday that one can now read the initials SWH in the PLANCK spectrum. It was a fun way to finish his lecture, but I couldn't see really it!

12. **Maciej**
    March 23, 2013

    Peter,

    I think you are saying that falsifiability is not a sufficient criterium to say that a theory is scientific. Clearly. However it is essential and ST does not even fullfill this.

    Maciej.

13. **Peter Woit**
    March 23, 2013

    Maciej,

    Yes. But the question of string theory itself is complicated by not even knowing what the theory is. The multiverse, as being promoted now at events like this one, is the ultimate in unfalsifiabilty.

14. **Maciej**
    March 23, 2013

    I see.

    Well in that case (i.e. that we do not even know what ST is) it is even easier to claim that ST is not scientific since we don't know what we are talking about.

15. **dark**
    March 23, 2013

    Is the multiverse a way of avoiding the conclusion that string/m-theory predicts the wrong dimensionality (4 vs 10/11)?

16. **Peter Woit**
    March 23, 2013

    dark,
    String/m-theory doesn't predict any particular observable number of dimensions. It doesn't really predict anything, and the multiverse pseudo-science is just being used as a way to avoid doing honest science and drawing the standard conclusion that a theory that predicts nothing has to be abandoned.

17. **dark**
    March 23, 2013

    doesn't gauge anomaly cancellations require 26 in bosonic, 10 or 11 in string/M-theory?
    hence, a "prediction" if wrong.

18. **Peter Woit**
    March 23, 2013

    dark,
    The standard story is that you can use compactification or "branes" to get solutions to the 10/11 d theory that have other numbers of large dimensions at observable energies (e.g. 4).

    Perhaps if string/M-theory were more precisely defined, you could simply show it made an incorrect prediction. The current state of the art is that with what is known about the possible definition of such a theory, you can get pretty much anything you want. String theorists used to argue that once string theory was better understood, one would find that it had certain specific solutions and you would get predictions. The newer ideology is that once string theory is better understood, it will have a landscape of solutions and not predict anything.

This is getting off topic, and it's by now a very old story, enough about this.

19. **Nick M.**
March 24, 2013

Peter Woit *says:*

> "But the question of string theory itself is complicated by not even knowing what the theory is."

Thank You so much, Peter, for this comment. When I was an undergraduate at UC Berkeley in the early to mid 2000's, I remember asking a GSI friend of mine, who was working on String/M-Theory at the time for his doctoral thesis, what he knew of M-Theory, and could he tell me more of what it was all about. He put his index finger to his lips, and whispered in a quite and a somewhat whimsical voice, "Shhhhhh…, the big secret is, is that there really is *no* M-Theory". Although he tried to explain what he meant by this at the time, it's only over the intervening years that I have come to appreciate what exactly it was that he was trying to get across.

Now per your admonishment, I will say no more on this topic.

20. **Tammie de Cortez Haynes**
March 24, 2013

Dear Dr. Woit

Your account of this episode was most depressing.
Pardon me while I make it more so.

You thought the audience was left thinking there's not much difference between what well-known scientists do and what stoned college students do.
I doubt that.

I suspect the audience was left admiring their own superiority, as among the few smart enough to share in the enlightenment of our greatest scientists.

21. **socrates**
March 24, 2013

Do people actually feel superior for being in the audience of anything? That's stoned enough for me.

22. **P**
March 24, 2013

pred,

Sorry for the delay. Busy weekend.

The falsifiable test for axion monodromy is a higher than usual scalar to tensor ratio, usually written as r in the literature. I forget the precise numbers, but they're in the literature and I can look them up if you'd like.

Make no mistake about it: there are experiments to measure r, axion monodromy predicts that it is larger than many models (including slow roll, I believe), and this is absolutely falsifiable as experiments bound the value.

Cheers,
P

23. **Bernhard**
March 25, 2013

P,

Is this prediction unique to string cosmology models?

24. **mat noir**
March 25, 2013

Was it Gellman who said: Given 3 variables, I can make an elephant. With four, I can make it walk.

25. **aleph/eleph**
March 25, 2013

John von Neumann apparently, quoted from Enrico Fermi, and it was 4 and 5, not 3 and 4:
"I remember my friend Johnny von Neumann used to say, 'with four parameters I can fit an elephant and with five I can make him wiggle his trunk."

http://mahalanobis.twoday.net/stories/264091/

But Dorothy Parker said it better
"I like to have a martini,
Two at the very most.
After three I'm under the table,
after four I'm under my host."

http://www.goodreads.com/author/quotes/24956.Dorothy_Parker

26. **P**
March 25, 2013

Bernhard,

No. I believe, in fact, that before the axion monodromy mechanism was understood people thought one couldn't get large scalar to tensor ratios out of string cosmology.

27. **piscator**
March 27, 2013

P:

I think many people still think that.

28. **P**
March 27, 2013

Piscator:

You may be right. I'm not enough of a string cosmology expert to know if or why there is a debate about axion monodromy as a model.

29. **Randioactive**
March 27, 2013

What of AMS-02?

30. **Jim Akerlund**
March 27, 2013

This is off topic, but FQXi has just put up a new contest for 2013 called "It from Bit or Bit from It". It runs until 6/28/13.

31. **emile**
March 28, 2013

@Randioactive

Please find details and poster related to the SPECIAL CERN-EP Seminar on Wednesday 3rd of April 2013 in Main Auditorium (500/1-001) at 17h00:

"Recent results from the AMS experiment"
by Prof. Samuel TING (Massachusetts Inst. Of Technology (US))

32. **Beelzebud**
March 28, 2013

I tried to watch that debate. Watching educated people sit around debating on the definition of nothing is as fun as watching paint dry. As a layman I just don't quite see what the entire topic has to do with science. I can see why philosophers would discuss it, but what has it got to do with science?

The only insightful part of it was when the gentleman with the fabulously colored suit explained his model about branching universes, but even then, how does science test something like that?

33. **Raizonator**
March 30, 2013

I watched the debate and there is one nagging question that came to my mind:
When we talk about our Universe, we mean the ONE (classical) Universe we observe. O.K. But if we extrapolate back in time until the Universe is as big as an elementary particle and QFT "kicks in" then one is forced to speak of a universe being in a "one particle state" (for example). That is the number of universes we are talking about gets uncertain (Heisenberg).
So with a certain probability it could also be in a zero-particle state, i.e. in a state of "nothingness" if one likes. But what does that mean anyway if nobody (i.e. no classical observer) can be around to do the measurement and find out how many quantum universes there are? That's where things really get weird, I think, and where I can't trust extrapolations via (conventional) QFT any more.
Are these thoughts too naive ?

34. **MS**
April 1, 2013

@Beelzebud: It is a business (not science) thing.

Are they wrong? US research funding

March 28, 2013
Categories: Uncategorized

It seems to be part of the job description of anyone in the sciences to periodically complain that scientific research funding is insufficient, with the situation going from bad to worse. For some recent examples, see this from Bruce Alberts, the Editor-in-Chief of Science, and this endorsement from Professor Matt Strassler.

In the contrarian spirit of this blog, I want to suggest that the situation is actually quite a bit more complicated, and the story of research funding is not completely a one-sided one of the oppression and impoverishment of scientists. Also in the spirit of this blog, I want to avoid topics I don't know much about, which in this case includes the vast majority of scientific research and how it is funded, especially outside the US. The biggest component of R&D funding in the US is the military, and I have no idea what this money is going towards and whether it is being well-spent. I've also heard that there are increasingly vast sums being spent by the US on classified research, not necessarily accounted for and showing up in obvious places in the budget, but I have not idea whether this is even true or what the size of this is. While ignorant about what military R&D spending is going to, I confess to a general prejudice that it seems to me to be huge and if I knew more I'd probably be strongly in favor of there being less of it.

The next biggest component of R&D spending is biomedical, and again, I'm woefully ignorant. Unlike spending money to find better ways to kill people, biomedical research is inherently something worthwhile, so more of it undoubtedly is better. But whether it is now being spent well, or whether taking away from some other priority to spend more in this area would be a good idea, I haven't a clue.

On overall US federal spending levels, Alberts compares a level of .87% of GDP in 2013 to a level of 1.25% of GDP in 1985. He's getting his data from here, but those numbers do tell a more complicated story. Measured in constant (2012) dollars, non-defense R&D/year went from $32 billion in 1985 to a maximum of $67 billion in 2004, and has been relatively flat since then, with $64 billion projected for 2013. Defense R&D went from $65 billion in 1984 to a maximum of $90.5 billion in 2008, has dropped significantly in recent years to $76 billion for 2013. Another set of overall numbers from the same source are for the NSF budget, which went from $4.6 billion in 1998 to $7.25 billion in 2013.

For a while on this blog I used to try and keep track of the US budget situation and periodically report on it, at least the numbers I could find and understand for math and physics. The most important thing to say about the situation of recent years is that the US federal budget process has completely broken down. Budgets have gone from being passed late to never, with government spending now allocated by some baffling system of continuing resolutions and last-minute "cliffs". There appears to be nothing anymore like a sensible process for making future plans and sticking to them. Those responsible for managing research facilities are not only in the dark about how much money they'll have to spend over the next few years but sometimes don't know how much they'll have to spend next month or next week. No matter what you think spending priorities should be, trying to run organizations this way is completely nuts and a disgrace to the country.

Getting close to fields I do know something about, here are some other numbers (also 2012 dollars): NSF yearly spending on math and physical sciences has gone from $924 million in 1998 to $1,323 million in 2013. DOE Office of Science has gone from $3.3 billion in 1997 (including $895 million for HEP) to $4.5 billion in 2013 (including $764 million for HEP).

Theoretical physics is very much small potatoes on the scale of science funding in general. For FY2012 the DOE spent $67 million on theoretical and computational physics, the NSF $13.6 million (+6 million for Physics Frontier Centers), up from $11.7 million (+6.3 for Physics Frontier Centers) in FY2008 (real, not inflation adjusted dollars). Increasingly, large amounts of funding are coming from the private sector. The Simons Foundation spent $40 million on grants for math and physics in 2011. The Perimeter Institute has gotten $150 million or so from Mike Lazaridis over the years, and the Templeton Foundation has recently provided $2 million to Perimeter, after $8 million to FQXi, and millions more in other grants such as $2 million for the philosophy of cosmology. Yuri Milner has in the past few months handed out about $37 million in checks to physicists, with one goal that of supporting their research.

The overall pattern seems to be that science in general has not been doing that badly, although HEP funding in the US has been cut significantly, as the US lost leadership in HEP to CERN with the LHC becoming the focus of attention. US experimental HEP faces huge challenges in the future, but they have more to do with the SSC debacle of 20 years ago and the lack of a compelling technological way forward to higher energies than with general federal science budget cutting. Funding for theory from conventional government sources has been fairly flat, with new sources of private funding starting to have a major impact.

As for the work conditions of US academics, Matt sees the situation as:

> Whereas before the year 2000 it was easy for U.S. universities to attract the best in the world to teach and do research at their institutions, and to train the next generation of American scientists, the brain drain since that time has been awful.

On the other hand, my own experience at Columbia (a wealthy private institution) and in mathematics has been that the post-2000 period has been one where the US in general and Columbia in particular have done very well in competing for talent. While the middle class in the US has been in decline, top-flight US academics have seen significant salary increases. The AMS compiles yearly numbers for salaries (see here), which show the mean academic-year salary for a mathematics full-professor to be $127,674 at large public research universities, $148,074 at large private research universities. Back in 1999 the numbers were $85,571 (public) and $95,977 (private). Comparing to median US incomes, the ratio has increased from 4.26 to 4.73 during this time in the public university case, 4.77 to 5.49 in the private university case. At the top of the profession, average salaries for full professors at Harvard (in all fields) were $122,100 in 1998-9 (6.07 times US median), $198,400 in 2011-12 (7.36 times US median). The general pattern is that of the rest of US society, with the rich getting richer, and staying very much competitive for talent with the rest of the world.

As usual, informed and on-topic comments are welcome. If you just want to rant though about the evils of government spending, or go on about how in a just society scientists would get lots more money, please do it somewhere else.

Comments

1. **X**
   March 28, 2013

   Firstly, the very topmost universities such as the Ivies will be the last to depopulate. Secondly, much of the impoverishment of the university system is being done at the state level and is destroying state public university systems. Thirdly, the defunding of the system is done by removing the bottom tiers of the system: low pay and few hires for assistant professors, sending young people to the eternal damnation of sub-professor-level migrant academic and lecturer jobs. This does not cause pay for full professors to decline. (Learn more about such trends by looking at "wage stickiness" in the econ lit.)

2. **Peter Woit**
   March 28, 2013

   X,

   I don't think what is going on is "wage stickiness", since what's happening is not salaries at the top of the scale going down more slowly, but salaries at the top of the scale going up. You see this throughout the US economy. In the universities, another place you see it is with administrative salaries which have been growing even faster than star professor salaries (Columbia's president makes nearly $2 million/year). This isn't only the Ivies: Berkeley may have massive budget problems, but it still came up with a big increase in its chancellor's salary for their new chancellor.

The phenomenon of exploitation by universities of the labor pool that they themselves flooded (by dramatically increasing the size of Ph.D. programs) is by now a very old one, and the destruction of wages at the bottom of the scale has coincided with large pay increases at the top of the scale.

3. **X**
   March 28, 2013

   Hi Peter,

   I wonder if in a twisted sense, those crazy salaries for top bureaucrats might be worth it. Since a main job of top bureaucrats is to use political savvy and shenanigans to funnel money from various sources into the university, a university president who gets paid 2M$/yr but pulls down 100M$/yr in donations is a good investment. Of course, then you have to wonder about the marginal costs and whether a 500k$/yr president would pull down the same donations anyway, but the optimal salary seems non-obvious to me.

4. **Yatima**
   March 28, 2013

   "I confess to a general prejudice that it seems to me to be huge and if I knew more I'd probably be strongly in favor of there being less of it."

   Woah I got the impression of a witness having to make a statement in front of some Popular Court on his current view on whether the governement is, in his opinion, indeed working for the Greater Good of The People. Or not.

   Luckily the flames of passion are being fanned in the next paragraph.

5. **Peter Woit**
   March 28, 2013

   X,

   That's certainly the argument being made to justify huge increases at the top of the pay scale, in all industries. The guy running Lehman was using it to justify his $22 million payday right up to the moment they went bankrupt.

6. **srp**
   March 28, 2013

   This post opens up a huge can of worms, many of which you probably will not want crawling around on this nice, clean science blog. For example, your distaste for military R&D ("better ways to kill people") could easily lead off into a complex discussion about pacifism, whether it's better to kill people using worse ways, US foreign policy, etc. I'm betting that comments about this aspect of the post would get snipped as being "off-topic" even though, as the lawyers would say, you opened the door to these issues. For the record, though, that kind of statement about military R&D does not increase the credibility of the rest of the post. End of on-topic though off-topic comment.

   In general, you are right that the US government and private donors have not been chary in supporting science of all kinds over the last decade. The increasing difficulty in winning grants is more the result of the well-known "sorcerer's apprentice" effect caused by the requirement in most grants that new PhDs be trained. (And of course those PhD students provide the cheap workforce for the senior investigators.) The more grants given, the more PhDs spawned later, and the more competition for whatever level of funding has then been appropriated. With this system, no level of spending will ever recreate a situation where a high percentage of grant applications are funded.

   In my opinion, the reason why this training policy is maintained is that the government and science bureaucracy prefers to have a large and lower-paid STEM workforce. They are not entirely irrational in this regard; President Obama's former economic advisor Austen Goolsbee has published econometric studies showing that increases in government R&D spending tend to mostly raise the wages and incomes of researchers rather than producing greater quantities of research. The training requirement partly neutralizes this effect, which would otherwise be even more severe. Lots of cheaper researchers helps the government get more research done for less money, gross of training costs; the interesting question is whether using initially low-skill PhD students as the front-line workforce in labs is really the most efficient way to get the research done.

7. **Peter Woit**
   March 28, 2013

   srp,

   My disclaimer that I have little idea what military R&D spending goes for was meant quite sincerely and intended to provide appropriate background for any of my comments on the subject. But, yes, I'd rather not host or moderate a "military spending, good or bad?" argument here.

8. **Peter Woit**
   March 28, 2013

   As for the "efficiency" argument for the desirability of a massive low-wage work force, surely the most efficient work-force structure would be slave labor, with a small overclass keeping armies of needed scientific researchers chained in labor camps, kept in line by brutal physical methods, and fed just enough to keep them working long hours optimally.

   While this would get the most work done at the cheapest price, perhaps there are other desirable goals in a society more important than extracting from human beings as much as possible at the lowest possible cost.

9. **Felipe Pait**
   March 28, 2013

   I am not very knowledgeable but I share your view of military research. I worked on military-funded R&D for a short while, at what I judge to be a top-notch operation, and my impression was that the funds were not spent very efficiently – the US was not getting a lot of national security per dollar spent. Classified research appears to be less effective than the less secretive components. There is a lot of waste on questionable projects. Rerouting military funds to science research or to engineering development would, for the admittedly little I know, be good for the country.

   On the other hand, perhaps we should not be comparing the effectiveness of military research with science research. National security by brute force is massively expensive, and painful. To the extent that military research can make defense operations even a little more effective or deadly, or prevent wars, it is justifiable in its own terms.

10. **Bob Levine**
March 28, 2013

@srp

There's a kind of no-win situation that seems to have come about in the sciences. Yes, the induction of young researchers with bleak prospects into these fields is from one angle cynical, callous and exploitive. But on the other hand, we know—the relatively few Max Planck examples notwithstanding—that it's the younger investigators who are likely to make the major breakthroughs. A field which is aging demographically is in danger of withering; older established scientists are unlikely to make the kind of huge conceptual leaps that the likes of Einstein, Feynman, Dyson and von Neumann achieved. If you don't actively recruit the best of the youngest, your field has a bleak future indeed. So the idea of having Ph.D. training as a component of grants isn't bad in itself; the difficulty is at the other end. A lot of the blame has to go to the universities themselves, and university administrations in particular, for the gradual elimination of a permanent, reasonably well-compensated professoriate as its core faculty, with jobs waiting up the line for those new Ph.D.s, in favor the disgraceful 'Kelly prof', migrant-labor model that academic managers have been doing their best to create.

11. **lun**
March 28, 2013

the administration overhead is definitely a large part of the problem.

The processes you describe is a good experimental refutation that the "market", in this case, the academic job market, is a "statistical system of many equal players" rather than a power structure of generally hyerarchical power relations. The problem is, in the latter case a decrease of funding just makes the system more corrupt instead of leaner and higher average quality.

So, paradoxically, the author of "Am I wrong?" is correct, but the "anonymous scientist" commenting on page 2 (a very thoughtful comment, starting with "Yes you are wrong") is correct as well. More funding might make the system less corrupt and bloated, and less funding will worsen the "politics".

12. **Peter Woit**
March 28, 2013

Bob Levine,

One should keep in mind that typically it's not faceless administrators that want to expand Ph.D. programs, but department faculty. And when faculty go to the administration to request lower teaching loads (so they can do more research), and are told, "OK, you can teach less and we'll hire some adjuncts to cover the courses", do you think faculty say no to this?

13. **Bob Levine**
March 28, 2013

Peter—

"when faculty go to the administration to request lower teaching loads (so they can do more research), and are told, "OK, you can teach less and we'll hire some adjuncts to cover the courses", do you think faculty say no to this?"

There's no denying that senior faculty are often complicit in perpetuating the system as it's developed during the past 30 years. But what I've seen at my own university is a disappearance of the tenure-track jobs themselves, as faculty retire and their lines are frozen, or cancelled, or merged together. And *that* initiative is coming from administrative management policy, whose creators have figured out that if you can strip as many benefits as possible from the majority of your academic work force, you'll save enormous portions of your budget. At public institutions such as the one I teach at, this makes senior administrators look good to the legislators who supply our funding (although way, way less than they used to), and, maybe even more important, it increases the value of those administrators in the eyes of other institutions looking to hire cost-cutting, efficient managers in what now seems to be the private sector business model that many (most?) academic institutions seem anxious to follow. The jobs that are sacrificed to make our provosts, chancellors and executive deans look look like CEO material and keep their bosses in the Statehouse happy are the jobs that our newly trained Ph.D.s aren't ever going to get….

14. **Peter Orland**
March 28, 2013

Peter and Bob Levine,

Both of you are right. As more adjuncts replace faculty, less research is done, resulting in fewer grants, hence less need to hire full-time faculty, and so on… There are some enlightened deans/provosts/presidents who see that flushing faculty lines down the toilet leads to for-profit U. of Phoenix-style degree mills.

I sometimes vainly try to explain to non-academic friends that research-oriented faculty are the best people to learn from (that was my experience anyway. Give me a scowling teacher, who would rather be in the lab or busy doing calculations. He or she can answer questions, not BS through them).

15. **Ray**
March 28, 2013

Once for amusement I compiled a list of quotations of scientists over the last 50 years. They always said, funding is being cut and the job market is getting worse. I guess whining is a permanent feature of being an academic.

16. **Lowell**
March 29, 2013

Perhaps the production of PhD students is too large and not determined by their quality.

At a place where I once taught, the number of entering graduate students was determined by the number of graduate student TA's needed to teach undergraduate labs and grade papers. It was not determined by the number of outstanding students that could be attracted to enter the program.

17. **dark**
March 29, 2013

What role do you think string theory and current LHC results has had in attracting funding, research, academic positions, and graduate student applications/interest?

18. **Z**
March 29, 2013

David Helfand had a similarly austere editorial on the state of science funding last month, as it relates to Astronomy: https://aas.org/posts/news/2013/02/presidents-column

and broaches the idea that, perhaps, there is some birth control necessary at an early stage.

19. **Chris Oakley**
March 29, 2013

Sorry – but I really do not accept that training a large number of Ph.D.'s when there is little possibility of them getting an academic job is a valid one. Only about one in five of my peer group (Oxford theoretical particle physics circa 1984) got a commensurate academic job, and I was not one of them. But even if I had known that I was not going to be able to continue I would still gladly have entered the Ph.D. (or D.Phil. as they call it in Oxford) program simply for the privilege of doing it. In the U.K. there is a also a persuasive demographic reason for doing more degrees. When I took my degree, 5% of eligible students went to university. Now it is more like 40%. Having a masters or Ph.D. is thus a way of distinguishing one from the crowd when applying for (non-academic) jobs.

20. **chimpanzee**
March 29, 2013

"Better to have Brain Drain, rather than Brain-in-the-Drain"
— Indian prof, Re: India talent studying abroad in USA

There is a Reverse effect in progress (as pointed out by M. Strassler), talent is going away from USA. I went to famous HS (University High on UIUC campus)

[produced 3 Nobelists (Philip Anderson/Physics..Higgs mechanism, Hamilton Smith/Medicine..top-gun hired by Dr Craig Venter for JCVI "1st organism designed by computer", James Tobin/Economics. Other notable alumni are Bill Bardeen/Fermilab (son of John Bardeen, Nobelist), Shamit Kachru/Stanford]

which has the similar formula of high-end Academia: recruit top-students with top-faculty..GOOD THINGS will happen. 1 of my HS classmates (Dr Dave Albin, NREL/National Renewable Energy Lab, leading PV/Photovoltaic researcher) told me something alarming:

"I'm losing 2 of my staff to a Chinese solar company, who offerred them $300K/year salary"

This is American STEM talent being drawn away to foreign shores. China leads in Wind/Solar, the Obama's so-called "next Sputnik moment". The Solyndra failure (DoE, Dr Stephen Chu/Stanford & Dr Stephen Koonin/Caltech/Physics/Provost & BP Chief Scientist)..500 million wasted, since they couldn't compete with market flooded with low-cost Chinese solar cells. This is a sign of "too little too late". That OMB (Office Management & Budget) email that got leaked

"This [Solyndra] loan is not ready for prime time"

indicates they were RUSHING THINGS. Another sign of "too little too late". A123 (Battery Tech) failed..bought by Chinese company (250 million loan wasted)

The KEY to Economic Recovery is a STEM based stimulus package. Not only Alternative Energy (due to politicization of Global Warming hype/hoax), but Biotech, Nano Tech, Computer Tech. Apple Computer is the pinnacle of Tech which found mass-market monetization (#1 market capitalized company, exceeding "old Oil" Exxon Mobil)

It's a well known fact that Curiosity/Pure Research has long-term mass-market potential. The CD/DVD was a mass-market entertainment device, that was rooted in Theoretical Physics

"Einstein & Botha realized that photons in the same state..[laser]"
— Murray Gell-Mann, "From Student to Scientist" PBS Documentary

I view HEP (High Energy Physics) & Space Exploration as "push it to the limit" challenge-frontiers, which spinoff mass-market Technology. Silicon Valley was a product of

1) Physics research
Bardeen/Shockley/Brattain, invention of Transistor at Bell Labs

2) NASA Apollo program
pressure to miniaturize electronics created the Integrated Circuit (chip)

It's clear that these 2 sectors need to be exploited ("seed funding" by US Govt), for further "Emerging Economy"..Economic Growth/Recovery. As part of America 2.0, NASA 2.0 (really hit hard by Sequestration), Science 2.0

"I have never tried, in even one single little instance, to help cultivate the cultivated classes. I was not equipped for it either by native gifts or training. And I never had any ambition in that direction, but always hunted for bigger game–the masses. I have seldom deliberately tried to instruct them, but I have done my best to entertain them, for they can get instruction elsewhere."
– Mark Twain, a Biography

Leadership in STEM needs to take the above to heart, & figure out a short/medium/long term strategy to leverage their KNOWLEDGE for mass-market ("masses") monetization.

"I'm interested in KNOWLEDGE, not Product"
— Dr Misha Mahowald, Calltech PhD CNS (Computational Neural Sciences), Neuromorphic Engineer, "Discovering Women episode"

["Physics of Computation" field by Dr Carver Mead (VLSI pioneer), kinda involved Feynman]

The above illustrates the tunnel-vision 1-sided nature of Science, it is IMPERATIVE to keep an eye on Product ("monetization"). In order to demonstrate to Funding Agencies the RoI (Return on Investment).

"You have to sell yourself"
— S. Hossenfelder, advice by her professor

The whole Fiscal Crisis in Washington DC could be a "blessing in disguise", to FORCE a Science 2.0 recovery that has more Perspective ("integrated solution")

Time for Vision, Leadership, Execution to "kick in".

21. **jackj**
March 29, 2013

I found this article interesting, but still feel that the references to Perimeter Institute are somewhat misleading. Perimeter is in Canada, which is a separate country with its own funding situation.

22. **Peter Woit**
March 29, 2013

jackj,

That's true, and I suppose should have been pointed out. But it's also true that Canada and the US are quite closely linked economies and cultures, with Waterloo just over the border. Matt is raising the alarm about "our ability to defend ourselves, especially since some of the most active spending on science is being done by countries that are hostile or potentially hostile to the free world." It doesn't seem to be Ontario he's concerned about, but who knows…

23. **Peter Shor**
March 29, 2013

When Matt says "active spending on science is being done by countries that are hostile or potentially hostile to the free world", by "countries" does he mean China? Certainly science funding has decreased substantially in the countries of the former U.S.S.R., and none of the Islamic countries have large research budgets.

24. **Peter Woit**
March 29, 2013

Peter Shor,
You'll have to ask him, I've no idea what he's talking about.

Looking at the Milner prize recipients, almost all the senior ones are in the US, but it is true that the young "New Horizons in Physics" prize recipients aren't. They are in Canada, Switzerland and Israel, but I don't know if Matt considers those places to be hostile to the free world. The fact that they're not in the US may just reflect this being kind of a string theory prize, and string theory hasn't been very popular among US physics departments hiring permanent people recently.

25. **Statistician**
March 29, 2013

On something slightly unrelated: is scientific blogging going to die? I've looked at google trends and it seems to be the case:

http://www.google.com/trends/explore#q=backreaction%2C%20peter%20woit%2C%20lubos%20motl%2C%20cosmic%20variance%2C%20clifford%20johnson&cmpt=q

Interest was great around 2005 – 2007 but slowly people just don't bother reading all these science blogs. I've included Peter, Lubos, Sabine Hossenfelder, Cosmic Variance and Clifford Johnson in the comparison chart.

26. **SpearMarktheSecond**
March 29, 2013

Concerning experiments at the high-energy frontier… the US has always had the land and once (and probably still) had/s the expertise… that led to Robert R. Wilson's `Desertron', the name for what turned into the SSC. But certain practicalities (who wants to live in the desert? Which desert state has a congressional delegation as powerful as that of Texas?) took the SSC to Waxahatchie. And then the money problems killed it.

Novel acceleration ideas have been researched for at least 30 years, with meager results.

So probably we are stuck with a physically large machine. What makes little sense is putting the next large machine in Japan, where land is scarce, although perhaps their government is ready to spend for a linear collider.

Can't say CERN makes sense either, where is the land? Quite a densely populated place.

A really grand concept would be an international collaboration that builds the next big one somewhere in Africa. The collateral benefits might be incalculably large.

But there seems to be little appetite for grand projects in the US. We seem to have leaned more to our finagler, swindler, litigious, squabbling side than our grand side in the past years. A giant international project costing $30 billion with major contributions from all the world's economies just sounds foolish in our current situation. We can only do $1,000 billion wars, nothing idealistic.

27. **Kernel**
March 29, 2013

I'm a graduate student at the Institute for Quantum Computing, another Lazaridis initiative, at the University of Waterloo. I like to ask questions about where the money for IQC and Perimeter Institute come from, and have found out enough to say that your statement that "Perimeter Institute has gotten $150 million or so from Mike Lazaridis over the years" is misleading.

I have heard the sum of $150 million quoted a few times, though I'm not sure where it comes from. However, the figure probably comes from the total funding received by PI, of which Lazaridis contributed only a part. In fact, at least half of that money has been provided by the federal government of Canada, and a substantial portion was also provided by the provincial government of Ontario. In other words, PI is largely taxpayer funded. Lazaridis and others (such as the Templeton Foundation) have made important financial contributions as well, but the sum of their contributions is probably far smaller than $150 million. As far as I can tell, the situation is similar for IQC.

I think an important difference in culture exists between Canada and the United States of America. In the US, there is significant political pressure to cut any government expenditure unless it is for something everyone agrees on, like military. Rationally speaking, a government agency that wants to protect its budget is well advised to claim that it is a military organization. Therefore, the fact that much US science funding comes through the military should not be too surprising. Just because spending is described as military, doesn't mean it actually is.

In Canada, people pay a lot less attention to what the government actually does, so the government can get away with spending money without coming up with arcane justifications. I wonder, for example, what value Perimeter Institute really provides to the Canadian taxpayer. I think a major reason that Canada can get away with hosting a place such as PI is that no one is really asking the pertinent question. It's of course in my best interests to keep my mouth shut, but I suspect that PI does very little for Canada despite the fact that it is mostly funded by taxpayer dollars.

28. **Peter Woit**
March 29, 2013

Statistician,

2006-7 was the period of the String Wars, after the appearance of my book and Lee Smolin's which got a lot of media attention. I can't say that I was sorry to see that period go, since most of the heavy blog traffic then came from people interested in arguing about things they didn't really understand. To some extent I think the story of the string theory debate was that it did get well aired on the blogs, and anyone who cared made up their mind back then, with few people still interested in revisiting the debate now.

The numbers I see on my web server have been pretty constant for quite a few years now. I do think some activity has moved from blogs to twitter/facebook/google+ (and google wants to encourage this by killing google reader).

29. **Peter Woit**
March 29, 2013

Kernel,

Here's one source for the $150 million number
http://www.perimeterinstitute.ca/news/mike-lazaridis-donates-additional-50-million-perimeter-institute

I believe Ontario provided another $50 million, and there have been contributions from other sources. Details of the Perimeter funding should be in its annual reports, latest one is here

http://pitp.ca/annualreport/2012/

I think you're dramatically oversimplifying the US science budget issues. For one thing, many fields of science get little to no funding through military channels. Biomedical research is a good example of something which the US pays for a lot of (the NIH budget is about $30 billion/year) and has wide support from many quarters. The NSF has long enjoyed political support from both parties. I doubt the average person or average politician in the US knows or cares any more about government science spending than their counterparts in Canada.

30. **srp**
March 29, 2013

Peter: Your slave-labor comment is odd. The government pays for people to get PhDs and conditions funding of research on new PhDs being trained. This is called "subsidizing" or "investing" in the creation of human capital. We may both agree that the policy is quantitatively excessive, but the rationale for it is as I stated earlier–the government is responsible for getting the most research output it can for its expenditures, and increases in research spending tend to raise compensation much more than research output unless something is done to make the supply curve of researchers more elastic.

It's fine to complain about the loss of tenure-track jobs and the switch to a contingent workforce in academia–folks over in the humanities have felt the brunt of this for decades, and its bad effects as well as its good points are pretty well understood. But the "exponential model" also doesn't make sense–you can't have an exponentially growing set of tenure-track jobs to match the exponential growth of PhDs implied by the current grant system. If each researcher pushes out two or three new grads each year, and each were to then get a tenure-track job and funding for research which entailed turning out two or three grads, and so on…pretty soon the number of researchers would exceed the world population. People are taking an atypical post-World War II situation in the U.S., where growth was exponential for a time, as normative.

31. **Peter Woit**
March 29, 2013

srp,
I'm in complete agreement about the fundamental problem of too many PhDs. My "slave-labor" comment was about the argument that the government is justified in using its power to intervene in the labor market in order to keep down labor costs. I'm curious whether this is done in other parts of the economy.

32. **dinotroll**
March 29, 2013

I feel at some point in time birth control has to be done. But I also agree that we cannot do it right after undergraduate since students are very raw at that time. Already PhD in Physics takes 6 years on an average. I would advise breaking it into 2 stages of 3 years each. The first would be something like a comprehensive masters, getting done with all graduate level courses and publishing a paper or two. Then when you apply for the next three years, birth control can be applied and the students themselves might realize whether they are cut out for physics research or no. At this stage the application procedure can also be made a bit more rigorous with interviews and research plans. With the present system it makes no sense that a person takes 6 years to finish PhD and then has to take up job in a software firm.

33. **srp**
March 29, 2013

Peter:

"My "slave-labor" comment was about the argument that the government is justified in using its power to intervene in the labor market in order to keep down labor costs. I'm curious whether this is done in other parts of the economy."

Great question. Answer part one: The government (which is not a unitary actor, but it's syntactically easier to discuss that way) is very interested in keeping down the prices of stuff that they have to buy, where they are a customer. They aren't very good at it, for a variety of reasons (especially the political influence of their suppliers), but there's a vast apparatus that tries to keep down the prices paid to military contractors, for example. Since most of the cost of these items is labor, especially white-collar labor, the effect is to depress the wages of defense industry workers. We also used to have this thing called a draft that enabled the government to confiscate the labor of every able-bodied male in the United States and pay almost nothing for it. (Thank you Milton Friedman and Richard Nixon for ditching that one.) But to this day, the government tries to get the cheapest volunteer force it can subject to quality and quantity constraints. Nobody wants the taxpayer to give government suppliers rents (returns in excess of what is necessary to call their resources into service).

Answer part two: Physicians getting Medicare and Medicaid payments are a different case, because the customer is ostensibly the patient. But price controls aimed at lowering spending have been included in the legislation for many years; they haven't been implemented because of political pressure from physicians and some patient groups, leading to annual "doc fixes" that put money back into the budget to cover the suspended price rollbacks. One school of thought on PPACA is that the various "accountable care organization" and IPAB innovations it includes are intended to stealthily push down the incomes of US physicians in the name of fiscal responsibility.

Answer part three: Politicians have (insincerely and cynically in my view) spent quite a bit of time arousing public indignation at the compensation of specific managers and financiers. One interesting example was the AIG case, where a group of mid-level workers who were not responsible for the initial problems were specifically retained by the government to do the toxic security clean-up job with the promise of substantial bonuses for not deserting the sinking ship. Congresscritters went nuts over those bonuses, to the point where one of the drones wrote an open letter that I think was published in the New York Times trying to explain the situation. And of course we have the continual bloviation over executive compensation, trying to lower the pay of that sector of the work force.

So I think it is fair to say that the US government regularly intervenes in various labor markets to reduce the compensation that specific types of workers receive. It is especially prone to do so when it has monopsony power, but shows little compunction about trying to beat down the wages of others it holds as undesirables or political untouchables.

34. **Peter Woit**
March 29, 2013

Thanks srp,
This is getting too far off topic, but I'll just comment that I think I see a pattern here, with the effectiveness of efforts to drive down wages inversely proportional to the size of these wages. From my experience here in Manhattan, I can assure you that those in the financial industry and at the top levels of other industries based here seem to be holding up pretty well under the federal government's lash, whereas those working in biomedical research labs are a different story.

35. **Stephen Olsen**
March 30, 2013

A serious problem is the fact that many senior faculty members at Universities and National labs have lifetime tenure & never retire, thereby locking up positions and large salaries that would otherwise go to young people. In fact senior faculty that do require usually free up funds for more than one junior faculty position. Lifetime tenure should be replaced with tenure to some fixed age. Faculty members over that age that are still productive should be eligible for subsequent fixed term contracts that they could negotiate with chairpersons & deans etc.

36. **PhysGrad**
March 30, 2013

Peter,

Any thoughts on the relationship between funding for graduate students in physics, the growing cost of undergraduate education (particularly at state schools where the cost is growing faster than at private institutions), and the ability of programs to attract and train talented graduate students who are coming in with higher debt loads and seeing very little growth in grad and postdoc stipends?

37. **Low Math, Meekly Interacting**
March 30, 2013

I'll briefly add to some comments above about military R&D. I happened to work with a "couple" people in my first job out of college who transferred to the NCI from another military facility not too far away. The reason they moved on was not because of some deep moral objection to the potential military applications of microbiology (otherwise, they never would have worked there in the first place, though I suspect their work was not on weapons, but countermeasures). Rather, they came to be dissatisfied with the professional isolation and, more to the point, the perceived lack of high standards for deciding what projects were to be tackled in the first place. Apparently military R&D of that time (late 80's, early 90's) wasn't be run by the sharpest knives in the drawer, and one needn't be so concerned that money was being spent finding better ways to kill people. Rather, be concerned that money was being spent by fools to do foolish, and ultimately useless, work.

I have little confidence the situation has changed much. Add to the idiocy the endemic waste of the Military Industrial Complex, and one can almost ignore humanitarian concerns altogether, and focus on the scandal of funding a jobs program that produces nothing. That money could be better spent on almost anything.

38. **Peter Woit**
March 30, 2013

PhysGrad,

The student loan situation in the US is horrific, with universities more and more funding themselves by getting their students to take on increasingly large amounts of debt, putting them in a situation Bruce Springsteen described as one of having "debts no honest man could pay". Students with this debt are now graduating and entering a very rough job market, with ugly results. In this larger societal context, I'm not sure that Ph.D. stipends and postdoc salaries keep people from going to grad school, since the alternatives may be more dismal. One popular alternative to physics grad school has sometimes been law school, but that's becoming another sad story.

I don't know much about the situation in physics. In the field I do know about, math in general, Columbia in particular, Ph.D. stipends are around 30K/year, and postdoc stipends I think have done pretty well. In recent years at the top places, you have things going on like the Simons Foundation postdocs paying 70K/year, and this does have an effect on bringing up what universities offer everyone, since they are trying to compete with these.

Both Math and Physics grad programs in the US are now producing Ph.Ds. in record numbers, so there's no numerical evidence that the loan problem has suppressed these numbers. The situation in Math and Physics is rather different, with Math Ph.D. students funded typically as TAs, Physics students funded out of grants. With government funding flat and increased faculty salaries and tuition, I would guess that has kept downward pressure on money available for student fellowships, so physics student stipends may be doing worse than in math. I have heard complaints from theorists in physics that the government is funding fewer of their students, but have to confess that this sounds to me like a good thing, given the absurdly small number of permanent jobs in the field.

39. **Al**
March 30, 2013

"Ph.D. stipends are around 30K/year"

is that including tuition? because if yes, it must be hard living on 12K/year in NYC.

40. **Peter Woit**
March 30, 2013

Al,

If the Ph.D. students were paying tuition out of their stipend, they'd get a negative stipend, since full tuition is nominally something like $40K/year. But Ph.D students are admitted on fellowships that pay their tuition, and also the 30K or so stipend. Some students make extra money teaching extra courses, courses during the summer, or tutoring.

The master's degree programs are a very different story. There typically the students are paying tuition, even full tuition.

41. **Otto**
March 30, 2013

> But whether [biomedical research money] is now being spent well, or whether taking away from some other priority to spend more in this area would be a

good idea, I haven't a clue.

From everything I've read, NIH R01/R21 paylines have been extremely tight lately (e.g., NCI at the 7th percentile). Meanwhile, the utterly useless NCCAM get $128 million (FY 2012) and things like the (equally useless) TACT trial gets $30 million. One could argue that these are pittances in the overall NIH budget, but it's not money well spent. *Science* recently reported that the sequester could cut success rates to ~15%.

42. **Bobito**
April 2, 2013

A country which has a lot of physics PhDs working as computer programmers is doing fine. The "liberal arts" training of our era is a broad technical background. To find the best physicists you have to fund based on potential, and inevitably only some subset of those funded will produce really creative work. However, if you had not funded the 100, you would not have have found the 10.

43. **StevenC**
April 2, 2013

Dear All:

I share Peter's worry about students – either their loan or their quality. I have supervised or help manage some graduate students before, and they produce work that is rather low quality. Unforuntely, I have no say on their graduation nor I am a thesis committee member; but I have made silent protests for skipping defenses of students that I myself have managed – laugh. Sadly, the poor-quality student problem falls under as a new spin to Publish-or-Perish: Have-Students-with-Thesis-or-Perish.

Student loan is going to be a time bomb. Not only debt levels are high, but youth employment is on the high across the developed world (not just in US – it is as big as a disaster in Europe and Asia). That is a dangerous combo: the young folks get in debt, and cannot develop their career to pay back.

SS

44. **StevenC**
April 2, 2013

Excuse my spelling – I mean "unemployment" instead of "employment". I now work in the UK, but I was talking about the work I did when I was back in the US few years ago.

45. **StevenC**
April 2, 2013

Sorry one more point:

I think the increase number of poor quality graduate students do have relationship with the problem with student debt and poor career prospects – going to graduate school become fads and quick fixes for poor employment prospects, and plays right into career expectations of senior research staff and professors. That is actually quite bad, imo.

46. **srp**
April 2, 2013

I worked for a while at a university that was on the edge of losing Carnegie Tier I status because it didn't have enough PhD students. University administration repeatedly pressured our department, which was one of the strongest at the school, to start a PhD program. Faculty resisted because a school at that level would never have been able to attract graduate students near the quality of the faculty themselves.

You want to think of your doctoral students as future colleagues. Nothing is more soul-sucking than a bad PhD program turning out marginal degree holders.

47. **Gilgit**
April 2, 2013

While the absolute numbers look OK, I think the chart on this page tells a lot:

http://mikethemadbiologist.com/2012/07/16/the-old-days-were-better-at-least-when-it-came-to-nih-funding/

The chart shows how the percentage of applicants for federal funding that actually gets funded is much lower than in the past. It also shows, at least for the NIH, that the number of applicants is much higher.

Which brings me to two points:

1.) One of the reasons America has continued to be a superpower for the last 30 years is because we lead in science and technology. And one of the big reasons for that is because of government funding. We have a lot of scientists/engineers and the decision was made after WWII to keep funding science (with a bump up after Sputnik).

To stay on top you have to keep spending. Since there is large core of scientists already out there, if you want to keep growing you have to keep increasing the funding.

2.) I notice the number of applications in the chart has kept growing. This may be because it is for NIH and the biological/pharmaceutical fields keep growing. But I keep getting the impressions that big companies don't plow their massive profits back into research like the used to. If we are going to keep leading in science then government money is going to have to take up the slack and needs to grow more than in the past.

Of course America doesn't have to keep being a technology powerhouse. The financial industry is still profitable. I'm sure they'll do us all proud.

48. **Peter Woit**
April 2, 2013

Gilgit,

From what I see of the numbers, there was a massive increase in the NIH budget 1998-2003, with more money going into the system causing a massive increase in the numbers of grant applications during the years after that. If you wanted the success rate for grant applications to stay constant, it looks like, after doubling the NIH budget in those years, you would have needed to double it again in recent years.

Exponential growth is just not sustainable, it has to stop at some point.

49. **Gilgit**
April 4, 2013

(My post went long. If you don't think I followed the rules you can delete it.)
OK, I followed your link and looked at many graphs and concede your point that we are not at low levels of funding.

I did think about it a bit, though. Are there strong reasons to increase spending right now? Some thoughts popped out at me.

Looking at the non-defense R&D chart, I see that we really were spending a lot on energy in the late 70s. Luckily, Ronnie Boy worked very hard and after 6 years was able to gut many of the programs. This lead to the current world were no one thinks about energy or any massive side effects of using energy. 🙂

Energy research might mitigate the effects of fossil fuels. Offsetting the amount of money going to drought relief, hurricane relief, and [you favorite catastrophe here] relief. And, thanks to Ronnie, we're 20 years behind.

Another thing that came to mind is the number of articles lately on diseases that have been showing up that are immune to every single antibiotic we have and how these strains have been appearing in western countries more and more. I'm thinking that if this trend continues and we have some deadly outbreaks, we might wish we'd spent more money in the preceding years.

And as for private drug companies:

http://www.slate.com/blogs/moneybox/2013/03/14/medicare_part_d_is_cheaper_ than_expected_because_the_drug_pipeline_has_dried.html

that says that the number of new drugs coming on the market is much lower than in the past. I've read that people are trying to get public funding specifically allocated to develop new antibiotics. I hope they succeed. In any case, private companies think its not profitable enough because the people dying today live in poor 3rd world countries. Gotta love that private sector.

Finally, I can't help but notice that the economy isn't as strong as it was. Maybe you've noticed too. It would be nice if – when the economy does pick up – we have lots of scientists and engineers trained and fresh for the fight. Instead of lots of ex-scientists who have moved on because they couldn't find work.

If the $64 Billion was increased to $74 or $84, would that really be unaffordable? The total budget is $3.5 Trillion.

By comparison, I'd point to a story NPR did a couple weeks ago about how the Americans with disabilities act, which was passed in the 80s has change the country. Many people who have become unemployable have been put on disability because we don't have any jobs for them. Not because they are too ill to work. They can't do manual work anymore or the only employer for miles around went bust. 14 million people that cost $260 Billion a year. I'm not against this, but as the report pointed out: we are spending $260 Billion to have people not work and almost no one noticed and few people even talk about it. It wasn't a plan, just how things have worked out.

I bring it up because if we can afford something that big by accident, we should be able to increase R&D funding NOW without breaking the bank. Even if the increase was only temporary. That chart (following your link) that shows "total non-defense R&D" spending – it says that in the late 70s, after Apollo was done, we spend $39 billion, so we still aren't double that. So spending doesn't sound unsustainable to me.

Grothendieck News

March 30, 2013
Categories: Uncategorized

On Thursday someone pointed out to me that it was Alexander Grothendieck's 85th birthday. Hopefully he is well and celebrating appropriately. Coincidentally I just heard the following rumor. Supposedly a couple months ago the librarian at the IHES got a phone call from a man who said his name is Alexander Grothendieck, that he needed a specific book from the library and asked if he/she could mail it to him at a certain address somewhere in the south of France.

The librarian said that books are lent only to IHES members and no books are sent by mail. The man on the phone said something and the librarian said that he/she must consult with the director. The director then went ahead and had the book sent.

Perhaps someone can confirm this rumor. Of course the first question that comes to mind is: "What book was it???" (And yes, if I do find out, I suppose I shouldn't blog the answer, to respect Grothendieck's privacy…)

Comments

1. **gizmo**
   March 30, 2013

   It is very unfortunate for mathematical community that Grothendieck stopped his mathematical research at the age of 42. I don't understand his decision, because, as far as I know, he was not very active in something political. He could continue his research. In wikipedia it says that
   "In this "Déclaration d'intention de non-publication", he states that essentially all materials that have been published in his absence have been done without his permission. He asks that none of his work should be reproduced in whole or in part, and even further that libraries containing such copies of his work remove them."
   Very weird for such a great mathematician.

   As for the book, I believe you shouldn't ask if you think it is improper to share it. (By the way I am very curious too.)

2. **johnmcAllison**
   March 30, 2013

   "He [Grothendiec] asks that none of his work should be reproduced in whole or in part, and even further that libraries containing such copies of his work remove them."

   I just hope that it wasn't Grothendiec asking for a book authored by some one else, since it would smear himself as a parasitic hypocrite. He comes across as a man of principle and I doubt he would do this.

3. **Deane**
   March 30, 2013

   I heard this exact story only a few weeks ago from a mathematician I know, and he seemed to have heard it from a reliable source. The version I heard is that Grothendieck called one of the permanent professors and asked for a particular book from the library. I don't remember what I was told about what ensued after that or which book it was. But what you say sounds pretty plausible.

4. **MathPhys**
   March 30, 2013

   @gizmo

   Grothendieck was mathematically active way past 1970. His *"Esquisse d'un Programme"* , which by all accounts is first-rate mathematics, was written in 1984, based on a 1,600 manuscript from 1980/81. He has at least one other 600 page manuscript on stacks from 1983. Put together, these works add up to more than what a typical good mathematician at a typical good university produces in a lifetime.

   @johnmcAllison

   I don't think that he's well enough to be consistent.

5. **Felipe Zaldivar**
   March 31, 2013

   @johnmcAllison

   Sorry to disagree, but I don't like your choice of adjectives to refer to Alexander Grothendieck. All the stories one hears about his work and work ethics contradicts your unfortunate words. The monumental work he left us is something we should, and are, grateful for. We may lament his early parting from our milieu, but we respect his reasons, whatever they may be. After all he did not harm anyone in doing so, and all the libraries have copies of his published works that we consult freely. Most of his published work is freely available, e.g. all the EGA volumes, from NUNDAM . Anyone familiar with his work knows how freely he shared his ideas, and let others add their own, as in his celebrated SGA at IHES, that are now being republished by the SMF (my local library has now new copies of two of the volumes on group schemes; I hope to see soon, the volumes from SGA4). Again, I am sorry to disagree with you, but allow me to end with a thought I recurrently have about this larger than human characters: we don't exactly know or understand what Grothendieck or Perelman are telling us, not about them, but about ourselves, minor players in the word of mathematics, but we must respect them for what they have done.
   Best wishes,

6. **Tim Campion**
   March 31, 2013

   @ gizmo

   If you're under the impression that Grothendieck was not very political, then you might want to read up a bit. His parents were anarchists. His father supposedly died in Auschwitz, and Grothendieck spent several childhood years in French refugee camps during WWII.

   Grothendieck himself was a dedicated pacifist. He taught seminars in North Vietnam to protest the war there. He left the IHES and refused the Crafoord prize partly because they received military funding.

This is just from wikipedia.

7. **gizmo**
March 31, 2013

@ Tim Campion

To my knowledge his political activities were not too dense to make him stop mathematical research. I don't say he don't have sharp political opinions, but if he wanted to change something, he should appear in public and defend his opinions, instead of living in reclusion. I don't know Grothendieck personally, so I don't want to say more.
On his views on funding of mathematics, V.I. Arnold has similar views:
http://www.pdmi.ras.ru/~arnsem/Arnold/Polymath.txt
Off topic: Maybe I am wrong, but I observed that while top theoretical physicists almost always on the faculties at most prestigious universities, there are many mathematicians of first rate, some earned fields medal, on faculties at less prestigious universities. Can someone explain why ? Maybe it is because mathematicians works more indepently than physicists (who works more or less on same topics, while mathematicians have much more freedom). If it is so, can we say that different universities have tend to different topics (in physics)? Princeton seems to have a clear bias to string theory but what about others ? Isn't this harmful to phd education ?

8. **Abraham Smith**
March 31, 2013

gizmo,

I think that's just selection bias on your part, and perhaps a misunderstanding of what "prestigious" means. A math department is prestigious because of who is there and what sort of community they are trying to build. When I think of top-tier math departments, that list correlates extremely highly with standard lists of world-renowned universities. In no particular order, I think of places like Princeton, Berkeley, Stanford, Columbia, NYU, etc.

Also, I don't think Grothendieck (or Perelman or anyone else) owes us anything. Many people have talents they choose not to pursue for all sorts of personal reasons. Maybe they have a family whom they refuse to neglect for the sake of a better position. Maybe they decide on more lucrative job options. Maybe they have physical or psychological conditions that make the experience unpleasant. Maybe they just prefer gardening!
I don't believe I would make the same decision that Grothendieck did, but I will also never be in that position. I was not a victim of any particularly horrible historic events as a child, and while I strive to be a fair second-rate mathematician, I will never be known as an earth-shattering influence like he is. At the same time, it's always tempting to say "screw this!" and go live in a cabin in the mountains somewhere, and I can only envy those who had the courage to pursue their desires.

9. **OMF**
March 31, 2013

Maybe it was a book on LaTeX?

10. **socrates**
March 31, 2013

Sources tell me it was "Not Even Wrong" by a certain Peter Woit

11. **MathPhys**
April 1, 2013

@gizmo,

It is my impression as well that the distribution of prominent physicists peaks at a (much) smaller number of universities compared to that of prominent mathematicians. I think the reason is that it is easier for a mathematician to work in relative isolation (think of Langlands) and produce influential mathematics than for a physicist. Physicsists seem to need to talk to others, or at least to have the chance to do so when they want to, on a non-stop basis.

12. **Jon**
April 1, 2013

April fools?

13. **Thomas**
April 1, 2013

A book by Pierre Lochak which seems to be e.g. about putting Grothendieck's way of thinking into a braod context: http://www.math.jussieu.fr/~lochak/textes/mf.pdf

14. **a**
April 1, 2013

By the way, are you aware of audio recordings of 1973 Grothendieck's lectures at SUNY at Buffalo? It appears the copyright of all these recordings is that of the Department of Mathematics of SUNY at Buffalo and one can actually listen to them.

15. **Peter Woit**
April 1, 2013

a,

Thanks (that site is down now, was up earlier). Do you know if any kind of transcription of those lectures exists (i.e. is there any kind of written version of the material of those lectures)?

16. **Felipe Zaldivar**
April 1, 2013

There are some notes, of the first part of the course, written using these recordings by F. Gaeta. Scans of the notes are in the "Mathematical Texts" section of the Grothendieck's site (www. grothendieckcircle.org) under the title "Introduction to Functorial Algebraic Geometry" and, as emphasized there these are the notes with commentaries by F. Gaeta, apparently there were no pre-notes by Grothendieck himself that were later expanded by the note-taker. It would be nice to compare the recordings with the notes.

Strange connections to strange metals

April 2, 2013
Categories: Uncategorized

In recent years much of the attention of string theorists has turned to applications of string theory (via AdS/CFT) to heavy-ion physics and condensed matter physics. Since I'm no expert on either topic, I've been curious to hear what experts think about this. In the case of heavy-ion physics, as far as I can tell, this doesn't seem to have worked out very well, with string theory not of much use to say anything about heavy-ion physics at the LHC (although I'd be interested to hear from those more knowledgeable about this). There does still seem to be some promotional activity in this area, with Joe Polchinski last month giving a popular talk in which he claimed that

> The quark-gluon liquid, produced at the RHIC accelerator in NY and by the LHC, is best modeled as a black hole, by applying AdS/CFT duality.

On the AdS/CMT front, one expert is now being heard from. In the latest Physics Today, Philip Anderson has a piece called Strange connections to strange metals, in which he responds to an earlier Physics Today article by Hong Liu, From black holes to strange metals, which claimed:

> String theory relates gravity to the physics of a novel phase of matter observed above the superconducting transition temperature.

Anderson writes:

> It is one of many quasi-journalistic discussions I have seen of results using the AdS/CFT (anti–de Sitter/conformal field theory) correspondence from quantum gravitation theory ostensibly to solve condensed-matter physics problems such as the "strange metal" in the cuprate (high Tc) superconducting metals. As the probable source of the buzzword phrase "strange metal" to describe the phenomena observed in the cuprates and of a theory that bids well to explain those phenomena in detail, I think I have a reasonable motivation to object to the publication of those claims, even though advanced tentatively, when so much is known about this particular phase.

He ends with a summary of what he sees as the problem with the whole AdS/CMT idea:

> As a very general problem with the AdS/CFT approach in condensed-matter theory, we can point to those telltale initials "CFT"—conformal field theory. Condensed-matter problems are, in general, neither relativistic nor conformal. Near a quantum critical point, both time and space may be scaling, but even there we still have a preferred coordinate system and, usually, a lattice. There is some evidence of other linear-T phases to the left of the strange metal about which they are welcome to speculate, but again in this case the condensed-matter problem is overdetermined by experimental facts.

Hong Liu responds here.

Anderson will be here at Columbia to give a colloquium April 15 on The Discovery of the Anderson-Higgs Mechanism. I've written something about this history here, look forward to hearing about it from Anderson himself. There's much speculation about a possible Nobel for the Anderson-Higgs mechanism this year, one wonders if the Nobel committtee has any AdS/CMT proponents…

Update: An additional comment about this just occurred to me: the criticism of Anderson's work on the Anderson-Higgs mechanism has always been that he didn't appreciate how different relativistic systems. Now he's claiming the AdS/CMT proponents don't appreciate how different non-relativistic systems are.

Comments

1. **bitboy**
   April 2, 2013

   Hi Peter,

   Sachdev has written about this connection. He has some articles on his website: http://sachdev.physics.harvard.edu/

2. **Bob Jones**
   April 2, 2013

   I think the key point here is explained in the last paragraph of Liu's response:

   "Whether or not one finds a 'conventional' explanation for strange metals, connections between the physics of strange metals and black holes are worth exploring. They hint at a new paradigm for thinking about strongly correlated quantum soups. As an added bonus, we may also obtain new insights into quantum gravity from advances in condensed-matter physics."

   Research into the AdS/CFT correspondence is important not only because of its potential applications in condensed matter physics. It's also a very important general idea in quantum field theory, and it has led to important insights into the holographic nature of quantum gravity.

3. **lun**
   April 3, 2013

   I believe the key test in science is falsifiability:
   Is there an experimental outcome (realizeable or Gedanken) that would mean that "strange metals cannot be described by a theory with a classical gravity dual"?
   If not, then AdS/CMT is essentially a very fancy way of parametrizing data, rather than a physical theory.
   The fact that most such work is based on "bottom-up" potentials chosen by hand makes it likely this is indeed the case, but the jury is still out.

4. **Christopher Herzog**
   April 3, 2013

   Replying to lun's comment, it is an interesting thought exercise to replace "theory with a classical gravity dual" with "effective field theory". Like any particular effective field theory, any given theory with a classical gravity dual of course produces falsifiable predictions. It is a rather formidable enterprise to falsify the framework of effective field theory. (Perhaps we should try.) Nevertheless, I think there is general consensus that effective field theory is a very useful framework for describing the world we live in. Gauge/gravity duality promises to become (or perhaps already is) a somewhat less general although nevertheless very interesting framework in which to write down specific physical models.

5. **lun**

April 3, 2013

The EFT analogy is indeed often used, but I think it is flawed.
The applicability of any generic EFT has a stringent well-defined
set of requirements:
A hyerarchy of scales (the “typical scale”<<"the fundamental scale"), and
a stable vacuum.
It is usually very easy to see whether a system fails at these characteristics,
and there are plenty of systems where applying any EFT, intended in the conventional way, is plainly foolish (turbulence, glasses, phase boundaries with EFT of one phase. Of course sometimes people try to apply EFT to domains where it clearly fails, but this is a problem of EFT practitioners, not EFT itself).

From what I can see very little effort is being made to define
a similar domain of validity for AdS/CMT.
Note I am not saying it is impossible to do, simply it is not considered
an important problem, and is generally disregarded: For instance, one
obvious criterion for the validity of the classical gravity description is that
N, the number of YM colors, is large. Yet there are well-cited papers by
famous people who attempt to model 1/N effects by classical gravity
descriptions. There is a fundamental issue there, 1/N corresponds to
deviations from classical gravity, but this is usually not even mentioned
in the paper.

Part of the reason is objective difficulty: For almost all systems
where Gauge/gravity is used, we do not know the the Gauge theory.
For bottom-up systems, which seem to form the basis of AdS/CMT models,
we dont know either the Gauge or the Gravity description.
But it is still bothersome that some people who do this essentially use
some complicated AdS concoction to draw a line through a bunch of data,
and then say "this system can be described by string theory".

6. **Peter Woit**
April 3, 2013

lun,

I think Anderson is wisely not getting into very general arguments about falsifiability, but addressing the question of whether, in this particular case, AdS/CMT methods give a better or worse model for the system in question. It seems to me that his claim is that he and others have models that explain much more about these systems than the AdS/CMT-based models. If so, publication of articles aimed at non-experts claiming that the way to understand this physics is via strings, quantum gravity or black holes (even in the case of Polchinski and heavy ions, that the system is “best modeled” this way) is quite misleading.

The hype level in the past associated with AdS/CFT methods has been very high (these supposedly provide the “harmonic oscillator” of the 21st century…). No one would object to people pursuing ideas about use of such methods in condensed matter theory (“falsifiable” at this stage or not), as long as they’re not misleading people about how well their methods work compared to others.

Various Links

April 2, 2013
Categories: Uncategorized

- The AMS-02 experiment results will be announced tomorrow, 1700 CERN local time, webcast here. The normally reliable Jester says rumor is no dark matter. For this kind of astrophysics news, you should find a site with an expert to interpret the results, I'll try and provide a link here.
- Weird. The Templeton Prize was supposed to be announced on Thursday, but they've changed their announcement to read "April 2013 (exact date to be determined)". Did someone turn it down or something?
- There's a very long oral history transcript here of an interesting interview with Joe Polchinski. It covers a lot of ground of the history of what went on in particle theory during an era which included the rise of string/M-theory. The interview took place in 2009, and has a certain amount of "string wars" sort of material, since that was the period when this was winding down. Someone should fix the proper names in the transcript though…
- As part of his Einstein Chair at CUNY, Dennis Sullivan has run a seminar for many, many years, with quite a few interesting speakers. There's now video online of many of the talks.
- Howard Burton, who was the founding director of the Perimeter Institute now has a multimedia magazine called Ideas Roadshow, with one of the first programs a long interview with Nima Arkani-Hamed (access free for to this if you sign up).
- I keep on finding out about more math blogs worth a look, for instance Chromotopy and DZB's blog (via Motivic Stuff).
- Eckhard Meinrenken's book Clifford Algebras and Lie Theory is now out. The book is online here if your institution is paying Springer.

Update: A live blog from the AMS talk is here. See the comment from "M" here which has an abstract of the talk giving some of its main conclusions.

Update: CERN has a press release with the results here.

> … these features show evidence of a new physics phenomena.
>
> The exact shape of the spectrum, as shown in Figure 2, extended to higher energies, will ultimately determine whether this spectrum originates from the collision of dark matter particles or from pulsars in the galaxy. The high level of accuracy of this data shows that AMS will soon resolve this issue.

Update: For a summary of the significance of this for dark matter, see Resonaances.

The paper is here. The delay in the public announcement was clearly caused by Ting's decision, unusual these days, to not submit a preprint to the arXiv when the results were ready, but just quietly submit to a journal (PRL, on March 14th), and say nothing publicly until the paper was accepted and published.

Update: Better (as in free) link for paper.

Update: The Templeton Prize was announced today, April 4: Desmond Tutu.

Comments

   You're missing the colon after http in the "Clifford Algebras and Lie Theory" link.

2. **Peter Woit**
   April 2, 2013

   Anon,

   Thanks. Fixed.

3. **Mark**
   April 3, 2013

   Peter,
   Thanks for this (as usual) very valuable collection of links. I enjoy reading your blog a lot !

4. **M**
   April 3, 2013

   The abstract of one AMS talk is public:

   Alpha Magnetic Spectrometer (AMS-02) is a general purpose high energy
   particle detector which was successfully deployed on the International
   Space Station (ISS) on May 19, 2011 to conduct a unique long duration
   mission of fundamental physics research in space.
   The results of the AMS experiment on the primary positron fraction in
   the energy range from 0.5 to 350 GeV are presented. Events have been
   collected in the first 18 months of data taking, for a total statistics
   of ~6 million electrons and ~600,000 positrons. The data show that the
   positron fraction is steadily increasing from 10 to ~250 GeV. The
   positron fraction spectrum shows no structure and the positron to
   electron ratio shows no observable anisotropy.

5. **Slothrop**
   April 3, 2013

   Here is a free link to the AMS paper:

April 4, 2013

Peter, OT to this thread, but a talk on some of the stuff you have talked in the blog
http://pirsa.org/displayFlash.php?id=13040115

7. **Hansi**
April 8, 2013

By the way peter,
what do you think of this brand new string theory book:

http://www.amazon.com/Concepts-String-Theoretical-Mathematical-Physics/dp/3642294960/ref=sr_1_1?s=books&ie=UTF8&qid=1365427927&sr=1-1&keywords=luest

Publication Date: October 4, 2012 | ISBN-10: 3642294960 | ISBN-13: 978-3642294969 | Edition: 2013
The purpose of this book is to thoroughly prepare the reader for research in string theory at an intermediate level. As such it is not a compendium of results but intended as textbook in the sense that most of the material is organized in a pedagogical and self-contained fashion.

8. **Peter Woit**
April 8, 2013

Hansi,

From the table of contents, looks like it mostly covers string theory/unification from the point of view popular 20-25 years ago, very little about AdS/CFT, which has dominated the field the last 15 years or more. But, I'm not the target audience for this book, not sure who is…

9. **Hansi**
April 26, 2013

Peter woit wrote:
But, I'm not the target audience for this book, not sure who is…
end quote

Well, the book by luest, blumhagen and theisen is meant as a simpler introduction into string theory than green schwarz witten or the books of polchinki.

As such, it avoids phrases like "it can be shown", or "it obviously follows" and it does not assume any knowledge beyond field theory and relativity basics.

It is however, more difficult to read than the book of Zwiebach, which does not even describe supersymmetry. In contrast to Zwiebach, the new book of Luest, blumhagen and theisen aims to threat the subject seriously. Regarding to your comments on ads/ cft: The book contains 42 pages on ads/cft. For example, becker becker schwarz only write 31 pages on this, with using a much larger font!
Furthermore, on the chair of the author, a regular lecture is held on ads/cft. The book on string theory by luest blumhagen and theisen aims to just covering the "basics" as an introduction. With that book having read, one then can get into the lecture on ads cft…

This Week’s Hype

April 3, 2013
Categories: This Week's Hype

The award for this week’s hype goes to the people at CERN, who normally are pretty good about this, but somehow thought it was a good idea to spin the AMS-02 results in a way that makes it sound as if they provide significant evidence for dark matter. The press release has:

> The international team running the Alpha Magnetic Spectrometer (AMS1) today announced the first results in its search for dark matter….
>
> These results are consistent with the positrons originating from the annihilation of dark matter particles in space, but not yet sufficiently conclusive to rule out other explanations….
>
> One possibility, predicted by a theory known as supersymmetry, is that positrons could be produced when two particles of dark matter collide and annihilate. Assuming an isotropic distribution of dark matter particles, these theories predict the observations made by AMS…

which, is inconclusive if you read it carefully, but sure makes it sound like this was an announcement of significant evidence for dark matter if you don’t. As one might expect, this immediately led to press stories about how:

> A $2 billion particle detector attached to the International Space Station has detected the potential signature of dark matter annihilation in the Cosmos, scientists have announced today…
>
> By doing a tally of electrons and positrons, physicists hope the AMS will help to answer one of the most enduring mysteries in science: Does dark matter exist?
>
> And today, it looks like the answer is a cautious, yet exciting, yes.

the kind of thing which, as usual, made it to Slashdot.

I won’t bother explaining here why this is nonsense, since this has been done much better and at length by Jester and Professor Matt Strassler.

Comments

1. **Bernhard**
   April 3, 2013

   Good that you put it so clearly. In the previous post I was already about to ask how come the result could be “evidence of a new physics phenomena” while at the same time they could not tell for sure whether the “spectrum originates from the collision of dark matter particles or from pulsars”….

2. **Avattoir**
   April 3, 2013

   Ethan Siegel is calling the CERN spin not merely misleading, but deceitful; no, worse -planned and deliberate fraud (since he predicted it 6 weeks in advance):

   http://scienceblogs.com/startswithabang/2013/04/03/itll-take-a-lot-more-than-ams-to-find-dark-matter/

3. **ohwilleke**
   April 3, 2013

   It would be nice if someone could do theoretical expectation charts in different scenarios to compare to the results. This may not be possible in all scenarios, but ought to be calculable in dark matter annihilation scenarios with some precision.

4. **Z**
   April 3, 2013

   Well, it gets worse. This is the Huffpost’s front page right now: http://i.imgur.com/ISgvNps.jpg

5. **OHNOES**
   April 3, 2013

   The Over-Hype Network for Objective Estimates of Significance has announced, in its first analysis of the media data, that along with the expected hype emitted by the AMS collaboration, there are very large quantities of antihype being produced by local sources in the blogosphere. We believe that the volume of antihype emission is significantly greater than would be produced purely by a desire for rational balance, and that it therefore constitutes evidence for the existence of “dark motives”.

   One popular theory of dark motives is “superskepticism”, a state of mind which reflexively scorns and belittles any claim of significant novelty or discovery. According to the theory, superskeptics would characteristically be found in hype-rich environments.

   The quest for evidence of superskeptics has been dominated by the search for great voids, cosmic battlegrounds created by the mutual annihilation of hype and antihype, several of which were observed in the mid-2000s. We believe that our observations may constitute the first direct detection of superskeptics engaged in real-time production of antihype.

6. **paddy**
   April 3, 2013

   First: kudos to PW (for the links to knowledgeable discussion of AMS-02 results).
   Second: it is sad that the success of such an intricate instrument is, apparently, besmirched by PR seeking.
   Third: I await the formulation of a simply unnatural “superskepticism” perhaps split?

7. **Hal Porter**
   April 3, 2013

   Just a quick add-on. Nature’s take seems pretty much yours and Jester’s, which I had had read before the CERN release. I assume it was the CERN press office to blame, but I can assure you that as this goes down, the more intelligent and discerning of the science press press may well remember this with great negativity and future suspicion if they feel they were misled.

Really stupid/self destructive of CERN, in my opinion.

8. **Shantanu**
April 4, 2013

This hype maybe due to the amount of trouble/ difficulties/delay
this experiment faced.

9. **Natalia Kiriushcheva**
April 4, 2013

Many news on AMS-02 results start with mentioning $2bn. Is it too big to fail ?
http://gravityattraction.wordpress.com/2013/04/01/boltzmann-brain-discovery/

10. **Bernhard**
April 5, 2013

And, as this nonsense goes around the world and is translated to other languages, the level of hype increases through a sort of Chinese whispers effect. One Brazilian newspaper states "Scientists detect existence of dark matter for the first time":

http://www.diariodepernambuco.com.br/app/noticia/ciencia-e-saude/2013/04/04/internas_cienciaesaude,432320/cientistas-detectam-existencia-de-materia-escura-pela-primeira-vez.shtml

11. **Chris W.**
April 5, 2013

…and an AP story, via the Weather Channel…

12. **steve newman**
April 9, 2013

can someone refer me to a paper that spells out how these ams observations
connect to dark matter. the prl paper doesn't even contain the word 'dark'.
what do we know about dark matter other than its presumed gravitational effect?
how does dark matter relate to positrons? what would cause dark matter to
annihilate? i assume that the people commenting on this blog understand the connection, so someone please provide a link for those of us to whom this is all new.
thanks.

13. **Peter Woit**
April 9, 2013

Steve Newman,

For much more of a background explanation, follow the links I provided at the end to Resonaances and Matt Strassler's blog, both of which provide a lot of such discussion. The fact that the connection to dark matter is so slim that AMS didn't put it in their PRL paper, but that they then went ahead with a press release trumpeting such a connection, is exactly what the controversy is here.

14. **Low Math, Meekly Interacting**
April 9, 2013

Is CERN being faulted here for hyping, or for parroting Ting's hype? Statements he made in this release and via other sources seem to be wildly at variance with the skeptics. The latter complain that not only do these data provide nothing like firm evidence of dark matter, they may never be able to unless cosmic backgrounds are far better understood than they are at present. I'm not going to pass judgement, but the dissenters seem to saying, in a nutshell, that Ting is all but spreading falsehoods. It seems as if there's some effort shoot the message (or its couriers) and not the messenger, i.e. no one seems to be calling Ting out directly. Deference to a Laureate? I don't know if my impressions are mistaken, but that's the general picture I'm getting.

15. **Peter Woit**
April 9, 2013

LMMI,

I think there's plenty of blame to go around here. Ting is known for running a tightly-controlled operation, so he likely approved the press release. The CERN press people however are not random journalists but often physics ph. ds, and should have been aware that dark matter hype was a danger here. Both parties had to agree to put this out, either one could have stopped it.

16. **El-Coco**
April 10, 2013

For the record: Hawking gave a pro M-theory talk yesterday in Los Angeles. http://www.latimes.com/news/science/sciencenow/la-sci-sn-stephen-hawking-cedars-sinai-20130410,0,7704203.story

20. **Low Math, Meekly Interacting**
April 15, 2013

Sorry, should have checked out Resonaances first before bothering you…

21. **Peter Woit**
April 16, 2013

LMMI,

Besides Resonaances, some of the news stories are fairly reasonable, see for instance
http://www.huffingtonpost.com/2013/04/15/dark-matter-found-underground-detector-particle-physicists_n_3086829.html

which quotes Cabrera about the experiment

"We're not claiming anything,"… The finding "does not rise anywhere near the level of discovery, nor does it rise anywhere near what we would call 'evidence for,'" Cabrera said. It is, however, a "region of interest" for future study.

This isn't much of a signal, and arguably inconsistent with other results. Best to ignore, if you ask me…

To Mars and Beyond

April 14, 2013
Categories: Uncategorized

I'm not sure either of these stories from the past week is particularly important in and of itself, but since I try and keep up on trends in theoretical physics, and two is a trend, here's some news from two of the greats of the field:

- There's an interview here (via John Baez) with Gerard 't Hooft about his role as "ambassador" for the Mars One project, which plans to send people on a one-way trip to Mars in 2023. This will be financed with an associated reality TV show, and already 40,000 people have signed up for a chance to get to go.
- Stephen Hawking has even more radical ideas, which he talked about in a visit to Cedars-Sinai in LA last week. He believes humanity is guaranteed to trash this planet, so our best hope is to use M-theory to find a way to move on to another one:

> For him, the answers to the largest and tiniest questions lie in M-theory.
>
> "To understand the universe at the deepest level, we have to understand why is there something rather than nothing," Hawking said, speaking through a computer program that converts his eye and cheek movements into spoken speech. "Why do we exist? Why this particular set of laws, and not some other? I believe the answers to all of these things is M-theory."
>
> The theory, he said, combines multiple ideas about math and physics. It suggests that there are multiple dimensions or universes, and offers solutions for the behavior of super-massive black holes and the properties of the fabric of space-time. M-theory is a work in progress, but Hawking said he believes that it's the most promising lead to a unified theory.
>
> The payoff to solving M-theory, Hawking said, is understanding where we fit in — and, perhaps, how we can thrive.
>
> "We must continue to go into space for humanity," Hawking said. "We won't survive another 1,000 years without escaping our fragile planet."

Update: On Tuesday Hawking gave a talk to students at Caltech, with a report here that includes smuggled audio of the talk. Evidently Hawking told students that they don't need God, but they do need M-theory and anthropics:

> During his talk, he cited M-Theory — a wide-ranging and as-yet-incomplete explanation of the universe that attempts to unite the factions within String Theory — as the only workable theory going forward that can explain the true nature of the cosmos.
>
> M-Theory suggests that the multi-dimensional "strings" of the universe are bound together by a strange material sometimes called membranes, but also known by other names. It suggests that matter, space, time and every possible history exists simultaneously across dimensional planes that were created out of nothing at the moment of the Big Bang some 13.8 billion years ago. Only in very few of these dimensions can a species like humanity come into being.

Comments

1. **NLR**
   April 14, 2013

   This is absurd. The whole point of going to Mars is to get away from all the nonsense going on on Earth. If they have a reality TV show then we're just bringing it with us. Also, perhaps the reason to study M theory (or any other fundamental theory) is not, as Hawking suggests, to help humans thrive, but to learn about something about an aspect of reality that has nothing whatsoever to do with humanity and that we cannot tamper with.

2. **Peter Woit**
   April 14, 2013

   I think the main problem with the reality TV show would likely be too much reality. When an oxygen/food/waste processing system fails and spare parts are 140 million miles away, the show might still have viewers, but maybe not advertisers.

   I don't really understand Hawking's logic. Either humanity can't be stopped from trashing its environment, in which case we should hope that M-theory won't allow us to leave and go wreck the rest of the universe, or this can be stopped, in which case working on that should be the goal, not making plans for leaving.

3. **CIP**
   April 14, 2013

   This reminds me of a conversation which a couple of slightly famous physicists had after seeing a lecture by Eddington in his eccentric age:
   Physicist A: "Oh my gosh, is that going to happen to us when we get old?"
   Physicst B: "Don't worry, a genius like Eddington may go nuts, but guys like you just get dumber and dumber."

4. **Maciej**
   April 14, 2013

   I coudn't agree more with CIP. Physics is not about "why laws of Nature exist" but about "what they are". Hawking clearly confuses that, which is embarrassing. This is not the first time he does it.

   Let me also add something else. M-theory will not, of course, answer the Leibniz's question "Why there is something rather then nothing". There is a good reason for that namely, M-theory has got nothing to do with our Universe (except the fact that some people study it – which is ok I think).

   Imagine however (but this requires a huge doze of imagination) that M-theory describes our Universe. But M-theory itself assumes some laws e.g. principles of quantum mechanics. Therefore it will not be able to explain them anyway.

   The statement that any, not only M-theory, can answer Leibniz's question is in my opinion close to lunatism.

5. **GM**
   April 14, 2013

   I don't understand Hawking's logic either.

It is absolutely true that we're on a path towards self-inflicted extinction and we're going to take most of the rest of the planet with us. The main reason for this is that we have exceeded the carrying capacity of the planet, which is a problem that could be solved in two ways – (1) we reduce our population and consumption so that we are back safely within the carrying capacity of the planet, or (2) we find an unlimited source of energy that would allow us to solve most of our environmental problems and colonize the rest of space. As far as we can tell at present, (2) is physically impossible and if there is a way to somehow circumvent the laws of physics as we know them, or perhaps find out that they are in fact different, it will take many decades, centuries, maybe thousands of years to do the research and figure it out. Unfortunately, the projected timeline for the coming global Malthusian catastrophe is much shorter than that, and if that happens, not only is that research not going to be done, but with quite a high probability, we will lose a lot of the knowledge we have worked so hard to acquire. I don't expect string theorists to fare well in the kind of world we can expect after the collapse of industrial civilization, and if anything, Hawking himself, who would not even be alive if it wasn't for the very complex support system around him, is the epitome of how dependent the existence of the scientific elite of today is on its largess. So the only practical solution is (1) so that we can give ourselves a chance to take a shot at (2) in the indefinite future, fully knowing that the chances of success are quite small.

However, claiming "M-theory will solve the problem" seems quite counterproductive to me, because most people will simply take it as another magic solution, when they should instead face reality and do what we know will work.

6. **Bernhard**
   April 14, 2013

   "Why do we exist? Why this particular set of laws, and not some other?"

   Hawking forgot one important question:

   "What is M-theory?"

7. **the sleep of reason**
   April 14, 2013

   What is more likely: Stephen Hawking believes M-theory will help us colonize space, or a journalist misunderstood something? The article has already had one error corrected.

8. **Peter Woit**
   April 14, 2013

   the sleep of reason,

   The idea that advances in fundamental physics far in the future will provide new technology making things like long-distance space travel feasible isn't exactly an unusual one among physicists. For Hawking or anyone else putting their money on M-theory as the source of such advances, it's not implausible they would suggest this as a possibility.

9. **N.**
   April 14, 2013

   Hawking is right. Not about theM-theory, methinks, but this planet is fragile indeed. It takes just a piece of space junk weighing a couple of thousant tons at ten clicks per second or maybe a real good blowout of a supervolcano like Yellowstone to make us and the rest 90% of living matter join the dinosurs – history. It has happend before, it will happen again.

   It's not if, it is when. And if, perhaps, we may have means – in the next 100yrs maybe – to divert the naughty asteroid, there is no way to stop a supercaldera exploding.

   The only solution is to move on, to colonize planets.

   We do not need the M-theory (or N, O, P, Q…), what we need is warp drive!

   So, my dear theoretical physicist, get to work!

   I am only half joking.

10. **N. Nakanishi**
    April 14, 2013

    Prof. Bernhard:

    Of course, M-theory means Mad theory!

11. **emile**
    April 14, 2013

    There is something I'm missing here: if a supervolcano explodes, or we get hit by a big space rock, or we pollute the planet to the point where life is threatened, we'd still be in better shape here than on Mars. Not easy to make Earth more of a hostile environment than Mars.

12. **John**
    April 14, 2013

    Emile

    I think Venus would be worse than Mars, and also more likely than any of the other cinematic disasters listed if you listen to James Hansen.

13. **CIP**
    April 15, 2013

    @N

    I think you are off by a factor of a million or so on the size of the required cosmic interloper. The recent Russian meteorite was several thousands tons, I think.

14. **Nathalie**
    April 15, 2013

Hawking is a great physicist who, unfortunately, never fails in failing to predict the future of physics. A good example of his failed prophecies is found in his 1980 Inaugural Lecture "Is the End in Sight for Theoretical Physics?"

15. **Kasuha**
April 15, 2013

The fragile thing on this planet is the humanity and that's also the thing we need to care about. The planet doesn't care what we do with it, it's just a ball of cosmic dust. We need to care about what we do with it and how to improve our chances of survival in this hostile universe.
Finding a way how to travel to distant worlds will not save our planet and will not save people on our planet. Only tiny fraction of people will be able to travel that far and they'll most probably never return. But finding other planets to inhabit will improve chances of intelligent life and life in general persisting. And that's the ultimate purpose and reason why life is here at all.

16. **Paul Titze**
April 15, 2013

Stephen has mentioned before in past articles that things will get bad for us in the future (200 years onwards would be more accurate though). Think Mysterious-Theory isn't the solution either. To "thrive in space" one needs to be able to get large amounts of hardware into orbit without relying on chemical rockets, that would be a good start.

Cheers, Paul.

17. **Volunteer**
April 15, 2013

Is NASA proceeding with an M-theory spaceship? There are probably a few technical challenges to overcome.

18. **Cloud**
April 15, 2013

A good theory about M-theory.

…

[If] humanity can't be stopped from trashing its environment, [then] we should hope that M-theory won't allow us to leave and go wreck the rest of the universe …

I don't think this follows. The environment is being trashed because Earth is overcrowded — it turned out, topologically, to be a closed surface, whereas the 'blind watchmaker' essentially made humans (or any mammal) to treat the world as an unbounded plane.

So if we did have 'warp drive' (or 'tesseracts'), we could always move on to other planets before the colonies get crowded. The colony planets would for the most part not get trashed like Earth.

But generally I'm a pessimist, because there (almost surely) is no warp drive, and the *decline* (not sudden collapse, note) of industrial civilization will not magically transform people into gaia-loving eco-nomads. If you want a picture of the globe five centuries hence, think: almost all biodiversity destroyed, all old-growth timber consumed, and society a mass of peasants malnourished on maize and rice diets, ruled by a small mandarin class.

19. **Cloud**
April 15, 2013

As for physics, I think we can safely predict its continued ossification into what J. Horgan calls 'ironic science': into a post-empirical, doctrinaire, even theological mode.

20. **Stephen**
April 15, 2013

Hawking's oversight is that figuring out M theory, like other advances in physics, would simply give us more efficient means of destroying the planet.

21. **Michael Gogins**
April 15, 2013

Surely the desire to understand the laws of Nature and the desire to explore and colonize interstellar space can be pursued at the same time, they do not conflict at all. Knowing more physics would surely help with space travel, and surviving a planetary catastrophe in colonies, whether that catastrophe were self- or other-inflicted, would surely help with fundamental physics.

Ecological problems caused by us here on Earth have been going on since we started killing large mammals and cutting down forests. This is a real, terrible problem that is getting worse fast but it is not at all likely to kill us all off, or even cause a fall back in technological level. Even a substantial decline in human population is very unlikely to cause a fall back in technology. If there were any big wars, that would probably even speed things right up again. A ridiculously tiny number of scientists, engineers, farmers, and manufacturers are keeping this immense wheel spinning right now, and the knowledge they need is scattered all over the world and will never be destroyed.

No, the real question here is one that has not yet been answered properly, what kind of world shall we build for ourselves to live in?

22. **johnnythelowery**
April 15, 2013

Bill Stone has already volunteered to go with a one-way propellant payload to Shackleton Crater on the moon. Because it costs @ $20,000 per KG to get into space, and that 90% of the weight of space craft is the propellant, what is needed is a gas station in space. HE is proposing collection of hydrogen and storage of it in orbiting inflatables. Here's his TedTalk.

http://www.youtube.com/watch?v=-Bn6Gel7yEs

23. **Spencer Tracy Jr.**
April 15, 2013

The bad news is that the mission is tied to reality TV. The good news is that some reality TV enthusiasts will be leaving the planet. If the ship were big enough to transport all involved in reality TV, Stephen Hawking might have a little less to worry about here. (However, Elton John once said: Mars aint the kind of place to raise your kids –

in fact it's cold as hells).
The part I don't understand is how can it not be cheaper and easier to perfect a meteor/asteroid defense system here than to pack up and move to another planet that by the way, they can guarantee will have a far less chance of being in the path of something?
Lastly – I must say that I did have the opportunity to talk quantum mechanics with Gerard 't Hooft a couple of years ago after one of his talks in NY. Very nice guy, very generous with his time.

24. **Not a Physicist**
April 15, 2013

It does seem that advances in fundamental physics, while they may seem entirely removed from practical application at their time of inception, may lead to real-world applications soon therafter that may facilitate our exploration of the universe. For example, quantum mechanics aided in the development of the transistor, which was essential to the Apollo missions. Thus, while perhaps M-theory in particular may not prove useful, cutting-edge physics in general will surely find practical application, perhaps in space travel, at some point in the future.

25. **dark**
April 15, 2013

Does Stephen Hawking have good science-based reasons to endorse M-theory, in light of the null results @ LHC?

26. **Bob Jones**
April 15, 2013

"Does Stephen Hawking have good science-based reasons to endorse M-theory, in light of the null results @ LHC?"

At the moment, M-theory does not say anything about physics at the LHC or any other experiment, so these experiments are not a reason for studying this theory. However, I do think there are good reasons for studying M-theory. At the very least, it's a unique extension of quantum field theory and a rich source of ideas in physics and mathematics. In particular, it's closely related to a quantum field theory in six dimensions with (2,0) supersymmetry. This theory is responsible for fascinating dualities between various mathematically interesting QFTs, and these ideas have important applications in pure mathematics.

27. **Maciej**
April 15, 2013

Bob,

the statement "M-theory is a unique extension of QFT" is a wishful thinking. First define M-theory please. Does it (the theory) exist anyway? (I mean, can one construct it by specifying the field content and their interactions explicitly?). Then explain what do you mean by "extension". Then we can talk about uniqueness if you like.

28. **Suzanna E-J**
April 15, 2013

I feel for Hawking's sense of urgency. He has a devastating disease and the only available treatment is palliative care. Clearly he was very impresssed with the persistence and innovation of molecular biologists investigating ALS at Cedars-Sinai labs. Their ongoing work will benefit future patients. His argument was that fundamental physics should should also pursue a unifield theory with just as much vigour. But I don't think you have to solve the unified theory first before you can appreciate humanity's place in universe! One can begin to apprecaite humanity's place right now. For example, Feynman, Hawkings, Weinberg, Smolin and of course Peter Woit etc have done much to explain their work to a lay non-technical audience. No mater how basic the understanding or politcal inclinations, at this time people know that there is a universe, there are galaxies, we live in the MWay galaxy, space is expanding, we have ongoing telescopic surveys of astronomical objects and that a unifed theory is ultimate goal etc
There needs to be an even bigger engagement between scientists and the public. This is not just restricted to cosmology/particle physics but in every other scientific discipline. So I agree with Hawkings that we can inspire each other and we can step up research in our respective fields. But Hawkings should realise that stem cell research would not be a promsing area of research if did not pass at least the proof of concept. Mtheory struggles with this aspect.

To Stephen who commented:
Hawking's oversight is that figuring out M theory, like other advances in physics, would simply give us more efficient means of destroying the planet.

Sounds very Grothendieck-esque! Alexander Grothendieck's disgust with the mathematical community stemmed from a distorted view of the application of science. But he could have used his academic position, charisma and intellect to pioneer solutions to these concerns. Hope this is not off-topic but look at the recent controversy around the publication of the mutated influenza virus genome (the H5N1-H1NI hybrid). Two separate experiments showed that this hybrid enabled the virus to be highly transmsissable. The submission to Nature in 2011 sparked debate about 'dual-use' research which involves weighing up the benefits of sharing reasearch with the scientific community vs risk to public safety via rogue individuals. The matter was referred to a biosecurity advisory board in USA. The board ruled against publication initially but after some months decided that in the interests of public health both manuscripts can be published although one of the manscripts had to go through a more revised version. This example shows that although difficult, there are ways to handle scientific reasearch that fall in the dual-use category.

April 15, 2013

Maciej,

What I'm saying is that if you want to extend quantum field theory by replacing point particles by extended objects, you will inevitably be led to string and M-theory. There are five a priori different ways of doing this consistently, and they all turn out to be related by duality.

Of course nobody knows how to rigorously construct M-theory, but there are lots of partial results. My point is that we can learn a lot about quantum field theory and mathematics by unraveling the structure of this theory.

30. **Raizonator**
April 16, 2013

For those who understand German:
http://www.wissenschaft.de/wissenschaft/inhalt/aktuelles_heft.html
with an interesting interview with E. Witten on M-theory, the landscape, etc.
E.g. "Was halten Sie von der Hypothese der Stringlandschaft?
Ich wäre froh, wenn es keine Stringlandschaft gäbe. Denn ich bevorzuge Einsteins Vision, dass es möglich ist, alle dimensionslosen Quantitäten der Natur aus ersten Prinzipien zu berechnen."

31. **Carl**

April 16, 2013

The sun is going to trash this planet anyway. Good that people are thinking about ways
to leave and save some of the life on Earth. It is shame that some people here think it is ok to let millions of years of evolution go to waste. Btw, humans are part of nature and whatever humans do is also part of nature.

32. **Tmark48**
April 16, 2013

M Theory is not going to help us engineer "Bussard Engines" nor build generational ships that will give us the possibility of real interstellar travel. Let science do its thing, and keep "physicists having jumped the shark" hidden lest they ridicule themselves. But maybe they don't care anymore…

33. **Tammie lee Sandoval**
April 16, 2013

Look at what happened to global warming. They made 15 year predictions. Dumb move.

By contrast, Dr Hawking has shown deep wisdom
When you predict a disaster, to get funding today, make sure the disaster in far in the future. 1000 years, Dr Hawking should be safe.

34. **Peter Woit**
April 16, 2013

Raizonator,

Thanks, I'd be curious to see the whole thing. It's not surprising that Witten says he'd prefer no landscape, but I wonder whether he would be willing to abandon string theory if convinced it led to a landscape with no predictions.

35. **Giotis**
April 16, 2013

"…so our best hope is to use M-theory to find a way to move on to another one"

I guess this is your interpretation. Such assertion is nowhere stated (or even implied) in the actual text.

I noticed that ever since Hawking embraced M-theory as the most promising way for a unified theory, you try to present him as an unreliable eccentric fool.

What you do is not right…

36. **Peter Woit**
April 16, 2013

Giotis,

What I wrote seems to me a reasonable interpretation of Hawking's talk, as described in the article (I don't have access to an actual transcript, or something more detailed). In any case, as usual, I quoted completely the text I was talking about, so people can make up their own minds.

No, I don't think Hawking is an unreliable eccentric fool. His views on M-theory are not eccentric, but widely held, and shared by many very smart, rather conventional people. I happen to think he's wrong that M-theory, the landscape and anthropics have any promise as a unified theory and that he's unwise to promote them to the public, for scientific reasons that I've often explained here.

About his views on humanity needing to leave this planet, again, I think such views aren't eccentric at all, but widely held by people who worry about the distant future of humanity. My own attitude is that it's best to worry about the immediate future, then the distant one will take care of itself, but, to each his own…

37. **QSA**
April 16, 2013

QG theories (string, LQG,AS…..) do not address full unification properly(including space-time), the origin (prediction) of the SM constants or the nature of QM. So I think these theories need to be saved first before they save us.

But anyway, I don't think earth is the problem. It is the people, you know, you can't live with them and you can't live without them. There will be a problem even if each person had a mountain of gold.

38. **Not a Physicist**
April 16, 2013

Perhaps Hawking was not referring to M-theory in particular when he commented on future space travel. Rather, he might have been referring to advances in fundamental physics in general. It seemed from the interview that he was simply emphasizing that a general conception of our place in the universe can aid in future technology. I don't think he was referring to string theory in particular but rather to fundamental physics and cosmology in general. Perhaps there was a slight misunderstanding on the part of the journalist.

39. **Peter Woit**
April 16, 2013

Not a physicist,

I don't see any reason to believe the journalist was misunderstanding Hawking (for one thing, because of the challenges he faces in communicating, Hawking is careful in choosing his words and in making sure they are understood). From the article it seems to me that Hawking was just saying two speculative, but not very surprising things: maybe advances in fundamental physics will provide technology that makes colonizing space possible, and M-theory is his current best bet for where advances in fundamental physics will come from. He wasn't saying anything about having a specific idea along these lines, just engaging in some speculation of a sort that seems to me not at all unusual among physicists.

40. **G P Burdell**
April 17, 2013

As someone who knows a bit about how Reality TV is produced, shot, and edited: those shows are mostly a sham, often semi-scripted, even employing stunt doubles if necessary. Locations are scouted and prepped before any of the “stars” arrive. If there are kooks who think the moon landings actually took place on a stage in the Nevada desert — maybe this Reality TV Mars “trip” really will! If not, there are going to have to be a whole bunch of camera, makeup, hair, and lighting crew going along on the ride. Sort of adds to the weight of the payload.. 🙂

As for those who worry about the Sun wiping out humanity — the only life that has lasted anywhere near as long as we have before that happens are bacteria. I expect that evolution will have taken care of wiping out pretty much any recognizable traces of the human genome well before then. As for the probability of teraforming Mars, or any other planet or moon in our solar system, into someplace even remotely habitable for humans: seems incredibly remote. And if all you could do was live out your life in some extra-terrestrial underground bunker, might as well do that here on Earth. We seem to forget that Star Trek is science fiction in more ways than just warp drives and teleporters.

41. **Not a Physicist**
    April 17, 2013

    G P Burdell,
    I do not think that Feynman was referring to initiating a mass “migration”, so to speak, of humans to places outside of Earth. Rather, I think he was talking about having a small colonization population outside of the Earth, perhaps of a few hundred space colonists or so. As such, it would not be nessesary to terraform an entire planet to make its surface habitable for a large number of humans; all that would be needed is a small space colony. And I don’t think he was talking about the end of the sun, either, when he talked about the end of humanity; he was probably referencing nuclear war, or some other human-caused threat. As such, it would always be useful to have a small “space colony” population elsewhere to ensure that humanity continues to exist, even after catastrophic events.

42. **Not a Physicist**
    April 17, 2013

    Error in previous comment-replace “Feynman” with “Hawking”.

43. **tommyboy**
    April 30, 2013

    I agree with Hawking and disagree with those who fail to see the importance of his point regarding the colonization of space. Let me illustrate why this is so with the following line of thought: Peter Woit presumably enjoys his profession/subject area, values a future continuation of his career in research and academia, takes pride in his blog, and the same can be said of most of us in our respective life situations. Further, Peter Woit would probably continue to behave in a way that promotes and maintains the things he values most in life. Different people may value other aspects or facets of living, but the one thing most of us have in common is that we strive to uphold our existence despite the challenges involved. In fact, challenges are what make life exciting and worth-living to a great many out there. Also, where there is life there is possibility. Thus, what could be more important than the civilization using at least some resources to ensure that the death of possibility itself does not occur, as human extinction represents the ultimate death of possibility: no more literature, no more science, no more philosophy, no more fine art, no more blogging, no more debating/sharing ideas, no more love, and so on. Species that remain in one area exclusively for too long eventually succumb to an extinction event—I think part of what Hawking is saying that human beings are in a unique position to prevent this from happening to our species and we should be actively pursuing this agenda and, of course, not to the exclusion of others.

Anderson on Anderson-Higgs

April 16, 2013
Categories: Uncategorized

Philip Anderson was here at Columbia yesterday, and gave a very interesting talk, mostly discussing what was going on in the late 50s and early 60s at the intersection of condensed matter and particle physics. This has attracted a lot of interest around the question of who first came up with what is now called the "Higgs mechanism" and who first predicted a "Higgs particle" (I've written a long blog posting about this here).

After the discovery of the BCS model of superconductivity, Anderson did important work on understanding the "gauge problem" of how gauge symmetry acts in such a theory, publishing a series of papers on this in 1958. He joked that he was "pretty naive about field theory" at the time, so much so that the spelling he was using was "guage". He had the advantage of regularly talking with Bardeen and with Nambu, and he described some of Nambu's work on the so-called "Nambu-Jona-Lasinio" model. His 1958 work explained how one avoids getting massless Goldstone bosons in superconductors due to the singular long range nature of the Coulomb force. His talk included an anecdote about escaping from handlers in the Soviet Union to get a chance to explain this to Shirkov during a visit there (he wasn't allowed to meet Bogoliubov).

He was at Bell Labs in the summer of 1962, and talked to J.G. Taylor, who told him that the problem of massless Goldstones was something those in particle theory were actively worrying about. Taylor also gave him a copy of Schwinger's Gauge invariance and mass paper, which had been published that January. This led to Anderson's Plasmons, gauge invariance, and mass paper, finished in November, and published in April 1963. This paper clearly explains the nature of what is now generally referred to as the "Higgs mechanism", in the Yang-Mills case, not just the Abelian case, ending with the very modern point of view

> We conclude, then, that the Goldstone zero-mass difficulty is not a serious one, because we can probably cancel it off against an equal Yang-Mills zero-mass problem.

In 1964 the papers by Brout-Englert-Higgs-Guralnick-Hagen-Kibble appeared that have drawn the most attention as earliest instances of the Higgs mechanism, but Anderson had the correct idea a couple years earlier. He described the situation as one where he and the 1964 authors all had the right explanation for why the W and Z have mass, although none of them (including him) had the actual physical Higgs particle, which he claimed first appears in a 1966 paper of Higgs.

The main point of his talk was the fruitful nature of research at the intersection between problems in condensed matter and particle theory, with the 50s-60s a happy period of such work. He ended with some comments on "supersolids", see his recent paper about this here. Anderson will be 90 years old later this year (he's almost exactly the same age as Freeman Dyson) and it was great to see him still going strong.

Update: See here for a write-up by Anderson of a talk a few years ago covering much the same material as yesterday's Columbia talk (including the story of meeting Shirkov).

Update: A commenter points to this recent talk by Guralnik at Brown and mentions some comments that might be about Frank Close.

I just watched the talk, and he explicitly refers to this exchange in the London Times. I don't see how when he says

> the person involved as far as we can tell has no understanding whatsoever of mass renormalization and how these things work.

this can refer to anyone except Close (about whom it is completely absurd). The point of contention here is a very simple one. Guralnik's paper (unlike Higgs's) has no potential term for the scalar field. In his talk he says this is because it was the practice at Harvard not to write such terms down, while knowing they had to appear to renormalize the theory. Close's point I think is just that Higgs went further than the other authors at the time in terms of exhibiting what would be needed to study the dynamics of the physical mode of the scalar field. From what I can tell, of course everyone writing these papers knew about potential terms for the scalar and how they worked, but the whole issue is a bit irrelevant: none of the people involved at this period seem to have thought seriously about this physical mode that describes the Higgs particle itself. They were thinking about something entirely different, the mass of the gauge field, and in any case these are Abelian models that have nothing to do with the real non-Abelian model that describes the Higgs particle.

The main point of Guralnik's talk as far as this controversy goes I think is his explicit and repeated claim (which seems to me debatable) that Higgs's paper was just wrong for technical reasons, in the sense of reaching correct conclusions by an incorrect argument. This appears to be Guralnik's argument for why he and his collaborators should be preferred to Higgs as candidates for a Nobel, and is made much more strongly here than in other places (such as here, where he doesn't use the term "wrong", emphasizes more why Higgs's argument was "incomplete").

Leon Cooper was in the audience, and asks Guralnik about the Anderson explanation for why the Goldstone theorem is violated here: the long range nature of the Coulomb potential. Guralnik seems to acknowledge that this is the right physical way to understand what is going on, but says that relativity makes things more complicated. He explicitly acknowledges that he understood not at all Anderson's arguments, saying

> we were woefully ignorant, had barely heard of superconductivity.

About the crucial question of priority, the fact that his competitor's papers were published earlier, were read by him before submission of his paper, and explicitly referenced in his paper, all he says is

> as we published it, we found out about other papers.

which really doesn't do justice to the situation. In this piece, written after the Higgs discovery, he describes the history as

> We finally submitted our paper to PRL with the proof of the general mechanism to avoid the Nambu Goldstone theorem (the only work to have this) and the special example. We were surprised to discover that two very different but related papers, with parts of the example, one by Englert and Brout and the other by Higgs also existed. All three papers appeared in the same volume of PRL in 1964.

which is highly misleading.

Comments

1. **Garrett**
   April 16, 2013

   Thanks for sharing this about Anderson. (I included him in my first slide in this short talk on the Higgs: http://www.youtube.com/watch?v=wfALJzn1hE8) I hope he is strongly considered for the prize.

2. **emile**

April 16, 2013

I would like to point out that Anderson did his best to make sure that the Higgs boson would not be found, at least in the US. Given his stance against high energy colliders, it would be highly ironic if he got a Nobel prize because of them… If he does get the prize, the Nobel committee better find a way to give it also to experimentalists who actually found the damn thing.

3. **gimmedatprize**
April 16, 2013

I was going to post very much the same thing as emile. Anderson says that in the 1950-60s he was one of several people working on the intersection of condensed matter and high-energy physics. But, in later years at least (for example in his attitude to the supercollider), Anderson has been one of the leading lights of condensed matter people opposed to particle physics.

4. **Yatima**
April 17, 2013

> that the Higgs boson would not be found, at least in the US.

That would be the Clinton administration, killing the SSC, right?

Note that Murray Gell-Mann received a Nobel prize for something he didn't believe in for quite a long time, too.

And really, who cares whether the "Higgs is found in the US"? I'm getting flashbacks to the shenanigans and political interference of the highest order to prove that the AIDS virus was "found in the US". It was all made-up of course.

5. **Bernhard**
April 17, 2013

Well, it is true that Anderson spoke against the SSC and this ultimately greatly contributed to killing the project. However, this does not change the fact he did understand the mechanism before others. I think Jester once put this quite nicely in

http://resonaances.blogspot.se/2012_03_01_archive.html:

"However, the name of Higgs somehow stuck, probably because it's cute, or maybe because we all hate Anderson for cutting the throat of the SSC."

Scientists are not immune to hatred, nationalism and others "isms" but, as best as we can, we should try to be. As I see, it is clear Anderson nailed it first, so everything else he might or might have not done should not be relevant….

I know that in the end this will be taken into account and the Nobel committee is certainly not made by neutral people without bias. However, this is what we should strive for. We should speak in favor of Anderson despite "hating his guts".

6. **emile**
April 17, 2013

@Yatima: 1-Congress killed the SSC, not the Clinton administration who had funded the project in its budget (just like the Reagan and Bush Sr. administrations). 2-Your comment on Gell-Mann would be relevant if he had opposed the construction of machines to prove or disprove the existence of quarks. 3-Indeed, where the Higgs was found is not the issue. The issue is that Anderson opposed funding colliders. Now, there is no high energy collider in the US: PEP, the Tevatron, all shutdown and US colleagues will have to go out of their country for the next 20 years (at least).

@Bernhard: I don't want to take away from Anderson's achievements. I've given many talks on the Higgs boson and I have always mentioned his name in conjunction with Higgs, Brout, etc. He is an outstanding physicist and I find it inspiring that he is still going strong at 90. That said, he was opposed to funding experimental particle physics, and worked actively to kill the SSC. That should also be part of his legacy (I'm not blaming him alone for killing the machine of course…).

7. **Low Math, Meekly Interacting**
April 17, 2013

I've always been very conflicted about Anderson for the role he played in the SSC debacle (I lack the ability to comment intelligently about his contributions to physics). That said, virtually everything he has ever written about science and science funding that was geared towards a lay audience struck me as virtually unassailable. His point seemed to be that the size of the pie is limited, and there's no compelling argument for experimental HEP getting such a big slice at the expense of other branches of physics. My solution to that problem, if anyone cared about my opinion, would be to increase the size of the pie. But it was and is a zero-sums game, and those on the condensed matter side of the profession, it would appear to this layman, possibly had a legitimate complaint about priorities. That, and maybe they were sick and tired of being called "squalid staters", and relished the opportunity to strike back a bit too much.

In the final analysis, while I remain quite ambivalent about Anderson, I can't ascribe so much of the blame to him. Congress had the knives out already, and at most I think Anderson made it easier for them to play political football. I'm not sure how much guilt someone should bear for putting a fig leaf on the naked opportunism of purported budget hawks, who feel no remorse over their assault on science in general.

8. **Peter Woit**
April 17, 2013

LMMI,

The SSC was cut at a time when there was a huge campaign to cut the federal budget (for some reason this happens under Democratic presidents, under Republican ones you get big spending increases…). It wasn't just Anderson, much of the scientific community looked at the SSC, and at their field's budgets being flat or getting cut, and argued that the SSC should probably not be supported, with the funds redirected to other deserving causes (like their own research). I remember having to point out to many people at the time that if the SSC was cut, that didn't mean the money would get redirected to other scientific projects.

9. **Low Math, Meekly Interacting**
April 17, 2013

All too true. OK, virtually unassailable except for the sad fact that it can turn to a negative-sums game all too easily.

10. **Roger**
April 17, 2013

Anderson has a review of a biography of Freeman Dyson, and says he (Anderson) "sensed his [Dyson's] ambiguity about conventional liberal positions … most of which I hold unambiguously."

Clinton did sign the bill to kill the SSC in 1993. Congress was controlled by Democrats at the time.

11. **Peter Woit**
April 17, 2013

Roger,

Thanks for the link to the Anderson review of the Dyson book.

About the SSC, yes, but the Democrats in the Senate voted 29-26 against cancellation, the Republican voted 31-13 for cancellation.

The fact of the matter is that, no matter how much people try and turn this into yet another partisan issue, it wasn't one then, and current debates over more or less science funding are not partisan issues now, with Democrats and Republicans on both sides of these kinds of votes.

Please all, resist the temptation to engage in the tedious arguments now found everywhere about how everything is either, to taste, the fault of the Democrats or the fault of the Republicans. Mercifully, HEP funding just isn't a partisan issue.

12. **Yatima**
April 17, 2013

> and current debates over more or less science funding are not partisan issues now, with Democrats and Republicans on both sides of these kinds of votes

They are definitely "bipartisan", in a very, very bad sense. Anyone who wants to know more should grab a copy of David Stockman's "The Great Deformation", now on sale. Or one may reflect on the fact that the SSC with all its cost overruns is just 4 days of 2013 military activity. I'm too lazy to adjust for inflation of course.

I can only refer the esteemed readership to this brief writeup: The Decline and Fall of the SSC by John G. Cramer

13. **chickenfeed**
April 17, 2013

Don't try to compare HEP funding (or SSC cost) against military funding. As someone said (back in the 1970s) "The cost of US support for HEP (then annually $350M approx) is not chicken feed. The cost of chicken feed is about ten times that amount." So … starve the chickens to pay for atom smashers?

The military has its own priorities and reasons for its budget. The internet by itself is a military invention. (Yes. Read about ARPAnet.) Microwave ovens are also a (byproduct) military invention. Indeed bellbottoms are also a military (US Navy) invention.

The SSC was mismanaged from the beginning. But people such as Anderson, with his parochial attitudes, were significant.

14. **Peter Woit**
April 17, 2013

Please, all, if it's not about Anderson/and or the mechanism, it's off-topic.

15. **Hmunu**
April 17, 2013

Peter,

Anderson also has a rather terse response in this month's Physics Today concerning an article from last year in the magazine about applications of AdS/CFT correspondence to condensed matter systems.

Shorter: "You are welcome to continue to play in your sandbox with your toys as long as it doesn't bother the adults who are trying to get work done."

16. **Peter Woit**
April 17, 2013

Hmunu,

I wrote about that recently here

http://www.math.columbia.edu/~woit/wordpress/?p=5717

17. **Anonymous**
April 17, 2013

I think the only example of overt political bias in the Physics Nobel was Pascual Jordan being the prize for being a Nazi. I don't think Anderson's "crime" of opposing the SSC is enough for losing it.

18. **yet another anon**
April 17, 2013

Except that Anderson already has a Nobel.
SSC aside, he is a truly outstanding physicist,
and probably deserves a second Nobel anyway,
even if not for the higgs.

19. **SpearMarktheSecond**
April 18, 2013

I asked Anderson directly about his opposition to the
SSC. His answer was emotional, not rational. He
said he detested the hordes of experimental particle

physicists who didn't or couldn't think for themselves.

I had hoped he had a more thoughtful reason for his
opposition. Certainly the money slated to be spent on
the SSC didn't end up in condensed matter physics.
Maybe in the end the NIH got a big bump though…
not because of the SSC.

20. **Krzysztof**
April 19, 2013

Yesterday, Frank Close gave a CERN colloquium on the higgs saga, and offered his personal nominations for the nobels. In his opinion, Anderson should not be in the final three – see http://indico.cern.ch/conferenceDisplay.py?confId=243243

21. **Bernhard**
April 19, 2013

Krzysztof,

This was very interesting. The question is of course if Close´s interpretation of Anderson´s role (as in slide 54) is really fair or biased (whatever the bias is..).
For one thing, I would love to hear Anderson´s own thoughts on what Close is claiming.

22. **IM**
April 19, 2013

Polyakov in `A View From the Island' (arXiv:hep-th/9211140) says:

Sasha and I started to analyze Yang-Mills theories with the dynamical sym-
metry breaking and in the spring of 1965 came with the understanding that the
massless particles must be eaten by the vector mesons, which become massive after this meal.
We had many troubles with the referees and at seminars, but finally our paper
was published (Migdal–Polyakov [6]). We did not know, until very much later
about the work on "Higgs Mechanism" which has been done in the West at about
the same time, or slightly earlier.

[6] A. Migdal and A. Polyakov, ZHETF 51, 135 (1966).

23. **socrates**
April 19, 2013

One assumes Anderson was not too thrilled with the Higgs discovery?

24. **Peter Woit**
April 19, 2013

Kryzysztof,

Thanks for the link.

Bernhard,

The main argument against Anderson has always been that HEP people at the time thought relativity was relevant, and he didn't provide proof they were wrong. On the other hand, his claims about how you should understand the mechanism, that it was something where relativity wasn't relevant (you don't need antiparticles) turned out to be perfectly correct. The claims from the HEP side about the Goldstone theorem and relativity being crucial turned out to be wrong.

IM,

"at about the same time" isn't a very accurate way to refer to work done nearly 3 years earlier (Anderson), and more than 1 year earlier (Brout-Englert-Higgs). I have no idea what the situation was in the Soviet Union back then, but it's surprising they had no access to the Physical Review. The story from Guralnik-Hagen-Kibble about not having access to the main journals at the time due to post office problems is also rather odd.

25. **John**
April 19, 2013

chickenfeed
"The internet by itself is a military invention. (Yes. Read about ARPAnet.)"
Yes, but don't confuse the web and the internet.

Peter,

That relativity was not an issue had to be proved. It's not enough that it turned out not to be.

In any case, Anderson's is a lost cause.

26. **Peter Woit**
April 19, 2013

John,

What's odd about this is that traditionally the Nobel prize is not a mathematical physics prize. Ignoring the fact that someone had the proper physical understanding of the phenomenon and wrote a paper explaining it, in favor of later more technical work is hard to understand other than sociologically.

This would make more sense if one was arguing that Anderson didn't have the relevant model, but in this case the relevant model didn't appear until Weinberg-Salam. People are trying to make the case that a prize should be given not for the right model (which has already happened), but for the physical mechanism of how gauge-fields acquire masses. The mechanism is the same in non-relativistic models and relativistic models, so I don't see why you can justify ignoring Anderson's work on the non-relativistic model and his (accurate) insight that relativity wasn't relevant.

27. **John**
April 19, 2013

"What's odd about this is that traditionally the Nobel prize is not a mathematical physics prize. Ignoring the fact that someone had the proper physical understanding of the phenomenon and wrote a paper explaining it, in favor of later more technical work is hard to understand other than sociologically."

Yeah, tell that to 't Hooft.

28. **John Brown**
April 19, 2013

Guralnik addresses some of these points earlier in the month (April 2013) during a talk here at Brown – his home campus.

He compares the Englert-Brout, Higgs, and Guralnik-Hagen-Kibble papers and seems to directly take on the "blogs" and Frank Close. Guralnik explains what was wrong in the other papers.

http://www.youtube.com/watch?v=WLZ78gwWQI0

So either he does not get it or people like Frank Close don't get it. Maybe someone here can enlighten (on the physics not the politics of the Nobel).

29. **XYZW**
April 19, 2013

If so many people came up with the Higgs mechanism, then it doesn't matter who came up with it first.

30. **Lanny**
April 20, 2013

Just watched the Close video from CERN. He seems to change his view that it should be Goldstone, Higgs, and Kibble. See below link where he pushes that.

http://www.abc.net.au/radionational/programs/scienceshow/higgs-boson-to-reveal-the-mechanism-for-origins-of/2964744#transcript

That must have been "too Anglo" or someone at CERN had a "talk" with him to point out CERN (and t'Hooft) was pushing Englert hard. I vote for the later.

The Guralnik video poted seems to state Close (and some others) is not qualified to comment on this given is lack of understanding. Is Frank a flip-flopper or is he not well-versed in field theory? I don't kow enough about his "real" physics work.

31. **Peter Woit**
April 20, 2013

lanny,

Goldstone and Nambu were two of the most important figures in this story, so with Nambu but not Goldstone recently rewarded with a Nobel, it makes sense to try and fit Goldstone in. But, with Englert publishing first, there's a strong case for him, so I wouldn't be surprised if Close changed his mind back and forth on this.

I haven't yet watched the Guralnik video, but his main problem is that his paper was published later, after he and his collaborators had read the papers of Anderson, Brout-Englert and Higgs, putting too many people in line for the Nobel ahead of him and his collaborators. I don't think accusing Close or others who point this out of being ignorant is going to help his case.

32. **Nige Cook**
April 20, 2013

Frank Close: "So I asked Brout and Englert, why didn't you mention this [massive spin-0] boson in your paper? They said, well, we thought it was sort of obvious. But Higgs alone is the one who identified that in particle physics there will be a particular implication, and that I think is why he is rightly named for it. In fact Peter Higgs amusingly said to me, 'Oh Brout and Englert are quite right, it is completely obvious.' In fact, in the first draft of the paper that Higgs wrote he didn't even mention it, and the referee turned the paper down and then Higgs thought maybe I'd better think of some implications, and he added this extra implication which is now the boson. So if the referee hadn't turned the paper down, even Higgs might not have mentioned it."

33. **Lanny**
April 20, 2013

Peter:

Agree with you to some degree and thanks for reply. As for the videos, I should state that it is not explicitly clear Gerald Guralnik is talking about Frank Close (as he is not mentioned explicitly). I am merely assuming this as it seems to make the exact counter to the points in Frank's talk at CERN given a couple weeks after the Brown talk.

Close does not seem to making his points on timing on the 1964 PRL papers. This is probably sound given the independence, the different approaches, the references, and the timing of the papers have been discussed in many forums – including this blog. Guralnik discusses this in this paper http://arxiv.org/abs/0907.3466 (p. 18)

Close seems to be making his points around this "massive vs. massless" boson. Guralnik states that those making this point don't understand the details field theory – and challenges those to look closer at this mass calculation. He makes this point in the video (http://www.youtube.com/watch?v=WLZ78gwWQI0) and to a lesser extent in this paper http://arxiv.org/abs/1110.2253. Guralnik's points are over my head as I clearly don't have the depth in field theory to properly evaluate.

The other theme of the GG video is how it started from his thesis and a paper prior to the Higgs PL paper. Since there were errors in the earlier paper, they sat on the GHK paper longer than they would have otherwise.

At the end of the day, the Nobel committee certainly needs to determine if the prize should match the history or the statutes.

34. **Peter Woit**
April 20, 2013

Lanny,

I did just watch the talk and added some comments about it as an update to the posting. Guralnik was definitely talking about Close.

I think Close emphasizes the inclusion of the potential terms in the Higgs paper because he's arguing for a connection of Higgs's work to the recent Higgs particle discovery, making it a good candidate for a Nobel. The argument he is trying to counter seems to me more the following: these authors back in 1964 were only considering the question of the gauge field mass, and had no interest in the physical mode which is a U(1) analog of the relevant Weinberg-Salam Higgs now discovered, so rewarding them based on the discovery is not justified. About Guralnik et al. the priority question is very clear: having to choose three, there's zero chance of the Nobel committee deciding to award Guralnik, Hagen, Kibble the prize over Higgs and Englert. The one way you could see that happening I suppose is if a discussion of the physical Higgs mode was in GHK but not in Brout-Englert or Higgs, which is definitely not the case.

35. **Xu Jia**
April 21, 2013

Dear Peter,
Close's argument is weak, since none of the three papers can give an assertion whether the scalar boson should or should not have a mass, which is model dependent. The necessity of introducing a scalar of weak-scale mass may be reflected in the fact that the WW sccatering needs cancel unwanted infinities. This was realized even after the renormalization work was done. The Nobel is not given exclusively because someone said it "can" have mass. Hence Higgs doesn't have priority on this issue, but on chronology.
In my opinion the crucial thing is 't Hooft's use of the massive gauge. It is unprecedented. It's not saying that there is a scalar field interacting with the gauge field, but the gauge field is fixed on a mass dome. None of the three papers indicate this usage.
Anderson's physics is absolutely correct and relativistics is not relevant. But he is correct only in the frame of our limited understanding. I always guess that all this eating and giving stuff is just a language, and is incomplete (since it has no way to give the mass of Higgs itself). Maybe the Nambu-Goldstone boson is fictious. The gauge bosons have mass per se, and the scalar field is the leftover of their interactions. Maybe it relates to gravity, big bang, or something totally unexpected.

36. **Pawl**
April 21, 2013

Closely related to Peter's point about what people were concerned about at the time:

There's a curious subjective element in these disputes, in that to determine what constitutes a Nobel-worthy advance people are in effect arguing about what the state of understanding was in 1962-1964. On an active research forefront, this is going to be ill-defined. So here one person regarded the appearance of the massive (scalar) boson as so obvious not to need mentioning, but on the other hand was unhappy with another's assertion that obviously there are no relativity issues.

Perhaps a prize based on a change of understanding within a subfield would go to someone different from one based on where the essential idea came from.

I don't usually spend my time feeling sorry for Nobel committees…. Of course, maybe it in all fairness should go to another area entirely this year.

37. **Roger**
April 22, 2013

UK newspaper:
Brout-Englert-Higgs, SM Scalar boson or BEHGHK? Scientists push to rename Higgs boson particle (but the alternatives aren't too snappy) …
Rival scientists have launched a campaign to rename the so-called 'God particle', claiming that British physicist Peter Higgs does not deserve all the credit for the breakthrough discovery.
http://www.dailymail.co.uk/sciencetech/article-2312425/Brout-Englert-Higgs-SM-Scalar-boson-BEHGHK-Scientists-push-rename-Higgs-boson-alternatives-arent-snappy.html

38. **chris**
April 22, 2013

ah, the lofty world of academia, where only the factual truth matters and nothing else….

39. **Bernhard**
April 22, 2013

Roger,

Now they are starting the campaign? This should really not taking seriously, the name "Higgs boson" is here to stay for historical reasons already. I did not see any serious campaign to change it BEFORE the discovery, which makes me think they were all OK with giving Higgs the credit if the idea was wrong. I am all OK with calling the mechanism "Anderson-Higgs" but calling it the BEHGHK boson is really ugly. I hope people in HEP will just ignore this.

40. **bcs**
April 22, 2013

Did Bardeen and/or Schrieffer ever complain that 'Cooper pairs' were not instead named 'Bardeen brothers' or 'Schrieffer sisters'?

41. **Peter Woit**
April 22, 2013

bcs,

In this case, Cooper really was first, about the pairs. Wikipedia does suggest you can also call them "BCS pairs" if you want….

42. **Thomas**
April 22, 2013

To give a prize for the discovery of the Higgs boson/Higgs mechanism and not include Higgs as one of the recipients would obviously be difficult to explain to the physics community and the general public. In addition to that, there are perfectly good reasons for selecting Higgs, and I think the best one is not the one that Close mentions (the fact that he has a potential for the radial mode). At this point the best evidence we have for the "mechanism" in addition to the "particle" is that we have observed H->2 vector bosons with the predicted strength. This process was considered by Higgs in his longer paper, but not by anybody else.

Beyond including Higgs there are obviously many permutations, and I find it hard to distinguish between them (except, unfortunately, I see no plausible way of including Hagen and Guralnik). There is Higgs/Anderson/Goldstone (except that I am not sure if Anderson really needs or deserves a second Nobel), Higgs/Brout/Goldstone, Higgs/Brout/Kibble (based on Close's observation that Kibble added group theory, and Weinberg was influenced by Higgs/Kibble), …

43. **emile**
April 22, 2013

@Thomas: I agree that the second paper helps given that the experimental evidence shows this particle decaying to vector bosons. I think you meant Englert and not Brout since Brout passed away. The committee will need to find a way to acknowledge the huge experimental component to all this. If they can't give it to "CERN" they should give it to the CERN DG. That would at least ackowledge the experimentalists and accelerator physicists, without which this debate would not take place. Had we listened to Anderson, there would be no debate about who gets the prize either… So, to me: Higgs, Englert, and CERN (and not Anderson given his negative contribution to the experimental discovery).

44. **prizes**
April 22, 2013

There will almost certainly be separate Nobel prizes for expt and theory. Lamb and Kusch won in 1955 for expts which revealed significant QED effects. Feynman, Schwinger and Tomonoga had to wait 10 years till 1965 to get their Nobels for QED theory (and Dyson received no prize).

45. **Bernhard**
April 22, 2013

" they should give it to the CERN DG".

Spot on, emile. This is what I have been also defending as the only sensible way to acknowledge the experiments (one should not forget the LHC collaboration).

To give the prize to the spokespersons is nonsense, so one could give it "to CERN" and the DG could go get it.

46. **edin**
April 22, 2013

Look at this from the University of Edinburgh
http://www.ph.ed.ac.uk/higgs/brief-history

A paragraph is devoted to Anderson and why PWA didn't really understand what was going on. Brief mention of the other hopefuls.

47. **Peter Woit**
April 22, 2013

emile,

I definitely agree that first priority should be a prize for the huge experimental achievement of the Higgs discovery. To react to this discovery by ignoring experimental effort in favor of giving a prize to somewhat off the main point theoretical activity from 50 years ago would have priorities quite backwards. It's worth noting that the theoretical activity being discussed here was in some ways basically misguided: the people doing this were trying to come up with a theory of the strong interactions, not the weak interactions. It was only with Weinberg-Salam in 1967 that the right idea about the Higgs was finally found, and they already have their prize.

As I've mentioned before, I think this would be an excellent time for the Nobel committee to give up the "only individuals rule" and award the prize to CERN + ATLAS + CMS

48. **Peter Woit**
April 22, 2013

edin,

I don't think that text says Anderson didn't understand what was going on. It says he didn't explain why the Goldstone theorem didn't apply, which is true, but it's not clear to me that it should be prize-worthy to point out to some people who were not being careful that their argument wasn't any good. The text also says Anderson didn't discuss the radial mode, which Anderson doesn't claim to have done.

It's interesting that that text has:
"During October 1964, Higgs had discussions with Gerald Guralnik, Carl Hagen and Tom Kibble, who had discovered how the mass of non-interacting vector bosons can be generated by the Anderson mechanism."
which corresponds to Higgs's diary indicating he gave a talk in London about this just before GHK sent off their paper for publication. My understanding is that GHK claim this is simply not true, I've never seen the truth of this matter sorted out.

49. **M**
April 23, 2013

Certainty CERN experimentalists deserve a Nobel prize. Given that it is now clear that the "125 GeV resonance" is the Higgs, priority should be given to the less joung theorists. It would be sad if the semi-scientific issues here debated will be solved by passing away. Whoever the right theorists are, there is a ≈30%/year probability that this happens for at least one of them.

50. **King Ray**
April 23, 2013

Peter, if they give the Nobel to CERN+ATLAS+CMS, could each participant claim to be a Nobel Laureate, sort of like each member of a Superbowl winning team getting a Superbowl ring? If so, this could dilute the prestige of the award.

51. **Peter Woit**
April 23, 2013

King Ray,

They've been awarding the Peace prize to organizations for years, and you don't for instance see all the doctors in Medecins Sans Frontieres claiming to be Nobel Laureates. I don't think this is a significant problem, the difference between getting a Nobel prize in your name and belonging to a large organization that got one is obvious to everybody.

52. **prize4all**
April 23, 2013

The International Red Cross and other organizations have won the Nobel Prize. Only the Peace Prize has been awarded to organizations. All others have been awarded to individuals only. One can debate the prestige of the Peace Prize. But does every member of the Red Cross claim to be a Nobel Laureate?

53. **Arlene**
April 24, 2013

Getting pretty political now. Someone posted on this blog that Lars Brink (member of Nobel Committee) was at IC London in March for Kibble's 80th event, dinner, and private dinner…someone else confirmed this also

Is this something IC London pays for? Does the Nobel Committee pay for that travel to a Nobel promotion event? Given they don't let any documents get reviewed for 50 years it seems odd Lars would be so overt in attending such as event.

54. **Peter Woit**
April 24, 2013

Arlene,

I don't see why Brink or other members of the Nobel Committee shouldn't be attending gatherings like the one at Imperial. Actually it seems like a very good idea for them to be traveling and hearing directly from those people still around who were there at the time of these discoveries.

Time Reborn

April 23, 2013
Categories: Book Reviews

Lee Smolin's new book, Time Reborn, is out today. For more about the ideas in the book, see video of a talk here, and an interview here.

While I mostly vehemently agreed with what Smolin had to say in his last book, The Trouble With Physics, I find myself equally vehemently in disagreement with this one. On some of the topics covered, I'm indifferent to his arguments mostly as a matter of taste. While my views on human society are likely similar to Smolin's, I've never found the scientific insights of fundamental mathematics or physics to have anything significant to tell me about this part of life. Similarly, while I've spent some time studying philosophy, I've mostly found this of little help in gaining deeper understanding of math or physics. Others though have a very different experience than me, and I'm not about to argue against people looking for enlightenment wherever they happen to find it.

On some of the scientific issues dealt with in the book, again I'm mostly just indifferent. Smolin accurately explains how the lack of predictivity makes typical multiverse models empty, but I'm not convinced that his favored alternative ("cosmological natural selection") does much better. While I understand well the human appeal of wondering about what came before the big bang, I've yet to see any specific models of this that carry enough explanatory power about anything to make them particularly attractive or interesting.

Many of the ideas Smolin is arguing for are clearly labeled as what they are: speculative challenges from a very much minority point of view to some of the received wisdom of this kind of science. Unfortunately, parts of his argument that are most problematic are ones which are in danger of becoming the new received wisdom of the subject. The refusal to admit the failure of the idea of string/M-theory unification has left many of our most prominent theorists pushing the idea that fundamental physics is based on some new and very different degrees of freedom, with dynamics that just happens to be too complicated to allow them to find vindication by seeing how the Standard Model emerges at low energies. For his own reasons, Smolin signs on to a version of this point of view, writing:

> I'm inclined to believe that just about everything we now think is fundamental will also eventually be understood as approximate and emergent: gravity and the laws of Newton and Einstein that govern it, the laws of quantum mechanics, even space itself…
>
> A large part of the elegance of general relativity and the Standard Model is explained by understanding them as effective theories. The beauty is a consequence of their being effective and approximate. Simplicity and beauty, then, are the signs not of truth, but of a well-constructed approximate model of a limited domain of phenomena.
>
> The notion of an effective theory represents a maturing of the profession of elementary-particle theory. Our young, romantic selves dreamed we had the fundamental laws of nature in our hands. After working with the Standard Model for several decades, we are now simultaneously more confident that it's correct within the limited domain in which it has been tested and less confident of its extendability outside that domain.

This notion that the SM is "just an effective theory", with its fascinating and deep mathematical structures nothing but an artifact of low-energy approximation has become the reigning ideology of the last few decades. One impetus for this has been string/M-theory, with its conjectured very different physics at short distances. This has been put together with our modern understanding of renormalization, according to which non-renormalizable theories make perfect sense as effective theories. The argument is then made that this is all there is to the SM, neglecting to note that to a large degree the SM couplings are asymptotically free, meaning that (most of) the quantized geometric degrees of freedom make perfectly good sense at all energy scales.

Smolin's view that the recent history of particle physics makes us "less confident of its extendability outside that domain " is one I strongly disagree with. Despite endless "naturalness" and "fine-tuning" predictions based on the "nothing but an effective theory" argument, the SM has not only been vindicated at the LHC over a large new energy range, but the discovery of the Higgs has shown it to have just the right characteristics to make perfectly good sense up to extremely high energies, far beyond anything we can test.

I've been teaching a course this past year on quantum mechanics for mathematicians, emphasizing the role of Lie groups, unitary representations and symmetries in providing not only useful calculational methods, but governing the underlying structure of the theory. Smolin argues instead that, based on Leibniz's "identity of the indiscernibles", symmetries cannot be fundamental (although a footnote says this doesn't apply to gauge symmetries):

> Symmetries are common in all the physical theories we know. Several of the most useful tools in the physicist's toolbox exploit the presence of symmetries. Yet if Leibniz's principles are right, they must not be fundamental.

This applies to the very structure of quantum mechanics:

> Quantum mechanics, too, is likely an approximation to a more fundamental theory.

since it is linear, and he bets thus just a linear approximation to some fundamentally non-linear theory. Again, mathematical simplicity is seen as an artifact of approximation, not indication of something fundamental.

Smolin ends with a vision that is pretty much the exact opposite of mine, one with a vastly diminished role for mathematics in understanding the nature of reality:

> The most radical suggestion arising from this direction of thought is the insistence on the reality of the present moment and, beyond that, the principle that all that is real is so in the present moment. To the extent that this is a fruitful idea, physics can no longer be understood as the search for a precisely identical mathematical double of the universe. That dream must be seen now as a metaphysical fantasy that may have inspired generations of theorists but is now blocking the path to further progress. Mathematics will continue to be a handmaiden to science, but she can no longer be the Queen.

Unfortunately it seems possible that Smolin's arguments about mathematics will resonate well with the current backlash against sophisticated mathematics that one sees at many physics departments in the wake of the failure of string theory. In a footnote he explicitly argues that the problem with string theory was too much symmetry:

> Indeed, we see from the example of string theory that the more symmetry a theory has, the less its explanatory power.

I don't understand this argument at all. The problems with string theory are something I've written about endlessly here, but too much symmetry is not one of these problems.

Smolin has been quite right to point out in recent years that fundamental physical theory is in a state of crisis, but I think his diagnosis in this book is the wrong one. Abandoning the search for a more powerful mathematical understanding of the world because the huge success of this in the past has made further progress more difficult is the wrong lesson to draw from recent failures (the nature of which he lucidly described in his previous book).

My own interpretation of the history of the Standard Model is that progress came not from finding more, larger symmetries, but from a deeper appreciation of the various ways in which gauge symmetry could be realized (spontaneous symmetry breaking, confinement, asymptotic freedom). The arrival of string theory pushed the study of gauge symmetry into the background, and these days one often hears arguments against its fundamental nature, such as this one from Arkani-Hamed

What's as a misnomer called gauge symmetry, whose beauty is extolled at length in all the textbooks on the subject, is completely garbage. It's completely content free, there's nothing to it.

Smolin's arguments against the fundamental nature of symmetries, even if gauge symmetry is let off the hook in a footnote, just reinforce some of the attitudes at the root of our present-day crisis. The problems that remain in fundamental theory are difficult, but denigrating now the powerful ideas that have led to success in the past won't help find a way forward.

Update: For more about this, there's a review in the NYRB, and a piece at edge.org (with responses).

Comments

1. **David Appell**
   April 23, 2013

   Peter, could you elaborate about why you see a "current backlash against sophisticated mathematics that one sees at many physics departments"?

2. **Sebastian Thaler**
   April 23, 2013

   Thanks Peter, very interesting review. FYI, there seem to be several forthcoming books of interest to this blog's readers, including "String Theory and the Scientific Method" by Dawid, "Farewell to Reality" by Baggott, and "Bankrupting Physics" by Unzicker.

3. **P**
   April 24, 2013

   Hi Peter,

   Gauge symmetry is an absolutely central concept in string theory.

   Why don't you like what Nima says? What do you think he means?

   Cheers,
   P

4. **Roger**
   April 24, 2013

   I am surprised that you so vehemently agreed with Smolin's earlier book. He subscribes to an extreme philosophy of science. I won't try to summarize it here, but I think that it is one that not many scientists would agree to.

5. **Bee**
   April 24, 2013

   I read a draft of the book half a year ago or so. Now reading your review makes me think I read a different book altogether! The one I read basically argued that emergence in time cannot be accurately described by mathematics and therefore there is a limit to what can be described by (eternally true) mathematical laws. It's a mistake, he says, to attempt a time-less understanding of the world, and with some good will you can extend this line of thought to less fundamental problems that plague the world today.

   I don't think this has so much to do with philosophy, it's more a matter of contemporary thinking. It is typically the case that insights from science reflect in sociology and politics. Just consider how much Darwin has shaped our thinking of adaptive systems, of trial and error, of selection of the fittest. Just think how much we've had to rethink our own space in this universe with the realization that ours is not the only planet, not the only galaxy, and that the universe isn't static but evolves. Don't you think that influences the way we perceive of our environment and how we interact with it? I find it quite plausible that the way we model and develop theories of nature today does influence how we attempt to manage our planet.

   Now I disagree on pretty much every step in his argument, but I agree that there are probably limits to what we can learn about nature using mathematics. (For reasons I elaborated on here.)

   All this now makes me think I should probably read the final copy.

6. **Cliff**
   April 24, 2013

   Wow, Peter. I watched the talk, expecting some philosophical disagreement, but I am absolutely flabbergasted by how totally nonsensical so many of these statements are. "Speculative" is way too kind an adjective .

   You're wrong about string theory, but if this heap of nonsense can get some of the Not Even Wrong treatment for its manifest scientific irrelevance and logical absurdity I could come to appreciate that. (I mostly come here for your links which are sometimes pretty good 😉

   P: I agree that string theory would also fall into the category of new "ways for gauge symmetry to be realized", and it subsumes all the other ways, so I would also object to that statement. And I've heard Nima make this point, that we shouldn't use the word "symmetry" when talking about gauge *redundancy* because it doesn't correspond to an operation we can *physically* perform, but a redundancy in the description. Thats fine, as far as that point goes, but the key observation is that symmetry and redundancy are two sides of the same coin. So I've never understood the impetus to emphasize the distinction in that way. All available physical evidence indicates that symmetry is a fundamental, organizing principle – the *exact* opposite of what Smolin claims on purely philosophical grounds.

7. **chorasimilarity**
   April 24, 2013

   I shall read the book. From what you mention in the review, I salute the appeal to Leibniz (who seems to more and more relevant to today's science, like in CS) and I totally agree with Smolin "That dream must be seen now as a metaphysical fantasy that may have inspired generations of theorists but is now blocking the path to further progress."

   As for "Mathematics will continue to be a handmaiden to science, but she can no longer be the Queen", it simply ignores that mathematics currently used in physics is the late bloom of 19th century math and not the 21st century hottie.

8. **Bernhard**
April 24, 2013

What is rather strange and self-contradictory w.r.t The Trouble of Physics in this Leibniz's "identity of the indiscernibles" argument of Smolin is that in that book he quite convincingly discussed the failure of using "beauty" arguments to build successful physical theories discussing the example of SU(5) and the absence of observation of proton decay.

Now he is questioning the fact that symmetries are fundamental based not on science, but by subscribing to Leibniz's philosophical principle that we have no scientific reason whatsoever to believe it is correct (not yet at least).

9. **T. H. Ray**
April 24, 2013

Just received my Kindle copy of Lee Smolin's new book yesterday. Read your and Lubos Motl's reviews this morning. When you two agree, I'm all the more convinced that I will find Lee's book as enjoyable and thought provoking as his past works.

Chorasimilarity's reference to Leibniz is on point. No less a light than Hermann Weyl — who lived in some world intersecting mathematics, philosophy and science and who synthesized the best of all three — took Leibniz at his word that the universe is best understood in the behavior of the infinitely small. Considering Weyl's further insights into the Continuum, it is no leap of faith or logic to extend the principle to the infinitely small and continuous.

Tom

10. **Bernhard**
April 24, 2013

T. H. Ray,

Being inspired by philosophy to do physics is all good if you use the physics and not the philosophical inspiration itself to convince your fellow scientists. Beyond Weyl there are many other examples of scientists using philosophical guidance that led to correct physics, the most striking one being perhaps Heisenberg and his positivist views that inspired him on writing the foundations of quantum mechanics. However, it was experimental predictions and confirmations that convinced the scientific community, not some philosophical debate. There are also good examples of inspirations that led to incorrect physics and Lee Smolin himself points to good examples in The Trouble of Physics.

Smolin could even be right about Leinibz, the "identity of the indiscernibles" and symmetries, but on what science is concerned is not enough to have the inspiration, you have to do the work.

11. **stan**
April 24, 2013

"Lubos Motl's reviews this morning"

I doubt that Motl even read the book.

12. **Anonyrat**
April 24, 2013

I had thought that if you take all the symmetries that you can think of and the physical priciples we think should hold true and try to build a model, what you end up with is superstring theory. If superstring theory does not work, then one or more physical principle is approximate or symmetry is not applicable. Is Peter saying that no, we need to dream up of new ways the same principles can manifest themselves?

13. **Lee Smolin**
April 24, 2013

Dear Peter,

Many thanks for your review, which is mainly a statement of disagreement on points off the book's main argument. Disagreement is fine, of course, but you don't even mention the main ideas, nor do you critique the actual arguments the book presents for them. As a result you take the main claims out of context.

Very briefly the book focuses on a single question: How are we to make theories of the whole universe, rather than isolated systems? The main novelty of the book is the claim that this cannot be done by scaling up the theories we have; to make a successful cosmological theory requires new principles.

There are two main contentions: First that the standard form of physical theories of fixed laws acting on fixed spaces of states breaks down when we try to extend them from theories of isolated systems (where they work fine-hence I have no issue with the standard model) to theories of the whole universe.

Second that to address issues which arise when making a cosmological theory, time must play a more central role. In particular, the book argues that laws must evolve in time if we are to explain how the laws and initial conditions are selected.

The book embraces the relational philosophy of Leibniz, Mach and Einstein, which means it is very friendly to local gauge invariances as the main way we have to express relational theories. This is hardly a radical point of view given the successes of general relativity and Yang-Mills theory.

There is an argument that global, non gauge symmetries cannot be fundamental on a cosmological scale, nor can they be realized operationally in a cosmological context. I have no issue with the central role of global symmetries in the physics of isolated systems and, indeed explain why they arise in these cases, thus no disagreement with their use in quantum mechanics or quantum field theory. The issues I have arise only in the context of attempts to make theories of the whole universe.

General relativity provides an example of this. When applied to closed universes it has no global symmetries, but when boundary conditions are imposed appropriate to the description of isolated systems, global symmetries appear.

Can I suggest that if you consider the actual argument of the book, rather than take the conclusions out of context, you and your readers might find yourselves in agreement with more of it,

Best wishes,

Lee

14. **T. H. Ray**
April 24, 2013

    Bernhard,

    Your point is well taken. However, I have never found Lee Smolin's research overly philosophical. As Lee himself says above, "The book embraces the relational philosophy of Leibniz, Mach and Einstein, which means it is very friendly to local gauge invariances as the main way we have to express relational theories. This is hardly a radical point of view given the successes of general relativity and Yang-Mills theory. "

    Or as Einstein put it, in a simple but meaningful way: "All physics is local."

    Lee is also right that without boundary conditions, general relativity is restricted not by anything *physical,* only by the special relativity limit.

    Personally, I have found that general relativity suffers no loss of meaning when being described as "finite but unbounded" — usually taken to be finite in time (bounded at the singularity of creation) and unbounded in space (a geodesic returns to its starting point) — when converted to a theory finite in space and unbounded in time.
    Which of course supports Lee's concept of the enhanced physical role of time.

    Tom

15. **P**
April 24, 2013

    Cliff,

    Thanks for the reply. I agree with most of what you say, but when people make this point regarding redundancy vs. symmetry, the point is precisely that they are *not* the same thing.

    When people like Nima (or Seiberg) say things like this, or something to the effect of "gauge symmetry is not a symmetry", what they really mean is to remind people that gauge "symmetry" generators map states in the Hilbert to totally equivalent quantum states. With global symmetries this is not the case, and you know it well: in the path integral you divide out by the gauge orbits to avoid an overcounting of physical states, but this is not true of global symmetries! This is an important distinction, and it's the distinction Nima is probably trying to make. Cosmologists make it all the time. It's also the reason why anomalies in gauge "symmetries" are theoretically unsound, but anomalies in global symmetries are just fine.

    Cheers,
    P

16. **Peter Woit**
April 24, 2013

    Hi Lee,

    Thanks for writing. You're right that it would have been a good idea for me to address the main point of your book, since you're arguing from that to the conclusions I disagree with.

    The problem I see with the argument for laws that evolve in time is one that you yourself identify in the book: what you call the "meta-laws dilemma". You speculate a bit in the book on ways to resolve this, but I don't see a convincing answer to the criticism that whatever explanation you come up with for what determines how laws evolve, I'm free to characterize that as just another law. And based on experience with the entire history of physics, new, more fundamental laws come together with deep connections to mathematics. One problem here of course is words, we may not agree on what I'm allowed to call a "law" (a word I've always disliked in this context anyway…)

    About global vs. local symmetries there is much to say, but a specific question would be about global internal symmetries. Is electric charge conservation (global U(1) symmetry) just an approximation? I'm willing to believe that such global internal symmetries are replaced by something else in regimes where gravity gets quantized, but the replacement requires an insight we don't now have into how space-time and internal symmetries unify. This insight seems to me likely to require more mathematics and deeper use of symmetry arguments, not less.

17. **piscator**
April 24, 2013

    P: this (gauge symmetries are a redundancy of description) is a standard point of graduate quantum field theory – I don't see the need for big names, this is not some special profound insight.

    That said, I have no idea what is meant by the statement that gauge symmetry is content free. That the coloured particles of the Standard Models organise into colour SU(3) representations, with associated multiplicities, is anything but content free, with profound experimental implications.

18. **Gene**
April 24, 2013

    Maybe in the end the Lorentz symmetry isn't fundamental- I can't imagine that, but it certainly is a logical possibility. Still, the constraints are formidable and certainly whatever conception of time emerges it won't be a return to the one held by Newton.

19. **Peter Woit**
April 24, 2013

    David,

    I've always followed quite closely what goes on at the intersection of math and physics departments especially in the US, and, while I've no solid numbers, my observation is just that on the whole there's now quite a lot less interest in math coming from typical physics departments than there was say 20 years ago (Witten was discovering remarkable things at the math/physics boundary, drawing interest from both sides). One big counterexample is the Simons Center, but except for that, it's hard to find examples of anywhere in the US where physics departments are showing much of an interest (for example in their hiring) in mathematics.

    Roger,

If you're referring to Smolin's interest in Feyerabend, that's something on which I would mostly agree with Smolin.

P,

Arkani-Hamed's was speaking in the context of certain work on scattering amplitudes, where there's a serious issue. The over-the-top comments on gauge symmetry I don't think were sensible, and reflect an attitude I think is problematic. But gauge symmetry is a huge, huge subject, and a serious discussion of it is best left for another day.

20. **P**
April 24, 2013

picastor,

You're pretty much right. When people make this distinction, they define symmetry to mean something that isn't a redundancy — which global symmetries are not — and hence gauge symmetries do not fit into this category. Contrary to what you say, this is not always stated correctly in QFT courses, hence Nima's (and Seiberg's, and others . . .) reason for complaint.

But as Peter would say, we're getting too far afield 😉

21. **King Ray**
April 24, 2013

I think the problem with theoretical physics today is that many of the theorists are divergent thinkers–the trade space keeps getting larger and larger. If you have an optical system with all divergent lenses, then you never converge. You need people that are like converging lenses, such as Einstein, who simplified things, so that gravity was just geometry. The truly gifted simplify, the less gifted complicate.

22. **Ben Dribus**
April 25, 2013

Dear Peter and Lee,

While I haven't yet had a chance to read Lee's book, I wanted to point out that questioning the fundamental physical role of symmetry, understood in the specific sense of Lie groups and Lie representation theory, need not entail a general rejection of mathematical sophistication in modeling nature. Rather, such an approach may reflect an effort to understand these central concepts in a broader context, by relaxing some hypotheses on underlying structure.

As an example, one might try to generalize representation theory in an order-theoretic context. A not-totally-unheard-of setting for such an idea is causal set theory, though I personally believe causal sets to be somewhat deficient. At any rate, such an approach might be based on the following rather obvious statements:
1) An important instance of Lie group symmetry is given by symmetry groups and local symmetry groups of spacetime continuum geometries, such as the Poincare symmetry group of Minkowski space; 2) breakdown of continuum geometry often arises in quantum-theoretic approaches to fundamental spacetime structure; 3) in this context, one may expect modification of spacetime symmetry groups into mathematical structures more general than Lie groups; 4) causal structure encodes much of the structure of classical spacetime, while extending to much more general order-theoretic settings; 5) it is then natural to ask what are the analogues of symmetry groups for causal structures, and to examine their "representation theory."

One might expect this to lead merely to the study of order automorphisms of partially ordered sets, which still form a group, but this is only the "active" view, corresponding to diffeomorphisms of classical spacetime. The other half of the story is the "passive" view, given by refinements of partial orders, which has nothing to do with group theory in general; this corresponds to changes of coordinates in classical spacetime. For those unfamiliar with this point of view, a good example is the relativity of simultaneity, which illustrates how the causal order on relativistic spacetime admits different refinements, which may order causally unrelated events in different ways. A few such refinements are coordinate systems in the usual sense, but most are not. The moral of all this is that important applications of group symmetry in conventional contexts can bifurcate into multiple points of view in more general settings, some still involving symmetry, others completely different.

My personal hunch is that the next experimentally verifiable progress we will see in elementary particle physics will probably come from the same old well of gauge theory that has produced so much over the last fifty years. In a thousand years, however, I doubt that fundamental physics will still be based almost exclusively on continuum geometry, which was already established as the cornerstone of still-current theory in the days of the Gruppenpest, when no one knew anything about modern algebra, information theory, or computer science. Most people with a real passion for understanding nature and no personal stake in the outcome of current or pending experiments are probably more interested in the thousand-year view. Take care,

Ben Dribus

23. **lun**
April 25, 2013

I think the problem is, in principle, that symmetries have both a "physical dimension" (there should be a physical understanding of what it means to have a symmetry, and to "change point of view" wrt a symmetric object), and a mathematical dimension (mathematicians came up with great ways to see symmetries, and tools to manipulate them).

For relativity, our understanding of both physical and mathematical aspects is complete: We know what "symmetry w.r.t. reference frames" means in physical terms, and can directly relate this symmetry to experimental observables.
Similarly, in General Relativity the "Gauge transformations" have a ready physical interpretation as changes to non-inertial reference frames.
Mathematically, this symmetry is extraordinarily subtle, but the physical interpretation of the symmetry is apparent even when, from a mathematical point of view, the geometry is not really "symmetric" in the usual sense (for example the closed universes Lee Smolin cites).

Gauge theory is very different in that the symmetry is defined mathematically but lacks a ready physical interpretation. We know that theories which have lots of symmetries have fewer infinities, and infinities are typically less observable (technically, theories with symmetries

are more anomaly-free and renormalizeable).
We know the consequences of such symmetries (there is such a thing as “charge”), and they can even be used to get predictions out (the Higgs, as a manifestation of the fact that Gauge symmetry “has to be there in the UV”).
Nevertheless, we do not know what it really
means to “change the Gauge”, its something the theorist does to make
calculations easier. For relativity, or for that matter angular momentum invariance or translational invariance, “changing the Gauge” is
something experimentalists can readily connect to their apparatuses.
And string theory (post 2nd revolution) has not really
helped this point, the justifications given
for Gauge symmetry are really not that convincing.

It is “experimentally evident” that more and more clever ways to mathematically
manipulate symmetries is not adding to physical understanding: Very very smart
people did this for decades, and we came up with either proposals which seem not to hold up to experiment, like GUTS and Supersymmetrical models, or
really profound insights about theories which are
phenomenologically unviable, like N=4 Super Yang Mills. But perhaps rather than
“abandoning symmetry”, a good start would be “explaining what symmetries mean”.

24. **Peter Woit**
April 25, 2013

Please all,
If your comment is not about the book, it’s off-topic.

25. **Nathalie**
April 26, 2013

We are living in the age of grandiose speculations in physics and Smolin has become one of its most visible actors. His talk at Perimeter was vague and loaded with self-contradictions. I found it very disturbing that a scientist would give such a talk to a general audience. What did they get out of it?

Until the near end of the talk it was all blah, blah, blah, as he said himself – he was attacking others all along and when he was finished with that there was little time left for him to describe his own ideas.

As an example he criticized the laws of physics for being deterministic whereby the future is predictable and there is no place for the free will. But then quantum mechanics tell us that these deterministic laws often lead to a multitude of possible outcomes, each with its own future. He attacked mathematical formulas of physics because they don’t allow the laws to change with time. I would say, go ahead and propose your model, compute its “observables” and let the results be tested by experiments. Before having done so it is wise to shut up. He says “Every application of physics to parts of the universe is an approximation, it can’t be exact.” So what! What a vague statement! What has the word exact got to do with physics? We never measure any quantity with infinite precision. As physicists we understand that we will never be able to make “exact” statements. A concept such as TOE (Theory of Everything) is of course unphysical as it can never be tested but that should not stop us from making progress by refining our theories or inventing new ones.

26. **Lee Smolin**
April 26, 2013

Dear Peter,

I am also very much in favor of the invention and use of new and deeper mathematics to describe nature. I only argue that it is unreasonable to motivate this by the mystical fantasy that the mathematical description is truer than our experience of the present moment and its passage in time. There are sufficient reasons to believe that mathematics is useful in nature without believing there is some mathematical object isomorphic to nature in all aspects.

A metalaw may evade the infinite regress problem if it doesn’t have the form I call the Newtonian paradigm, which involved fixed timeless dynamical laws operating on a fixed timeless space of states. Such a metalaw would be different in important ways than our present laws. I do give several examples in the book of ideas under development, some of them in papers. I agree these need much more development but the examples I give show how the metalaw problem may be solvable.

Dear Nathalie,

I am sorry you didn’t like the talk, it is hard to present this argument in an hour to a mixed audience. That is one reason I wrote a book. But, please note that I didn’t attack anyone personally, I gave a critique of certain issues blocking the progress of science and proposed alternative solutions. I agree the time was too short to give details, but those are described in the book and in scientific papers going back to 1992. It is exactly because I have, proposed …” models, computed “observables” and let the results be tested by experiments” that I feel it is OK to describe them in a public forum. One model, cosmological natural selection, made two predictions, both published in 1992, that have stood up to test since then. One, that the heaviest neutron star be less than two solar masses was confirmed again in a paper just published in science (Antoniadis et al.,Science,Vol 340). The other, that inflation, if true, is governed by a single field moving in a potential determined by a single parameter, is confirmed by the recent Planck observations.

In the book I describe these in detail as well as newer models of evolving laws and how they might be tested.

Thanks,

Lee

27. **Jamahl A. Peavey**
April 26, 2013

Dear Peter,

I thought time and the measure of time were different. So is Lee Smolin talking about the measure of time reborn or time reborn? The measure of time as represented mathematically is reversible but time as described in thermodynamics or as we experience it has an arrow and is not reversible.

28. **Roberto S.**
April 26, 2013

What I think I see going on with these type of books is more of a slow-motion meta-argument and academic positioning about where to focus your collective brainpower, because perhaps we have reached some sort of collective limit in what we (er, you) can figure out, and it will take every learned neuron to acheive some breakthrough. So if it's one of those "fellow scientists, we need to study this novel idea as the way forward" book, I will pass.

Oh, and Hawkings has gone "full sci-fi" in my opinion.

29. **Yatima**
April 26, 2013

"I only argue that it is unreasonable to motivate this by the mystical fantasy that the mathematical description is truer than our experience of the present moment and its passage in time."

FWIW, I couldn't agree less. Nothing could be LESS true than our "experience of the present moment". That "experience" which no-one can even grasp (witness the endless fruitless discussion about qualia) is a second-hand, unconsistent, faked-up, stitched together, event-reshuffling and event-inventing narrative of "what happened a bit earlier", a datastructure thrown barfulously together by a cognitive apparatus made to acquire food, sleep, safety and sex with least energy expense. Which is why Penrose's ideas about the human mind as a self-consistent theorem prover are ludicrous.

If you want to do and think consistently however (using the amazing capacity of the human cognitive apparatus to use external physical machinery and memory to remember things and keep on track), you need consistent models.

Mathematics *is* the setting up of consistent models. Those that do not give you a kilo of gold when you turn clockwise once.

As the universe *is* consistent (axiom #0), a (infinite set of) mathematical model of it exist.

Whether that model can be discovered, approximated or whether "time" has any part in it is another question entirely

30. **Nick M.**
April 26, 2013

Lee Smolin has just published an article in New Scientist titled "It's Time Physics Recognised That Time Is Real". You will, however, have to register with New Scientist to read the article, and the article will only be viewable (using that "for free" registration) for about another ten days, or so.

– Nick

31. **noko**
April 27, 2013

The only book on Time worth reading is Indian polymath C. K. Raju's "The Eleven Pictures of Time"

32. **David Gillett**
April 27, 2013

A 'lay' perspective- I have a doctorate in molecular quantum mechanics, so not the really hard stuff.

I welcome Lee's book because it challenges us to think in new scientific directions. Having followed cosmology and particle physics for 30 years, I believe the field has reached an impasse; since the mid 1980s we've been confirming existing theory with no new breakthrough ideas or unexpected results.

I believe we're in a time similar to that just before Einstein, and when Special Relativity was published it was initially ignored- similar to Lee's ideas, not well received but necessary to move thinking on to a new position with radically new insights. Is Lee he next Einstein? Maybe, maybe not- but he is prompting the challenges that create the space for the next Einstein.

33. **David Gillett**
April 27, 2013

A paragraph I omitted:

Dark matter, dark energy and the accelerating expansion, plus the 'axis of evil' in the CMB. Aren't these the 'aether' and michelson-morley experiments of our day?

34. **noko**
April 27, 2013

"when Special Relativity was published it was initially ignored"

no it wasn't

35. **Nathalie**
April 27, 2013

Dear Lee Smolin,

In your reply to my comment you say "please note that I didn't attack anyone personally". It is true that except for Max Tegmark you didn't specify the names of those you were criticizing but that makes the situation even worse. In addressing a general audience, you made statements such as "Physicists claim that they know the answers to these questions" and that the theories by those physicists were false. Because the audience doesn't know who these physicists of yours are, they must have thought that you mean the entire physics community while the majority of physicists, for example, those working on graphene or on fractional quantum hall effect have hardly been involved in the process you were describing. Your "physicists" make up a tiny fraction of the physics community – those who love to speculate.

By the way the reference you gave (Antoniadis et al., Science, Vol 340) does not refer to your work. Neither can the authors test your theory, at least not yet. They make observations in a nonlinear regime – a "previously untested regime, qualitatively very different from what was accessible in the past." I am afraid you have to wait to see what such observations in the nonlinear regime have to say about your theory.

Because I am not familiar with your theory, I hope someone else will check your statement that the recent Planck observations confirm it.

Best regards,

Nathalie

36. **David Gillett**

April 27, 2013

Noko

You are right “ignored” was too strong. But recognition of its implications did take some time, and Einstein certainly didn’t gain instant acclaim.

37. **layman**
April 27, 2013

I listened to the talk carefully. It is just horrible. I hope the audience does not think everybody in physics is so shallow and trivial. I am a little encouraged by the reviews on Amazon, the public is not that stupid it seems.

38. **Lee Smolin**
April 27, 2013

Dear Nathalie,

The prediction of cosmological natural selection that was tested in the paper in Science was that the upper mass limit of neutron stars is at most two solar masses. This is tested each time a neutron star mass is measured. The paper doesn’t have to reference the prediction to confirm the prediction, it is enough that the measurement they report confirms it, which it did.

All physicists, whether working on graphene or condensed matter physics, employ the framework of fixed laws acting on fixed state spaces-the framework I call the Newtonian paradigm. As I explain in the book, this is exactly what they should be doing. My criticism is not of the usual practice of physics, it is confined to the extrapolation of the usual practice to cosmological theories. ie the only thing I criticize is attempts to apply the Newtonian paradigm to theories of the whole universe.

This point-that the methodology which succeeds so well when applied to laboratory systems fails when applied to the universe as a whole-is the first step of an argument that was sketched in the talk and is described in detail in the book. So my intention was hardly to criticize anyone, it was to make an argument about whether the Newtonian paradigm can be applied to answer cosmological questions. Does this make it clearer?

Thanks,

Lee

39. **Spencer Tracy Jr.**
April 27, 2013

I’m up to p. 202 and so far I think the book is excellent.

40. **Nathalie**
April 27, 2013

Dear Lee Smolin,

In order to make a convincing case for your model you need to have predictions that are significantly different from the standard ones. The measured neutron mass (2.04 in the units of the solar mass), listed in table 1 of the paper by Antoniades et al., falls in the expected range in general relativity. No big deal as far as I can see.

Best regards,

Nathalie

41. **Maynard Handley**
April 27, 2013

“Simplicity and beauty, then, are the signs not of truth, but of a well-constructed approximate model of a limited domain of phenomena.”

Peter, I fear you are being so protective of what you love (the beautiful mathematics) that you are missing the point here — that this beauty doesn’t mean it’s physically relevant.
It is a historical fact, which I’m sure you know as much as anyone, that not only does beautiful mathematics not imply that physics works that way, but ALSO (and just as relevant) it’s possible to get so hooked up on one aspect of the mathematics that you actually MISS the larger structure behind the scenes.

The poster child for this (a good example because it’s easy enough to understand) is quaternions and the whole foolish battle of the 19th C between those who did and did not support their use in physics. And what was the ultimate resolution? Both sides were so obsessed with one aspect of the issue (algebra) that they got the geometrical interpretation wrong, and ultimately missed out on the huge wider world of Lie groups, spinors and the rest of it.
One could argue the same thing for pre-Minkowsi EM, where incredible ingenuity going into solving Maxwell’s equations missed out on the more significant issue of understanding them in full geometric consequence.

If I were to make a modern analogy I’d ask (at the risk of appearing foolish, because I haven’t studied this enough to be sure I’m correct) whether Clifford Algebras fall in the same sort of pattern. They meet all the mathematical desiderata: they unify a lot, they’re conceptually extensible to all dimensions, they result in a non-obvious large-scal pattern across dimensions; and they’re a neat practical tool for calculating certain entities. BUT I’d argue that what physics really needs is a better geometric understanding of simple Dirac spinors in 3+1D, that Clifford Algebras have not delivered that, and that it doesn’t seem likely that they will. Beautiful math, yes, but shining a powerful light in the wrong direction for physics.

Since at least GR and Dirac physics have operated on a kind of “if the math is beautiful enough it has to be right” autopilot, and this is what has brought us to supersymmetric strings. It is THIS against which Smolin is reacting, not a generic dislike of sophisticated math.
(It may be easier to understand the sentiment by imagining applied to a different field. Economics is another science where appreciation of beautiful math has proved immensely destructive to the task of understanding the actual world in which we live, as opposed to the better world of our minds.)

42. **Lee Smolin**
April 27, 2013

Dear Nathalie,

You miss the point. The point is that CNS predicts the upper mass limit is 2 solar masses which is substantially lower than predicted by the conventional picture of neutron stars. Had the NS mass been 2.5 solar masses or more it would have been a clear refutation of the prediction of CNS. Please look at arXiv:1202.3373, which is a recent review article about cosmological natural selection, or read the book before making further incorrect claims.

43. **Low Math, Meekly Interacting**
April 27, 2013

I'm an atheist, but this stuff makes me hope to God we see something new in the LHC before it's shut down.

44. **Marcus**
April 27, 2013

The talk Peter linked to was Lee's April lecture for wide audience
http://pirsa.org/13040103/
there is also one given 26 February in the quantum foundations seminar
http://pirsa.org/13020146/
clear, cogent, efficient presentation, with interested questions from audience e.g. Rob Myers, Neil Turok
I would recommend anyone interested to watch the February talk.

It seems to me that the idea of law-like regularities emerging in a process of past events generating a new layer does not at all depend on CNS, which is just one example of an evolutionary process. However the highest mass estimate for neutron star I have been able to find appeared in October 2012, and was for the pulsar
PSR J1311−3430
http://arxiv.org/abs/1210.6884
It's newly discovered and the authors cautiously say "if confirmed". They say that "all viable solutions" to their data give a mass > 2.1 solar. But they seem to think a considerably higher mass than that is likely.

Before that, the highest mass estimate was for a longer-period pulsar and (I gather) less precisely determined: PSR B1957+20
http://arxiv.org/abs/1009.5427
van Kerkwijk, M. H., Breton, R. P., & Kulkarni, S. R. 2011, ApJ, 728, 95
They said 2.4±0.12
but also acknowledged some systematic uncertainties and but the minimum at 1.66 solar.
There's the very recent estimate of 2.01 that I think Lee referred to already:
http://arxiv.org/abs/1304.6875

Really two topics here: CNS hypothesis and the neutron star mass limit prediction, on the one hand, which has been around for some 20 years(!)
And on the other hand this new, rather beautiful, idea of a meta-law process which explains both the flow of time itself and the appearance of seemingly timeless regularities we think of as natural laws.

Again, check out the quantum foundations seminar talk of 26 Feb!
http://pirsa.org/13020146/
My advice is not to get sidetracked arguing about the wide-audience public lecture.

45. **Marcus**
April 28, 2013

Smolin's arguments against the fundamental nature of symmetries, even if gauge symmetry is let off the hook in a footnote, just reinforce some of the attitudes …

Symmetry is something that needs to be explained and it doesn't make it less important or beautiful to have an explanation for how it arose. To take an analogy, the bilateral symmetry of many animals can be explained by digging into evolutionary history, and having an explanation doesn't diminish it's importance as a fact of biology.

46. **Nathalie**
April 28, 2013

Dear Marcus,

Thank you for the references on neutron star masses. What an exciting and rapidly developing field of research!

You give us the advice "not to get sidetracked arguing about the wide-audience public lecture."

Actually, the major point of my comments concerned the wide-audience public lecture aspects of Smolin's talk.

When we scientists talk to each other and at our seminars we can say almost whatever we like. Under such circumstances the audience, usually equipped with healthy skepticism and sufficient amounts of grains of salt, has the capacity to understand and analyze what the speaker is talking about. The general public doesn't and can easily be misled.

Smolin is a leading figure at an Institute with a very high academic reputation. The general public will tend to consider him as an authority and believe in what he says. Therefore he, as well as other speakers at such occasions, should not mislead the audience by making sweeping statements of the kind Smolin did – attacking mathematics, saying all physicists were wrong and so on.

It is just fine that someone like Smolin takes an alternative approach to physics. But it remains to be seen if his approach will teach us anything new about the world we live in.

47. **franco zoccheddu**
April 28, 2013

Sir,
I beg your pardon, if my use of english language is not that good I'd want.
I'm very interested on what consequence has and will have in the near future (say 10 to 15 year) "sophistication" of mathematical ideas, theories, physicists will take advantage of for improving predictability power without exiting SM framework.
Does Lee Smolin's book also deal with this topic?
I'm a physic teacher, sometimes students fond of math and phys ask me about.
I thank you!

48. **Chris Kennedy**
April 28, 2013

Lee,
This is a great, much needed book that will hopefully spark discussion in areas of physics that are largely ignored. (I just gave it a 5 star review on Amazon a little while ago.) For the sake of brevity however, I will get right to my criticisms:
Although several times you examine time theories and their possible consequences on the relativity of simultaneity, you didn't specifically explore how time dilation (during relative motion and proximity to mass) fit in with a real, global theory of time. I think this was a mistake since, in my opinion: only through a better understanding of what makes clocks speed up or slow down, will we be able to understand what makes them run at all.
Also – would you consider all time theories described as "emergent" to be illusory? And if so, why would they have less of a chance of being time-arrow asymmetric than real global time? For example – my starting point is the question: Do all of the fundamental behaviors expressed among particles, forces and fields exist in time, or are those behaviors themselves the actual expression of time? It is my contention that the behaviors actually are time (each atom is its own clock). If we suppose that is true for a moment, I can't think of any scenario where all behaviors in the universe would spontaneously and simultaneously run in the reverse direction.
Personally, I think the time reversibility concept is bizarre in general. We assume that why everything different about today than yesterday is due to probabilities given certain rules among all of the particles, forces and fields in the universe. If time were to start running backward, then either all of the above would have to miraculously run in reverse with a sudden opposite cause & effect for each set of forces or "reverse time" would externally drive them on some sort of auto pilot. The former is highly improbable and the latter is not logically consistent. Why would the forward direction of time be driven by the behaviors of various forces while the reverse would be driven simply by reverse time itself? Please let me know if I have misunderstood something here?
Many thanks,
Chris

49. **srp**
April 28, 2013

I watched the video Marcus recommended. The model Smolin proposed seems to have momentum traveling backward in time from "child" events to their "parents" as part of a momentum balancing process. I'm not sure how that makes sense, but maybe it's just some sort of convention that physicists are used to.

50. **Ashish Sirohi**
April 29, 2013

Einstein-Leopold's book, the "Evolution of Physics" has been my favorite popular book (not because it is the best written popular description but because it contains Einstein's thinking in his own words) — as Neils H. Abel said, study the words written by the masters themselves, not their pupils. I have read that book a gazillion times. Smolin's book "The Trouble with Physics" is the other popular book I have read multiple times and the page that stumps me is p.257 and its statements about time and Smolin's not being happy with the simple diagram he drew there.

Now Smolin has a whole book on time! Well, it is not available at Indian online stores so have just ordered from Amazon, where they really loot you on international shipping. Jeff Bezos ships free in the USA, rips-off the rest of the world. Maybe I could have saved some money by searching places like Ebay etc but that takes time. I plotted a money-time graph and realized I really don't know what time is! Can't wait to find out 😉

What I admire most about Smolin is that he one of the two professors who gets special mention on my favorite site about special relativity: physicsnext.org!

51. **John Merryman**
April 29, 2013

Chris,
Good question. It does go the the main problem of time. Whether the events are the denominator and the present the numerator, with this eternally existing fabric of spacetime, or it is the present as the denominator and the events the numerator, so that it is just one constantly changing present.

52. **Lee Smolin**
April 29, 2013

Dear Chris,

Many thanks, that is an excellent question. The importance of shape dynamics, the development I describe in Chapter 14 of Time Reborn, is exactly that it explains how time dilation and other phenomena of special relativity can be made consistent with a real global time. To put this briefly, shape dynamics has a gauge symmetry under local scalings of volume. But if you shrink the volume a clock occupies you make it tick faster because clocks are physical devices and their size affects their rates. This is evident in models of clocks called light clocks in which what ticks is a photon bouncing back and forth between two mirrors. Hence you can trade a relativity of time with fixed sizes for a relativity of size with fixed times. This leads to an equivalence with general relativity and, as Barbour and collaborators have shown in detail, there emerges all the phenomena of special and general relativity. How this works in detail requires of course a bit more technicalities.

Thanks for your thoughts on irreversibility. This issue is the subject of work in progress with Marina Cortes, so please look for papers to appear.

Dear srp,

I'm not sure how you got the impression momenta run backwards in time in the model I discussed in that talk; all momenta run from past events to future events.

Dear Marcus,

Many thanks for those references. I agree that these NS's have central values of their measured masses larger than 2 solar masses, but the error bars are large enough this is consistent with 2. But these make me hopeful that soon a NS may be discovered with a mass definitively above 2 solar masses. I would not be unhappy to be able to write a paper saying that a prediction of cosmological natural selection has been falsified because this supports my key point that it is more scientific to posit evolving laws than timeless laws.

Dear Nathalie,

I understand that you are concerned that by discussing philosophical and methodological issues in public we may mislead laypeople to confuse ideas in progress with settled facts. This is a great concern of mine as well and I don't believe I was doing that at PI-because I made it clear more than once that I was not addressing the normal practice of physics but only its extension to a theory of the whole universe. But I do share your general concern and if you have any concrete suggestions I'd be very happy to incorporate them into my future public talks. Meanwhile I would very much appreciate it if you would look carefully at the book and/or the talk and understand that I am not attacking mathematics in general or saying all physics is wrong etc. I don't mind at all if my argument is criticized but it is helpful when the criticism is directed at what I am actually saying rather than being based a misunderstanding.

Thanks,

Lee

53. **T. H. Ray**
April 29, 2013

Lee,

In re … ". . . you can trade a relativity of time with fixed sizes for a relativity of size with fixed times. This leads to an equivalence with general relativity and, as Barbour and collaborators have shown in detail, there emerges all the phenomena of special and general relativity."

Except that Barbour et al are compelled to trade the geometry of spacetime (GR) for a geometry of space without temporal causality. I can't see how this view is at all compatible with yours, if you want a model in which time is physically real.

On the other hand, I find no conflict between the conventional view of general relativity which describes a universe "finite and unbounded" — taken to mean bounded in time at the singularity of creation and unbounded in space by continuous positive curvature — and a universe finite in space and unbounded in time. I think that would preserve spacetime as physically real, as well as the physical evolution of time itself. I am skeptical of assigning a causal role to geometries and symmetries — however dynamic we imagine them to be — independent of a guiding physical principle.

Best,

Tom

54. **Lee Smolin**
April 29, 2013

Dear Tom,

There is real time with temporal causality in shape dynamics, at least at the classical level, and there is a beautiful recent paper about this by Barbour, Koslowski and Mercati, http://arxiv.org/abs/1302.6264.

Thanks,

Lee

55. **N.**
April 29, 2013

BTW, anyone who claims that he has read the book in these few days – should reconsider. Peter included, although I suspect that he (like Bee) had access to the volume beforehand. This is not a book to be read in four days. Be patient and give it the time and thought it deserves.

56. **Chris Kennedy**
April 29, 2013

Lee,
Thank you for adding that response because quite honestly, I didn't connect the dots between your GR application of shape dynamics (time is universal and size is relative) and the other statements about SR in that same chapter. After rereading chapter 14 along with Barbour's paper from the link you provided (I assume Barbour's dimensionless time variable and your real preferred global time mean the same thing) I sort of get it now – but I don't know if I agree with it.

On p. 170, you say: "This global notion of time implies that at each event in space and time there is a preferred observer whose clock measures its passage." Then, according to shape dynamics, you could argue that both GR and SR time dilation effects would produce "deviations" from the preferred global time because of the "size relativity" experienced in each. But, even if you consider a particular object to be at absolute or preferred rest, it is still in some other object's gravitational field even if by just a trace, and will have a miniscule deviation from the true global time. If I have that right, then doesn't real global time become a theoretical value that is not experienced by anything in the universe?

Also, how closely does the "size relativity" in shape dynamics relate to the length contraction hypothesis in special relativity? I want to make sure I understand your comment in your earlier post along with another statement of yours explaining Barbour's position from chapter 14: "Shrink everything in one place and somewhere else, enlarge everything by the same amount." I ask because according to SR, length contraction, along with time dilation is considered to be a reciprocal effect from the perspective of both the observer and traveler. And the "shrink everything/enlarge everything" statement seems to hint at an inverse proportion rather than reciprocal effect. Unless the shrinking and enlarging doesn't necessarily apply to two clocks running at different rates? Can you clarify?
Thanks again

John M. – Thanks, hope all is well. I noticed the early time of your post. I envy you. I wish my brain worked in any capacity before 6:00 am.

57. **Marcus**
April 29, 2013

I'm curious to know if the book contains this Youtube link to a short conversation between Richard Feynman and Fred Hoyle recorded around 1972:
http://www.youtube.com/watch?v=uNOghidK2TY
The clip is 9 minutes and 35 seconds long but if you are in a hurry you can skip the first 8 or 9 minutes.
Relaxed conversation at a Yorkshire pub. If you start around minute 8:00 you get some of the atmosphere. But the main thing is in the last 35 seconds of the clip.

A Caltech archive has the text of what Feynman says there:
http://calteches.library.caltech.edu/35/2/PointofView.htm
Scroll 3/5 of the way down the page.
"It is interesting that in many other sciences there is a historical question, like in geology – the question of how did the earth evolve to the present condition. In biology – how did the various species evolve to get to be the way they are? **But the one field which has not admitted any evolutionary question is physics. Here are the laws, we say. Here are the laws today. How did they get that way?** – we don't even think of it that way. We think: It has always been like that, the same laws – and we try to explain the universe that way. So it might turn out that they are not the same all the time and that there is a historical, evolutionary question."

There seem to be two problems being addressed: the Problem of Time, and the Problem of Laws. (Why these laws? How did they come about?) The Barbour Koslowski Mercati paper Lee mentioned solves the first–the problem of time–in the shape dynamics context, but does not address the second.

58. **Daniel Tung**
April 30, 2013

Hi Lee

I have a few questions:
1) Does the reality of time imply that (total) information is always being created at a fundamental level (and thus non-unitary)?

2) I do not understand your statement that since the universe includes everything, there could be no eternal mathematical truths or laws outside of the universe that nature can correspond to.
But, mathematical laws need not be physically lying outside of the universe – they are mental products, and thus of a different category from the physical universe. It is wrong to say that they are outside of the universe.

3) Maybe the reality of time depends on our viewpoint, whether it is from inside or outside? For an observer inside the universe, using tools defined entirely from inside, time can be shown as real. But if we see from outside (God's eye view) like Newton's theory, all time is equal.

59. **Marcus**
April 30, 2013

Daniel, about your question (2) I don't remember Lee saying what you have him saying there. A handy way of distinguishing a mathematical law from a physical law is that a law of physics *could be different*. It's a key distinction.

With a law of physics one can reasonably ask "why is it this way rather than that?" because there is empirical content. You rightly point out that mathematical truths are of a different sort. Mathematics is an evolving human language within which true statements are deduced non-empirically from sets of axioms.

Have a look at slide #5 of PIRSA 13020146. It's a talk Lee gave *about the book* in the Quantum Foundations seminar at Perimeter. You can download the slides PDF and review the logical outline of the talk after watching the video. Slide 5 gives a couple of concise principles that the rest of the talk (and I believe the core argument in the book) is based on.

The first principle shown (labeled PSR) is carefully worded so that it applies to laws of physics and not to pure math.
I can't recommend watching the February Quantum Foundations seminar talk too highly. It's an immediately available clear concise presentation of the logical argument at the heart of the book.
http://pirsa.org/13020146/

My kibitzing like this is not meant to detract. Hopefully Lee will provide a more complete authoritative response later.

60. **T. H. Ray**
April 30, 2013

Lee,

Having read the Julian et al paper you linked, I want to echo Chris's comment "(I assume Barbour's dimensionless time variable and your real preferred global time mean the same thing) I sort of get it now – but I don't know if I agree with it."

Except that I'm not sure that I even sort of get it. A dimensionless time is dimensionless spacetime. And I don't see how shape without geometry differs from change without differentiation. We can believe it, philosophically — yet how can we hope to demonstrate that such is fundamentally "physically real" in Einstein's terms, i.e. " … independent in its properties, having a physical effect but not itself influenced by physical conditions." (from The Meaning of Relativity, 1956.)

Minkowski spacetime and general relativity may be old hat, and perhaps I'm a Philistine, yet I cannot get my mind around a more fundamental background-free starting point for energy exchange between bosonic and fermionic particle properties.

Best,

Tom

61. **Marcus**
April 30, 2013

Tom, I don't see how you come to your stated assumption: "I assume Barbour's dimensionless time variable and your real preferred global time mean the same thing." They seem quite different animals to me! Surely they are constructed in entirely different ways. Can you clue me in to your thought process?

What Lee said earlier in these comments was: "The importance of shape dynamics, the development I describe in Chapter 14 of Time Reborn, is exactly that it explains how time dilation and other phenomena of special relativity can be made consistent with **a** real global time. To put this briefly, shape dynamics has a gauge symmetry under local scalings of volume…"

I bolded the article "a" because it as much as says that they are NOT the same global time, as far as the speaker knows. The point seems to be that there exists at least one global time which is consistent with such and such phenomena.

Alain Connes and Carlo Rovelli have also proposed a global time, based on the Tomita flow on star algebras—theirs seems quite different from either of the others although agreement is possible where applicable in special cases: all might be found to agree with the global time of Friedman equation cosmology in that model. Anyway a global preferred time is not such a rare beast that whenever you see two of them you must assume they are the same. But maybe you have reasons to equate them and I'm being too cautious. 🙂

62. **T H Ray**
April 30, 2013

Sorry to add confusion, Marcus. I didn't say it. Chris Kennedy said it. I haven't even gotten to chapter 14 of Lee's book. The Barbour et al paper I did read, however, and I cannot reconcile what I know that Lee has said in the past with Julian's concept of shape dynamics and the (nonphysical) role of time.

I thought Lee was a relativist, albeit with an enhanced physical role for time and the possible inclusion of nonlocal hidden variables (the class of theories in fact, to which string theory belongs).

I think global time is a pretty slippery concept. I'm compelled to agree with George Ellis that without a well defined local arrow of time, there is no life — even further though, I think, no matter — whether baryonic or dark. The more I look at these causal structure theories, the more convinced I become that physically real spacetime and general relativity still hold the key to theoretical completeness.

Best,

Tom

63. **Chris Kennedy**
April 30, 2013

Marcus,
I assumed it, but wasn't 100% sure, so I threw it in there in case I needed to be corrected. However, I believe all of the the comments below that are pretty consistent with questioning preferred global time, so I hope Lee comments on the issues I've raised.

64. **Lee Smolin**
May 1, 2013

Marcus,

That Feynman quote is in the intro, page xxvi

Daniel:

In reply to your questions by number:

1) I would argue that there must be a cosmological theory which quantum mechanics approximates for small subsystems of the universe, which would have an evolution law which is expressed in a language not that of quantum theory. This would of course conserve probability but might not be expressed as unitary evolution on a Hilbert space.

2) If you think mathematical objects are "Mental products" you are not a platonist and you believe mathematical objects are within the universe as are the brains or minds that created them. I claim that mathematics can provide excellent models of the records of past observations of subsystems of the universe. But all such models, describing subsystems, involve truncations and are hence incomplete. I however argue in the book that they cannot be completed by extending the model to encompass the universe as a whole. The core of the argument of the book, which I won't repeat here is why this cannot be done.

3) I deny there is any scientific sense to a description of the universe from outside of it, for reasons given in detail in the book.

Tom,

I don't mean to imply that shape dynamics gives a view of real time in all the aspects I mean that, which are specified on page xiv. What shape dynamics does do is show how the existence of a preferred global time, in which the spacetime evolves through hamiltonian evolution, is compatible with relativistic causality.

Also, Barbour's previous arguments that time disappears in quantum cosmology are not the same as or necessarily relevant to shape dynamics, which is so far only understood at a classical level.

Chris,

It is important to distinguish special relativity, where the lorentz group describes a global symmetry from general relativity, where the many fingered time, or spacetime diffeomorphisms describe a gauge symmetry. Shape dynamics is a reformulation of the latter in which the many fingered time gauge symmetry is replaced by a local scale gauge symmetry. To address your question in detail of exactly how time dilation arises in shape dynamics is possible-because SD is equivalent too GR, but a technical exercise as global symmetries are already a subtle issue in general relativity.

Thanks,

Lee

65. **T. H. Ray**
May 1, 2013

Lee,

Thank you — that's a relief. If I am to understand shape dynamics in a classical framework, I can also grasp preferred global time as continuous, with classical time reverse symmetry. I'm afraid this discussion is getting a bit ahead of my reading the book — need to catch up!

Best,

Tom

66. **Chris Kennedy**
May 1, 2013

Lee,
I guess after learning what little I know about shape dynamics, I will limit my observations to its explanation of time dilation in Special Relativity.
The clarification I'm looking for is whether the relativity of size correlates with the reciprocal length contraction proposed for SR during relative inertial motion. This is an extremely important question. By the way, in certain relativity writings, "reciprocal" refers to equal but identical, which is how I use it here. In other words, I see the moving ship contract, and the moving ship sees the space it's traveling in contract. SR also says that I will see the ship's clock run slower while the people on the ship see mine run slower as well.
I am asking this because you said in your book that: "SD achieves an accord between the experimental success of the principle of relativity and the need for a global time….."
Any sane person who has studied relativity would have to admit that all of the experimental evidence certainly shows that time dilation during motion and proximity to mass is a real phenomenon. But there are a lot of sane people who are not aware that certain physical evidence (GPS system) shows that the time dilating effect is not reciprocal during relative motion. If the satellite clocks are running slower from the perspective of the ground (having already adjusted for the gravitational effect) and the satellite sees the ground clock running slower than itself, there is no compensation that can be applied to either clock (or both) to get them to run in sync from both perspectives simultaneously – but yet they do and the system works quite well.
So, if shape dynamics is not reliant on the framework of these reciprocal effects in SR, then I would say it has a chance, but if it is reliant on that aspect of SR, then I would say it is in serious trouble.
I think I speak for all of the questioners here when I say we appreciate your continued participation in this conversation. "Time" is an important issue that never seems to get the attention it deserves.

67. **Daniel Tung**
May 2, 2013

Hi Lee,

What I wanted to say is that even if there is nothing outside the universe, this does not imply that there is not a realm of mathematical truths where nature corresponds to. Platonic realm is conceptual, and not something physically lying outside the universe. So its existence does not contradict the fact that there is nothing outside the universe.
"Outside" is a relationship between two physical objects.

68. **Henrique Gomes**
May 2, 2013

It is easy enough to represent global Poincaré symmetry in Shape Dynamics, as long as you have (as Lee mentions), a flat ansatz*. The way this comes about (at least mathematically), is that due to the high geometric degeneracy, there is a family of exactly 4 time directions which cannot be traded for conformal symmetry in the construction of Shape Dynamics. These directions correspond to time translation and boosts, or alternatively, to Minkowski and Rindler. In this degenerate case, quite unexpectedly, the Shape Dynamics algebra of the 4 respective Hamiltonians (supplemented with the isometries of flat 3-space) form the Poincaré algebra.** So I would say that at least in the way its been derived it does not depend on the reciprocity you mention. The appearance of a singled out time direction, once the trading of symmetries is complete, would appear only when you add inhomogeneities to the Universe.

* (in fact all you need is a spatial spherically symmetric ansatz in asymptotically flat SD with no boundary mass charge)

** I should mention that this algebra is already represented as a boundary charge algebra in this circumstance, but the charges are slightly different than in GR, see http://arxiv.org/abs/1212.1755 .

69. **Henrique Gomes**
May 2, 2013

I should have mentioned that my comment was addressed to Chris Kennedy's remark, my apologies.

70. **Tobias Jürgens**
May 3, 2013

To anyone who might know:

In Barbour's book "The end of time" he talks about the timeless formulation of quantum mechanics. I only read the book once so far and couldn't understand if it is working or just how he imagines it to work, in contrast to Newtonian mechanics, SR and GR, where I understood the construction.

So is there a mathematical formulation of timeless QM? And could You please point out a (some) paper(s) on this?

Thank You,
Tobias

71. **MathematicianNotPhysicist**
May 7, 2013

I've just finished reading the book, and I have questions. I don't know if Lee Smolin will see these, but anyone is welcome to answer.

1. In Cosmological Natural Selection (CNS) you need to get Big Bangs to come from Black Holes, but obviously the theory of if/how this happens needs much more development. In particular you don't know what it takes for a Black Hole to make a good baby universe, not just with good constants, but also with the special initial conditions like our own Big Bang, and still following GR and QT to the extent that there's a choice, and so on. Given this uncertainty in the theory, what does that imply for prediction and falsifiability in CNS? It might be better for a universe to have fewer fitter offspring (just as in biology), so just maximizing the number of Black Holes cannot be a necessary requirement of CNS.

2. If there is a to be a global time, then it is a totally ordered set (of "instants"). What does this sequence of instants look like? The integers, the rationals, the reals, something else? Or is this a case where mathematics cannot fully capture the physics? Or are the "instants" actually blurred out and uncertain, and least by the order of one Planck time?

3. How strong is the argument that "real time implies global time" anyway? What's wrong with real time (now is real, past and future is not) while still having multi-fingered time, as long as neighboring patches of space keep up with each other? What if you had two or more totally causally disconnected universes: would they need to share a global notion of simultaneity with each other? Maybe I'm being dense but I'm not seeing it as settled that there either must be a global time, or no (real) time at all.

4. If there is to be a global time, does it necessarily have to be one picked out by the shape dynamics argument? There's lots of ways to map a partial order to a total order? How do you choose which is the "true global time" (or was this just an in principle argument about what might be the true global time)?

5. What viable proposals are there where GR and QT are not taken to be absolutely true, but where some dynamical process tends to push violations of these laws towards zero? (This is meant to be analogous to various feedback mechanisms in a living organism, on a faster timescale than evolution.) As a possible very specific example, take a spacetime, find the global time t picked out by the shape dynamics argument, then reformulate GR, by describing how a spacelike slice S(t) at constant time t, with appropriate fields, and satisfying appropriate conditions, would evolve as a function of t. But then extend these dynamics so that they can be applied to an arbitrary spacelike slice, and you want it to be that as you evolve it into the future as a function of a time parameter t, that the future spacelike slices converege to the spacelike slices you get from the shape dynamics argument. Is something like this done?

6. Is there a connection between "constant mean curvature slicing" (Note 10 of Chapter 14) and Penrose's Weyl curvature hypothesis?

7. As an idea of where QT could break down, what do you think of Penrose's proposal that the laws of physics are such that a quantum superposition of macroscopically different ditributions of mass/energy will not occur, (i.e. despite QT, things won't deviate too far from classical GR, except possibly near singularities)?

8. What does it mean for space to not be real? It seems to be pretty much a 3-dimensional sheet of stuff to me even when it's "empty" (and even if it sometimes looks like an arbitrary graph, I'd still just call that unfamilar, not unreal)?

9. Any idea why nature "tricks" us into thinking that there are laws with (sometimes broken) symmetries, when in reality the symmetries were never there to start with (so there's no symmetry to break)? You say there is a global time, preferred inertial observers, and so on. So for example local Lorentz symmetry is not imposed by any law, but it looks true. Is this something amazing to be explained, and what is the explanation (perhaps some dynamical process as in 5. above might work)?

72. **Lee Smolin**
May 12, 2013

Dear MNP,

Sorry for the delayed response to your excellent questions. btw I am soon to be launching a blog to discuss questions like these with readers. To answer yours:

1) To make the theory predictive in the absence of a detailed model of a bounce I assumed that each black hole yields a single viable universe. Obviously you could complicate the model in many different ways and one could also try to take advantage of progress in quantum gravity since then to model the bounce.

2) This is a good question.

3) What do you mean that they keep up with each other? Isn't that a global time? But of course its not settled, I give several independent arguments, please disagree specifically with them.

4) Of course, but SD shows a global time can be compatible with experimental tests of SR and GR. There could of course be other choices. I mention several in the notes.

5) This is a good research program to pursue.

6) No

7) Its an interesting hypothesis to investigate.

8) The point is that an arbitrary graph with some graph metric on it does not embed isometrically in a low dimensional space

9) There are dynamical systems whose low energy excitations have emergent or accidental symmetries.

73. **Marcus**
May 14, 2013

There is a great 58 minute Smolin core-dump on Edge
http://www.edge.org/conversation/think-about-nature
Lee thanks, it puts a lot of things together.

74. **Marcus**
May 15, 2013

Having read the book, as well as the Edge piece http://www.edge.org/conversation/think-about-nature
and watched the Quantum Foundations seminar talk
http://pirsa.org/13020146/
I would say that the main idea being supported is to find and test a *more elegant* description of how Nature works by explaining how the existing body of physical law came about.

It doesn't matter whether you call a proposed governing principle (by which known regularities could have developed) a description of "how Nature works" or a "meta-law" or simply a more basic law of Nature.

What seems to matter is that the body of physical law has become seemingly over-intricate and arbitrary. This makes for a general desire for one deeper law that explains where all the previous laws "came from", and Smolin presents a case, based on many interesting arguments, that the most promising area to search is in the direction of historical/evolutionary principles.

A frivolous paraphrase of one example he presents might be "Nature tends to run in ruts it made itself earlier" or "being the universe is habit forming". This harks back to the examples of biological evolution and the development of English Common Law by the accumulation of precedent. It seems to me that any such principle would have to be formulated with the help of some new mathematical language before it could be used predictively and tested. And it would itself be outside of the evolutionary process.
Any description of how Nature works is going to have some postulate or rule that does not itself evolve and which is not reciprocally acted upon by what it guides.
So the main idea is not to reject timeless law, expressed in partly mathematical language, it is to find *more elegant* description and *more economical* explanation.

And the case is made that this must involve the temporal development of previously recognized regularities–so it looks like we must accept (I think he would say) the idea of a preferred global time slicing of events.

75. **David Gillett**
May 15, 2013

A message for Lee: The one area that really raises questions for me is precedence: how and why would that become established, causing universe wide behaviour under similar circumstances to be consistent and thus create a "law" ?

David Gillett

76. **Marcus**
May 15, 2013

David, I hope Lee responds to your question, but would like to observe that I addressed that issue. Precedence, if you can pull off a workable formulation, is just a more elegant basic law of nature. It is a single law that might be capable of explaining how the previously recognized physical laws arose. It isn't any more crazy to assume precedence (if you can formulate it) than any other fundamental law. How does an electron know it's and electron and that it should behave such-and-so way? Indeed precedence sounds potentially LESS preposterous to me than other fundamental laws—it is just that one has gotten used to it that one doesn't notice how crazy it is that matter should behave according to the Standard Model.
The basic idea is that somehow (we don't know how) Nature is able to blindly stumble into repetitive behavior and acquire habits. That Nature has something analogous to an associative memory of its own past behavior.
I see no qualitative difference between assuming that (if one can formulate it clearly) and assuming Newton's Laws of Motion. It's just that we are used to Newton's laws.

The problem I see for Smolin and collaborators would be with formulation. It is similar to the difficulty of programming artificial intelligence, one must be able to make a toy model of Nature that uses a *similarity* criterion for recognizing the similar past situations which would constitute precedents to be sampled randomly. It seems similar to the AI problem of programming an *associative memory* to use in constructing some almost completely unintelligent habit-forming automaton.

Newton explained his absolute space and time as Sensorium Dei. That was weirder than this, or so I think anyway. Basically it is a fun idea whose time is come. Hopefully they can make a toy model work and actually generate some law-like patterns of behavior.

77. **T. H. Ray**
May 16, 2013

MNP's question # 3 hit a chord:

"What if you had two or more totally causally disconnected universes: would they need to share a global notion of simultaneity with each other?"

I think yes! Lee's rhetorical resp0nse — "What do you mean that they keep up with each other? Isn't that a global time?" — agrees, yet I think more needs to be said about what "causally disconnected" means. In Einstein's relativity, simultaneous though relativistically separated events are causally disconnected; multiple universes sharing a boundary and also sharing simultaneously branching binary events make Smolin's "real time" proposition even more attractive. Given, as Wheeler noted, "The boundary of a boundary is zero," spatial boundaries do not obviate analytical continuation of the time metric — as I have found, general relativity suffers no loss of generality when described as a model bounded in space and unbounded in time (rather than, as conventionally thought, bounded in time at the singularity of creation and unbounded in space).

Tom

78. **Lee Smolin**
May 16, 2013

Dear David,

That is an excellent question and one that I am focusing on as I try to develop the hypothesis of precedence further. As formulated in the original paper arXiv:1205.3707 I just assume it does so. What intrigues me is that the question of how precedence develops might be investigated experimentally by studying quantum systems complex enough to have no natural precedents. Nor is it necessary to have a detailed model of how precedence develops to test for deviations from the expected Schroedinger evolution in such cases.

Let me stress that this idea, like CNS, doesn't have to be right to prove the point that theories of evolving laws are testable and hence at least as scientific as the claim that laws never evolve-which leads to attempts to explain the choices of laws that have no testable consequences.

Lee

79. **srp**
May 17, 2013

Dear Prof. Smolin:

Thank you for your earlier correction; I re-checked the relevant slide and saw that I had misread it.

One warning/heads up: The notion of laws evolving as the universe gains "experience," and your ideas about precedence bear a superficial resemblance to the concept of "morphogenetic fields" propounded by Rupert Sheldrake. He has argued for example, that when one lab gets a certain chemistry experiment to work then all future versions of that experiment at other labs are more likely to work. His ideas have the flavor of the paranormal and attract those who are sympathetic to such things. You might want to be prepared with a response in the not unlikely event that your work is cited in support of his theories.

80. **Marcus**
May 19, 2013

I would like to ask Lee the following question, if he is still checking this blog for discussion and wishes to respond. Can you imagine a precedence process by which the quantum theory called Causal Dynamical Triangulations arises?

CDT has a preferred time or at least a preferred foliation, and is built up in layers with a certain thickness.
(This resembles what was described in the February seminar talk.)
And there is a certain random probabilistic process that governs the formation of the each layer (based on a Regge-like partition function). That could be seen as similar to "sampling from the past" in the precedence process—though not identical by any means! So I can just barely imagine how something like CDT might arise through geometric habit-formation. I'd like to know what other people (Lee in particular) think about this.

81. **Marcus**
May 19, 2013

Here is Chris Kennedy's 5star review on Amazon of Smolin's book.
http://www.amazon.com/review/R2F83657IVWFJ9
If you happen to read it and find it helpful consider clicking the accompanying "yes" button, because something like Smolin's metalaw operates at Amazon. Customer reviews that don't get noticed and don't acquire "yes this was helpful" votes stay at the bottom of the pile and may not ever get noticed and yessed enough to rise the top of the pile where people see them.

Right now the top of the pile of "customer" reviews is all composed of quite disagreeable 2star reviews and the like. It appears that visitors see the half dozen negative reviews, mark them as helpful, if for no other reason than because they help one decide not to delve further and take any further interest in the book. So unless you are experienced it's actually a bit difficult to even FIND Chris Kennedy's review (which only 8 people have approved of so far).

I also contributed a review which is here:
http://www.amazon.com/review/R2Y6HLLSQH5KSN
It appears to have little chance of ever getting read, but at least adds to the raw number of 5star reviews.

82. **Chris Kennedy**
May 21, 2013

Marcus,
Thanks for posting the link that goes directly to the review and my comment below the review. I wanted to make people aware that part of my criticism I originally offered was a little reckless when I said: "he didn't specifically explore how time dilation (during relative motion and proximity to mass) fit in with a real, global theory of time" and after Lee straightened me out on the applications of shape dynamics, I posted the correction. However, as someone who is interested in the nuts and bolts of the nature of time, any theory for how and why time dilates deserves much more discussion and clarification. Putting all of our eggs in the shape dynamics basket might be too simple of a path to take at this point.

Arkani-Hamed Colloquium

April 30, 2013
Categories: Favorite Old Posts, Uncategorized

Nima Arkani-Hamed was here at Columbia yesterday to give the physics colloquium, which clocked in at a bit over 1 hour and 45 minutes. He did reveal the secret of why his talks are this long: when invited to give a 1 hour colloquium, he plans on talking for at least 1 hour 30 minutes. The content of the talk was similar to many others he has given recently that are available on the web, see for instance this one at the IAS, this recent one at BNL, or for a written version, see here.

As a performer, he's a powerful speaker: smart, vigorous, and supremely self-confident. His arguments lead to "inevitable" conclusions, not just implying results but "nailing" them. It's clear why he's the most influential person in the field these days. With most theorists made worried and unsure by 40 years of failure to get anywhere in their efforts to improve on the Standard Model, he knows exactly what he thinks and will tell you forcefully what you should think. The fact that none of the ideas about BSM physics he is famous for (large extra dimensions, split SUSY, Little Higgs, etc…) have ever worked out doesn't seem to slow him down, and he has a professorship at the IAS and a $3 million prize from Yuri Milner to back him up.

Despite his long-time advocacy of SUSY, according to Arkani-Hamed, the negative results from the LHC are "not making many of us worried about SUSY". He (accurately) points out that he's not one of those like Gordon Kane who for decades has been predicting the discovery of superpartners to be six months away. It has long been clear that the simplest versions of SUSY should have shown up at LEP and the Tevatron, and pre-LHC the lack of any indirect evidence for SUSY indicated to him that it was unlikely to show up at the 8 TeV LHC. So, by his lights, there's no reason that LHC results so far should cause any new worries about SUSY, beyond those he already had pre-LHC. On the more limited question of whether a "natural" version of SUSY will work out, one where the superpartner masses just barely avoid large amounts of fine-tuning, a year ago (see here) he was saying we were at the "eleventh and a halfth hour" for this possibility. Now that the 8 TeV results are here (and negative), he argues that it is only with the 2015 data that the results will be decisive. The current wisdom about "natural SUSY" I guess is summarized in slide 8 here: **Keep Calm and Wait for 14 TeV**.

The main point of the talk was one that Arkani-Hamed has been consistently making for nearly a decade, that the role of the LHC is to decide between two possible futures for fundamental physics:

- The small value of the Higgs mass (in Planck units) has a "natural" explanation, most likely using SUSY, in which case we spend the rest of our lives unraveling the complexities of a SUSY-extended Standard Model.
- The small value of the Higgs mass (in Planck units) indicates "fine-tuning" that can only have an anthropic explanation, just like the one for the CC. In that case, we live in a multiverse, with physics determined by something like the string theory landscape. About this whole conceptual framework, he says the "ideas are so poorly defined, not clear if they make any kind of mathematical sense", and it's "not clear progress will happen anytime soon" but, no need to worry or get discouraged, since this is an "attractive problem".

Based on the LHC results so far, it looks like all evidence is that we're headed to the second alternative.

Arkani-Hamed's talk was structured so as to present a long chain of argument (needing at least 1h 30 min to explain) leading to these two alternatives. One of the alternatives (SUSY naturalness) is essentially already dead, with the die-hards intent on hanging on a couple more years. The other is essentially what David Gross has called "giving up": you just announce that the problems you haven't been able to solve can never be solved. In this vision, the 20th century with its huge success at finding a highly predictive, mathematically beautiful fundamental theory was an aberration caused by only being able to see physics at energies way below the Planck scale. In this new 21st century physics, you just postulate that at higher energies things are much more complicated, in ways we can't hope to ever know, and theorists devote their lives to making excuses, not predictions. Witten may end up being right that "string theory is 21st century physics that fell into the 20th century", in a much more negative way than he intended.

If a long, complicated argument leads you to the conclusion that the only viable alternative is to give up, then it seems to me you have two choices: give up, or examine more carefully your argument. A much more interesting and more useful talk than Arkani-Hamed's would be one less devoted to forcefully insisting on the conventional chain of argument based on the technical problem of sensitivity of the Higgs potential to the cut-off, instead looking carefully for weaknesses in the argument (one possibility is discussed here). Arkani-Hamed is a brilliant physicist, but this may be a time when what is needed is not self-confidence in the power of one's arguments, but instead a suspicion that one has been making a mistake somewhere for quite a while now.

Comments

1. **Nex**
   April 30, 2013

   Science advances one funeral at a time.

2. **BB**
   May 1, 2013

   " A much more interesting and more useful talk than Arkani-Hamed's would be one less devoted to forcefully insisting on the conventional chain of argument based on the technical problem of sensitivity of the Higgs potential to the cut-off, instead looking carefully for weaknesses in the argument (one possibility is discussed here). "

   I think it is simply preposterous to present the work of Lykken at your link as a valid alternative, as I have already explained in the comments to that post. Conformality cannot be invoked, per se', as a solution to the hierarchy problem as long as other scales exist in the deep UV and your CFT isn't screened from them (as it happens instead e.g. in RS or SUSY theories).

3. **Neil**
   May 1, 2013

   I'm not a physicist, just an interested bystander, but surely there are more than two futures, one of them depressingly bleak. There is BSM physics to explore at the high precision, high intensity frontier and at the cosmological frontier. It will not all end at 14 TeV, I hope.

4. **Shantanu**
   May 1, 2013

   Peter, did someone ask any of these hard questions after the talk?
   or there was no time for questions, given the length of the talk?
   shantanu

5. **Dave Miller in Sacramento**
   May 1, 2013

Peter,

Isn't part of the issue here unrealistic expectations about the pace of progress?

The first three-quarters of the twentieth century saw an unprecedented explosion in the rate of discoveries in physics, partly because of the early revolutions in relativity and quantum theory, and, then, after WW II because of the huge influx of government funds to pay all of us and to build bigger and bigger accelerators.

For reasons we all know, that post-war boom just could not continue — in particular, we could not keep exponentially growing the size (and cost) of accelerators. So, it seems to me that the present slower pace is really a return to historical normalcy. We had a period where we frantically grabbed all the low-lying fruit, and, now, we need to sit back and digest the fruit.

Personally, I think we have a lot to digest concerning the structure of QFT and even QM itself. It took quite a while to go from Maxwell to QED and even longer to go from Newton to Einstein. Why should we expect any progress forward from the Standard Model to be fast or easy?

Dave

6. **Jeff**
May 1, 2013

"Armani-hamed is a brilliant physicist" – what exactly does that mean? I'm a mathematician, math is hard because we actuallly have to prove things. I've always thought physics was hard because things had to WORK. Arkani-Hamed doesn't have to prove anything, and from what I can tell he hasn't come up with anything that works.

7. **Peter Woit**
May 1, 2013

Nex,

If you're referring to Arkani-Hamed, he's about the youngest person of any prominence active in this field, and very influential on those younger than him. On the other hand, if you're referring to me, yes I'll likely be long gone while he's still around…

8. **Am I Lloyd**
May 1, 2013

It's a little troubling to hear a scientist speak of so many results as "inevitable", especially in a field like string theory.

9. **Peter Woit**
May 1, 2013

BB,
I wasn't claiming Lykken's talk as a solution to the problem, just pointing it out as an example of ideas about solutions to the problem that it would be more fruitful to examine, in preference to arguing that no SUSY at the LHC implies anthropics as the only way out.

I avoided going on here about my own take on this, since I do this endlessly, most recently in the last posting a couple days ago. There seem to me many more serious problems with the Higgs field than its quadratic sensitivity to the cutoff, and the argument from that technical issue to anthropics via the philosophy that the SM is just an effective theory, with something quite a bit more complicated at a high scale, is one I keep pointing out as likely flawed.

10. **Peter Woit**
May 1, 2013

Neil,

Arkani-Hamed near the end did quickly go over his favored scenario for BSM physics we might hope to see (mini-split SUSY), but didn't seem particularly optimistic that there was really a significant chance of the that scenario working out.

11. **Peter Woit**
May 1, 2013

Shantanu,

Little time for questions after such a long talk, and nothing like a "hard question" was asked.

12. **Peter Woit**
May 1, 2013

Am I Lloyd,

This talk didn't really deal with string theory at all, although in some sense failed string theory ideas motivate the overall framework.

13. **Bob Jones**
May 1, 2013

A much more interesting discussion of supersymmetry recently appeared on the arXiv:

http://arxiv.org/abs/1304.7798

14. **Georges**
May 1, 2013

I am really shocked at the chutzpah of that person explaining that his "secret" is to plan a one hour thirty minutes talk when invited to give a one hour colloquium. And then he even talks for fifteen mors minutes! This is despicable behaviour, encouraged by the audience not leaving the room in protest. I know that this happens frequently, but I have decided to no longer tolerate such misbehaviour and encourage you to do likewise.

15. **Peter Woit**
May 1, 2013

Georges,

To be fair to Arkani-Hamed, I shouldn't have called it a "secret". At the beginning of the talk he warned people basically that he intended to go on for at least an hour and a half, and said that he didn't mind at all if people left while he was still talking. But, yes, the word "chutzpah" did come to mind…

16. **P**
May 1, 2013

Bob,

The article you cited is a detailed analysis of superstring perturbation theory, and the results have no immediate / obvious connection to the N=1 field theory story Nima discusses.

Cheers

17. **Bob Jones**
May 1, 2013

P.,

Yes, I know.

18. **Nathalie**
May 2, 2013

Dear Peter,

Thank you for the reference to Arkani-Hamed's IAS talk. It was a nice talk.

AH argues that in all possible worlds with proper long distance behavior you have (assuming the validity of local quantum field theory) consistent theories only for fundamental particles with spins 0, ½, 1, 3/2 and 2. Because those with 0, ½, 1 and 2 have already been seen the 3/2 must also exist. Hence supersymmetry.

It seems to me that one could just as well argue that since nobody has ever seen the spin 2 the spin 3/2 will also be invisible to us humans. We must humbly admit that we don't know what we are talking about when we make such strong statements.

Another comment is that the proper long distance behavior of electromagnetism is due to the fortunate fact that matter happens to be electrically neutral at large distances. Otherwise, AH could not have presented his talk.

19. **piscator**
May 2, 2013

Jeff: It means he is a charismatic speaker who has a lot of power in the community. Seriously, you are totally correct. Physics is about stuff that works and agrees with experiment. People whose reputation is built on models that do not work and do not agree with experiment are not brilliant physicists whatever other qualities they may have. Anyone who thinks otherwise needs to recalibrate their BS detectors.

20. **JJ**
May 2, 2013

Arkani-Hamed is NOT a brilliant physicist; he is in fact a good car salesman. Of course he knows a lot about his cars, but he couldn't care less about customers. All he really cares about is to make money, and he has proven his ability to do that. The way he does this, as all good car salesmen do, is to blow his customers away by his show business skills. So DO NOT listen to him, as he is full of BS.

21. **M. Wang**
May 2, 2013

In most professions in the US, the best bullshiters rise to the top. The only conclusion here is that particle physics is no longer science but just a profession, but this should not be news to readers of your blog.

22. **Sum Perspektive**
May 3, 2013

JJ (and Peter, as the moderator)

These personal attacks on N. A-H. are really inappropriate, and foolish. There is an element of truth in the claims that Nima is a good showman, this cannot be denied. But anyone who denies his brilliance, in terms of an incredible track record of remarkably creative approaches to very (Very!) difficult problems, is simply foolish (or possibly jealous, I suppose). Think back to before large ED's, Little Higgs and Dimensional Deconstruction, and you had a situation where almost everyone worked solely on SUSY models. Nima was one of the leaders whose originality opened up whole fields, that were justifiably of immense interest. Sure, these things didn't work out, and Nima has largely moved on to other topics, like a good scientist would. But without his ideas it seems likely that many more people would have been working on the same old (failed) SUSY ideas. Nima's ideas were precisely the kind of fresh and original approaches that (I understand) Peter would advocate (ie exploring more general possibilities, which are hard to come up with).

(For the record, I completely disagree with the "SUSY or anthropic/tuning" divide that NAH discusses of late, and suspect there is another way of understanding the issue of E/W naturalness. But my dislike for these ideas does not prevent me from recognizing his abilities).

M Wang: The presence of "non purists" in science is as old as science itself. Read Einstein's talk at Planck's birthday, where he describes Planck as one of the few (presumably like himself) who would not be equally happy in some other ladder-climbing profession, as one who instead worships at the temple of science, so to speak. Most in the field are trying to get great jobs, and are willing to spew rubbish in the name of their cause, but this is not a recent development.

23. **Peter Woit**
May 3, 2013

Sum Perspective,

I don't disagree. It's interesting to note that for the last few years Arkani-Hamed has mostly abandoned BSM phenomenology and concentrated on working on a mathematical physics topic, that of understanding the mathematical structure of certain scattering amplitudes in terms of the cell structure of the positive Grassmanian. He advertises that with some of the same showman techniques (and the same tactic of taking up to two hours for a scheduled one hour talk…), but it's a much more interesting and fruitful thing to be pursuing than failed ideas about BSM physics.

It's too bad though that he maintains his other career as promoter of those failed ideas, where, unlike Kane who just denies reality, he is following them to their logical and empty conclusion.

24. **piscator**
May 3, 2013

I'll say this again: brilliance in physics comes from discovering stuff that works and agrees with experiment. I find talk of incredibly creative approaches to difficult problems a bit creepy and fawning to be honest. It's like calling a mathematician brilliant because he made twelve different attempts to prove the Riemann hypothesis and none of them worked.

And for the record, I don't think the ideas you mention are actually particularly good. Really good ideas tend to have an impact trajectory that grows over time as their profundity becomes appreciated and more and more applications are found (eg AdS/CFT). Something like LED is a more like a pump-and-dump stock.

There's nothing wrong with not being a brilliant scientist, that's the situation pretty much everyone is in, but we have to be honest about what is necessary for first rate science (agreeing with experiment) and what is not (being charismatic and giving great talks).

25. **A**
May 3, 2013

If a mathematician came up with 12 *original* ideas to prove the Riemann hypothesis, none of which were obviously wrong, I think a lot of people would call that mathematician brilliant, whether or not the proofs actually worked out.

I'm not really a big fan of how Nima presents things, and a lot of his ideas can be pretty half-baked, but the fact that he's actually producing new ideas (even if they've all been completely wrong) puts him ahead of the game for most of the field these days.

26. **Bill**
May 3, 2013

A, this is complete nonsense. There is a big difference between "none of which were obviously wrong" and "even if they've all been completely wrong". I don't know one example of a mathematician that fits your description and has the same stature as NAH.

27. **different fields**
May 3, 2013

Math \neq physics, otherwise experiment wouldn't be needed. Theoretical physics isn't just about proving "theorems" about the real world, nor is it *just* describing experimental results. Look at the history of 20th century theoretical physics, there were a myriad of wrong directions that still led to a lot of progress in understanding our universe. There were also many things that were proposed as an incorrect description of the phenomena they intended to describe, e.g. Yang-Mills Theory, but as we all know they turned out to be pretty important much later. Instead of all the vitriol and what sounds like Fox news pronouncements in the comment section about personalities, it might be useful for people to understand the field a little better before jumping to such strong conclusions.

28. **Bill**
May 3, 2013

different fields,
I do appreciate the difference between math and physics, and I do appreciate the way physicists think. Mathematics would not be anywhere near where it is today without physics. But we are talking about some fairness and balance (speaking about Fox News). Yes, it is not all "natural selection" in mathematics and there is some "breeding" by way of awards and recognition of certain people, results and areas. But nothing like this. At least, Witten is a genius who contributed enormously to mathematics even if string theory turns out to be completely irrelevant to physics. But can you say the same about NAH? If string theory turns out to be a failure, what exactly will be left to justify the Fundamental Physics Prize?

29. **Nex**
May 4, 2013

@7 Peter: It's just a quote due to Max Planck which aptly describes how prominent people in science are unwilling to change their established views even in the face of contradictory evidence. It takes new generations to really move on.

And we will likely all be dead by the time string theory is completely abandoned.

30. **David**
May 4, 2013

Bill,
If string theory is proven wrong that will have minimal relevance to Nima's work and the Fundamental Physics prize would still be justified. Nima's work on scattering amplitudes is an example of how ideas from ST can help develop and lead to advancements in our understanding of QFTs and gauge theory, as is evident just by looking at the kind of talks given at Strings conferences. You can't completely untangle the two.

Also I think the comparison to mathematics is unfair in that physicists really have to deal with the arbitrariness of nature. It would be like a mathematician finding 12 different solutions to a problem and having their result rejected by his/her fellow mathematicians because they don't like the method. In physics there are plenty of legitimate answers to open questions, but to a certain extent it becomes a matter of luck if its actually realized in nature.

31. **Bill**
May 4, 2013

Does anybody know what NAH is talking about after 1:34:10 mark in this video?

http://www.youtube.com/watch?v=rKvflWg95hs

What are those "new remarkable mathematical structures" related to number theory?

32. **Jim Akerlund**

May 5, 2013

I just saw the video and the “new remarkable mathematical structures” comment occurred at the 1:36:10 time mark for me. The video was released on youtube on 4/12/13 and looks to be about a six months old so I am guessing that the mathematical structures he is talking about is based on his recent paper about positive Grassmannian, arXiv:1212.5605 It is his only paper in recent years that was cross posted into these math subjects Algebraic Geometry (math.AG); Combinatorics (math.CO).

Jim Akerlund

33. **chris**
May 6, 2013

“In physics there are plenty of legitimate answers to open questions, but to a certain extent it becomes a matter of luck if its actually realized in nature.”

excuse me for stating this so bluntly, but that and exactly that is the kind of unscientific laissez-faire approach towards understanding nature that stalled the advance of science from Aristotele to Copernicus for almost 2 millenia.

physics is not an intellectual game of abstract brilliance. physics is about understanding nature. there is a very definite line between true and false and this is experiment. a theoretical concept, however brilliant it might seem, is just plain wrong if disproven. it might still serve as advice for future generations how one can fail. but that is it.

wrong is wrong and faliure, as spectacular as it might be, is still flaiure. i mean, please, just reflect for a second on the hubris of a statement like “but to a certain extent it becomes a matter of luck if its actually realized in nature”. i could understand it kind of if you had said something like “but to a certain extent it becomes a matter of luck whether one can guess the correct laws of nature” – even if i strongly disagree already with that statement. but the thought of physics as a purely intellectual effort that might or might not have to do something with the world outside (and whether it does – coincidentally i suppose – not having any bearing on the brilliance and admirability of the ideas) sort of lets me loose faith in our discipline.

just to get things straight: it is a choice one makes early in a particle physics career if one indulges in unfounded speculations and produces model after model that can be searched for and falsified. there is the alternative path of sticking close to experimental fact and doing the hard, grinding groundwork of amassing new knowledge. of course the first one is more sexy and of course the grandiose ideas get more media attention (which seems to be so central these days), but working science needs to weed out failed branches mercilessly and fast once they have died. there are too few people willing to provide this essential service to the community today. this blog being one notable exception.

once all the fuss has cleared, i hope things will be back to normal again and theoretical particle physics will be once more be about understanding nature and not about intellectual ego trips.

34. **Mitchell Porter**
May 6, 2013

“there are too few people willing to provide this essential service to the community today”

In his talks, Arkani-Hamed says technicolor is dead, focus point supersymmetry doesn’t work, and infrared modifications of gravity are outlandish. Is he one of the few people boldly rejecting failed hypotheses, in your opinion?

35. **Peter Woit**
May 6, 2013

Mitchell Porter,

There’s never been a shortage of prominent theorists willing to denounce unpopular theoretical ideas. Yes, Arkani-Hamed puts tombstones with “Technicolor RIP” in his talks and announces that he’ll kill himself if the Higgs is a technidilaton, but interest in technicolor has always been a minority viewpoint. The real question is when if ever he’ll start denouncing mainstream ideas that have failed.

36. **Bill**
May 6, 2013

Jim Akerlund,
Between 1:34:10 and 1:36:10 he is talking about deep connections to number theory and, in particular, Riemann hypothesis. The introduction to the paper you mentioned, arXiv:1212.5605, sounds very grandiose and mentions “remarkable new structures” too, but I did not see anything connected to number theory.

37. **Peter Woit**
May 6, 2013

Bill,

I think this is the sort of thing he is referring to

http://arxiv.org/abs/1105.2024

As usual with Arkani-Hamed, you might want to take some of his claims with a grain of salt….

38. **Bob Jones**
May 6, 2013

Bill and Peter,

I think Arkani-Hamed is probably referring to some connection between gauge theory scattering amplitudes and Grothendieck’s standard conjectures on algebraic cycles.

http://en.wikipedia.org/wiki/Standard_conjectures_on_algebraic_cycles

As Peter has already pointed out, there are results from the theory of motives that allow physicists to simplify expressions for these amplitudes. This is the “symbol” technique of Goncharov, and the original reference is

http://arxiv.org/abs/1006.5703

39. **Peter Woit**

May 6, 2013

Bob Jones,

If you know of any significant connection between new techniques in gauge theory scattering amplitudes and the Grothendieck conjectures you link to, I'd be curious to see a reference for it, since I've never seen such a thing.

To the extent that these new techniques involve use of the cell-structure of the Grassmanian, it's not surprising that one gets connections to quite a few areas of mathematics. Connections to deep conjectures about algebraic cycles in general, and specifically arithmetic aspects would be a lot more surprising (and interesting…)

40. **Bob Jones**
May 6, 2013

Peter,

There was a talk by Goncharov at this conference

http://www.birs.ca/events/2012/5-day-workshops/12w5053/videos

where I think he mentioned something about the standard conjectures. Unfortunately, the video is not online, so I don't really have a reference.

But yeah, the cluster algebra stuff that people are using to study the Grassmannian arises in many other parts of mathematics and physics. I've also heard Arkani-Hamed suggest in some of his talks that there might be physical reasons for the ubiquity of cluster structures since all of the theories that he and his collaborators are studying come from the six-dimensional (2,0)-theory.

41. **David**
May 6, 2013

Chris,

Sorry if you misunderstood me. You wrote

wrong is wrong and faliure, as spectacular as it might be, is still flaiure. i mean, please, just reflect for a second on the hubris of a statement like "but to a certain extent it becomes a matter of luck if its actually realized in nature". i could understand it kind of if you had said something like "but to a certain extent it becomes a matter of luck whether one can guess the correct laws of nature"

What I meant was the latter, that its a matter of luck in guessing the correct laws of nature. What I had in mind was pure SU(2) Yang Mills theory as was pointed out earlier. Its a beautiful idea but phenomenologically is off. The only point I was trying to make is that you cannot compare physics and mathematics in terms of how you define success because of the different ways in which we say something is true. In mathematics it has to be a logically consistent and rigorous solution. In physics it has to be a logically consistent (not rigorous obviously) solution and be observed. Its having your model be the right model of all the ones created that I think has an element of luck to it.

Also I think you have a distorted view on what most particle theorists do. I'm sure that the number of people looking hard at the data and numerical work for the LHC and other particle experiments is much larger then the people who work on the sexy topics of SUSY, ST, and what have you. Its just the latter you'll hear more about on this blog and in the media (which makes sense).

42. **Mitchell Porter**
May 7, 2013

Do the people complaining about the supersymmetric hegemony actually read hep-ph? There are about a hundred non-susy, beyond-standard-model papers there, every month.

43. **Julian Frid**
May 13, 2013

Categories: Book Reviews

Back in the year 2000, Gordon Kane published Supersymmetry: Unveiling the Ultimate Laws of Nature, a popular book promoting supersymmetry and string theory. The thrust of the book was that there was already indirect evidence for SUSY, with confirmation by discovery of superpartners due to come soon from LEP (which was running at energies near 100 GeV/beam) and the Tevatron (where Run II at high luminosity and nearly 1 TeV/beam was to start in 2001). The LHC was also discussed, mainly as the place that would confirm and extend the LEP/Tevatron superpartner discoveries.

Thirteen years later, with no hint of SUSY showing up as promised, not only at LEP/Tevatron energies, but also at the much higher energies and luminosities of the 8 TeV LHC, Kane has a new popular book promoting supersymmetry and string theory, entitled Supersymmetry and Beyond. It includes his claim to have predicted the Higgs mass using string theory (see Matt Strassler's take on this here, mine here). Much of the book though consists of exactly the same text as the 2000 version.

How does Kane handle the detailed failed predictions of the 2000 edition in the new 2013 version? Basically by editing them out, with no indication to the reader that this has been done. What's the right word to describe the result of an Orwellian exercise like this? You can make up your mind about that yourself, since I've gathered together here some examples of the book text, showing the edits that were done to create the new version.

Pages xvii/xviii

> Supersymmetry is still an idea as this book is being written ~~(mid-1999)~~ in late 2012. There is considerable indirect evidence that it is a property of the laws of nature, but the confirming direct evidence is not yet in place. That is not an argument against nature being supersymmetric; rather, the ~~accelerator~~ collider faciliti~~es~~y that could confirm it (the LHC) ~~are~~ is just beginning to cover the region where the signals could appear ~~(Chapter 5)~~.

Pages 2-3/3

> If we understand supersymmetry and its implications correctly, direct experimental evidence for supersymmetry will be found in the next few years – possibly soon after this book is published (or, with great luck, even before).

Pages 13/16

> ~~Only now are~~ colliders and detectors at laboratories are now achieving the energies and luminosities (amounts of data) and sensitivities needed to explicitly detect the superpartners ~~explicitly~~, at least if our thinking about their properties is more or less right.

Pages 70-71/77-79

> The manner in which supersymmetry explains the Higgs physics is elegant and has important consequences for how we expect to test supersymmetry experimentally. It is rather technical. ~~A more detailed description is given in Appendix B; here I will give a short version.~~ There are three parts…
>
> Therefore, the supersymmetric Standard Model explanation of the Higgs mechanism would not make sense unless ~~the~~ some superpartner masses were not much larger than the Standard Model masses they explain. That gives us an estimate of the masses we should expect the superpartners to have as we search for them~~, and it tells us at what stage we should question the validity of the theory if the superpartners have not been detected~~. Such estimates are only approximate, but luckily the expected masses are small enough that they imply the superpartners should be detected soon.

Appendix B was deleted entirely, it contained the text (page 156)

> ~~Therefore, the superpartner masses cannot be very much larger than the Z boson mass if this whole approach is valid. This is the only place where we can use the theory to relate the unknown superpartner masses to known masses, so on the one hand, it is a major test of the correctness of the supersymmetry explanation of the Higgs physics, and on the other, it is the most significant reason whey we expect the masses of the superpartners to have values that allow them to be produced at Fermilab or even LEP. This connection also suggests that if the superpartner masses are much larger than the Z boson mass, then the apparent success of the supersymmetry theory in explaining the origin of the Higgs physics of the Standard Model could be an accident.~~

Pages 88-89/89

> Several arguments imply that some sparticles are within the reach of ~~Fermilab~~ the LHC. ~~The strongest~~ One of the most appealing is based on the explanation supersymmetry gives for the Higgs mechanism of the Standard Model, as described in ~~the last chapter~~ Chapter 7. Basically the qualitative argument is that ~~because~~ since supersymmetry provides the Higgs mechanism that accounts for the masses of W and Z, ~~the~~ some sparticle masses cannot be much heavier than the W and Z masses themselves. ~~Fermilab has already produced and detected thousands of W's and Z's.~~ When this argument is ~~framed~~ put in a technical form, it implies that gluinos and probably charginos and neutralinos ~~and stops~~ should be ~~in the Fermilab~~ within the LHC reach. ~~If they are not, the impressive successes of supersymmetry listed at the beginning of Chapter 4 may be meaningless coincidences.~~ There are some arguments, both theoretical and phenomenological, suggesting that squarks and sleptons will be too massive to produce at the LHC.

Chapter 8, on SUSY implications for matter/anti-matter asymmetry, proton decay, rare decays like mu to e-gamma, and CP violation has been deleted. Appendix D, on large extra dimensions, has also been completely deleted.

Witten's preface has been edited:

> Experimental clues suggest that the energy required to produce the new particles is not much higher than that of present accelerators. If supersymmetry plays the role in physics that we suspect it does, then it is very likely to be discovered by the ~~next generation of particle accelerators, either at Fermilab in Batavia, Illinois, or~~ Large Hadron Collider (LHC) or its upgrades, at CERN in Geneva, Switzerland.

Comments

1. **In SUSY we trust**
   May 1, 2013

   We admire the consistency and the persistency of theorists who always predict that SUSY will show up at the next collider.

2. **johnnythelowery**
   May 1, 2013

Shameless is Kane. Kane is shameless. Kane is therefore Supersymmetric!
Good work and thanks for your Eagle eyedness.

3. **eric blare**
   May 1, 2013

   What's the right word to describe the result of an Orwellian exercise like this? The word is 'crimethink'. Email Gordy Kane a pdf or scanned copy of the above, with a prefatory comment that this is doubleplus ungood.

4. **jinb**
   May 1, 2013

   While there's no arguing against Kane's blind faith in supersymmetry, it's no more an argument against the appeal of the theory as a possible well-motivated mechanism in nature than to quote the rantings of an extremist muslim as an argument against religion being a bad idea in general.

5. **Colin Rosenthal**
   May 2, 2013

   He needs to future-proof his sentences – "Surely the workers will shake off their chains and rise to overthrow their masters within the next decade.". You don't even need to change that one for the second edition.

6. **theoreticalminimum**
   May 2, 2013

   Reminds me of Jonah Lehrer's copy-pasting/editing. Shame on Gordon Kane! Shame on the publishers!

7. **Bob**
   May 2, 2013

   The Amazon website has glowing reviews from Brian Greene and David Gross. Shame on them also!

8. **Peter Woit**
   May 2, 2013

   jinb,

   There might be evidence of a more general problem if the "extremist muslim" was being supported by the most highly respected other religious leaders, and leading interfaith organizations were awarding him prizes for his public pronouncements, as in

   http://www.aps.org/programs/honors/prizes/prizerecipient.cfm?last_nm=Kane&first_nm=Gordon&year=2012

9. **chris**
   May 2, 2013

   "the supersymmetric Standard Model explanation of the Higgs mechanism would not make sense unless ~~the~~ some superpartner masses were not much larger than the Standard Model masses they explain."

   Epic!

10. **Peter Woit**
    May 2, 2013

    Chris,

    My personal favorite among the edits is

    ~~it tells us at what stage we should question the validity of the theory if the superpartners have not been detected.~~

11. **El-Coco**
    May 2, 2013

    This is such a disgusting fraud on the public that Kane should be thrown out of his university. This is as bad, in its own way, as faking data for a paper.

12. **Shitake**
    May 2, 2013

    Peter: are there some parts of the book that are actually new? What percentage, roughly?

    What is most shocking to me is the edited blurb from Witten. Unless he had explicit permission from Witten for this, that is highly dishonest and unworthy of any scientist.

13. **Peter Woit**
    May 2, 2013

    Shitake,

    I'd say that maybe 1/4 of the book is new, mostly updated material about the Higgs and its discovery, some sections of the old book much more heavily edited than just replacing "Tevatron" by "LHC".

    Besides the edit I showed, a couple other sentences in the Witten preface have also been changed, (basically changing example of recent experimental progress from the discovery of neutrino masses to the discovery of the Higgs). The preface carries a revised date, and I don't see any reason to believe it was changed and reused without Witten's permission.

14. **Shantanu**
    May 2, 2013

Peter, great review.
just out of curiosity, does he mention evidence of neutrino mass as evidence for supersymmetry in his 2000 edition?

15. **old v new**
May 2, 2013

Send copies of the excerpts 'old and new' to Kane, Witten, Gross, Greene and ask for their reactions.

16. **Bill**
May 2, 2013

I don't see what the problem is with all these minor updates (e.g. accelerator to collider)? I couldn't find one change that would qualify as an admission of mistake, it sounds more like bringing the book up to date…

17. **Peter Woit**
May 2, 2013

Bill,

The fact that there is nothing at all in the new book that qualifies as an admission of mistake is precisely the problem (yes, I've shown the complete set of changes in these passages, some of the changes are minor). If you're a scientist and you write a book claiming to have a wonderful theory, that it makes specific predictions that are about about to be tested at LEP and Fermilab, and that your arguments are wrong if LEP and Fermilab don't see what you predict, what should you do after LEP, Fermilab, and the LHC at 4 times the energy don't see what you predicted? If you're going to "update" your book, don't you think you need to admit that your predictions turned out to be wrong? Instead, Kane has just deleted the predictions and the text saying that his arguments were wrong if the predictions were falsified, replacing them with new predictions about future observations at the LHC and future accelerators. Do you see a problem with doing this?

18. **Peter Woit**
May 2, 2013

Shantanu,

About neutrino masses and SUSY, both editions just say:

"Here supersymmetry is helpful in formulating ideas, but it has not played an essential role so far."

In the new edition he adds the claim

"If the underlying theory is supersymmetric, the needed extension of the Standard Model to include neutrino masses can be reliably done."

19. **Bill**
May 2, 2013

Peter,

Okay, I agree that he should have been more honest and admitted that his was too optimistic. But is it not possible that string theory will turn out to be correct in the end, maybe, after making necessary modifications?

20. **Peter Woit**
May 2, 2013

Bill,

I suppose that in principle it's possible that the product Kane is selling will some day turn out to have some value. But while he's selling the 2013 version, he owes it to his customers to inform them that almost the exact same thing in its 2000 version was defective and blew up in his face.

21. **Bill**
May 2, 2013

Peter,
Agreed.

22. **new book**
May 2, 2013

What justification does Kane offer for putting out a new book? Does he refer to his old book, or say why he did not publish a revised of his earlier book? In the latter case, it would be reasonable that most of the text would be the same, with some passages revised.

23. **Peter Woit**
May 2, 2013

new book,

Oddly, there's nothing at all anywhere in the text of the book to indicate that it's a revised version of an older book. On the cover, there's a new title, but also the words "Revised Edition", and the Library of Congress cataloging info on the copyright page describes the book as a revision of the 2000 version. Other than that though, I couldn't find any reference to the earlier version.

24. **Bill**
May 2, 2013

Peter, can you, please, explain in one paragraph to a non-expert what the experiments at CERN say about Standard Model, supersymmetry and string theory? What did the discovery of Higgs boson mean in this context and what do people expect to learn in the next few years? Maybe, you can point me to some relevant posts about this. How can the entire physics community be so wrong and dishonest? Am I wrong at interpreting your blog? Maybe, I should read your book, but some brief overview would be helpful.

25. **Peter Woit**
May 2, 2013

Bill,
Sorry, this is getting off-topic. A one-sentence answer though is that at the LHC the SM is confirmed, no evidence of SUSY, and string theory predicts nothing, results that most of the physics community (the wrong ones are a minority, the dishonest ones a small minority) expected.

26. **Eric**
May 2, 2013

Dear Peter,

I think that you are perhaps the most dishonest, by some margin. The fact is that the expectations for superpartner masses is closely tied to the Higgs mass, which was not known a decade ago. As the Higg mass turned out be somewhat larger than expected, although still below the MSSM bound, correspondingly the expected masses of the superpartners is larger. In particular, to obtain a 125 GeV Higgs essentially requres large radiative corrections from the stop quark. This implies that the stop quark and other scalars may be heavy, unfortunately possibly too heavy to be observed at the LHC. In addition, in the past decade or so, it has been realized that it is possible to have heavy scalars while still maintaining low-fine tuning, e.g. focus point supersymmetry. I see absolutely nothing wrong with Kane providing an update on the situation, which I must say is much more honest than your blatant attempt at negative propaganda.

27. **Mike**
May 2, 2013

Eric,

"As the Higg mass turned out be somewhat larger than expected, although still below the MSSM bound, correspondingly the expected masses of the superpartners is larger. In particular, to obtain a 125 GeV Higgs essentially requres large radiative corrections from the stop quark. This implies that the stop quark and other scalars may be heavy, unfortunately possibly too heavy to be observed at the LHC. In addition, in the past decade or so, it has been realized that it is possible to have heavy scalars while still maintaining low-fine tuning, e.g. focus point supersymmetry."

Assuming what you say is correct, wouldn't a more honest approach by Kane have been to at least mention his previous "predictions" and then use the foregoing as an explanation for why they fell short?

28. **CLAUDIE**
May 2, 2013

As a scientific observer – I truly cannot understand why there is such a disparity of opinion within the scientific community, regarding the topic of SUSY. There seem to be two conflicting camps – those whom see Supersymmetry as the light at the end of the otherwise boringly linear tunnel … and those whom regard those believers in Supersymmetry to be somewhat deluded. From what I have read no one knows or will know the true nature of the universe for some time (i.e. multiple lifetimes away!) so why be so dismissive. Surely to progress we must take a broader and more all encompassing approach. It's hardly a bunch of crackpots that believe in SUSY – it is in fact some of the greatest minds of out time. Nature is phenomenally complex after all…

29. **Peter Woit**
May 2, 2013

Eric and Claudie,

Arguments over the virtues or lack thereof of SUSY extensions of the SM have been going on for decades and will go on for more decades, with experiment for now (and I think for ever…) weighing in on the negative side. But that's not what this posting is about. It is about Kane's new book, and, more specifically, his choice to "update" the old one by just deleting every argument in it that experiment has shown to be wrong, without any acknowledgement that that is what he has done. I've documented accurately that in the posting, up to people to decide for themselves what they make of this.

To editorialize, I think Mike is quite right to point out that Kane owes his readers some explanations.

30. **DB**
May 2, 2013

Don't forget that SUSY was a useful argument to help justify the various colliders mentioned above, even if it was never the primary reason for building any of them. This is why physicists tolerated the nonsense hawked by the likes of Kane and Greene for so long. Now it's clear that there is virtually no prospect of the LHC ever seeing it, and very little prospect of a successor machine being built in our lifetimes. Therefore SUSY usefullness has expired and it's now an embarrassment. For this reason, it's increasingly career-toxic for young physicists to be seen to be associated with it.
The old men will cling to it, as without it string theory dies, and with it their hopes of immortal fame.

31. **MathPhys**
May 2, 2013

One of the reasons young people do science is the scientific ideal, wherein a scientist is perceived as honest, fair, and precise. Reading Mr Kane, one realizes that a scientist can also be a less-than-forthcoming salesman.

32. **M. Wang**
May 2, 2013

Over at Forbes.com, there is a columnist called Gordon Chang, who has predicted the total collapse of Chinese economy by year-end every year for the past two decades. He remains very popular at Forbes and has a sizable following. So, it would seem that some particle physicists has joined with stock market analysts in the rank of pseudo-sciences.

33. **kanefriend**
May 2, 2013

I've been a friend of Gordy Kane for many years, but this is going too far. It is technically not plagiarism, since the copyright says it's a revised version of the 2000 book. But it is scientifically unethical to erase, Soviet style, false predictions from the past as if they never existed. At the moment, there are no Amazon reviews. I hope someone (not me, since I'm not sure how anonymous they are) will write one pointing this out (with a link to this blog).

34. **Narad**
May 2, 2013

> What justification does Kane offer for putting out a new book? Does he refer to his old book, or say why he did not publish a revised of his earlier book?

Having made the acquaintance of a few acquisitions editors in my days, I wouldn't discount the possibility of the publisher's hoping to wring a few more dollars out of an old property.

35. **Peter Woit**
May 2, 2013

kanefriend,

Checking Amazon, someone seems to have taken up your suggestion.

36. **johnmcAllison**
May 2, 2013

Good work, the public needs to be informed.

I guess it's another example of physicists falling in love with the beauty of their theory, only to be slapped across the face by reality.

37. **Peter Woit**
May 2, 2013

new book, Narad,

I should make it clear that I see nothing wrong with putting out a revised version of a book like this, updated to include what has been learned over the course of the last 13 years. It is a little odd though not to mention in the preface that the book is a revised version and to explain a bit about the nature of the revision.

What is problematic is just the sort of editing going on in the passages I included in the posting, for reasons explained earlier.

One reason for this comment is that there seems to have been some misunderstanding about the point of this posting, see here:

http://blog.physicsworld.com/2013/05/02/supersymmetry-revisited/

38. **Maciej**
May 2, 2013

Quite ironically – individuals like Kane, while popularizing ST and writing a lot about it, are at the same time responsible for making other scientist literally laugh at ST claims.

I remember once at AEI there was a seminar about ST phenomenology given by B. Ovrut (who was all the time defending the point that ST makes predictions). At some point somebody asked "…yeah but Kane claims that he can predict 125GeV exactly!" to which Ovrut replied "It's amazing, isn't it?" – and then everybody laughed.

I think this example makes it clear that even for devoted string-theorists, claims by Kane are simply embarrassing.

39. **Henning Dekant**
May 3, 2013

It'll be funny if it wasn't so pathetic.

I see that some commenters suggested that there should be consequences for such blatantly unethical conduct. If somebody was to fake data for a publication there'd be a process to follow to get some traction.

Apparently when it comes to books for the great unwashed masses all is fair game?

40. **book**
May 3, 2013

Books come under the First Amendment. Publishing fake data is fraud. But writing a book, even a nonfiction one, and making idiotic or unsubstantiated or unjustifiable claims is different. As long as there is no libel or fraud or trade/patent/copyright violation or intellectual property theft, Kane can publish what he likes. If large numbers of people pan the book, well, Kane can cry all the way to the bank.

41. **M**
May 4, 2013

Eric, you are confusing two different arguments.
The naturalness argument (that correctly lead Kane et others to claim years ago that SUSY should be discovered at Tevatron) is only weakly affected by the measurement of the Higgs mass.
Next, this measurement offers a new, different, argument to guess the SUSY scale.

So, in order to avoid Orwellian doublethink, one should honestly say that the previous expectation has not been confirmed by Tevatron, nor by LHC.

42. **Eric**
May 5, 2013

M,

The naturalness argument is actually greatly affected by the measurement of the Higgs mass such that it leads to a new problem known as the little hierarchy problem. In point of fact, the mass of the putative superpartners in the MSSM is directly related to the mass of the Higgs via REWSB. If the Higgs mass had been below 120 GeV as expected for the last decade, one would have expected the superpartners to have shown up by now on the grounds of naturalness and all of Peter's arguments would have been correct. However, to get a Higgs mass as large as 125 GeV requires large radiative corrections and/or large left-right mixing from the top/stop sector. This generically means heavy squarks leading to the problem of introducing some fine-tuning. However, in cases such as focus-point supersymmetry, the squarks and sleptons can all have multi-TeV masses while fine-tuning remains low. So, it is quite possible that supersymmetry solves the hierarchy problem naturally while having squarks and sleptons which are too heavy to be observed at the LHC. Thus, not finding superpartners at the LHC does not make the existence of supersymmetry less likely or imply that supersymmetry has 'failed'.

43. **paddy**
May 5, 2013

Eric,
Do you have any idea how much your rationale sounds like sophistry (if not cavilling) to us practicing non-hep physicists out here?
Paddy

44. **Eric**
May 5, 2013

Paddy,

It is not my fault that persons such as yourself do not possess the technical knowledge to understand the real issues involved in this topic. If you were able to actually follow the physics and do the real calculations on your own, you would realize that what I am saying is completely accurate, while most of what you learn from PW is pure BS.

45. **paddy**
May 5, 2013

Eric,
Quite in character…the ad hominem attack. ..enough said.
(The so obviously ignorant) Paddy
PW: sorry about that distraction..I should have known better.

46. **chris**
May 5, 2013

Eric,

in all humbleness, i can follow and my BS detector is on red when i hear your arguments.

basically you are saying: well, there is this problem A (Higgs mass at the verge of excluding low energy SUSY all by it self), which we could not have forseen a decade ago. because of it, problem B (we see no superpartners) in not a problem at all.

the unnaturally high higgs mass naturally pushes the squarks unnaturally high. naturally this fulfills naturallnes, no?

take a deep breath, one mont off and look at it again. seriously.

47. **Yatima**
May 5, 2013

"If the Higgs mass had been below 120 GeV as expected for the last decade"

It is sad that one cannot post a reaction image. I somehow remember that "most" of the expectations were for m_H ≫ 120 GeV/c², what with the vacuum becoming unstable and all that.

Google-fu reveals:

http://arxiv.org/pdf/0708.3344v8.pdf

"Higgs-mass predictions" by Thomas Schücker

…in which we learn that there are 96 predictions, of which only 20 are below 126 GeV/c². One would of course need weight this with the "number of adherents"….

Anyway, let's have a quotation:

> Our list contains 96 Higgs-mass predictions. Supersymmetry is behind 26 of them with central values between 120 and 255 GeV. Compactified additional dimensions motivate ten predictions ranging from 117 to 450 GeV. There are three superstring inspired predictions: 117, 121 and 154.4 GeV. The embedding of the electro-weak Lie algebra su(2) ⊕ u(1) in the superalgebra su(2|1) produces four predictions: 130, 161, 250 and 426 GeV. Five predictions, between 124 and 317 GeV use the Coleman-Weinberg potential. One prediction, m_H = 125 GeV uses dynamical symmetry breaking with the Higgs being a deeply bound state of two top quarks. At the same time this model predicted two years prior to the discovery to the top its mass to be m_t = 175. Another prediction for the Higgs mass motivated by dynamical symmetry breaking via a neutrino condensate is at 178 GeV. We have listed four predictions from Connes's noncommutative geometry: 170, 203, 241 and 271 GeV. Lattice gauge theories lead to two predictions: 515 and 760 GeV. Eight predictions are based on the (approximate) vanishing of particular terms related to quantum corrections: 154, 155, 200, 210, 309, 374 and 536 GeV. We have two lower bounds for the Higgs mass and 37 upper bounds, 26 of which come from supersymmetry. Five predictions, one upper and one lower bound come from the recent idea that inflation is driven by the Higgs scalar together with a strong non-minimal coupling to gravity. The Higgs mass is obtained from fitting the observed spectral index and tensor-to-scalar ratio of the Cosmic Microwave Background.

48. **Yrast**
May 18, 2013

This is a very disingenuous review, and amounts to nothing but a personal attack on a first rate scientist…. The cover of the book clearly indicates that it is a REVISED EDITION. I don't see anything wrong with Kane's approach, which is common in popular scientific literature. The subject of the book is high-energy physics, not celestial mechanics. There are more wild ideas in his field than all the pages in the book…. Do you really expect authors of these bold theories to publicly declare their errors on every minute matter that is discounted by experimental results? To the best of my knowledge, they even don't do it in their professional milieu. They move on…

49. **Peter Woit**
May 18, 2013

Yrast,

This posting contains mainly just accurate information about changes Kane made to the 2000 version of the book. People can judge for themselves the significance of those changes, for instance whether the predictions about superpartners are a "minute matter", and whether Kane's approach is "common in popular scientific literature" (as well as whether, like you, they "don't see anything wrong with it").

50. **Yrast**
May 19, 2013

Peter,
The book has a 2 star rating on Amazon, mainly because of your posting (2 reviewers give it the lowest possible score with references and links to your blog). Certainly the gist of the posting as seen by those reviewers and me is not “just accurate information about changes…”. “Orwellian exercise!” really?

I have enjoyed reading your book (which has references to Kane’s books) and am an avid follower of your usually very informative blog.
Thank you for the great job.

Categories: Uncategorized

- There's an interesting discussion amongst philosophers at Brian Leiter's blog about the effects of Templeton money (and I contributed my two cents…). In other Templeton news, they're funding a new "literary science magazine" called Nautilus. Also via Leiter, they have awarded $3 million to two philosophers at Saint Louis University ("one of the largest grants SL has ever received in the areas of the humanities or the sciences") for them to study the subject of intellectual humility.
- In the category of rumors I've heard from so many reputable sources they must be true and I can't really be violating confidentiality, W. Hugh Woodin is moving from Berkeley to Harvard, and Simon Donaldson from Imperial College to the Simons Center at Stony Brook.
- Via Simon Willerton at the n-Category Cafe, Edinburgh now has a gallery with a wonderful collection of portraits of seventy mathematicians, including commentary from Michael and Lily Atiyah, an online version is here.
- The publisher sent me a copy of Tony Zee's new GR textbook, Einstein Gravity in a Nutshell, which I very much enjoyed looking through. Zee takes the textbook concept to new levels of informality, so it includes a wealth of interesting and amusing comments, spread throughout the text, footnotes and endnotes, including quite a few about quantum gravity. At over 800 pages, it's a pretty huge book, including a lot of conceptual material (as in his QFT textbook), but more calculational detail than the QFT book. Undergraduate physics students should find this quite an approachable text (unlike the QFT one, which I think you need graduate level training to really follow).

  This definitely is a text for physicists, not mathematicians, with the geometry taking a back-seat. Differential forms and orthonormal frames don't appear until nearly the end of the book. Personally I've found using the same language of connections on principal bundles to do gauge theory and gravity to make the most sense, but this involves getting familiar with quite a bit more formalism than most physicists are willing to deal with.

- I'd been curious to hear more about recent work of Jacob Lurie and Dennis Gaitsgory on Tamagawa numbers, and had been waiting to see a paper from them. Turns out there's something much better: Lurie has been teaching a course about this at Harvard this semester, with notes appearing here. For some indication of why you might take an interest in this if your interest is gauge theory, see here.
- While about the only bipartisan agreement in Washington these days is that something must be done to deal with the terrible problem of the shortage of STEM graduates in the US, someone has noticed that there actually is no shortage, see here.
- This past weekend there was a conference in honor of Bruno Zumino's 90th birthday at Berkeley, and one can hope that some version of the talks might become available online here.
- A hot topic in HEP remains that of when the failure of the SUSY picture that has been heavily over-sold for several decades will finally be acknowledged. From the list of titles at the Zumino conference, Maiani's was "Supersymmetry: not time to give it up, yet". Cormac O'Raifertaigh reports here that Nati Seiberg is saying ~~"only certain aspects of minimal models had been ruled out so far. As for the future, who knows?".~~ (now corrected, see Cormac's blog). Physics World has a story here, with Ben Allanach claiming that "data taken at the LHC have excluded roughly half of supersymmetry's parameter space" and that now one has to wait until 2015 when, if SUSY is right, it will be found nearly immediately:

  > "My hopes are pinned on the next run," he says. "The energy jump now is going to make the big difference. And if supersymmetry is the correct theory of nature, I would be expecting to see a big signal within the first month. If it doesn't crop up, I'll then be getting pretty depressed."

  Bill Murray of ATLAS makes the excellent point that

  > "Proving wrong would be as important as proving it right," he says. "Null results are hard to sell to newspapers, but they are really important to scientific progress."

  Killing SUSY will be one of the great achievements of the LHC, and complaining about this might be kind of like being upset that Michelson-Morley didn't find the ether.

Update: I've been pointed to an impressive photo of Robbert Dijkgraaf that unfortunately did not make the Atiyah Gallery.

Update: The New York Times has a story today about the new Templeton-funded science magazine Nautilus.

Update: The news from Britain is that Stephen Hawking has joined the academic boycott of Israel, cancelling plans to attend a conference there this month. Please discuss your views on the Israeli/Palestinian conflict elsewhere. There's no way I'm going to moderate such a discussion, and there are now surely dozens of other sites carrying this story where comments are encouraged.

   May 6, 2013

   My bad, my Seiberg quote wasn't very accurate, I have corrected it on the blog. What Nathan actually said was
   "…even if supersymmetry is not realized in the energy range explored by the LHC, it is still and will always be important. The impact of supersymmetry on theoretical physics and on mathematics has already been huge and it will continue to be essential..there are many parallels with other theoretical ideas that did not solve the problems they were designed to solve but turned out to be crucial in other contexts"

   Re PW comment above that "Killing SUSY will be one of the great achievements of the LHC" , I'm not sure what you mean; I don't see how the LHC can do anything except rule out certain models. And even if some successor to the LHC does, this doesn't preclude the idea that the general principle of a symmetry between fermions and bosons might be right at some level…which I think is how the cosmologists see UFT

2. **Alex**
   May 6, 2013

   Half of Susy parameter space? Killing Susy? That doesnt make sense, what on earth is Ben on about?

3. **Peter Woit**
   May 6, 2013

   Hi Cormac,
   I changed the posting to reflect the inaccuracy.

   I'm curious to follow how SUSY proponents are dealing with the current situation. Do they admit that the idea of electroweak-scale SUSY breaking, solving the so-called "hierarchy problem" is now pretty much dead (since if you believed that picture, you should have seen superpartners at LEP and the Tevatron, and the extra factor of four in energy at the LHC so far should have finished the idea off). Or do they hang in there, insisting that the next energy jump, by a factor of 13/8, will finally vindicate them?

I think the more sensible ones see the writing on the wall.

I don't disagree really with the revised quote from Seiberg. If the field replaces the idea that a MSSM broken SUSY extension of the SM is the way to pursue unification with the idea that SUSY as a general concept may have some connection to reality, in a way we don't yet know, that will be progress. And we'll have the null result from the LHC to thank, so it's quite important. On the other hand, if all the null result from the LHC achieves is inducing prominent theorists to keep moving up their SUSY mass estimates a la Gordon Kane, that will be just a sad chapter of scientific history.

4. **Peter Woit**
May 6, 2013

Alex,

I also wonder what measure Allanach is using on SUSY parameter space.

5. **Bill**
May 6, 2013

I will be very surprised if Jacob Lurie does not win Fields medal next year.

6. **MathPhys**
May 6, 2013

Now that I have accepted the fact that string theorists will keep on pushing the masses of the superpartners higher and higher, year after year, I also to accept the fact that anti-string theorists will express disapproval and disappointment every time that happens. Nothing will change.

The susy debate has officially moved from the domain of science (*"Let's see what the experiments say"*) to the domain of ideology (*"There is no way, no way in hell, that anyone can rule out supersymmetry"*).

Since there is no point, and no reason, to argue with another man's religious beliefs, let's talk about something, please.

7. **Kyler**
May 6, 2013

Actually Jacob Lurie's class is being taught at Stanford, where he is currently visiting.

8. **GT**
May 7, 2013

I believe that Donaldson is actually splitting his time 8 months/4 months between Simons/Imperial, rather than moving altogether.

9. **cormac**
May 7, 2013

Hi Peter, many thanks for the revised text.
Re e-w SUSY breaking, I don't know, only the SUSY theorists themselves can answer that, as you know! yes, Natt'squote is great, I immediately thought of Yang-Mills

10. **Marcel van Velzen**
May 7, 2013

"Killing SUSY will be one of the great achievements of the LHC, and complaining about this might be kind of like being upset that Michelson-Morley didn't find the ether"

Well, things are not always that simple: Due to the constant speed of light, all fundamental particles in the electroweak theory have to get their mass from the omnipresent Higgs field. (As far as we know now a particle is not composite (and so by definition fundamental) if and only if 1 it is massless or 2 gets its (rest) mass only from the Higgs field). So Michelson-Morley did find some kind of ether when they found that the speed of light was constant. In that respect I agree with Cormac above "the general principle of a symmetry between fermions and bosons might be right at some level".

11. **Krzysztof**
May 7, 2013

Peter,

Funding interdisciplinary activities across science vs philosophy borders is not trivial, whereas 'the question of God' is obviously one of the central ones in philosophy (be it in a positive or negative way…), so why you have problems with these funds by Templeton? Are you maybe part of the S. Weinberg et al. efforts?

12. **Peter Woit**
May 7, 2013

Krzysztof,

I've written extensively about Templeton here on the blog (search on "Templeton" on the main page if interested). It's a complicated subject, but the simple part is that they're spending hundreds of millions of dollars with the goal of bringing science and religion together, and I strongly believe they are best kept apart, especially when it comes to fundamental physics. I also strongly believe that discussions of religion on internet blogs are basically always stupid and a waste of time, so, please, not here….

13. **Krzysztof**
May 7, 2013

Peter,

Of course I will obey… but let me just stress that above I was not talking about religion, but about philosophy. Unless you think that there is only philosophy of science there, my argument is still valid I would think, and I hence do not get your point – you think there is misuse of funds? But then we might consider closing all humanities… Please, keep in mind that I am just asking an academic question (in the direct sense:) and not trying to bring closer religion to fundamental sciences.

14. **Peter Woit**

May 7, 2013

Krzysztof,

My concern here is about the Templeton Foundation's very well financed goal of injecting religion into this (and I think this is the same concern being discussed on Leiter's blog). It's not a "misuse of funds", they are very clear about what they are trying to do, and they have every legal right to do it. I just think that people need to be aware that, for instance, when they all of a sudden see "Philosophy of Cosmology" conferences, talks, blogs, books, etc., there is a reason for this. A very wealthy group devoted to bringing religion and science together has decided this is an effective way to spend their money. Some of what comes out of this will be perfectly respectable science or philosophy of science, some of it will be pseudo-science (the multiverse), and some of it will be dubious injections of religion into science, but, in any case, people should be made aware of what is going on here.

15. **Krzysztof**
May 7, 2013

Peter,

I promise this is my last post and I shut up, but you mix two things I think:

1. I agree – multiverse is not physics, and its (very many) promoters should not claim so, but that is not the same as doing some properly labeled, inter-disciplinary stuff.

2. Fundamental science naturally, 'by definition', is raising philosophical questions. Many of us are very curious what is 'meaning' of physics – is for example the probabilistic QM end of story etc.

Finally, I think you are a bit oversensitive to religion – it plays so little role in the 'western' academia anyway.
(And it is not all bad maybe at the end – two greatest revolutions in cosmology were led by priests – Copernicus and Lemaitre – after all 🙂

16. **Peter Shor**
May 7, 2013

Re: the STEM job non-crisis report, let me point out that you can prove anything with statistics. One quote from the report:

"For computer science graduates employed one year after graduation (i.e., excluding those unemployed or in graduate school), about half of those who took a job outside of IT say they did so because the career prospects were better elsewhere, and roughly a third because they couldn't find a job in IT. "

This means that many of those who took a job outside of IT did so because these were better jobs. I don't know what these jobs are, but I am assuming many of them are reasonably high-level (since they're better than the IT jobs these students were offered). Do we really want to fill them with technologically illiterate people?

That, of course, depends on the job, and the report doesn't give enough detail to answer this question.

17. **aether**
May 7, 2013

Let's main some sense of historical perspective. The Michaelson-Morley experiment never disproved the luminiferous aether. The theory simply became more and more contrived as new data came in. For example Lorentz-Fitzgerald and the length contraction idea was introduced to explain some of the observed null results for the aether wind. But as more measurements were made, the theoretical constructs became more and more artificial. But the theory was never *disproved* per se. What happened was that Einstein introduced the Special Theory of Relativity, and that not only explained all the observed data, but it was able to fit new results without modification of its basic principles. And so people simply abandoned the aether theory in favor of relativity. So about LHC and SUSY, nothing will ever disprove SUSY. The models will simply get more contrived. What needs to happen is that an alternative theory will come along, which can explain all observed phenomena (explain naturalness?) and also fit all future measurements without change to its fundamental principles. That simply hasn't happened yet, but that's the way theories die out.

18. **Chris W.**
May 7, 2013

On the conference in honor of Bruno Zumino, see [this post] from Steve Hsu, with photos of a few of the participants.

19. **paddy**
May 8, 2013

@Peter Woit concerning Brian Leiter's blog:
My head is aching attempting to follow the arguments pro and con (I think) of the potential of bias on accepting Templeton funds. The only phrase that comes to my bewildered mind is "slippery slope"–a locale where I believe these folks frolic and you are just pissing in the wind…so to say.
paddy

20. **ca$$$$h**
May 8, 2013

It's all well and good to turn up one's nose at Templeton funding, but the fact remains, one needs funding anyway, and where do you propose to get it?

Written in 1946 when Brookhaven National Lab was being planned, and a sequel in 1956

Take away your billion dollars

Arthur Roberts, 1946

Upon the lawns of Washington the physicists assemble,
From all the land are men at hand, their wisdom to exchange.
A great man stands to speak, and with applause the rafters tremble.
'My friends,' says he, 'You all can see that physics now must change. Now in my lab we had our plans, but these we'll now expand,
Research right now is useless, we have come to understand.
We now propose constructing at an ancient Army base,
The best electronuclear machine at any pace.

Oh — It will cost a billion dollars, then billion volts 'twill give,
It will take five thousand scholars seven years to make it live.

All the generals approve it, all the money's now in hand,
And to help advance our program, teaching students now we've banned.
We have chartered transportation, we'll provide a weekly dance,
Our motto's integration, there is nothing left to chance.
This machine is just a model for a bigger one, of course,
That's the future road for physics, as I hope you'll all endorse.

And as the halls with cheers resound and praises fill the air,
One single man remains aloof and silent in his chair.
And when the room is quiet and the crowd has ceased to cheer,
He rises up and thunders forth an answer loud and clear:
'It seems that I'm a failure, just a piddling dilettante,
Within six months a mere ten thousand bucks is all I've spent,
With love and string and sealing wax was physics kept alive,
Let not the wealth of Midas hide the goal for which we strive.

Oh – take away your billion dollars, take away your tainted gold.
You can keep your damn ten billion volts; my soul will not be sold.
Take away your army generals, their kiss is death I'm sure.
Everything I build is mine, every volt I make is pure.
Take away your integration and let us learn and let us teach.
For beware this epidemic, for colitis I beseech.

Oh, dammit – engineering isn't physics – isn't that plain?
Take, oh take your billion dollars. Let's be physicists again.

1956, ten years later (sequel)

Within the halls of NSF the panelists assemble.
From all the land the experts band their wisdom to exchange.
A great man stands to speak and with applause the rafters tremble.
'My friends,' says he, 'we all can see that budgets now must change.
By toil and sweat the Soviets have reached ten billion volts.
Shall we downtrodden physicists submit? No, no — revolt!
It never shall be said that we let others lead the way.
We'll band together all out finest brains and save the day.

Give us back our billion dollars, better add ten billion more.
If your budget looks unbalanced, just remember this is war.
Never mind the Army's shrieking, never mind the Navy's pain,
Never mind the Air Force projects disappearing down the drain.
In coordinates barycentric, every BeV means lots of cash,
There will be no cheap solutions, — neither straight nor synoclash.
If we outbuild the Russians, it will be because we spend.
Give, oh give those billion dollars, let them flow without an end.

21. **Peter Woit**
May 8, 2013

paddy,

I think I agree with you. By now I can't even figure out what it is that Tim Maudlin was trying to argue with me about there, presumably I missed his previous point so my response caused a complete divergence from coherent discussion. In any case, the various relevant arguments seem to have been made multiple times.

ca$$$$h,

If Templeton will fund the next energy frontier accelerator, I'm all in favor of having theologians speak at the Lepton-Photon and other conferences where results are announced.

For those who just can't get enough Templeton, at the Leiter blog I did learn of a bizarre Templeton-funded contribution to mathematical logic, see here:

http://www.math.osu.edu/~friedman.8/pdf/ConMathThe122512.pdf

For more discussion of the physics/God/Templeton issues, Sean Carroll has this:

http://www.preposterousuniverse.com/blog/2013/05/08/on-templeton

22. **ca$$$$h**
May 8, 2013

Has anyone suggested to Templeton to fund the next energy frontier accelerator? Or maybe a detector? Or at least R&D into, say, a muon collider?

Private organizations (e.g. Keck) do fund telescopes. Telescopes are cheaper, relatively speaking, maybe 1B, are quicker to build, and the results yield better PR for the funding agency. A serious problem with accelerators is the induced radioactivity. One can't just build even a low energy accelerator in one's back yard, even if 100% privately funded. The radioactivity automatically makes the device subject to many federal regulations.

23. **Galileo's Meme**
May 9, 2013

I think the funding for "free will" studies is what needs to be regarded with the greatest wariness. Free will appears to be a major hobby horse for the current right-wing establishment–presumably for for a variety of reasons, not the least of which is certainly the way it is constantly trotted out to defend the USA's draconian sentencing requirements and staggering incarceration rate, and the bourgeoning private prison industry that feeds off of them.

Currently the preferred defense of free will in right-wing circles seems to be an appeal to religion, but it looks to me like they want the respectablity of a "scientific" defense of free will, preferably free will of the philisophically "strong" variety rather than the namby-pamby compatibilist sort that packs little more rhetorical oomph than the physicist's metaphorical invocations of "God". An early attempt that mixed together some warmed-over process theology with handwaving about the delayed-choice experiment seems to have landed with a dull thud, but I doubt it will be the last we hear on the subject.

(Perhaps not coincidentaly I've heard that some Chinese univeristiess are starting to push process theology as some sort of "indigenous" approach to science–and coming from an archetypically Chinese name like Alfred North Whitehead why not–maybe someone ought to look into whether some stateside group is beavering away over there as well.)

24. **Carl**
May 10, 2013

Galileo, you forget something.. No free will also means that the judge and the jury has no free will. Without free will how can you criticize a judge for handing out tough penalties for minor crimes?

25. **paddy**
May 10, 2013

Are not discussions which employ words and phrases such as "god" and "free will" a sure sign that we have gone "one toke over the line, sweet jesus"?

26. **anon**
May 10, 2013

Apparently there are different opinions on the "STEM shortage." Below is a link to a discussion of a study that find results that disagree with the study you linked to.

http://techcrunch.com/2013/05/10/3-graphs-explain-why-there-is-a-tech-talent-shortage-and-immigrants-are-needed/

Hard to tell which study is closer to the truth. The same discussion goes back and forth in Germany, where companies keep complaining about a shortage of engineers etc, yet are unwilling to increase their salaries or invest in their education.

27. **Peter Woit**
May 11, 2013

anon,

I don't actually see anything in those numbers that disagrees with the other study. The numbers in your link show it takes longer to fill H1-B STEM jobs and they are better paid than average. Presumably this has always been true, and says nothing about the argument that there are plenty of US STEM graduates out there, but they are choosing to take other kinds of jobs, would take the H1-B STEM jobs if they paid better.

The article linked to is also kind of dishonest in its use of numbers. It says STEM wages are "growing", with an 8% growth since 2000, neglecting to mention that all the growth was in 2000-2004, with wages basically flat over the last ten years (down recently in one category).

All in all, I see no numbers addressing the argument that there are plenty of qualified workers in the US, and that whatever problems employers are having hiring people are simply due to their offering lower wages for STEM work than for other opportunities STEM graduates have.

28. **srp**
May 11, 2013

All employers facing normal, upward-sloping supply curves for labor (meaning they would have to pay more to attract more workers) say they face a "shortage." This is not what an economist would call a shortage, but it is common for managers to see it this way: "If I could only hire more workers as good as the ones I have at the same compensation level I could make more money." But every firm tends to hire workers up to the point where it is no longer expected to be profitable, so every firm's managers feels that they face a "shortage."

Strictly speaking, a shortage would only occur if the wage were artificially suppressed so that at that "going" wage quantity demanded exceeded quantity supplied. That would be like when rent controls keep rates below the market-clearing value so that more people are always willing to be tenants at those rates than there are spaces available to be rented. But nothing like that is going on in the US STEM labor market. We just have employers saying that it isn't profitable to hire at the wages they would need to pay to attract more workers.

29. **Peter Woit**
May 12, 2013

srp,

Some of the companies most loudly complaining about the "shortage" though are extremely profitable (e.g. Apple and Google). It's hard to believe that paying higher wages to attract certain employees would really ruin their business and make it unprofitable.

30. **PeterPetersonSenior**
May 12, 2013

This is a comment on STEM workers short paragraph. I was hiring a lot of STEM professionals, and met all range form people that can do their job to bright stars to people that destroyed all projects they were part of. On another positive note, I know history of professionals that graduated in STEM and some time later found a different line of work – sometimes using their education directly and sometimes not.

I would say, if you think about any specialty of physics you will have to concede it applies there as well, and pretty much in any other profession with which you have close familiarity.

After many years of personal involvement, my impressions are:
1) There is tremendous shortage of very high level engineers. You taught a lot of students yourself, and you know that there is a whole distribution of talents – from genius to great to average to below average to some that graduated with lowest possible grade. The final GPA ofter correlates with engineer's performance for many years after graduation, sometimes forever. The top talent is rare, also education is to a large extent a memory exercise on BE, BS or MS level, creativity is somewhat different talent.
2) People receiving a (specifically) engineering degree are not necessarily working by their major specialty (either immediately, or after a few years). There are a lot of people in sales, support, etc. that do well. There are people that decide they just want to do something different, and no one can force them.
So the point is to bring talent into the country. There is a protectionist uproar pretty actively going on, and it is understandable. However bringing 20 STEM professionals to find 1 that makes all the difference for their company is very important (that is assuming that company acts as meritocracy, and many most dynamic are). And having

this talent makes it possible for their a bit less talented coworkers to have jobs where they can do just as important footwork after the new concept is invented.

31. **Peter Woit**
May 12, 2013

PeterPetersonSenior,

I've never heard the argument before that the US needs to bring in large numbers of mediocre engineers in order to also get a small number of highly talented people. In the academic fields I know of, the most highly talented people from outside the US are generally recognized as such, there's active competition among US universities to hire them, and as far as I know there's never a significant problem getting them visas to work in the US.

If the H1-B program only applied to exceptional job candidates that the hiring company was willing to pay an exceptionally high wage for, it wouldn't be an issue.

32. **PeterPetersonSenior**
May 13, 2013

I think we are in agreement on H1-B – at least regarding the goal to get exceptionally talented people. However there no way to definitely verify one's abilities, not until after they start working. This is why my 1 in 20 guesstimate.

As for paying exceptionally high wage for exceptionally good performance – this was always my approach. And this is where I was hitting the shortage. I understand that other companies may have different attitudes, but I don't think the primary motivation is to get cheaper mediocre engineers for all of them.

A short remark about Apple – Apple is very profitable, but you may be aware of the debate going on in investing community whether after Steve Jobs demise Apple has enough talent to move company forward (and stock price dropped exactly because of profitability percentage drop). I am sure Jobs was not the only reason for Apple's rise, but often there is a need for just a handful of people that make a lot of difference even for company of Apple size.

33. **PeterPetersonSenior**
May 13, 2013

Sorry for sending second response in a row. Just one observation – when you note: "In the academic fields I know of, the most highly talented people from outside the US are generally recognized as such, there's active competition among US universities to hire them, and as far as I know there's never a significant problem getting them visas to work in the US."
Let me turn the question other way around and ask: what is instead accepting talented people from anywhere in the world, we decided to fill the positions by US born and educated people. Surely, we are graduating more than enough PhD s to fill all academic positions? With all H1-B reasoning attached? I am sure, this would not be ideal.

34. **tt**
May 13, 2013

umm, actually that sounds good to me.

35. **Peter Woit**
May 13, 2013

PeterPetersonSenior,

Sure, if US academia couldn't hire exceptional non-US citizens, you could still fill all academic positions, but that would seriously weaken many departments. But, still, I don't think the issue of exceptional cases is relevant to the debate I'm seeing over H1-B. There people are talking about dramatically expanding a program that is already bringing in over 100,000 people, only a small fraction of whom are exceptional cases.

36. **G P Burdell**
May 14, 2013

When you think of hiring STEM graduates, don't think in terms of hiring established researchers; think of accepting graduate students as teaching assistants. Because that's the equivalent level of knowledge and understanding. Even the most talented ones will need years of experience and further training to become fully contributing professors and researchers. Yet most companies today look for a newhire with a particular set of skills (that they find using key-word searches of resumes), and expect skill levels capable of almost immediate contribution on major projects with essentially no further training.

Add to that that in most companies, any further training (formal or informal) is now almost always confined to an employee's private time. (I've been told by corporate-level software development managers that they expect an employee to be "enthusiastic" enough to learn new technologies on their own, not at company expense — even while those people are working 12- and 14-hour days with no overtime pay.) And since most engineers change jobs several times, actual mentoring is almost unheard of.

Then, the starting salaries for these positions, whether for graduates or for those with experience, haven't advanced beyond inflation in the last decade — in fact, some went down during the recession.

Hence the compaints about the "shortage" of "qualified" STEM talent in the U.S.

For these companies, most engineers are cogs in their machine — interchangeable parts. If they can buy a cheaper cog, then they buy it; hence the H1-B Visa push, using the self-created "skills shortage" as an excuse.

Number Theory News

May 12, 2013
Categories: Uncategorized

A special seminar has been scheduled for tomorrow (Monday) at 3pm at Harvard, where Yitang Zhang will present new results on "Bounded gaps between primes". Evidently he has a proof that there exist infinitely many different pairs of primes p,q with p-q less than ~~17,000,000~~ 70,000,000.

Whether this proof is valid should become clear soon, but there still seems to be nothing happening in terms of others understanding Mochizuki's claimed proof of the abc conjecture. For an excellent article describing the situation, see here.

Update: The "bounded gaps" talk is now on the Harvard seminar listing with abstract

> The speaker proves that there are infinite number of pairs of primes whose difference is bounded by 70 million.

For more on the significance of this, see this Google+ posting by David Roberts.

I haven't seen a paper, but rumor is that one exists and two referees at a major journal have found it to be correct.

Update: The most recent version of Mochizuki's lecture notes for a general talk about his work is here. As mentioned in the Caroline Chen article, Go Yamashita has been talking to Mochizuki. Yamashita has now posted a short document FAQ on "Inter-Universality" and promises "For the details of the theory, please wait for the survey I will write in the near future." He also notes:

> I refuse all of the interviews from the mass media until the situation around the papers will be stabilised.

Update: In a weird coincidence, another major analytic number theory result is out today, a proof by Harald Helfgott of the ternary Goldbach conjecture. This says that every odd integer greater than 5 is the sum of three primes. The result had been known for all integers above e^{3100}, and Helfgott's proof reduces that bound to 10^{30} which is small enough so that all smaller values can be checked by computer.

Update: *Nature* has a story up about the Zhang result, including details of one of the *Annals* referee reports (I gather the paper will be published there).

Update: For some background to the methods being used by Zhang, see here. For Terry Tao on Zhang, see here, on Helfgott, here.

Update: New Scientist has a story about the Zhang result here, with quotes from Iwaniec, who has reviewed the paper, finding no error.

Update: A report from the talk at Harvard is here.

Update: There's more about the Zhang proof at Emmanuel Kowalski's blog, including a link to the Zhang paper.

Update: Nice piece about this in Slate from Jordan Ellenberg.

Comments

1. **Jeff M**
   May 12, 2013

   So I'm tempted to believe this simply because it's 17 million, yellow pigs and all that…

2. **JG**
   May 12, 2013

   hmm, 17 million, they're not exactly twin primes, Hardy and Littlewood would be only mildly impressed (but impressed nonetheless)

3. **Ninguem**
   May 12, 2013

   There is nothing on the Harvard Math. Dept. website about this seminar at the moment.

   http://www.math.harvard.edu/seminars/index.html

   The only mathematician by that name that I found is a lecturer at UNH that goes by Tom Zhang. Is that him?

   http://www.math.unh.edu/faculty

   Peter, could you give the source of your information?

   If this result holds, it's a big deal, JG's comment notwithstanding. Chen Jin Run's old result was a big deal and this is a lot more. Twin primes is a hard, hard problem.

4. **Peter Woit**
   May 12, 2013

   Yes, this is the Yitang Zhang at UNH. The source of the information is an e-mail circulated by Yau to announce the seminar. There's been a correction to the 17 million, now it's 70 million.

5. **Shecky R**
   May 12, 2013

   need to correct the correction (UN-strikeout 70,000,000)

6. **S**

May 12, 2013

Awesome news link on the ABC, Peter, thanks. I was a little perplexed by this quote, though:

"For centuries, mathematicians have strived towards a single goal: to understand how the universe works, and describe it."

I thought that was physicists?

7. **Urs Schreiber**
May 12, 2013

I have been disagreeing a bit here https://plus.google.com/108081058828040288656/posts/aTMDLugKbHR with that article by Chen, concerning the claim that what Mochizuki writes is plain "gibberish".

8. **Steve L**
May 12, 2013

@S, I had the exact same reaction to that line. "Science journalism," sigh. Still, pretty good summary of the situation … especially with Mochizuki maintaining radio silence to the consternation of the entire math community.

I'm curious, did anyone send the author money? Ten years from now there will either be no content providers; or we will have figured out how to compensate the class of professional freelance content providers.

9. **Art Brown**
May 12, 2013

@Steve L: I tried (for $1) but my (good) card was not accepted by Paypal. So much for the future…

10. **Peter Woit**
May 12, 2013

Schecky R,
Thanks, fixed.

11. **Mike**
May 13, 2013

Mochizuki's claimed proof is not even wrong!

12. **Clayton**
May 13, 2013

I sent the author $4. I thought the article was exceptionally well-written and clear, overgeneralizations about mathematics aside. In fact, I was planning to ask Peter for an update on the status of the ABC conjecture sometime soon. It seems like the status is not very promising.

13. **arx**
May 13, 2013

Nothing on the arXiv?

14. **Peter Woit**
May 13, 2013

arx,

No paper publicly available on the arXiv or elsewhere as far as I know. But rumor is that there is a paper that has now been checked by referees at a top journal, so there's a lot of optimism that Zhang has a correct proof.

15. **Thomas**
May 13, 2013

from the abstract of the talk : "The speaker proves that there are infinite number of pairs of primes whose difference is bounded by 70 million"
And so what?
What is the significance of this result?

16. **Jeff McGowan**
May 13, 2013

@Thomas,

Not that I'm a number theorist, but I believe the best know result in this direction is that there are an infinite number of pairs of primes with p_{n+1}-p_n less than c log(n) (due to Erdos I think) and recent results show that you can let c -> 0. This of course is a significant improvement on that since there is no dependence on n. Someone please correct me if I'm wrong, i was too lazy to check on Wikipedia, and I haven't really followed number theory since I took a class with Peter Sarnak in grad school…

17. **Peter Woit**
May 13, 2013

Thomas,

I'll add something to the posting about the significance, but, basically this is progress towards the "twin prime conjecture". Naively one might think that primes just become uniformly sparser and sparser as you go to larger numbers, but this says that you're always going to find pairs relatively close (e.g. for 70 million "close") no matter how far out you go.

18. **Thomas**
May 13, 2013

Jeff & Peter, thank you for taking the time, this helps.

19. **Michael**
May 13, 2013

"…rumor is that there is a paper that has now been checked by referees at a top journal…"

Come on, this blog is all about objecting to hype. You shouldn't be doing this.

20. **Peter Woit**
May 13, 2013

Michael,

I've seen no evidence so far that this is hype. Spreading rumors is part of the mission statement of this blog, when they're rumors I have good reason to believe…

21. **Richard**
May 13, 2013

> You shouldn't be doing this.

Meanwhile, over at Matt Strassler's scrupulously peer-reviewed and rumour-free blog, not a breath about prime gaps! Now *that's* what I call professionalism.

If you do feel you need to learn more than scurrilous hype surrounding this 70 megascalar "result-like" scale-independent gap exclusion, you ought to respect the scientific process and wait until it is had been properly vetted and the publisher has printed the journal and mailed it to your institution's library.

22. **Jon**
May 13, 2013

If two journal referees back it up and a Harvard seminar is planned, then that's a rumor worth spreading!

And I'm quite curious how this will pan out: that would be a major result, and Zhang seems to be a 50+ lecturer with few previous papers, so that's potentially a nice story too.

23. **prep**
May 13, 2013

If two journal referees back it up and a Harvard seminar is planned, then it makes no sense not to already circulate a preprint. Someone should ask him to post something on the arXiv and/or personal website.

24. **Ionica**
May 13, 2013

I wish there was a like-button for some of the very funny comments above. I think it is nice to post about these rumors, doing so adds a little excitement to our field. It is not as if we all stop working and hold our breath until we see the proof.

25. **Richard**
May 13, 2013

I would like to know what you think about this "proof as a social construct" idea:

http://mathbabe.org/2012/11/14/the-abc-conjecture-has-not-been-proved/

http://mathbabe.org/2012/08/06/what-is-a-proof/

26. **Peter Woit**
May 13, 2013

Richard,

I pretty much agree with mathbabe on this, as most things (by the way, she's a good friend). For a related take on the role of proof, see Bill Thurston's fascinating essay "On proof and progress in mathematics", available here

http://arxiv.org/abs/math.HO/9404236

Something that struck me when I moved from the physics to the math community was the extent to which mathematics really is a living, oral tradition. Several times when I asked mathematicians where I could go read about something, their answer was "there's nothing easily readable available, but call up or go see X and he/she will explain it to you." (this was before the internet or e-mail or mathoverflow…).

One thing that Cathy doesn't emphasize is that it's not necessary for someone trying to convince the math community that they have a proof to travel around, talk to people, give lectures etc. It's fine if they don't like doing this, all they have to do is to follow the standard tradition of writing up their work in a form others can understand and sending the manuscript to a high-quality journal for refereeing. If it's an important result, the best experts in the field will generally be willing to work very hard as referees to check it. As far as I know Mochizuki hasn't done this, and I don't know what his reasons are. His papers are so difficult to follow that the refereeing process would likely be a hard one to carry through, but this is not that unusual. The initial reaction from expert referees might be "this is not comprehensible for reasons X, Y, and Z, the author needs to rewrite the thing before it can be checked."

So, there's lots of interesting things to discuss and argue about concerning how proof really works in the math community, but in this case, there's one very simple thing to say: if Mochizuki wants people to acknowledge that he has a proof, he needs to submit one or more papers with complete details to a good journal for refereeing. I hope what is going on is that now that he thinks he has a finished proof, he is writing up all the details in as clear a form as possible, and planning on sending the result to a journal.

27. **S**
May 13, 2013

I would have to say, I think that (with all due respect to a very interesting blog) mathbabe is pretty out there when she suggests that, if the proof is right, but this is not discovered for many years, and it is then realized to be right through the work of some fictitious additional "M", then "M" should receive equal credit with Mochizuki. I can't really see this happening, given the primacy that is rightly granted to coming up with the big ideasl; nor should it.

We have a recent example of something not entirely dissimilar. Perelman's proof presumably would have remained incomprehensible for a long time if not for the serious and dedicated work by a few small teams in translating and expanding on it. Several of those involved were rewarded with improved stature and even better jobs, which is only fair; but I don't think anybody makes the mistake of thinking that they, and not Perelman, proved the Poincare conjecture.

28. **S**
May 13, 2013

(I suppose there is a sliding scale, though. Various people who "rediscovered" something that CF Gauss had not bothered to publish do typically get dual credit for discovery; I suppose one can imagine a spectrum, where if a paper were released that was so genuinely incomprehensible that even much work were not rewarded in understanding it, then somebody who, perhaps inspired by the general approach, managed to reinvent the techniques and illucidate the paper would probably also get and deserve dual credit.

Sorry for the double post)

29. **Peter Woit**
May 13, 2013

S,

I think she's exaggerating a bit to make a point. For instance, no one believes that referees should share significant credit for a result they check, no matter how hard they have to work (unless they have to fix serious errors…). You can make up all sorts of hypothetical situations to argue about how to balance credit for an author's work and what needs to be done so that others understand it, but sticking to actual examples, the Perelman story was very different. He did not provide details of his proof, but did provide sufficient explanation of the new ideas needed for a proof so that experts could fill in the details (with a sizable amount of work..). He travelled around to meet with experts and give lectures explaining his ideas (I was at one here at Columbia, as it happens, sitting next to Richard Hamilton), and he patiently answered questions from experts who wrote to him to ask him for details of specific arguments. From what I remember, it fairly quickly was clear to experts what his new ideas were and what his argument was, even if checking in detail that the argument worked was a fairly long process.

So, there are lots of ways of doing this, of communicating the ideas that make up a proof to the rest of the community. At first I thought that the Mochizuki story would be somewhat like the Perelman one: experts would hold seminars, go through his papers, and puzzle out how his argument worked, even if they needed to reconstruct a lot for themselves since his writeup was hard to follow. So far, we have a failure to communicate here….

30. **Tiger Woods**
May 13, 2013

I made 70 millions in my prime…per year!

31. **tigger**
May 13, 2013

Tiger, the goal here is to make less, not more!

32. **KCd**
May 14, 2013

There is definitely a paper by Zhang. I was at the Harvard talk and a paper was available in the room. It has not been made publicly available, but some well-known experts in this area have read the paper and think the proof is correct.

33. **Thads**
May 14, 2013

How convenient for Helfgott that he is 35, the International Congress is one year away, and there are no obvious front-runners!

34. **Thads**
May 14, 2013

In fact, one could regard both breakthroughs as the revenge of the middle-aged and mathematically unproductive. Zhang's first paper dates from 1985, yet he has only 2 papers on Mathscinet and holds the rank of lecturer at UNH. And Helfgott's work was done "in close coordination with" that of David Platt, who received a computer science BA in 1983, but only got his mathematics doctorate 2 years ago and is pictured on his home page with his grandson. Who says mathematics is a young man's game?

35. **Jeff M**
May 14, 2013

Just a note, the New Scientist piece doesn't say anything about Iwaniec refereeing the paper, only that he read it. Goldston has also read it, it must have made the rounds some at least. It would be unusual for someone to publicly acknowledge refereeing something (though I have seen it, at a 60th birthday conference for Scott Wolpert, where someone admitted refereeing two papers of Wolpert for the Annals because "he was the only person who could understand them" 🙂

36. **Peter Woit**
May 14, 2013

Jeff M,
You're right, that was an unjustified inference from the New Scientist story, I've edited the text.

37. **Mathematician**
May 14, 2013

It's strange to say that H. Helfgott proves the Ternary Goldbach conjecture (the abstract of the paper says "The ternary Goldbach conjecture, or three-primes problem, asserts that every odd integer N greater than 5 is the sum of three primes. The present paper proves this conjecture.") This is an unusual way of putting things because we have already known that the conjecture is true for each sufficiently large number: First, conditionally, due to Hardy and Littlewood, and then unconditionally due to Vinogradov. Not to take away from Helfgott's work, but it would have been better to present things as extending the range of validity of Goldbach by a finite amount, or in terms of complementing Vinogradov's proof, but not appear to claim credit for the proof, which confuses non-experts.

38. **Michael**
May 15, 2013

Mathematician: I think the point is that one can check by computer the range not covered by Helfgott's theorem (which one could not do with the earlier results), so now the ternary Goldbach conjecture is known to be true. Of course it would be more satisfying if the proof didn't involve the number-crunching-by-computer aspect, but the at least the conjecture has now been verified.

39. **Mathematician**
May 15, 2013

Michael, surely it takes a lot of optimization work to lower the constant from gazillion or whatever it was down to a range checkable by a computer, but it is still an arbitrary finite range… Of course someone had to do it, but in light of Vinogradov's theorem it's more accurate to say that the proof of the 3-prime problem has been completed, or that the finite number of possible exceptions in Vinogradov's theorem has been ruled out. I guess I might be missing something, especially since I don't know well the culture surrounding Vinogradov's theorem. On the other hand, I consider hypotheticals like, what if Wiles' proof of FLT had worked only for n > n0, and years later mathematican Y were to prove it via brute-force, case by case, for n = 3,.,n0, would it be reasonable to say that Y proved FLT? Or, say, the Riemann hypothesis was proved for t > gazillion, and then it was a matter of further optimization and brute-force (so inevitable, requiring no breakthroughs or the breaking of a barrier) to verify it in the remaining range…etc. Of course, ruling out a finite number of exceptions can require turning ineffective constants into effective ones, or a wholly new proof strategy, or eliminating exceptions from an infinite range, or…etc, which can be very difficult.

P.S. Regarding using number-crunching in proving mathematical theorem, I have no problem with that provided the number-crunching produces a certificate that can be quickly checked (possibly via computer) by anyone wishing to do so. If not, then I might still get convinced if the computation is carried out by multiple independent sources and their results agree to the expected precision. Of course, number-crunching has a lot to offer in gaining insight or to obtain support for conjectures, but perhaps is not suited for proving theorems since it usually doesn't meet the accepted standards of a mathematical proof.

40. **David Roberts**
May 15, 2013

@Mathematician

the number crunching was done by interval arithmetic with 'safe' margins of error. Helfgott has said that the number at which his pen-and-paper proof takes over in his article is purposefully chosen to have large overlap with what has been done by the computer, and that he's actually checked it further down than what the article says. He also said that he believes the bounds he gets are far from optimal, since that isn't his forte, and people experienced in arriving tight bounds will be able to improve his result, lessening the reliance on the computer.

41. **Mathematician**
May 15, 2013

David, the issue is not solely whether high enough precision was used by the computer, which is just one possible source of error. There are other obvious sources such as code bugs and arcane hardware/software details that were overlooked. For me, a sufficient standard is that multiple independent sources get the same result to within expected precision, which is far more convincing of the correctness (even if it doesn't meet the usual standards of a mathematical proof!). In any case, I still prefer not to use number-crunching in proofs unless the computations produce easily verifiable certificates or the code is readable-enough that it can be verified by an independent human outsider (this is very hard to achieve in practice except in the simplest of cases).

42. **Michael**
May 15, 2013

Mathematician,

"…if Wiles' proof of FLT had worked only for n > n0, and years later mathematican Y were to prove it via brute-force, case by case, for n = 3,.,n0, would it be reasonable to say that Y proved FLT?"

By the standards of the profession, I do think it would be considered that Y proved FLT. Many results today rely on the cumulative efforts of many, and the person(s) who finishes the proof of the theorem is considered the person who officially proved the result, even when it's the end of a long string of theorems. Standing on the shoulders of geniuses and all that.

"… I still prefer not to use number-crunching in proofs unless the computations produce easily verifiable certificates or the code is readable-enough that it can be verified by an independent human outsider (this is very hard to achieve in practice except in the simplest of cases)…"

I would expect that the programming aspect of the proof would be held to the same standards as the mathematical aspect, meaning that the theorem would not be declared proven unless the code was vetted as thoroughly as the proof. It may be complicated, but so is the mathematical argument, so I think this vetting will occur.

43. **Mathematician**
May 15, 2013

Michael, I respectfully disagree with your assessment of the FLT hypothetical. Consider another hypothetical, suppose the Riemann hypothesis is proved for t > gazillion, and then a person Y (a mathematician or not, but who happens to have access to enough computer power), brute-force their way in the remaining range, is it reasonable to say that Y is the one who proved the RH…? Also, I think it's a legitimate point of view for a mathematician not to accept computer number-crunching as part of a proof no matter how much vetting the code goes through, simply because there are hardware/chip/compiler issues that won't/can't be checked. Or maybe because the requested standard is impractical, such as evey block of the code should come with a mathematical proof, or the code should be completely written in assembly, both of which are actually reasonable requests if the goal is to meet the usual standards of mathematical rigor. In particular, if tomorrow, mathematician Y (or a group of hardworking grad students) puts in enough effort to tighten the bounds Helfgott's work so as to reduce to a range checkable by hand and by other mathematical techniques, then according to this point of view it would be Y rather than Helfgott who proved the weak Goldbach conjecture… In any case, one certainly shouldn't take away from the new result, as we now can say the weak Goldbach conj. applies for each odd n > 10^30 (or n > 5 if you're willing to believe the number-crunching), rather than n > 10^10000, or whatever it was, which is a nice thing.

44. **Yatima**
May 15, 2013

"Or the code should be completely written in assembly, both of which are actually reasonable requests if the goal is to meet the usual standards of mathematical rigor"

Well that's just completely wrong and betrays a sad misunderstanding of what programs are about. One might as well demand full brainscans and chemical analysis of the mathematicians' brains.

Even in engineering, you will rather have recourse to a well-written compiler of a subset of Ada, lots of contracts and assertions and three devices operating on a voting principle than to go down to manual checking of assembly language.

"Also, I think it's a legitimate point of view for a mathematician not to accept computer number-crunching as part of a proof no matter how much vetting the code goes through, simply because there are hardware/chip/compiler issues that won't/can't be checked."

No it isn't.

45. **Peter Woit**
May 15, 2013

Please, enough about the reliability of computer calculations. This has now been beaten to death, and has little to do with the interesting news from Helfgott.

46. **Mathematician**
May 15, 2013

Yatima, I guess that we can agree to disagree, but I'm wondering, when you say "Well that's just completely wrong and betrays a sad misunderstanding of what programs are about.", what are programs about?

47. **Mathematician**
May 15, 2013

To Peter Woit, OK it's your blog, and I enjoy reading it, so I'll stop with that 🙂

48. **Yatima**
May 19, 2013

At the oh-so-british "The Register" (Motto: 'Biting the Hand that feeds IT') we read:

[I know who 'Satoshi Nakamoto' is, says Ted Nelson]

Sociologist, philosopher, computer industry pioneer and inventor of the term "hypertext" Ted Nelson is claiming that he knows the identity of Bitcoin inventor "Satoshi Nakamoto". In a rambling – and, let's face it, odd – 12-minute post on YouTube, Nelson spins out the suspense, throws in a dialogue with himself as Sherlock Holmes and Doctor Watson, and finally ends with the statement that the mystery developer of the cryptocurrency is Japanese mathematician Shinichi Mochizuki, research professor of mathematics at Kyoto University. … Australian writer Stilgherrian told The Register that while it'd be easy to dismiss the claims, in spite of his eccentricities, Nelson "has the annoying habit of being right."

49. **msmith**
May 19, 2013

50. **Felipe Zaldivar**
May 24, 2013

Just an update: Zhang's paper is now available on the Ann. of Math. site:

String Theory and the Scientific Method

May 14, 2013
Categories: Book Reviews

There's a new philosophy of science book out, Richard Dawid's String Theory and the Scientific Method (available online here if your institution is paying Cambridge University Press appropriately or if you have a credit card). It comes with endorsements from string theorists David Gross and John Schwarz, with Schwarz writing:

> Richard Dawid argues that string theory plays a novel role in the scientific process that has been neglected by philosophers of science. I believe that this book is a valuable contribution to the philosophy of science, which should interest practicing scientists as well as those who are more interested in the methodology of science.

Dawid is a particle theorist turned philosopher, and as you might guess from the endorsement, he approaches string theory from an enthusiast's point of view. The fundamental question addressed is how one can reconcile string theory's failure in terms of conventional methodology of science with its continuing hold on at least part of the physics community. He explains how the book came about as follows:

> This book has been on my mind ever since I left physics and turned to philosophy in the year 2000. A core motivation for making that step at the time was my feeling that something philosophically interesting was going on in fundamental physics but remained largely unappreciated by the world outside the departments of theoretical physics – and underappreciated even within. Twelve years of grappling with the specification of that general idea have considerably changed my perspective on the issue but left the overall idea intact. This book is the attempt to present it in a coherent form.

Reading the book in an odd way reminded me of my recent experience reading Gordon Kane's reissued book on supersymmetry and string theory written in 2000, especially Witten's essentially unchanged introduction. The degree of self-confidence of string theorists at that time was much different than now: AdS/CFT was a new idea, with a solution to QCD on its way, SUSY a sure thing at the LHC if not at the Tevatron or LEP, and at least half of the new jobs in the field going to string theorists. No landscape or multiverse pseudo-science was around to sow dissension in the ranks. No failure of SUSY to show up anywhere. No discouraging numbers like those for the last two years which show, in the US at least, 9% of jobs going to string theorists, with more jobs going to lattice gauge theorists in 2011 than to string theorists. And of course, a uniformly positive press, with no naysayers like Smolin and Woit causing trouble.

In Dawid's description, string theorists are still partying like it's 1999:

> String theory has attained a pivotal role in fundamental physics and has been treated as a well-established and authoritative theory for quite some time by the community of string theorists and by physicists in related fields. As we have described above, large parts of fundamental physics are influenced by string theoretical analysis. The string community is one of the largest communities in all of theoretical physics and for many years has produced the majority of the field's top-cited papers. Moreover, many string theorists express a remarkably strong trust in their theory's viability.

For the actual list of last year's top-cited papers in HEP, see here, and "remarkably strong trust in their theory's viability" seems to me more 2000 than 2013. He does go on to mention skeptics, but to him a majority of the field is behind string theory, with the skeptics only coming from outside particle theory:

> On one side of the divide stand most of those physicists who work on string physics and in fields like inflationary cosmology or high energy particle physics model building, which are strongly influenced by string physics. That group represents a slight majority of physicists in theoretical high energy physics today. Based on an internal assessment of string theory and the history of its development, they are convinced that string theory constitutes a crucial step towards a better and more genuine understanding of the world we observe. On the other side stand many theoretical physicists of other fields, most experimental physicists and most philosophers of physics. They consider string theory a vastly overrated speculation.

Dawid's main thesis is that string theory critics fail to recognize that a new paradigm of scientific methodology is now needed:

> String theory thus should not be taken to announce an end of science but rather to represent a new phase of scientific progress. In this new phase, progress in fundamental physics is no longer carried by a sequence of limited, internally fully developed theories, but rather by the discovery of new aspects of one overall theoretical scheme whose general
> characteristics identify it as a candidate for a final theory, yet whose enormous complexity bars any hope of a full understanding in the foreseeable future.

What is the reason you should accept this final theory that no one can understand? Obviously the lack of any empirical support is a problem, so Dawid turns his attention to a detailed study of the subject of "non-empirical theory assessment": how do you assess scientific progress absent connection to experiment? This is a real and serious problem, which Dawid studies in detail, although from a point of view which just naively accepts all arguments made by string theorists. He considers three main reasons for studying a theory with no empirical support:

- The No Alternatives Argument. This is the best argument for string theory: there aren't a lot of viable unified theories out there. Of course, the way science progresses is that there always are unsuccessful ideas with no good alternatives, until the day someone come up with a better idea.
- The Unexpected Explanatory Coherence Argument. This is the idea that if a theory holds together better after you start studying it and understand it better, that's a good thing. Dawid repeats uncritically claims of some string theorists that this is the case for string theory. I think you could make an equally good case for string theory unification becoming a more and more dubious idea as it became better understood (see, the Landscape).
- The Meta-Inductive Argument. Here the idea is that if a theoretical research program worked before, so will a similar later one. Dawid claims that the string theory research program is just like the research program that led to the Standard Model:

  > Given the entirely theoretical motives for its creation, the lack of satisfactory alternatives and the emergence of unexpected explanatory inter-connections, the standard model can be called a direct precursor of string theory.

  Honestly, this I just find bizarre, and have no idea what he's talking about, with the history of the Standard Model and the history of string theory two radically different subjects.

In one crucial respect, this book is very different though than Kane's. Kane is well aware that the idea of an inherently experimentally untestable theory is something he can't sell to his colleagues and the public, so he devotes his book and its argument for string theory to supposed experimental tests. More savvy string theorists than Kane though are seeing the writing on the wall: no SUSY at 8 TeV means almost surely no SUSY at 13 TeV, and thus no prospects for experimental evidence for SUSY during any of our lifetimes. To prop up the string theory unification program past SUSY null results from the 13 TeV LHC in 2016 is going to require relying on Dawid's "non-empirical theory assessment" and convincing people that string theory and the multiverse represent a new paradigm for how to pursue fundamental science. This book will be welcomed by those pursuing such a goal.

Update: For a different take on the book you can see Lubos Motl's review (as you might expect, he's a big fan). The case of the most prominent string theorist blogger reminds me of one of the funnier things in the Dawid book that I forgot to mention, this footnote:

> It should be emphasized that physicists on both sides of the divide are aware of the slightly precarious character of the "non-physical" arguments deployed in the debate. Lee Smolin has applied the concept of groupthink to the community of string physicists (which, incidentally, seems a quite accurate representation of what

many critics of string physics do think about string physicists) but is careful not to present it as a core argument. String theorists, when entering a discussion with their critics (see e.g. Polchinski in his reasoning against Smolin), try to keep the debate at an entirely physical level.

Comments

1. **Bill**
May 14, 2013

   I just went to a conference attended by a mix of mathematician and physicists. Since I started reading this blog (recently) I was curious to ask a few physicists what they think about string theory. My motivation was pretty simple: I just find it a bit doubtful that one guy arguing against so many of the top physicists in modern times can be right. But to my surprise I consistently got nearly the same answer: "it is clear that predictions of string theory have no chance to ever be observed experimentally". It is truly bizarre to me that such as state of affairs is possible in physics. And, by the way, none of the people I talked to knew who Peter Woit is.

2. **Bob Jones**
May 14, 2013

   I think Dawid is right about string theory being treated as a well-established and authoritative theory.

3. **Cliff**
May 15, 2013

   These posts are so predictable and shallow. You just state your conclusions as facts, and then act shocked when someone "fails" to "reason" to your answers, when they obviously do not agree with your premises at all.

   Nobody is forcing you, or anyone, to "accept" string theory, Peter. It is a project that a lot of brilliant people choose to work on out of their own free will, for reasons that are become pretty clear to someone with the right preparation who bothers to investigate it. There is no sane reason to complain about the top people in theoretical physics doing what they obviously see as the most productive use of their talent. Nobody is suggesting that string theory be presented as fact to be "accepted" – that's just a ridiculous straw man – it should be presented honestly for what it is: an extremely promising and insightful yet unproven framework.

   If a superior idea ever emerges that is demonstrably more promising to address the big mysteries of physics, then the attention and status will shift accordingly. In the meantime trying to maximally tear down and obfuscate all the promising properties and insights that motivate the study of string theory does nothing to help advance either the public understanding or science.

4. **chris**
May 15, 2013

   Cliff,

   it's the intrinsic notion of "top" you have that needs to be dragged out of the closet and publicly debated. In the past it meant those who came forward with predictions that were later verified by experiment. i still like this definition best. You obviously don't.

5. **Roger**
May 15, 2013

   This must be the only field that justifies itself by bragging about how smart its leaders are, and claiming to have the only theory that attempts to have a theory of everything while actually explaining nothing.

6. **phmer**
May 15, 2013

   As I see no reason why the Universe would not be infinitely complex, isn't the idea of "theory of everything" a far-away dream? Is not the investment of resources into such a business an extremely risky gamble? It is my impression that Nature suprised us over and over again during the history of high-energy physics, each time with new structural layers, new forces, unexpected mixings, etc., which could not be predicted before they were actually found and measured, and which revealed that some successful models were in fact low-energy approximations of more advanced (but not necessarily simpler) constructs. Examples: Who could have imagined such a thing as the weak interaction before the observation of beta decay? Who could have devised a theory of nuclear interactions when nuclei were not even discovered? Who could have described QCD before the interior of nuclei were probed? Now we have 15 more orders of magnitude in energy to explore until we reach the Planck scale, surely there can be quite a few unforeseen phenomena with little to do with our current theories to be revealed out there… Science without experimental guidance and evidence, to me that sounds more like faith.

7. **Jeff Moreland**
May 15, 2013

   Peter,
   I'm curious why you think that no SUSY at 8 TeV means almost surely no SUSY at 13 TeV. 5 TEV seems a big gap; is there some reason I'm missing why there won't be any evidence for SUSY in this range?

8. **Peter Woit**
May 15, 2013

   Jeff Moreland,

   By the standard arguments for SUSY, it was supposed to appear at energy scales of 100 GeV. Roughly, the Tevatron probed energy scales up to a couple hundred GeV, so one expected SUSY to be there, but the factor of 4 in going to the 8 TeV LHC should definitely have done the trick. There's just no argument for why SUSY should appear if one goes up by an extra factor of 13/8.

   This is kind of off-topic though, the point of the book is to give a justification for string theory research assuming no relevant experimental data.

9. **Bernhard**
May 15, 2013

   I did not read the book yet, but judging from the same old arguments you've listed, what is surprising to me is that this is still material for a new book.

10. **Joel Rice**
May 15, 2013

It would be a lot easier if they would just stop calling it a theory. At least electroweak includes QED. If they can not similarly include the standard model, then in what useful sense can one refer to it as a theory ? I have no problem with speculation. Just don't call it a theory.

11. **Thomas**
May 15, 2013

this fundamental belief in string theory is nothing more than a fundamental belief in a religion. thank you, and good night science

12. **Peter Woit**
May 15, 2013

Joel Rice,

In string theory, the argument is that you can include the Standard Model. The problem is that if so you can probably include just about anything else, getting a theory of everything, just not in a good way. It's definitely a theory, but has turned out to be an empty one.

13. **francis**
May 15, 2013

Peter,
AFAIK in ST, all they can do is getting something that looks like the SM, but not the right SM (or any extension of it).

14. **Peter Woit**
May 15, 2013

francis,

I think a more accurate description of the situation is that you can't do reliable calculations in ANY realistic string theory model (e.g. one that gets the CC and basic SM structures right). There's no known reason though why, if you could do such calculations, you couldn't get the SM (and just about anything else…)

All: please, if you have something to say about the book, that's great, if you just want to discuss string theory in general, or rant pro or con, please resist temptation.

15. **Bob Jones**
May 15, 2013

"this fundamental belief in string theory is nothing more than a fundamental belief in a religion. thank you, and good night science"

Every time Peter writes a blog post on string theory, we see ridiculous comments claiming that string theory is a religion. It's fine to criticize string theory, but I think you first have to understand why so many people see it as a promising direction for research. There are some very good reasons for studying this theory. For example, string theory gives the right answer when used to calculate black hole entropy, and it has some general features that are expected to hold in any successful quantum theory of gravity. I don't see how you can criticize string theory without at least addressing these points, and I'm sure they must have been discussed in Dawid's book…

16. **Peter Woit**
May 15, 2013

Bob Jones,

I agree that the "string theory is a religion" arguments aren't either accurate or helpful to understand what is going on. To all, enough of this kind of thing.

Dawid's book doesn't pretend to be a serious evaluation of the arguments pro and con about string theory. Basically he just repeats uncritically arguments used by string theorists, with his interest not whether they make sense or whether there's a good counter-argument, but just what sort of general framework for "non-empirical" arguments they fit into.

17. **Bob Jones**
May 15, 2013

Peter,

I haven't read Dawid's book, so I don't know exactly what he says. But the strongest reasons for studying string theory are scientific and mathematical reasons, not sociological ones. I think it's unfortunate that so many laypeople misunderstand this point.

18. **Peter Woit**
May 15, 2013

Bob Jones,

The point is that some of the main reasons that people keep working on and promoting string unification schemes are not scientific, but sociological. To take an extreme example, Kane's recent "update" of his book violates standard scientific norms of how you are supposed to evaluate scientific theories, and what he is doing I think can only be understood in sociological (or psychological) terms.

What I think Dawid completely misses in his book is that a large part of the story of the scientific community's assessment of string theory unification is a completely conventional one: the idea didn't work out, but a lot of the people with their time and reputations invested in it deal with this by refusing to admit it. This doesn't require any new methodology of science to understand, it's a well-known phenomenon.

19. **Koray**
May 15, 2013

I don't have access to the book. I came here for the philosophy of science arguments presented by the book.

Does Dawid present any prior examples for the No Alternatives argument? Did any other branch of science struggle for decades with a very complex theory with no empirical support because there was nothing better? Does he recommend that they do so now since this is the "new" phase of scientific progress? Would he prefer, say, for cancer research, that if some biologists devise a complex model that feels like the right one to those who understand, yet is expected to yield no fruit for decades, the entire field should stick with it?

20. **Joel Rice**
May 15, 2013

I have to disagree with Dawid's idea that it is acceptable to change the idea of theory so as to throw Feynman under the bus. He calculated the Lamb shift and that is what made it a real theory – as opposed to a mathematically sensible thing that looks like a theory but numbers don't work out. OK, granted, Weinberg had a theory in 1967 before any numbers were in, but there was never any doubt about connecting with experiment, for better or worse. It becomes a 'real theory' by passing tests. If Dawid can find himself persuaded otherwise then we are reduced to who thinks which theory is mathematically prettier than the rest, and it becomes a matter of opinion. A bunch of physicists bet money that Parity was the truth. Opinion was worth zilch.

21. **Peter Woit**
May 15, 2013

Koray,

There's nothing much in the book about other sciences, and little about history (no specific parallels are given). To some extent Dawid is arguing that the situation with string theory is an unparalleled one (a "final" theory that is impossibly hard to test), justifying new scientific methodology. He's not claiming that such methodology is necessarily justified in other fields.

22. **Cliff**
May 15, 2013

phmer,

Your view is a common one, but its not a truly accurate portrait of how these developments have gone. Nature has surprised us with new manifestations of the basic principles of relativity and quantum mechanics, but none of the surprising developments you mention has altered these basic principles. It took time to fully appreciate, but electromagnetism and its non-abelian generalizations are the only possible ways to have an interacting spin-1 field consistent with relativity and quantum mechanics. Many people were impressed with this idea of generalizing electromagnetism but were discouraged because the lack of new long-range forces seemed to rule them out. It turned out that new mechanisms were required to implement the ideas – the Higgs mechanism for electroweak and confinement for the strong force – but it was still based on the one unique option that existed to generalize electromagnetism. There is a big difference between finding surprising and novel ways to implement well-established principles of physics versus a development that actually requires abandoning them. A priori, it would be totally conceivable that nature would select a genuinely radical departure, as you seem to think, but it just didn't.

So, sure, there is always some small chance that around the next bend everything we know about physics will just go out the window. But speculation based on these principles that are backed up by 100+ years of evidence will almost always beat speculation that is totally random and baseless. And thats exactly what string theory is, the one fully-consistent way to talk about quantum gravity while incorporating the principles of relativity and quantum mechanics. (If the extrapolation seems dubious, remember that GRB090510 verified the principle of Lorentz invariance up to Planckian energy scales, where many of the "discrete spacetime" people were predicting something else.) Unless there appears solid evidence to the contrary, the idea that preserves those principles will remain the most promising. Especially as long as it remains such a fantastically productive idea for thinking about physics in general as Maldacena's #3 ranking in Inspire's 2012 most-cited list indicates.

23. **Peter Woit**
May 15, 2013

Cliff,

Hype such as "a fantastically productive idea for thinking about physics in general" isn't any more convincing than what you are responding to.

All: No more comments not about the book. Just stop.

24. **book**
May 15, 2013

How do you expect comments about the book since most people will not have read read it?

25. **Peter Woit**
May 15, 2013

book,

Some people do have access to the book itself via the CUP page I linked to. Also, Dawid has been writing about this with similar arguments in quite a few places, he has links to such papers on his website, see here.

http://homepage.univie.ac.at/richard.dawid/Homepage-Publications.htm

From such materials and the posting it should be clear what the topic of the book is.

26. **paddy**
May 15, 2013

I risk failing the "purely on the book dictum", since I have not read it but only gathered excerpts here and elsewhere on the web as well as perused the authors papers. 'Twould seem though from what I have gathered that the argument is that we should change our (empirically derived) standards of what is or is not considered to be a useful empirical scientific model just because (1) a "promising" field of research has failed as of yet to meet those standards and (2) there is a paucity if not a complete absence of alternatives (note: though no uniqueness theorem or conjecture is posited). Is this a fair assessment?

27. **Peter Woit**
May 15, 2013

paddy,

Kind of, although your formulation leaves open what "promising" means. Given the lack of progress towards making any predictions with string theory, it's hard to argue that it's "promising" in terms of moving towards a predictive, testable theory. Dawid is interested more in other reasons string theorists see the theory as "promising", reasons that have nothing to do with testability or prospects for testability.

I actually think this is an interesting question. When you are starting thinking about a speculative idea, the reasons for examining it more closely often are not that you see some potential way of testing it. Instead, the idea may be attractive for other reasons: it embodies some powerful and beautiful mathematical concepts, it's related by analogy to some other ideas that have worked well, etc. etc. You can think of a lot of good reasons why people decide to pursue one speculative idea rather than another.

The problem here is that these things are very slippery, and easy to fool oneself about or be less than honest about, with one's vague argument for why one should look at something evolving into a protective armor of hype as one keeps arguing with those who are skeptical your idea is going anywhere.

Unfortunately I don't thing Dawid really comes to terms with the real problems of this kind of "non-empirical theory assessment", since he sticks to taking at face value things which are heavily hype-ridden.

28. **Lee Smolin**
May 15, 2013

Dear Peter,

I am shocked that the no alternative argument still gets a hearing given the major progress on key issues in loop quantum gravity and spin foam models. Does the book acknowledge this progress? Ten years ago it was possible to be skeptical of LQG because of open issues such as getting the 1/4 right in black hole entropy and deriving general relativity as the low energy limit. However the last five years there has been major progress on both of these and other issues including having a detailed and credible account of the onset of inflation following a quantum bounce. If it was valid to deny LQG the status of a full alternative approach to quantum gravity because of these issues any honest account must acknowledge the progress made.

The no alternative argument fails on sociological as well as scientific grounds. This summers upcoming LQG meeting has already reached more than 200 registrations. Its fair to say that LQG is now after 25 years a healthy and vibrant large established research community. This doesn't mean its right but it does puncture the no alternative argument.

There is considerable progress as well on other alternative approaches to quantum gravity including causal dynamical triangulations and causal sets.

I would be curious to read the book and see if the author has an up to date account of of the alternatives he claims do not exist.

Thanks,

Lee

29. **Peter Woit**
May 15, 2013

Hi Lee,

Dawid discusses LQG on pages 91-94, with a very string theory-centric point of view. The oddest part is this

"Leading exponents of loop quantum gravity tend to be fairly confident regarding their theory's chances of success. However, compared to the way the status of string theory is assessed by that theory's leading exponents, it may be fair to say that assessments of loop quantum gravity are significantly more timid. While the sentiment that their theory is "too good to be false" is widespread among string physicists, adherents to loop quantum gravity are more inclined to emphasize that their approach constitutes one possible solution that has some attractive features but may well turn out false in the end."

which kind of argues against you on the grounds that you are insufficiently arrogant. Other than that, he evaluates things by his three kinds of arguments I explained in the posting. For "No Alternatives" (which he calls AAA), string theory is supposed to be a promising way to unify with the SM, while LQG doesn't really address this. For "Unexplained Explanatory Coherence" (his UEA) he explains the nice explanatory features of both approaches to quantum gravity, then somehow decides string theory is better. For "Meta-Inductive" (his MIA), again he's using the argument that we should believe string theory because it's like the SM (an argument that just baffles me), whereas LQG is like GR, which somehow is less desirable.

30. **bsm**
May 15, 2013

What testable BSM predictions do LQG and/or spin foam make, in particular at LHC scales? Have ATLAS and CMS published results of searches, or excluded regions of parameter space, for the BSM predictions of LGG/spin foam?

31. **Peter Woit**
May 15, 2013

bsm,

Neither string theory nor LQG/spin foam make any predictions about LHC scale physics.

32. **Alex**
May 16, 2013

We all agree that it is important to think about what the correct model of quantum gravity is, right?
Demanding that there are hard TeV scale predictions of something that by necessity involves the scale 10^19 GeV, that is basically a lamp post argument. There is no reason to think that dis/favouring approaches based on the amount of predictions they make *at the weak scale* can be a very misleading strategy. Of course one should try this (a la ADD and so on), but other than the hierarchy issues, there is no reason to think that quantum gravity should be so nice to us.

Quite the contrary, the fact that something as baroque as the Standard Model is to come out of this at low scales, makes it for me unlikely that there should be anything fundamental to the observed low-scale physics. I don't think anyone can seriously expect that the SM gauge group and particle content with such and such parameters are the unique consistent model that can come out of the correct theory of quantum gravity.

Given this, I find it disingenuous to criticize string research for the lack of predictive power at the weak scale. There is a lot of predictive power near the fundamental scale, smoking gun signatures if you will – it is merely a technical reason why we can't observe them, not a philosophical one.

@Joel Rice
Arguing about the name is silly, you could just as well criticize quantum field theory for its name. The names of stuff are all over the place for historical reasons and don't conform to the terminology we should impose in discussions with the general public (in order to avoid arguments like "Evolution is just a theory" from the anti science crowd).

The Standard Model is a Theory
Quantum Field Theory is a mathematical framework
String Theory is a mathematical framework
Any explicit realization of the Superstring is correctly called a “Model” in the literature.

33. **Alex**
May 16, 2013

That was supposed to read:

There is no reason to think that dis/favouring approaches based on the amount of predictions they make *at the weak scale* is a sensible strategy to find the correct theory of quantum gravity.

34. **bsm**
May 16, 2013

Unlike ST, do LQG/spin foam make any testable predictions at all?

35. **Alex**
May 16, 2013

IANALQGE, but I think you would expect to see some violation of Lorentz Symmetry at gignormous Energy Scales.

36. **Krzysztof**
May 16, 2013

Peter,

From what you write about the book it seems to promote a real ‘scientific revolution’ – a huge change of the scientific paradigm. And, in a way it has some religious connotations, or at least philosophical ones. The main goal in that respect is to explain or motivate physics by itself – even more at the end, to explain all the reality, including its roots and reason, by science, and by science only. S. Hawking and other ‘top theorists’ since long have been voicing dreams about the ultimate theory which should explain also itself. As a side remark, I wonder what they say about the Goedel’s theorems in that context…

To me, an experimental particle physicist, string theory as such is a purely mathematical project, having (almost) nothing to do with physics, so far.

37. **Lee Smolin**
May 16, 2013

bsm:

LQG is a framework for the quantization of diffeomorphism invariant theories. But there are striking consequences if not falsifiable predictions for experiment. One comes from the existence of a new parameter necessarily in the gravitational action, analogous to the theta angle of QCD: the Immirzi parameter. When this takes complex values there are parity odd quantum gravitational effects. These imply a parity odd component to the polarization in the CMB, possibly visible in the B-T channel. This could be seen in upcoming measurements at Planck and other detectors. This is not a falsifiable prediction but its detection would be a striking confirmation of the framework. To put this another way, Planck polarization measurements will constrain the Immirzi parameter.

See papers of Magueijo et al for details.

btw I am not aware that string theory makes any falsifiable predictions for doable experiments.

Thanks,

Lee

38. **Peter Woit**
May 16, 2013

bsm/Alex,

The whole point of this book is that it starts from the assumption that string theory (and also LQG) can’t make any testable predictions, so the author is coming up with a new methodology of science to evaluate untestable theories.

The problem with string theory is not that it can’t make testable predictions about physics at the weak scale, but that it can’t make testable predictions about physics at any scale whatsoever.

39. **Alex**
May 16, 2013

Peter,

“The problem with string theory is not that it can’t make testable predictions about physics at the weak scale, but that it can’t make testable predictions about physics at any scale whatsoever.”

Are you seriously claiming that the superstring does not make any testable predictions about physics at *any* scale?
What about the 6 extra dimensions, the string spectrum, Regge excitations, measuring open string and closed string scattering amplitudes explicitly? Come on, if we could by some surprising feat built a Planck scale collider, there would be a wealth of stuff to observe.
As far as the first point is concerned, it could be that there is no real 10D supergravity regime because the compactification scale is at the string scale or so, but that is an extreme situation.

40. **JG**
May 16, 2013

Philip Gibbs in his quasi-review (the book is above his price range, as it is mine) says the following:

“The more evidence there is against SUSY, the more evidence there is in favour of the multiverse and the string theory landscape” and “the standard model succeeded because it was based on consistency arguments such as renormalisability which reduced the possible models to just one basic idea that worked. The same is true for string theory so we are on firm ground.”

OK, one thing I thought was true was that string theory rises and falls on SUSY. And, what is the “one basic idea” that works in string theory?

Is this as crazy as I think it is?

41. **Peter Woit**
May 16, 2013

Alex,

This one has been gone over a million times (and has nothing to do with the book). Yes, we would learn something from a Planck scale accelerator, no, string theory makes no falsifiable predictions about it, since we don’t know what non-perturbative string theory is: would there be black holes produced? would it be six extra dimensions or seven (according to M-theory)? But wait, we don’t know what M-theory is…

Sorry, but I’m just going to delete further comments not about the book.

42. **Peter Woit**
May 16, 2013

JG,

Please argue with Philip about his posting on his blog, not here.

43. **Neil**
May 16, 2013

Of his three principles of “non-empirical assessment”, I find the “no alternatives” one disturbing and destructive. The other two seem reasonable. You can never know there are no alternatives, so it is silly to presume such. By this reasoning we should always stay on the path we are on because we cannot imagine another. But why would we try if a presumption of no alternatives is part of our assessment package?

And of course, as Smolin points out, in fact there are alternatives.

44. **fuzzy**
May 21, 2013

i think that such a philosophical position if perfectly ok if we want to relocate string theory out of natural sciences; in a sense, dawid blesses the idea of string theory becomes a branch of math and philosophy, and its physical origins can be forgot. in this sense, the position of joel rice can be agreed upon, simply adding a bare word to his statement: “string theory is not a *physical* theory”. of course, here i argue that we should maintain the vintage position of old isaac: “to be termed scientific, a method of inquiry must be based on empirical and measurable evidence subject to specific principles of reasoning” — this should remain the rule of natural sciences, without implying any derogative position toward math and philosophy. however, i feel that if the position of dawid will be accepted, mathematicians should be ready to hear statements as “since we will explain anything, stop working on riemann hypothesis–this is our stuff”

45. **Raisonator**
May 22, 2013

Joel Rice,
“It would be a lot easier if they would just stop calling it a theory. ”
A good point. I thought about this too. A big problem to me seems to be that when you call it “theory” in the media, lay people tend to think that it is comparable to the theory of relativity or quantum theory which have been tested to incredible accuracy in so many ways.

David Gross likes to call it a “framework”, which I find a very good idea. Or “the string hypothesis” could also do.

Best.

46. **Adrian_H**
May 22, 2013

I can think of one good reason why this new version of string theory + landscape would be attractive to someone who has some philosophy behind them: it is essentially equivalent to the model theory of modern logic.

In that way of thinking, which philosophers tend to associate with the name of Leibniz, but that goes back to Duns Scotus, there are a set of logical truths, which are essentially a set of mathematical constraints that are common to all models; and there are sentences that are allowed to vary from one model, or possible world, to another — the contingencies. If one increases the set of “logical/mathematical truths” that are invariant then you decrease the size of the “possible worlds”. If logic is science I suppose that this can all be considered science too — but logic would be a better name for it. (And it would be falsified if one of the constraints is shown to be false.)

One Ring to Rule Them All

May 16, 2013
Categories: Uncategorized

This week in Sweden the Nobel Foundation is running a symposium on LHC results. It's invitation only, but the slides of the talks are available here.

One of the scheduled talks today was about string theory, and I was wondering how that would fit into the "LHC results" framework since string theory has nothing to say on the topic. Now that the slides are available I don't see anything about the LHC, but there are some remarkable revelations. The first is that string theory is not science but "Magic", with several slides describing the "Magic of String Theory". The relationship to mathematics is that in string theory "No concept in Math remains unambiguous", which I guess is about what you would expect when you're dealing with magic.

An even bigger revelation comes later in the talk: string theory is Sauron's Ring of Power! It is described as "Concentrated Power" and it seems that the markings on the ring are a SUSY Lagrangian. Part of the Ring Poem is quoted

> One Ring to rule them all, One Ring to find them,
> One Ring to bring them all and in the darkness bind them.

To put this back in context, recall that this is Sauron's ring he created in order to control everything from Mordor. Here's more of the poem, including the original language

> Ash tug Shakhbûrz-ûr Ulîma-tab-ishi za,
> Uzg-Mordor-ishi amal fauthut burgûli.
> Ash nazg durbatulûk, ash nazg gimbatul,
> Ash nazg thrakatulûk, agh burzum-ishi krimpatul
> Uzg-Mordor-ishi amal fauthut burgûli.
>
> One for the Dark Lord on his dark throne
> In the Land of Mordor where the Shadows lie.
> One Ring to rule them all, One Ring to find them,
> One Ring to bring them all and in the darkness bind them
> In the Land of Mordor where the Shadows lie.

This interpretation of string theory as Sauron's ring I suppose could explain a lot…

Comments

1. **rings**
   May 16, 2013

   "… I was wondering how that would fit into the "LHC results" framework since string theory has nothing to say on the topic." IIRC, the Higgs boson results were announced at Lepton-Photon at Melbourne, despite the Higgs boson being neither a lepton nor a photon nor even a gauge boson. Methinks the L-P conference organizers polluted the purity of essence of the bodily fluids of the attendees by allowing such talks.

   Would you prefer the Ring of the Nibelung? At the end of it all, Brunnhilde rides into Siegfried's funeral pyre and burns the whole world down. Note that Brunnhilde doesn't ask her horse if he wishes to join in the immolation. It's my guess that ST theorists won't ask your opinion if ST burns all of theoretical physics to an end.

   There were many talks, with slides for most of them (not fot John Ellis at the end). ST was one of many talks, in the session on BSM physics. (Note that Lepton-Photon has talks on supersymmetry, although SUSY is neither leptons nor photons.) I had a look at the slides on "Future Accelerators". It contained the standard blurb, but one could hardly expect anything else. There was a nice slide at the end though:

   I have a Dream
   E = mc^2
   Extended Multiprobe Collider Complex

   I admit I had to read it twice to catch on. I thought it was clever.

   So there were many talks. ST was but one of many. Nothing really new, but the Future Accelerators talk, which was very down to Earth, also had nothing really new. One could hardly expect anything else.

2. **Hack**
   May 16, 2013

   Lol! Yes Peter we all know how the ring corrupts any one that posses it, perhaps working on string theory for a time has a similar affect on particle physicists. Hobbits were especially resistant to Sauron's ring, perhaps we need more Hobbits in Particle physics….

3. **PeterPetersonSenior**
   May 16, 2013

   Thank you for the commentary and the link. A have got a lot of laughs, mostly kindergarten stuff, I am would be curious to hear the talk, and the audience reaction.

   My favorites (in addition to one's you covered, so I will not repeat):
   1. It is always funny how the black hole is always trumped, ST success and mystery. The accumulated mass determines the horizon radius, entropy and gravity gradient should dictate the radiation. I could not be more ambivalent about information fate in black hole – on current level of theory it is unprovable either way. – Not so much funny, I am just curious what was said along with this slide.
   2. "Singularities are a reflection of a breakdown of an approximation." – makes sense, so it follows: "Gravity has magic cloaks to hide its secrets" – Ha-ha-ha.
   3. The best laugh: "One Equation? Infinite number of solutions!!"
   4. "Algebra, matrices and representations to replace geometry ?" (last page) – I think this is what gets us in trouble in the first place, see 3.

   And pages 68 and 69 – partial admission of realization that there is no way out of this paper bag.

4. **Bernhard**
May 16, 2013

So, is Witten Sauron's human form?

5. **SpearMarktheSecond**
May 16, 2013

Creme de la creme of the 50ish experimental community, IMO. Alex Read, Kevin Einsweiler, Valerie Gibson, Andy Parker, Rene Ong… Nima's talk looks a bit odd…. bifurcatory moment?

6. **Peter Woit**
May 16, 2013

SpearMarktheSecond,

The Arkani-Hamed talk was basically the same as the colloquium he gave at Columbia a couple weeks ago. My take on that is here
http://www.math.columbia.edu/~woit/wordpress/?p=5747

Bernhard,

I don't know about that, but based on my years living there, I always suspected Princeton might be Mordor…

7. **CIP**
May 16, 2013

I thought that the LHC was the ring to rule them all.

8. **srp**
May 16, 2013

When I read the title of the post and the first paragraph I thought the reference would be to the LHC particle ring. Now that it's the "only game in town" the LHC really does "rule them all."

9. **Maciej**
May 16, 2013

Yep, Witten (or Maldacena) is the Dark Lord and Princeton must be Mordor.
Peter, you have managed to mentally resist the shadows in their nest!
Respect.

More seriously, in the slides Rabinovici argues why 1=3 and at the same time 4=10. This follows from magic of ST because strings are extended.

Damn, their proofs get more and more sophisticated!

10. **SpearMarktheSecond**
May 17, 2013

Thanks Peter. Nima makes me appreciate Dirac's communication skills.

11. **M**
May 17, 2013

The problem is not the Sauron ring quote, but the rest of the talk. String theory has nothing to say about physics.

12. **chris**
May 17, 2013

it seems strange to me to cite one ring ruling all on an LHC meeting and letting this ring be anything other than the LHC – but taste does not seem to be one of the fortes of Rabinovici (see slide 35).

13. **Erestarchos**
May 17, 2013

So, the Sauron's ring should be destructed. And we should hope this will destruct Sauron too and all his minions. 😉

14. **destruct**
May 17, 2013

Be careful what you wish for. Destroying things is a two edged sword. Destroying 'Sauron's Ring' will do more than just destroy ST. When the SSC was 'destroyed' the solid staters expected that this would "free up much needed funds" for condensed matter research. But the 'pot of money' did not flow to them. Quite the reverse, funding for physics was cut across the board. Destroying ST will likely destroy your own funding.

15. **Shantanu**
May 17, 2013

Peter, FYI another conference at KITP with talks on supersymmetry etc
http://online.kitp.ucsb.edu/online/lhc13/
Would be interested to hear your views on some of these talks

16. **Anonyrat**
May 17, 2013

Yes, as destruct pointed out, be careful of what you wish for. The destruction of the One Ring meant that the Elven rings – Narya, Nenya and Vilya – faded in power and the diminished Elves moved out of Middle Earth. This could be a metaphor for physics as well.

17. **TD**
    May 17, 2013

    Ask yourself this question: If I were asked to spend MY hard-earned money on a failed speculative theory (ST), would I? That is the fiduciary standard. Taxpayers' money is usually treated as "free" money, but it isn't.

18. **Kalyan**
    May 18, 2013

    Human's are so creative, even if I tried, I couldn't make up something so bizarre, but here it is as trying to be accepted reality using Sauron's one ring. Beyond astounding!

19. **MathPhys**
    May 19, 2013

    What ST conferences badly need is an anthem. Something along the lines of *'Rule Britannia'* in Conservative party meetings.

20. **anthem**
    May 19, 2013

    Why is that any different from many other physics groups?

21. **MathPhys**
    May 19, 2013

    I am not aware of any other group of physicists with a comparably ideological attachment to a theoretical idea in spite of their total failure to find a shred of experimental evidence for it.

22. **Tmark48**
    May 20, 2013

    @ MathPhys : Maybe not a group of physicists, but history has shown time and time again that single physicists (even/especially famous ones) tend to cling to their ideas even in face of failure. Hence the motto, science advances one funeral at a time.

23. **Mehmet Efendi**
    May 21, 2013

    Not related but since this is not a serious post I may as well attract your attention to : Hard evidence for the multiverse has been found, article in the Daily Mail.

    http://www.dailymail.co.uk/sciencetech/article-2326869/Is-universe-merely-billions-Evidence-existence-multiverse-revealed-time-cosmic-map.html

Hard Evidence for the Multiverse Found, but String Theory Limits the Space Brain Threat

May 22, 2013
Categories: Favorite Old Posts, Multiverse Mania, This Week's Hype

In recent years there have been many claims made for "evidence" of a multiverse, supposedly found in the CMB data (see for example here). Such claims often came with the remark that the Planck CMB data would convincingly decide the matter. When the Planck data was released two months ago, I looked through the press coverage and through the Planck papers for any sign of news about what the new data said about these multiverse evidence claims. There was very little there; possibly the Planck scientists found these claims to be so outlandish that it wasn't worth the time to look into what the new data had to say about them. One exception was this paper, where Planck looked for evidence of "dark flow". They found nothing, and a New Scientist article summarized the situation:

> "The Planck team's paper appears to rule out the claims of Kashlinsky and collaborators," says David Spergel of Princeton University, who was not involved in the work. If there is no dark flow, there is no need for exotic explanations for it, such as other universes, says Planck team member Elena Pierpaoli at the University of Southern California, Los Angeles. "You don't have to think of alternatives."

One of those promoting the idea that "dark flow" was evidence for a multiverse was Mersini-Houghton, who in a 2008 paper with Holman wrote:

> Our contention, then, is that these observations of bulk flow can be construed as evidence for the birth of the universe from the landscape multiverse imprinted on the superhorizon sized nonlocal quantum entanglement between our horizon patch and others that began from the landscape. When we calculate the size of the induced dipole in our theory and convert it into a bulk velocity dispersion, we will see that for the constrained values of our parameters we arrive at a velocity dispersion of order 670 km/sec, remarkably close to the observed value of 700 km/sec.

One might think that the refutation of their prediction by the Planck data would be a problem. Instead though, the Sunday Times reported a few days ago that Scientists believe they have found the first evidence that other universes exist. The story got picked up by other news outlets, and appeared in the Daily Mail as "The first 'hard evidence' that other universes exist has been found by scientists". The source for the story was Mersini-Houghton:

> Laura Mersini-Houghton, theoretical physicist at the University of North Carolina at Chapel Hill, and Richard Holman, professor at Carnegie Mellon University, predicted that anomalies in radiation existed and were caused by the pull from other universes in 2005.
> Now that she has studied the Planck data, Dr Mersini-Houghton believes her hypothesis has been proven.
> Her findings imply there could be an infinite number of universes outside of our own.
> She said: 'These anomalies were caused by other universes pulling on our universe as it formed during the Big Bang.
> 'They are the first hard evidence for the existence of other universes that we have seen.'

She will be in Britain soon promoting this at the Hay Festival on May 31 and at Oxford on June 11.

According to a New Scientist story just out, this hard evidence for the multiverse should be welcomed, since it (together with string theory) has just been shown to have the power to save us from "Legions of disembodied brains floating in deep space". The story, which appeared in print as String Theory Limits Space Brain Threat starts with

> LEGIONS of disembodied brains floating in deep space threaten to undermine our understanding of the universe. New mathematical modelling suggests string theory and its multiple universes may just provide our salvation – and that could win the controversial theory a few more backers.

It goes on to explain about Boltzmann brains and a recent paper by Bousso and Zukowski, and ends with news of yet another experimental success for string theory:

> "This is potentially an added experimental success for string theory and eternal inflation," says Daniel Harlow, a physicist at Princeton University. "We need to understand it better – the fact that it potentially explains something is motivation to understand it better."

Update: More here on how string theory will save us from the space brains.

Update: I've appended a response from Laura Mersini-Houghton and Richard Holman about this to a later posting, see here.

Comments

1. **Adam Treat**
   May 22, 2013

   Can you provide a link to the New Scientist article that you quote above? Also, it is unclear if Mersini-Houghton and others are talking to the press about a new paper where they discuss their analysis of the planck data. Is this the case or are they talking to the press in anticipation of a new paper?

   I am also looking forward to a follow-up on the claims by Penrose and Gurzadyan regarding evidence for Conformal Cyclic Cosmology found in CMB data. I wonder if the planck data will be used to bolster or refute these claims that seem to be still alive and kicking.

2. **Peter Woit**
   May 22, 2013

   Adam,

   I forgot to put in the link, it's there now. As far as I know there is no new Mersini-Houghton paper providing her own analysis of the Planck data. The Gurzadyan/Penrose claims about the CMB may also be in the category of things the Planck found too implausible to investigate themselves.

3. **Bob**
   May 22, 2013

   I just can't stop laughing at the headline . . .

4. **dark flow**
   May 22, 2013

   I thought that the dark flow was convincingly debunked already in 2011:
   "Measuring the cosmological bulk flow using the peculiar velocities of supernovae"
   De-Chang Dai, William H. Kinney, Dejan Stojkovic, JCAP 1104 (2011) 015 .

5. **Charles Wilson**
May 22, 2013

"LEGIONS of disembodied brains floating in deep space threaten to undermine our understanding of the universe."
Ed Wood, Director of "Plan Nine from Outer Space", just rolled over in his grave.
Ed, you were born 60 years too soon.

6. **Eric**
May 22, 2013

I am confused…. So is it hard evidence for the multiverse or not?

7. **Peter Woit**
May 22, 2013

Eric,

Well, the Daily Mail and Mersini-Houghton say there's hard evidence, and they don't quote anyone contradicting this. Other reporters might turn up someone who would disagree.

I assume the "hard evidence" is not the "dark flow" prediction that didn't work out, but something else (probably the CMB "cold spot" that WMAP found, which Planck says is still there).

8. **Student**
May 22, 2013

"LEGIONS of disembodied brains floating in deep space threaten to undermine our understanding of the universe. New mathematical modelling suggests string theory and its multiple universes may just provide our salvation."

Here's a picture of string theory saving the Empire from the Boltzmann brains:

http://www.perimeterinstitute.ca/personal/shossenfelder/return_of_bb.jpg

9. **paddy**
May 22, 2013

oops…I clicked a link for NEW though ended up in xkcd

10. **nasren**
May 22, 2013

My first thought on reading this was: O dear God what will Matt Strassler say about this kind of journalism. So far he seems to be ignoring it.

11. **Peter Woit**
May 22, 2013

nasren,

I don't think the problem here is the journalists, who are just reporting the exciting news about hard evidence for other universes and great progress on the disembodied brain front that they are hearing from physicists. Michio Kaku did seem to once get to Strassler, but in general he doesn't appear to think this kind of behavior by scientists is worth commenting on.

It's a plausible idea that if most prominent theorists just ignore it, Multiverse-mania might go away on its own. My suspicion is that most physicists subscribe to this. Unfortunately, that doesn't seem to be happening.

12. **Maciej**
May 22, 2013

"This is potentially an added experimental success for string theory and eternal inflation"

Wow! Experimental? Seriously?
Forget experimental. I am not sure if this is mental success at all…

13. **physicsphile**
May 22, 2013

I think it is a bit unfair to tar all multiverse work as being garbage because of this. There certainly is a lot of bad research being done on the multiverse but I think there is also interesting stuff like Weinberg's original claim that it may be how the cosmological constant problem is solved.

14. **mult**
May 22, 2013

There will always be something to laugh at other people. Do some better work of your own which captures the headlines. One never knows, this may inspire young people to get interested in science, and they will produce the 'correct' Theory of Everything, whatever that might be.

15. **Visitor**
May 22, 2013

"Michio Kaku did seem to once get to Strassler, but in general he doesn't appear to think this kind of behavior by scientists is worth commenting on."

Strassler might want to rethink things because the house of physics is becoming an Augean stable and if the interested and responsible parties can't or, possibly worse, won't clean up the mess, eventually the government is going to *seriously* curtail its funding. And then you'll see see how far some noveau-riche Russian oligarch's money is going to get a very few of you – with the rest of you driving taxis or teaching algebra and geometry in high schools across the land.

16. **M**
May 23, 2013

Boltzmann Brains are great, but can String Theory explain why chicken with cut head can survive for years? This phenomenon probably is related to the survival of theories found to be (not even) wrong.

17. **David Nataf**
May 23, 2013

Peter,

Your criticisms of the Dark Flow are quite unfair. Just because it could be explained by a multiverse, does not mean it would need to be explained that way.

The idea of the dark flow was that galaxies have a preferred vector of peculiar motion, which would break the anisotropy assumption that is fundamental to cosmology. There is definitely a coherent linear flow in the nearby universe up to several dozen megaparsecs, and people have debated whether this is due to a "great attractor" (a nearby supercluster), statistical coincidence, or a dark flow. If Planck is correct then it may just be a 1 in 20 statistical coincidence or so that affects the local volume.

Regardless of whether a preferred peculiar direction of motion for matter would be due to a multiverse or not, it is a legitimate scientific test to conduct, to investigate, to write papers about, et cetera. It doesn't need to exist, but it could have existed as dark matter and dark energy (for example), certainly exist, and dark radiation is now a 2-sigma phenomenon. The Friedman-Robertson-Walker-Lemaitre metric from General Relativity, that is the foundation of cosmology, predicts that there should be zero dark flow, similarly to how the standard model of particle physics predicts zero dark matter and zero dark energy. It is good and valid to test these things.

I do however apologize for astronomers' lack of imagination in naming mysterious phenomena. As such, please don't turn into Dark Peter.

18. **Peter Woit**
May 23, 2013

David Nataf,

I'm sorry if this was unclear, but I had no intention of in any way criticizing people for studying "dark flow" or for calling it that.

19. **dark flow**
May 23, 2013

David,

There is no bulk flow as initially claimed. The paper I mentioned indicates that while the direction of the "bulk flow" was correctly measured, its magnitude is much smaller than initially thought (200 km/s instead of 1000 km/s). This magnitude is consistent with Lambda CDM, so there is no need for any unusual physics, certainly not multiverses which are tugging on us. These findings were now confirmed by Planck.

20. **Dom**
May 23, 2013

A good day for solving all known problems, in The Guardian we have
Roll over Einstein: meet Weinstein
"What are we to make of a man who left academia more than two decades ago but claims to have solved some of the most intractable problems in physics?"

21. **Luis**
May 23, 2013

It should be noted that the usual "piece of evidence" claimed for "other universes" comes not that much from the dark flow but from a rather large cold spot in the CMB. Apparently, the consensus as of now is that the spot is simply an artefact of the analysis: http://arxiv.org/abs/0908.3988

22. **Avattoir**
May 23, 2013

The Daily Mail you say?

http://tinyurl.com/ylymnz5

23. **Peter Woit**
May 23, 2013

Dom,

Thanks. I added a new posting about that topic.

24. **Nick M.**
May 23, 2013

Peter,

I think you may have meant May 31, and not June 31, for the date of the Laura Mersini-Houghton appearance at the 2013 Hay Festival in London; i.e., see here, and scroll down the page to see the appropriate listing.

–Nick

25. **Peter Woit**
May 23, 2013

Thanks Nick, fixed.

26. **Stephen Heyer**
May 23, 2013

To me, the strange thing is the very odd and unlikely model of a Boltzmann brain that always seems to be discussed: In short, a complex, fully formed, self-aware being appearing out of nothing. Oh! And the life support system capable of supporting the brain from local resources (wisps of left over hydrogen?) is never mentioned, despite the fact that without it the brain's existence would be momentary.

Far, far more likely would be the Boltzmann equivalent of a bacteria with a built in tendency to survive, reproduce and become more intelligent, much the way we current Boltzmann brains did it. The only real difference being that Boltzmann brains are usually imagined as existing much later in the universe's history when resources are much more diffuse.

In fact, looked at like that, they become both familiar and very likely. All we are really saying is that life and probably intelligence will arise anywhere there are the resources to support it, even if those resources are very different to those we are currently used to.

A final thought, given the fascination these discussions always have with a late stage universe with mostly burned out stars, that universe is probably going to be already fully populated and it's resources carefully husbanded so there might not be much opportunity for late comers.

All it takes is for one high technology society from our period of the universe to not destroy itself during adolescence and stabilize and, it, or something derived from it, will be still there thousands of billions of years later using increasingly clever ways of living off the available resources (unless, of course, its cracked ways of making entirely new ones).

So you see, for almost all of its existence, the universe will be mostly observed by something like us, or something distantly derived from something like us. No problem!

Stephen Heyer

27. **Michael R**
May 24, 2013

Does anyone know how the proponents of the Dark Flow Multiverse concept explain how it is that light may not escape a universe but that the gravitational force of one universe acts on another neighboring universe?

28. **chris**
May 24, 2013

Michael,

the horizon was not always as small as today. all these proposed effects would be primordial remnants.

29. **Bob Hope**
May 26, 2013

No. Seriously, if there is a Boltzmann brain, then there must be a corresponding Boltzmann brane or a class or category of them which embed the Boltzmann brain. And yet I couldn't find any. Is not there any? Are these just Riemann surfaces too? Or are they higher dimensional branes?

Eric Weinstein on Geometric Unity

May 23, 2013
Categories: Uncategorized

Eric Weinstein is a Harvard math Ph. D. who has been working as an economist here in New York for many years, and someone I've often enjoyed talking to over the years. Going back to his days as a graduate student, he has been working on some of his own far out of the mainstream ideas about geometry and physics (which I've never seen the details of). Eric has finally gotten to the point where he is willing to talk about these ideas publicly, and he is giving a [lecture today in Oxford](), something that was arranged by Marcus du Sautoy. The Guardian has a long article about him and his work [here]().

There's a bit of an analogy with the Garrett Lisi physics outsider story here, although I think Eric will get less media attention since he doesn't have the surfing angle going for him. Both he and Garrett are pursuing what seems to me one of the deepest questions around: what is the relationship between the SU(3)xSU(2)xU(1) geometry of the Standard Model, and the 4d pseudo-Riemannian geometry of space-time and general relativity? Garrett was trying to understand this in terms of E(8) symmetry, and I'm looking forward to seeing what Eric's ideas about this are. I'm not sure when he'll have a paper out on the arXiv, or whether some sort of version of his lecture will be available.

Update: The Guardian now has a [very enthusiastic article]() about this by Marcus du Sautoy, while New Scientist has a skeptical take [here]().

Update: See [Jennifer Ouellette]() for a critical take on the Guardian coverage.

Update: It seems that claims that physicists were not invited to Weinstein's talk are not true: an announcement and posters were sent to the physics department, but did not get widely disseminated. For a small amount of info about the talk, see the comment here from "Leaker".

Comments

1. **isomorphismes**
   May 23, 2013

   FWIW, his economic theories are considered heterodox as well (see Eric Falkenstein's post on EW) but I think they make sense.

2. **fuzzy**
   May 23, 2013

   i'd like to recall that garret lisi's paper http://arxiv.org/abs/arXiv:0711.0770 was preceeded by fabrizio nesti's one http://arxiv.org/abs/arXiv:0706.3307 (published). fabrizio doesn't surf, though he is a good sailor; hope this helps to give him consideration.

3. **Nameless**
   May 23, 2013

   I'm not sure if even getting access to the lecture would be helpful. Simonyi Lectures exist "… to promote the public understanding of science". If the intended audience is higher level than Guardian readership, it's not much higher than that. The lecture is certainly not directed at experts in high energy physics. We'll have to wait for an arxiv paper to make judgments.

4. **David Roberts**
   May 23, 2013

   "[On Friday 24th May from 10:00 — 12:00 in L3](),
   Eric Weinstein (Oxford)
   Geometric Unity

   A more detailed exposition of Thursday's Simonyi Lecture."

   Anyone willing to go and take notes?

5. **Garrett**
   May 24, 2013

   Eric's been working on this for a long time — I'm happy he's now publicly airing some of his ideas. And I'm looking forward to seeing what he puts on the arXiv.

   To answer the raised issue of Nesti's previous work: I did have some good conversations with Nesti, and even climbed a mountain with Percacci — and I cited their work. The idea, in general, of graviweak unification is groundbreaking and needs more attention.

6. **fuzzy**
   May 24, 2013

   hi garrett,

   it is very kind from you to mention this, and i hope it will help the italian academia, a bit stiff and hard-eared, to recognize the great talent of nesti.

   (of course, i am a friend of nesti, not him. He would not use silly nicks as those i use, he would have signed with his name, just as you did)

   finally, i apologize for the offline statements here above — but i hope they will offer you other occasions of mutual exchanges.

7. **A.J.**
   May 24, 2013

   Paper, or it didn't happen.

8. **tea**
   May 24, 2013

   The Theory of Everything is by now old hat. What we need is a **T**heory **E**xplaining it **A**ll. The author of the New Scientist article claims that the Oxford physicists were not invited to Weinstein's talk. That is curious, considering that the talk was publicly advertised on websites. However, if there was indeed a scheduling conflict with a physics talk on alternative sources of CP violation, then that indeed was poor planning. There seems to be no statement that Weinstein has been invited, or is meeting, with multiple people at Oxford (physicists … Penrose?) to discuss/answer his ideas one on one. That is strange, but who knows. Hopefully an arXiv preprint or other public document will appear soon.

9. **NuclearHobbit**
   May 24, 2013

   Although not an abstract of this lecture, I think Mr. Weinstein may have outlined its content here:
   http://edge.org/responses/what-is-your-favorite-deep-elegant-or-beautiful-explanation
   (scroll down to Mr. Weinstein's answer)

10. **Nameless**
    May 24, 2013

    @NuclearHobbit his answer seems to be half history, half lyrics, and, if there's any of his own work in there, it's well hidden. (However, that does not exclude the possibility that it is, in fact, an abstract of his lecture.)

11. **Bob Jones**
    May 24, 2013

    Can someone tell me where Ed Frenkel endorsed this guy?

12. **Bob Jones**
    May 24, 2013

    Never mind. I didn't see the first Guardian article.

13. **outsider**
    May 24, 2013

    It is perfectly possible for an outsider to have ideas which fundamentally alter our world view, for example a clerk working in a patent office in Switzerland. But Einstein published his ideas in papers on Brownian motion, the photoelectric effect and special relativity, with detailed formalisms and calculations to back up his ideas. Weinstein really needs to put out a concrete preprint, and in fact he should have done it before giving his lecture. "Paper, or it didn't happen" — absolutely spot on.

14. **Nameless**
    May 24, 2013

    @outsider The amount of background information Einstein needed to come up with special relativity and the amount of information needed for a scientist today to unify QFT and GR are so vastly different that it's hard even to compare them. We are talking two, maybe three orders of magnitude.

    Special relativity involved some out of the box thinking, but, as far as background information, he needed basics of Maxwell's electromagnetism, kinematics, null result of Michelson-Morley experiment, and some knowledge of the theory of aether as it existed in 1905.

    To unify QFT and GR, you need to be familiar at least with QFT and GR. An adequate exposition of QFT that covers all progress through, say, 1980, without any prerequisites, would fill 1000 pages. Add another 500 pages for GR. If you want to include any fancy new stuff, volume of background information keeps growing and growing. Any half-hearted attempt at unification should probably give Einstein-Cartan in the continuum limit, E-C is not included in standard GR textbooks and you need to pick it up on the side. If you want to go in the same general direction as Garrett Lisi, you need to understand algebraic group theory and know a thing or two about E(8) (add another 1000 pages of mind-bending mathematical theory to your reading list.) Current situation is that a even a random third year physics grad student, who spent years and years on full time study and who has already covered everything up to and including fundamentals of QFT and GR, would find most articles in theoretical high energy physics section of Arxiv so incomprehensible that they might as well have been written in Greek.

15. **Peter Orland**
    May 24, 2013

    Nameless,

    Nobody knows everything. We learn things as we go along. Though it is true that learning without thought is ill advised and thought without learning is perilous (as someone famous once said), you can do both, just by working seriously on a real problem.

    Speaking of real problems, however, I am not sure unifying QFT with GR qualifies as one.

16. **Nameless**
    May 24, 2013

    What I'm not sure about is whether one can learn everything necessary to unify QFT with GR while working full time as a Wall Street quant and writing papers on economics in one's spare time.

17. **David Nataf**
    May 24, 2013

    Einstein was much more than a clerk at the patent office. He had a full PhD in theoretical physics, and he had written thoughtful papers on thermodynamics prior to his steps forward in 1905.

    The stereotype of Einstein is that he was bad at math in school, he failed all his math courses and he sucked, and then he was out of the field and had to work at the patent office, and then he solved every problem in physics at the time completely out of the blue, and there were no precursors in the literature that could motivate any of his advances. The idea is that he made his advanced entirely from pure thought, by visualizing himself riding a wave of light. This is of course absolute fiction, and it's extremely harmful to science.

    Albert Einstein was in fact very gifted at mathematics, and he had a full PhD in physics, where the standards might have been far higher in ~1900 than they are today. Relativity, for example, did not come out of the blue, as he and many other physicists had already seen the Lorentz equations in Maxwell's electromagnetic theory, he was merely the first one to make the connection to inertial reference frames.

18. **outsider**

May 24, 2013

Weinstein has a Ph.D. in mathematical physics from Harvard, and while I have not checked his publications list, I have no doubt that he has many published papers of highly accomplished research. Not exactly a nobody tinkering in his garage with no formal training. But he really needs to put out a preprint.

19. **fuzzy**
May 25, 2013

hi outsider, there is one database that is used by all physicists working in this field, named inspire. you can check that there is only 1 record there, his thesis
http://inspirehep.net/search?ln=en&p=f+a+weinstein%2Ce&action_search=find

20. **Narad**
May 25, 2013

> you can check that there is only 1 record there, his thesis

Given the title, I have to wonder whether it has an epigraph.

21. **nasren**
May 25, 2013

The case of Weinstein is interestingly dual to the other problem that has come up recently: that of established (ie employed) theoretical physicists talking absolute rubbish. I would think that physicists would be more concerned about THAT trend, rather that the possibility of a bright, qualified outsider saying something novel and interesting. So this adverse press reaction smacks of vested interests. (And I would like to see some clarification on what it means when a physicist claims that "physicists weren't invited". Does that mean they weren't informed about it? Or that they weren't sent an engraved invitation and a pretty-please?)

22. **David Nataf**
May 25, 2013

nasren,

It probably means that the email to the math department inviting them to the colloquium was probably not cc:ed to the physics department, which is common practice in inter-disciplinary talks.

23. **momerathe**
May 25, 2013

wake me up when there's a testable prediction.

24. **Tom Andersen**
May 25, 2013

There have been a few comments to the effect that without knowing QFT/Standard Model/GR/ in detail, its impossible to formulate a new theory. Rubbish. Why would Kepler have to know the Ptolemaic theory of deferent and epicycle in order to discover elliptical orbits?

Like most 'outsider' (is the ratio any better for the insiders?) papers, Eric's ideas are likely flawed in some way, but that does not mean that his contribution will not be useful. I have not seen much value from the official theoretical physics team from the past 30 years, even though the amount of time spent on the subject was easily greater than all the previous time spent on this subject throughout history.

There is so much baggage in the current theories of physics that 'knowing all of it' only serves to fasten the blinders on.

25. **Anonyrat**
May 25, 2013

The Guardian article says: "Weinstein begins the paper in which he explains his proposal with a quote from Einstein: "What really interests me is whether God had any choice in the creation of the world." "

Where is this paper?

26. **Peter Woit**
May 25, 2013

Anonyrat,

As far as I know, such a paper is not publicly available, and I haven't seen a copy.

27. **Jeff M**
May 25, 2013

To follow up on @fuzzy, checked mathscinet, Weinstein has no papers there either. du Sautoy is of course a serious mathematician, and assuming he's seen some sort of preprint (one hopes!!) then there might be some interesting math going on. Aesthetically I like the geometrization idea, and it might be possible that Weinstein has had an interesting insight somehow that Atiyah and Singer and all the rest missed somehow, but I wouldn't bet my house on it 🙂 Also, keep in mind that as a research mathematician du Sautoy is a number theorist, his serious papers are mostly on zeta functions and groups, not infinite dimensional geometry.

28. **CPV**
May 25, 2013

Jennifer Ouelette is absolutely correct. Weinstein et al are master manipulators. I've seen his act trying to claim that economies are best modeled as quantum field theories and other complete nonsense. He is best called out as what he is – a high-falutin' fraud. I have no idea how Frenkel got mixed up with him, but his movies show he is no stranger to publicity seeking activities. It's not bad manners to call these things for what they are, and not to get duped by a smart huckster.

29. **op-ed etc**
May 25, 2013

What is also puzzling is du Sautoy's behavior. He is after all an established math professor and knows 'the system' or the protocol to handle these claims. By his own admission, he met Weinstein at a bar in NY two years ago and heard Weinstein describe his ideas. Then he should have said something like "That's really great. You should write up something on the arXiv and I'll show it to people at Oxford. Let's get their feedback (both physics and math). Then I can arrange for you to give a lecture and meet people privately … " But instead there is no preprint of any kind, and physicists were apparently 'not invited' to the lecture, and du Sautoy goes so far as to write an op-ed piece for the Guardian. Puzzling.

30. **Kara Szathmary**
May 25, 2013

I hope that Weinstein's eventual paper will NOT be the likes of Nassim Haramein's "Schwarzchilds Proton". I did like Garret Lisi's paper and thought what a shame he's gone surfing, and like Grigori Perelman vanishing after proving Poincare's Conjecture.

31. **JoeMomma**
May 25, 2013

Has anybody seen this Geometric Unity? When and where can we access it if we're not at Oxford? It's kind of lame someone claims to have solved big problems but doesn't give the public any papers/lectures/whatever.

32. **gu**
May 25, 2013

Geometric Unity is a self-applied label. You can't access it if you're not at Oxford, and the evidence indicates that you can't access it even if you *are* are Oxford. Just about everyone has remarked that this is a glaring omission.

33. **King Ray**
May 25, 2013

Perhaps they are stringing him along in the hopes of a large financial donation from him or his employer.

34. **Terry**
May 25, 2013

I met a guy at an APS conference in the 1990's who gave me a hard bound book (the thesis kind, not the publishing company kind) that he wrote called "The theory of Unity" which he claimed solved all of the problems of physics and unified QFT and GR. I still have it. There are almost no equations in it and a lot of technical sounding words which were clearly invented by the author. At the time I complimented the author and assured him that I would look at it. I am sure almost everyone here has similar stories. Although it is not necessary to have a paper on the arxiv prior to giving your lecture (that happens all the time!), it is unusual that the slides, notes, audio, video, or even audience notes have, as yet, failed to appear.

Personally, I would rather have talks like Frank Nelson Cole at the AMS in 1903, or Andrew Wiles' lecture at Cambridge in 1993. I.e. the lecture is the place where the result comes out and the media fame follows that — not the other way around (like cold fusion, faster-than-light neutrinos, etc etc etc, and now Geometric Unity)

35. **hbar**
May 25, 2013

I attended an APS April Meeting once, where I saw in the abstracts that someone had a new proof from first principles that hbar = h/2pi. Unfortunately I was so stupid that I missed the talk by 20 min (these are 10 min talks in parallel sessions), so I regret to say I missed the proof.

36. **Terry**
May 25, 2013

Does anyone even know what group or space the theory is based on? How many dimensions? … or better yet, the predicted proton lifetime 😉

37. **Richard**
May 25, 2013

My take on this, for those who are interested — short version: this is not how science is done, and du Sautoy should know that.

http://excursionset.com/blog/2013/5/25/trainwrecks-i-have-seen

I think this does have similarities to Lisi, and also to Wolfram — stories about revolutions in science whose impact outside the community is greater than their impact on science itself.

38. **King Ray**
May 25, 2013

I think that good scientists and mathematicians seek the truth and not publicity and attention. Compare others' actions to those of Perelman.

39. **nasren**
May 25, 2013

With one breath people say that this is not how science is done — and usually it is not, agreed — but on the other it seems that Jennifer Ouellette and others are trumpeting the way science is usually done as the right way, even while we are being told that the way science is now done is not the way it was done in the past. If you follow me. 🙂 What I see are professional norms being broken all over the place and a discipline that is happy with that provided tenure is given and the money keeps rolling in. So when someone comes from outside it is a threat — to a status quo that is impossibly broken anyway.

New ideas are usually rubbishy old ideas repackaged — I have lost count of the number of times I have been handed a "book" with a solution to the entire universe — which usually ends up saying something like "it's all energy man". I was once handed such a thing from someone who claimed to square the circle ("hey, you just change the value of π to 22/7!") We all have. But Weinstein is not one of those guys.

P.S. Many years ago when I was on this site regularly (around 2004 or 5 I think) I heard of a guy who was doing maths physics outside of academia, while surfing in Hawaii. I thought this was very cool and have often thought of it since, wondering how it was going. And today I am delighted to find that it is Garrett Lisi and that he got his ideas out there! Amazeballs, as the kids say.

40. **momerathe**
May 26, 2013

look on the bright side: it may or may not be real, but maybe he'll get 3 million Russian dollars out of it.

41. **Monty Python**
May 26, 2013

Half a theory, philosophically,
Must ipso facto, half not be.
But here the half, that's not a theory,
Is all we see. Do you agree?

S U two, cross S U three,
Eric the half a theory.
G mu nu, is eight pi T,
Eric the half a theory.

Is this cryptic news story,
About an unknown PhD,
Scientific methodology?
No! It's Eric the half a theory…

42. **Daniel Tung**
May 26, 2013

It is great that people from outside of academia produce serious and significant work.
However, I doubt that the next step of revolution in Physics will require only beautiful mathematics and no deep conceptual re-considerations.

43. **Terry**
May 26, 2013

@nasren There is a reason that "the way science is usually done" is the right way. We tried it the other ways – they didn't work. Let's be real about this folks. I know it seems fun and exciting to speculate about the unknown hero riding in from the outside and revolutionizing physics, but that isn't going to happen here. The guy got a phd from Harvard a couple of decades ago and hasn't even published a paper since and now his math buddy from grad school invited him to give a lecture about his sideline musings. We all know how this story is going to end. The fact that he has spent 20 years doing hedge fund math does not make his insights more insightful. In fact, the opposite is true. Hedge fund math is not grand unification. Not even close. Weinstein's theory may contain one or two interesting mathematical ideas, but much more likely, and appropriately for this blog, it will end up being filed in the "not even wrong" bin of history.

44. **DLB**
May 26, 2013

Seems like everyone is debating reputations and speculating on whether an outsider can come with a new theory that correctly describes reality. That is not how science evaluates ideas.
Let's wait and see what this theory is, how well it describes reality and what predictions that are original to it that can be experimentally or observationally tested.
Theories are not validated by degrees or titles, but by experiments and observations.

45. **S**
May 26, 2013

Terry,

In fairness, it's not clear to me that the theory is likely to be filed in the "not even wrong" bin of history if it predicts 150 new particles with exotic properties, especially if they're at accessible energies. Wouldn't that be just plain vanilla wrong (if it didn't pan out)?

46. **mike**
May 26, 2013

Peter,

Do you know of anyone who attended? Any reports about content?

47. **Terry**
May 26, 2013

S, good point. That seems more likely. I.e. just plain old wrong.

DLB, when he goes to the press with vague statements, presents no paper, and no lecture notes or slides from the talk, there is little else we can do except speculate based on reputations of supporters, educational background, and what-not. The conversation would be much more technical and scientific if they had given us something tangible to discuss. (The conversation might also be much shorter. For example, "it predicts a proton lifetime of 10 nanoseconds, so no point wading through the rest of the screed")

48. **Leaker**
May 26, 2013

Some comments on the talk by a mathematician that were forwarded to me:

"The core idea seems to be to work with the 14-dimenional bundle of all metrics over a 4-dimensional manifold, as a way of generalising GR, the standard model, and QFT a the same time. The high dimensionality gives very large multiplets of as yet undiscovered particles, and he has no idea of their masses. …
…He still hasn't got all the details worked out and there's no preprint. My general verdict would be that it's certainly not nonsense, but I would take a lot more convincing that it's heading in the right direction."

49. **Oldster**
May 26, 2013

"Any half-hearted attempt at unification should probably give Einstein-Cartan in the continuum limit" —Nameless

Why? It's only one possibility.

50. **Nameless**
May 26, 2013

OK, "Einstein-Cartan or something like that". Point is, if you're doing unification, you will end up predicting (or, more likely, assuming) the effect of spin on the geometry. It may be null, but it probably isn't, and no one discusses it in standard textbooks because, except in the vicinity of Planck energy, it's so minuscule that it's not experimentally verifiable.

51. **Peter Woit**
May 26, 2013

Thanks Leaker,

That sounds consistent with the little that I've heard directly from Eric about this.

52. **Oldster**
May 27, 2013

I tend to agree with Roger Penrose that spin has been one of the great mysteries in quantum mechanics. As best as I can recall, he said it was one of two primary mysteries in a talk at NYU back in the late 1990's. At the moment, I don't remember what the second one was, but I'd agree that spin's effect on geometry is a necessary problem to be solved by a complete unification. But until a specific model is proposed, even the magnitude of the effect remains unclear. You are right that it is small in the specific Einstein-Cartan case …

53. **nasren**
May 27, 2013

Oldster — I think this is right. Atiyah has said the same thing. And understand spin and I think we'll understand entanglement a lot better.

54. **Nameless**
May 27, 2013

The effect of spin is likely small quite generally, from dimensional arguments. An iron magnet with spins of its atoms perfectly aligned has average spin density on the order of 10^-5 J*s/m^3. If spin is coupled to geometry through the same G as the stress/energy tensor, we can construct a quantity *G/c^3 with dimensions of inverse length, somehow related to the curvature of spacetime induced by spin, which works out (if I'm not mistaken) to about (10^40 m)^-1.

55. **cormac**
May 27, 2013

Hi Peter, I'm a teeny bit surprised at your reaction – isn't this exactly the sort of hype you are usually so critical of? No paper have been published, not even an abstract, so why all the fuss? Perhaps you have seen something something we don't…
As regards the du Sautoy article, I think it's an editorial. Think of all those published papers that never got a mention, never mind an editorial.
Btw, I was suprised by du Sautoy's sentence
"One proposal for the source of this push involves reintroducing the cosmological constant into Einstein's Field Equations. But this cosmological constant has always seemed very arbitrary and a retrospective fix."
As a constant of integration, there is no particular reason for the cc to be zero, which is why it never really went away

56. **Tony Smith**
May 27, 2013

Peter can you give a description of

the 14-dimensional bundle of all metrics over a 4-dimensional manifold

with details such as its bundle structure (base manifold and fibre),
symmetry groups, etc ?

Tony

57. **Peter Woit**
May 27, 2013

Hi Cormac,

There's an infinite amount of hype about science out there, I try to only spend time denouncing that part of it which seems most problematic, hype about ideas that are hugely influential despite their failures (string theory, SUSY, multiverses). When Marcus du Sautoy gets the Oxford String Theory Group renamed as the Oxford Geometric Unity Group, despite Weinstein's ideas not working out, then I'll add them to the list to denounce. Right now, I just don't see the problem of Weinstein getting too much attention for his ideas as a major one for physics.

Another reason for not writing more about this is that I don't know much about what is going on, which seems to be a good time to wait a bit before commenting more. Lots of people have been denouncing du Sautoy for not inviting physicists to the talk, when it turns out he did. Eric definitely needs to get a paper or slides or something out with details of his ideas, maybe that's imminent, maybe not, we'll see.

I'll write more about this soon though…

58. **Peter Woit**
May 27, 2013

Tony,

The metric tensor is a symmetric bilinear form, so 10 components in 4 d. So, you could make a bundle over your 4d spacetime, with 10d fibers given by the symmetric bilinear forms on the tangent space.

Beyond that, Eric is the one who needs to get details of this out, not me, since I'm still in the dark…

59. **Oldster**
May 27, 2013

Nameless, yes, you can do that as long as you're not dealing with some more exotic structure analogous to the original Weyl or Kaluza-Klein unified fields. In structures like those, the factor of G may not always lie between the physical and the geometric, that's all.

60. **Alex**
May 28, 2013

"The metric tensor is a symmetric bilinear form, so 10 components in 4 d. So, you could make a bundle over your 4d spacetime, with 10d fibers given by the symmetric bilinear forms on the tangent space."

Considering that there are 12 Gauge bosons, 14 sounds a wee bit low then… Well, we'll see, or not.

"
"One proposal for the source of this push involves reintroducing the cosmological constant into Einstein's Field Equations. But this cosmological constant has always seemed very arbitrary and a retrospective fix."
"

Yes, that's indeed strange. If I am not mistaken, in an effective field theory approach of SM + Einstein-Hilbert, the cosmological constant appears automatically as a counterterm. The problem has been for decades that naively, one has to tune it small, not that it is there in the first place.
The way the paragraph is phrased sounds to me like du Sautoy does not really know the stuff.

61. **Jamie Vicary**
May 28, 2013

Those who missed it the first time need only wait 2 more days — for it seems Weinstein is giving a re-run this Friday at 2pm in the Mathematical Institute in Oxford. Maybe the particle physicists will come this time!

62. **PhiGuy110**
May 30, 2013

Given how bloated and self-referential modern physics have become without offering many testable predictions (string theory anyone?) it's not surprising to me that real insight could come from outside the ivory tower echo-chamber. I think Weinstein probably deserves a fair hearing and open minds. However, without a paper or predictions, it's hard to say much of anything, good or bad. I look forward to following the story as it works it way through the physics community. I reckon that we'll know sooner rather than later whether there is anything to this.

63. **kevin dowd**
June 3, 2013

I would like to say that the faster than light neutrino gjys always get a bad wrap. AFAIK they stood up there and said we have this data, we can't get rid of it, it looks funky, and we ask you help in showing where we went wrong.

No wild claims .. I thought they were embarassed they had these results and could not suppress them because, well, you just don't go around suppressing data you don't like without a reason. And then later of course it was a cable problem. But they didn't know that.

64. **Peter Woit**
June 3, 2013

kevin dowd,

"And then later of course it was a cable problem. But they didn't know that."

That's why they get the bad rap. They should not have gone public until they had checked their cables. It's not about "suppressing data", it's about how hard you work looking for what could be the source of the problem when there is something weird in your data. Some members of the collaboration refused to put their names to the paper, knowing they hadn't checked things carefully enough to justify going public.

Anyway, that story doesn't really have much to do with this one.

65. **King Ray**
June 6, 2013

I think Eric's tweet from May 29 is instructive:

"You'll get an article whenever I've time to finish one & only because I really want to give you one. This is just a (time thirsty) hobby."

It seems like he is more interesting in getting attention than in contributing to science.

66. **Peter Woit**
June 6, 2013

King Ray,

I know Eric pretty well, and he's not doing this to get attention, get on TV, get a book deal, etc. As far as I know, the Guardian blog posts were not his idea. He seriously believes in what he is doing, has been working on it completely quietly for many years, and is deeply conflicted about discussing his ideas in public. Yes, he really needs to get a paper written so others can see what he has, but it's not because he's trying to get attention that he hasn't done that yet.

67. **King Ray**
June 6, 2013

Peter,

I stand corrected. It sounds like things haven't sufficiently converged yet for him to feel comfortable writing a paper–perhaps there are too many loose ends still. I've found that writing things down helps clear things up sometimes. The theory sounds like a large extrapolation on the SM though.

Various Links

May 25, 2013
Categories: Uncategorized

- The Smithsonian has a long article about Lisa Randall here.
- The Wall Street Journal has a shorter article about Randall's high school classmate Brian Greene here. Brian's World Science Festival will start here in New York on Wednesday.
- I'll probably skip the World Science Festival in favor of an event at the CUNY Graduate Center: a conference on the work of Jim Simons, in honor of his 75th birthday. The conference will start off Tuesday morning with talks by Witten and Deligne (for a recent piece about Deligne and the Weil conjectures by Ed Frenkel, see here)
- One of many worthwhile things funded by Simons is Simons Science News, which now carries some of the best science journalism around. There's a new interview with David Gross, who talks about the way QFT overcame those who wanted to do away with it in the sixties. About string theory:

  > String theory is not as revolutionary as we once hoped. Its principles are not new: They are the principles of quantum mechanics. String theory is part and parcel of quantum field theory.

  About the multiverse:

  > There are frustrating theoretical problems in quantum field theory that demand solutions, but the string theory "landscape" of 10^{500} solutions does not make sense to me. Neither does the multiverse concept or the anthropic principle, which purport to explain why our particular universe has certain physical parameters. These models presume that we are stuck, conceptually.

  About the current situation "Sometimes, he says, science is just plain stuck until new data, or a revolutionary idea, busts the status quo."

  The latest article at Simons is one by Natalie Wolchover, who was at the same Nima Arkani-Hamed talk I recently attended. See her take here, mine here. Will write yet again about "naturalness" and some of the content of this article in a separate posting.

- For the state of SUSY, and particle physics in general, check out recent talks here, especially Matt Reece's SUSY theory overview. I think a fair description of the current state of affairs is that the only SUSY theories standing are either "fine-tuned" (removing the main argument of LHC-scale SUSY), or highly contrived (e.g. by going beyond the MSSM in various ways to escape LHC negative results). For the latest experimental results about SUSY, watch for this CMS talk on Tuesday.
- For the latest in speculative theorizing about HEP and cosmology, see this past week's Planck 2013 conference.

Comments

1. **Tom**
   May 25, 2013

   In Wolchover's article Arkani-Hamed asserts that "naturalness has a track record", and she writes that "Time and again, whenever a constant appeared fine-tuned, as if its initial value had been magically dialed to offset other effects, physicists suspected they were missing something. They would seek and inevitably find some particle or feature that materially dialed the constant, obviating a fine-tuned cancellation." I found this very surprising because my opinion has always been that naturalness has no track record whatsoever as a useful physical principle, and when I asked people to give me an example the only thing anyone ever came up with was that you could have inferred the positron from the self-energy of the electron, if you hadn't already known about it. Does anybody know of any other cases?

2. **Shantanu**
   May 25, 2013

   Peter or others,
   has any BSM prediction or any other idea in any theoretical paper by Randall been vindicated by experiment? I don't think so, but maybe I am wrong.

3. **Peter Woit**
   May 25, 2013

   Tom,

   I've written a lot more about this in the next posting.

   Responses to Tom's question are encouraged, but please put them in the next posting.

4. **Peter Woit**
   May 25, 2013

   Shantanu,

   I don't know of any, but that's true not just of her, but of all BSM theorists.

5. **David Nataf**
   May 25, 2013

   I saw on astro-ph a month ago that JiJi Fan, Andrey Katz, Lisa Randall, Matthew Reece had an article on dark matter interactions.
   http://arxiv.org/abs/1303.1521
   http://arxiv.org/abs/1303.3271
   They did something I had never seen before … they had the standard 30 page version of their paper, and they also wrote a 5 page cole's notes version, I wonder which version will end up with more citations. A lot of people I spoke to found it funny, but, it's probably a good idea.

   I dont think the general idea of double-disc dark matter is that new, but they're probably pushing it to a more sophisticated and a more precise direction. And, as far as I can tell, that would make them among the first particle theorists to realize that the Gaia satellite has a good shot to be the highest-impact technological laboratory in the next decade in terms of putting fundamental physics forward. In my view there is a desperate need for more predictions for Gaia observations that are only a few years away, so this was a good step forward.

6. **Navneeth**

May 26, 2013

I came across the Simons Foundation/News website only recently when I found the link to the article about the recent advances regarding the Twin-prime conjecture. As a layman I thought the piece well written; not dumbed down at all (in the most pejorative sense of the term), for a popular level article.

The “Unnatural” Standard Model

May 25, 2013
Categories: Multiverse Mania

The Standard Model is a physical theory of a spectacularly successful sort. It is built on beautiful and deep mathematics, covers almost all known physical phenomena, and agrees precisely with the result of every single experiment ever done to test it. It leaves open a very small number of questions: why this specific combination of small symmetry groups and their representations? What determines the parameters of the model (18 if you ignore neutrino masses, 7 more if you include them)? What about gravity? Does it need to be extended to account for dark matter?

For several decades now, there has been a very active and heavily advertised field of “Beyond Standard Model” physics, the study of extensions of the standard model that remain consistent with experimental bounds. While BSM models have played a role in guiding experimentalists towards things to look for that are not already ruled out by what is known, they have never come anywhere near fulfilling the hope that they might provide some insight into the SM itself. They provide no explanation of the unexplained aspects of the Standard Model, instead adding a great deal of additional unexplained structure. Perhaps the simplest and most widely studied example is the minimal supersymmetric extension of the SM, which not only explains none of the 25 undetermined SM parameters, but adds more than 100 additional such parameters to the list.

Theorists have traditionally followed what has been described as “Albert Einstein’s dream that the laws of nature are sublimely beautiful, inevitable and self-contained”, and the SM is our closest approach so far to Einstein’s dream. If you shared this dream, the known BSM models would never have much appealed to you, since they just added complexity and extra unexplained parameters. You also would not have been at all surprised by the strong negative results about such models that are one of the two major achievements so far of the LHC (the other is the Higgs discovery). If you’re a follower of Einstein’s dream, the obvious reaction to the LHC results so far would be to rejoice in the vindication of this dream, welcome the triumph of the simplicity of the SM, and hope that further study of the Higgs sector will somehow provide a hint of a better idea about where the SM parameters come from (almost all of them are Higgs couplings).

Remarkably, a very different story is being sold to the public by those who had a great deal invested in now failed BSM models. In this story, the BSM models were the ones of Einstein’s dream: they were “natural”, and their failure leaves us with the “unnatural” Standard Model.

An article entitled Is Nature Unnatural? is the source of the above quote about Einstein, and it tells us that

> Decades of confounding experiments have physicists considering a startling possibility: The universe might not make sense…
>
> In peril is the notion of “naturalness,” Albert Einstein’s dream that the laws of nature are sublimely beautiful, inevitable and self-contained. Without it, physicists face the harsh prospect that those laws are just an arbitrary, messy outcome of random fluctuations in the fabric of space and time…
>
> “The universe is impossible,” said Nima Arkani-Hamed, 41, of the Institute for Advanced Study, during a recent talk at Columbia University .

What is behind this sort of claim that down is up is abuse of the English word “naturalness”, which in this particular case has been adopted by theorists to refer a technical property better described as “not quadratically sensitive to the cut-off scale”. There’s a lot to be said (and a lot that has been said on this blog) about the precise technical issue here. It’s a real one, and likely an important hint about the true nature of the Higgs sector of the SM and where all those undetermined parameters come from. Getting rid though of this technical problem by invoking hundreds of new undetermined parameters is not the sort of thing Einstein was dreaming about. He would see the LHC results as vindication and encouragement: as we investigate new energy scales we find the universe to be as simple as possible. It’s remarkable to see this great discovery being promoted as telling us that we have to give up on Einstein’s dream and adopt a pseudo-scientific research program based on the idea that physical “laws are just an arbitrary, messy outcome of random fluctuations in the fabric of space and time”.

Update: The Science News story has now appeared at Scientific American, with the title New Physics Complications Lend Support to Multiverse Hypothesis. The “New Physics Complications” are the LHC only seeing pure SM behavior. If the LHC had seen a complicated SUSY spectrum, that would have been “natural”, but somehow seeing the simplest possibility has become a new “Complication”. It is a “complication”, but a sociological not physics one. SUSY theorists do have an answer for the complication of their ideas failing: the Multiverse did it.

Comments

1. **Bernhard**
   May 25, 2013

   I agree this “The universe might not make sense…” or ““The universe is impossible,” thing from Arkani-Hamed is complete BS and has to do, to some degree, with frustration the BSM theory community (with Arkani-Hamed being the king of it) feels about the fact that the whole BSM businesses have not yet gone anywhere.

   But I think it is unfair to say ” They provide no explanation of the unexplained aspects of the Standard Model”. There are interesting BSM models that do explain things like strong CP problem, neutrino masses,quark-lepton family replication, etc in a quite conservative way and not adding too many parameters. There is really no way out, unless you are the Standard Model anything beyond it will have to add something, at least one new particle necessarily. None of those models have worked so far, but this might still change.

   One does not need to depreciate BSM physics to appreciate how spectacular the SM is. That the desperation led some people to do pseudo-science is a problem, but other people in the community tried to stick with the rules of the game.

2. **King Ray**
   May 25, 2013

   I think the things that made Einstein successful were his imagination, dogged determination and his sense of beauty and simplicity (his ‘nose,’ as he called it). BSM physicists on the whole seem to not use simplicity as a metric at all. You have to explain more things than you add to make things simpler.

3. **Igor Khavkine**
   May 25, 2013

   I’d like to second Tom’s question from a comment to Peter’s preceding post: What **is** the track record of naturalness? More precisely, when have considerations of naturalness correctly suggested the existence of previously unseen degrees of freedom, together with reasonable constraints on them, prior to their actual observation? The examples need not be restricted to high energy physics.

4. **MathPhys**
   May 25, 2013

The technical problem of quadratic dependence on the UV cut-off probably tells us something about the techniques that we use to compute radiative corrections, rather than the physical observables that we wish to compute.

5. **X**
May 25, 2013

Ignoring neutrino masses was *never* a good idea, and now that most of the parameters measured to fair precision, it's absurd to class them differently from the rest of the SM parameters. Maybe you could class Theta differently, but that might be a stretch for the standard Standard Model.

6. **Anonyrat**
May 26, 2013

Without "naturalness" the ideology of the standard model as an effective QFT evaporates. Irrelevant operators could have arbitrarily large coefficients enough to overcome the suppression by powers of the cutoff scale.

7. **Ben**
May 26, 2013

@Igor,

Arkani-Hamed himself goes into a couple of interesting historical examples of the success of naturalness arguments in a video Peter posted back in December; http://www.math.columbia.edu/~woit/wordpress/?p=5416. (link straight to video: http://online.kitp.ucsb.edu/online/higgs_m12/arkanihamed/)

If you skip to 16.40 he starts talking about the classical electron self-energy, the mass splitting between the charged and neutral pions, and very briefly mentions k-kbar mixing, though he actually starts talking about naturalness around 13.00.

8. **fuzzy**
May 26, 2013

hi peter,

i agree on the general statements, but not completely on the formulation of SM you gave. the gauge principle (and renormalizability) instructs you to write all the legitimate operators, not only those you like to include.

in the light of this principle, the SM as a gauge theory has also the theta term and the constant of the potential (cosmological). once you introduce right handed neutrinos, you do not have 7 parameters but much more.

furthermore, when you make the statement concerning "100 more parameters", you write BSM but you mean MSSM (SUSY). no problem to admit that MSSM is (was?) a very popular branch of BSM, but as a scientific concept, BSM is a much wider thing than MSSM: we better avoid confusion.

actually, i do not think it is wise to speak acrytically of BSM; we should speak of more specific things, to avoid falling again on metaphysics.

thanks!

ps i have only one question concerning the quotation: it is quite evident that the star is the chap who succeeded to explain us so clearly that "the universe is impossible," (douglas adams would be proud of him) but who is this einstein? maybe the idea was to write weinstein, and a "w" is slipped away

9. **francis**
May 26, 2013

Actually, there exist theories compatible with Einstein's dream.
For example, Connes' ncg model gives a conceptual explanation of the SM, reduces the number of free parameters and is compatible with experiment.

So IMO the hope of fulfilling Einstein's dream should not be abandoned but should be an indication to know if we are on the right track or not…

10. **Peter Woit**
May 26, 2013

fuzzy,

I pretty much agree with your comments, to make the point I wanted to make I didn't include many details which aren't relevant to the point.

There's very little one can sensibly say about all BSM models, the reason for concentrating on the MSSM is that it's the one that is most well-defined and well-studied. For instance, once one starts in with things like large extra dimensions, I have no idea how to characterize the size of the theory space one is invoking, other than that one has moved away from something highly constrained to something much, much larger.

11. **Toni**
May 26, 2013

Peter,

your last statement implies that you dislike emergence. Are you really stating that emergence is nonsense? And this despite the old argument that general relativity is a result of the thermodynamics of spacetime?

12. **Peter Woit**
May 26, 2013

Toni,

"Emergence" is just a word. I've no strong opinion about what the right fundamental variables are to describe gravitational degrees of freedom: maybe the metric is not fundamental, but "emergent". But that's a pretty empty idea unless you have some serious proposal about what really is fundamental, and what the relation is to the SM (where we do know exactly what the fundamental degrees of freedom are).

13. **fuzzy**

May 27, 2013

hi peter, thanks, but if we agree, then why to jump from MSSM to large xdim (of nima, gia and savas–again!) rather than remarking that the class of BSM theories that take care of neutrino masses have generally much less parameters, and they usually have firmer reasons of being called BSM?

moreover, i would like to insist on the old good gauge theories; they are not yet sufficiently explored! even the simple left right models — but this is true also for so(10) — need to be taken much more seriously than it was done till now.

in my view, rather than drawing rash conclusions, we need some time to think and critical attitude: i feel that the story of naturalness should have taught us that groupthink is not the way to explore the nature.

14. **Marcel van Velzen**
May 27, 2013

Recommended! Guido Altarelli presents an excellent, honest and balanced overview of the current state of naturalness here:

http://indico.cern.ch/getFile.py/access?contribId=27&sessionId=3&resId=0&materialId=slides&confId=239571

15. **imho**
May 27, 2013

From a cond matt theorist's perspective this is a pretty clear example of the limits of human understanding. In the absence of experiment, it seems progress grinds to a halt and science morphs into Philosophy with a mathematical cloak.

How did you guys and gals end up here? Why do so many unquestionably accept, what seems to me to be, unproven assumptions. Who determined that quantizing gravity is any more sensible than quantizing Navier-Stokes? Who decided that dimensional analysis should be used to define a Planck Length? Please explain to me why so many are completely certain that the only two options are multiverse or super symmetry… especially since we know absolutely nothing about 96% of the "stuff" in this universe? This whole thing smells like religions group think.

I'm on your team and I'm really struggling to see the value here. The funding agencies need to continue, and perhaps accelerate, the de-emphasis of unification research. There really shouldn't be more than a few dozen people in the US doing this kind of thing.

16. **Matt**
May 28, 2013

Okay, so now condensed-matter theorists are calling for other physicists' funding to be cut. That's exactly the kind of counterproductive feuding among scientists that doomed the SSC and eventually all high-energy experimental physics in the US altogether. Bravo!

Peter, I think this original post of yours is an incredibly important one, because I think it crystallizes (intentionally or unintentionally) a lot of your thinking on fundamental physics today.

I've been following your opinions on physics for a long time now, and what started as (justifiable) skepticism of string theory has morphed into a general bitterness toward essentially everything going on in high-energy theory today, string theory or not. It's become what I once heard called "sidewalk supervising." That's folks who stand on the opposite sidewalk shouting criticisms at the construction workers trying to repair a building. You've gone from being unhappy with one particular model of new physics (string theory) to complaining about essentially everything that tries to go beyond the Standard Model, regardless of the approach.

And yet, I have no idea what specifically you'd prefer be done instead. You seem to think that working on fundamental physics is something worthwhile to do, but apart from saying vaguely that you think more attention needs to be paid to chiral gauge symmetries (because you believe there's apparently something very deep about the fact that the internal gauge symmetries of the Standard Model know about leftness and rightness, even though it's trivial to think up simple models for which this is totally unmeaningful), there isn't much you've suggested.

In this post of yours, I think you make clear some of your motivations.

You write that "The Standard Model is a physical theory of a spectacularly successful sort." You also say that it "covers almost all known physical phenomena, and agrees precisely with the result of every single experiment ever done to test it."

Sure. But, as you well know, the Standard Model, like all realistic quantum field theories that actually describe practical physics, also predicts that it has a limited regime of validity. So its success and agreement with experiment in that regime of validity does not tell us that it should be valid outside that regime.

You say "It is built on beautiful and deep mathematics," but you know that's irrelevant. There is no metaphysical reason Nature should care about mathematical beauty at a fundamental level. Beauty may have been a nice guide to helping us guess way in advance that QFT should be the right description for low-energy physics, but you know that it cannot be a fundamental justification. Every argument originally inspired by beauty, from Dirac's argument for his eponymous equation to Einstein's argument for general relativity, has now been put on a better footing in terms of actual physical principles. We now have independent reasons for believing all those ideas — beauty may have gotten our foot in the door, but many, many beautiful ideas are wrong, and plenty of un-beautiful ideas are sometimes right.

There are very general arguments that physics consistent with locality, relativity, and quantum mechanics should look like a "beautiful" effective field theory at low energies. Maybe you find such arguments ugly or less inspirational, but inevitability is a far more important criterion than beauty for understanding the Why? of physics.

Einstein's theory of gravity is "more beautiful" and has "fewer adjustable parameters" without a cosmological constant or higher-dimension operators, but there's no physical argument they should be there — and lots of arguments that both the cosmological constant should be there (and experimental confirmation of said fact) as well as that higher-dimension operators should be present suppressed by large mass scales and thus very difficult to detect. And we already have models now in which the beautiful spacetime of general relativity is only an emergent approximation of altogether different physics, and that's an important proof of principle.

But, more importantly, the Standard Model isn't just incomplete in the sense that it predicts its own eventual demise at sufficiently high energies or doesn't explain many of its adjustable parameters or gauge groups. As you note yourself later in your post, the Standard Model doesn't account for a staggering 95% of the mass-energy in the universe whose existence we know from experiments and observations. Nor does it accommodate gravity at arbitrarily high energies in a manner fully consistent with quantum mechanics.

You go on to attack essentially all the BSM models. But people aren't proposing those models just because they are madly in love with, say, split supersymmetry of all things. There has to be physics beyond the Standard Model, and any physics beyond the Standard Model is, by definition, BSM. But the Standard Model, and, more generally, principles like relativity and quantum mechanics (which include conditions like unitarity, causality, etc.), put tremendous constraints on the allowed models one can propose. (And bounds on the validity of relativity and quantum mechanics are extremely small today, due to painstaking work by lots of people over decades.)

The people working on BSM physics are therefore operating under a very tight straightjacket. It's not easy work, and coming up with an idea that is consistent with everything we already know is very, very difficult. The vast, vast majority of ideas ("beautiful" in their mathematics or not) are simply ruled out. You may not like some of the ideas that are still in the running, but they've made it through a grueling gauntlet. They're favored because they've managed to jump through a million hoops. That was, after all, one of the reason people got so excited about string-inspired ideas in quantum gravity.

It's sort of like folks who think the idea of WIMPs as dark matter is an ugly idea, and would prefer, I don't know, modifying general relativity. Well, that just doesn't really work. People have expended a huge amount of energy on that, and it just doesn't work very well in a manner consistent with all the observations we already have and consistency with other physical principles we have exceptionally-strong bounds on.

If you think you have better ideas, then please join the fray! I know it's a cliche, but Roosevelt was right about how it's far more admirable to be a contender, to be getting one's hands dirty, than to be yelling criticisms from the stands that the contenders aren't doing it right. Unless you think physicists should simply stop trying to do fundamental physics, there is no alternative to what's going on. They're not doing BSM in ways you don't like just to piss you off — these are the only directions that have been found so far that are consistent. If you think you have a better approach, please go for it.

Because the only real alternative to trying to thread this million-dimensional needle is just to stop trying to do new high-energy theoretical physics altogether. Maybe there are people who think that's better. But pursuing fundamental physics, trying to resolve paradoxes, and trying to make seemingly inconsistent ideas work together properly has historically yielded helpful results, even if only to other fields.

Einstein was originally trying to reconcile a purely theoretical problem at the time he was trying to make gravitation consistent with relativity. If there had been no planet Mercury or a moon whose angular size in Earth's sky was the same as the sun, then experimental confirmation of his theory might well have taken decades. General relativity has been tremendously helpful to our understanding of lots and lots of physics and mathematics. We understand QFT far better because of many of the tools of general relativity.

Hawking was trying to resolve paradoxes when he ended up deriving black-hole radiation and black-hole thermodynamics, which now provide very strong constraints on proposed new physics and may give us another hint on how to proceed. We've learned a great deal about QFT in curved spacetime, and about phenomena like the Unruh effect, as a consequence.

Going back even further, we can look at the though-experiment paradoxes that presaged quantum mechanics, or Maxwell's corrections to Ampere's law that fixed up his now-eponymous equations that then led to prediction of electromagnetic radiation.

Even inflationary cosmology, which has generated actual predictions that have held up remarkably well, started out as (yes!) an attempt to solve various paradoxes with naturalness that arise in the old Big Bang model. (The horizon problem, the relic problem, the flatness problem — all are naturalness problems!)

There's a long history to show that pursuing fundamental theoretical physics for its own sake, like any kind of basic research, yields unexpected fruit, although most of the attempts end up not working. But to stop it all because of those mostly wrong directions would have been a disaster to all further progress.

Even supersymmetry and string theory have been immensely helpful in understanding QFT. Just as classical mechanics makes a lot more sense in light of quantum mechanics, and QFT sheds a lot of light on quantum mechanics, so too do ideas like supersymmetry and string theory teach us a lot about QFT. Supersymmetry has given us entirely new ways of understanding qualitative features that are otherwise intractable in simpler QFTs, confinement being a prominent example. And string theory has provided many new ways of understanding familiar QFTs as well; indeed, many realizations of string theory are now known to be dual to certain QFTs, so that the two subjects aren't as different as we once though they were. Collider physicists are literally using results originally from string theory to do far better calculations of actual events in their accelerators.

I don't know what else to say except that we have two options — either shut it all down, or do the hard work of trying to thread the needle in the ways allowed by what we already know and keep working until we finally stumble on the right answer.

What else do you propose? And please be specific!

17. **Bob Jones**
May 28, 2013

Many readers of this blog would benefit from reading this article:

http://arstechnica.com/science/2013/05/earning-a-phd-by-studying-a-theory-that-we-know-is-wrong/

18. **Mario**
May 28, 2013

@Marcel van Velzen: I cannot agree. Altarell' does not account for the conformal standard model and consider seriously anthropic ideas. I think that after this paper http://prl.aps.org/abstract/PRL/v110/i15/e151601 this approach should be considered a serious and viable way out to the question of naturalness.

19. **Marcel van Velzen**
May 28, 2013

@Matt,

Nice piece! There's a lot of truth in it. People should continue to work on BSM physics but should also realize what they are up against and don't make misguiding claims because it's here that the problem begins. To be specific:
"Hawking was trying to resolve paradoxes when he ended up deriving black-hole radiation and black-hole thermodynamics, which now provide very strong constraints on proposed new physics and may give us another hint on how to proceed. We've learned a great deal about QFT in curved spacetime, and about phenomena like the Unruh effect, as a consequence."

Although the mathematics is really nice and convincing Hawking radiation and the Unruh effect have never been observed so it should be that MAYBE we've learned a great deal about QFT in curved spacetime and to say that they provide very strong constraints on proposed new physics is also unclear and the hint they give us to proceed may be totally wrong. An exploding black hole has still to be found.

20. **Igor Khavkine**
May 28, 2013

@Matt, what you've written about keeping theories that have passed stringent empirical tests, be they "ugly" or "beautiful", is great and I agree with that wholeheartedly. But, some of the motivations that you list for going beyond the Standard Model are just wrong. I mean "wrong" in the sense that they are based on very shaky arguments. These include: (a) the Standard Model is *internally* inconsistent in some regime, (b) taking GR together with the Standard Model is inconsistent with quantum mechanics, (c) that hierarchy is a problem (or more generally that measured values of free Lagrangian parameters require an "explanation"), (d) that black hole entropy requires a statistical explanation. In the same breath, you've also pointed out real problems that do need to be solved for us to have a better working model of the universe: (a') dark matter is not included in SM + GR, (b') whatever quantum field that seeded primordial fluctuations (say "the inflaton") is not included in SM + GR.

To be fair, you didn't actually say (d), but that is what commonly stands behind the code phrase that "the Hawking effect gives us a hint about quantum gravity". Also, certainly, my opinion will likely not align 100% with Peter's, but since you asked for some specific suggestions, here are some. What not to do: try to solve problems (a') and (b') where there is actual data available to constrain possibilities by simultaneously trying to solve (a), (b), (c) and (d). The latter four are red herrings that prompt people to take uncontrolled flights of fancy into theory space. And it is these flights of fancy I believe attract most criticism, like Peter's. What to do: try to solve problems (a') and (b') by starting with SM + GR and using conservative effective field theory methods, constrained by the available data, to nail down the quantum numbers and interactions of the dark matter and inflaton fields. Actually, from what I've seen, there are some hard working cosmologists and particle theorists doing exactly that. So, your challenge of putting these guidelines in practice, is already being met, albeit by what it seems like a minority in these fields.

So, your proposed dichotomy "either shut it all down, or do the hard work of trying to thread the needle in the ways allowed by what we already know and keep working" is in a way false. A third alternative is to take a more careful look at "what we already know" and keep working on solving empirically constrained problems and not just aesthetic prejudice.

Just to be clear, here's what I mean about (a)-(d) being wrong. (a) & (b) Formal perturbative calculations and lattice methods (where available) do the job just fine and consistently. If you think not, say what cannot be computed using the GR + SM Lagrangian, dimensional regularization, and the renormalization condition that sets to zero all Lagrangian parameters that are empirically unconstrained away from zero. Any non-perturbative statement about consistency is only at the level of conjecture at the moment. (c) Almost precisely the topic of this blog post. (d) Hawking's calculation is its own explanation.

21. **Peter Shor**
May 28, 2013

Matt: you say "If you think you have better ideas, then please join the fray!"
Alain Connes has tried to do precisely that with his non-commutative geometry. He has been completely ignored by the physics community. It may be that his ideas don't work (this wouldn't be the first time a Fields-medal-winning mathematician has been wrong about things), but I have not found anyone who is able to explain why they don't work. I would love to hear a good explanation for why these ideas have been ignored.
A similar thing has happened with the idea (I believe due to Kitaev or Preskill) that physics at its lowest level might not be unitary, but that some kind of quantum error correction makes it unitary for interactions above the Planck scale. Nobody seems willing to consider this. Several of the high energy physicists I've mentioned this to dismiss it by bringing up a paper "proving" that if the universe were not unitary, it would have detectable consequences.When this paper was written, quantum error correction was a completely unknown phenomenon, and the paper does not hold up in the light of the existence of quantum error correction.

22. **Peter Woit**
May 28, 2013

Matt,

No time now for a long response to your comment. I'm heading downtown to the start of a week of talks at CUNY in honor of Jim Simons. The morning ones for the next few days are all ones about QFT at the boundary of math and physics, and I'm very much looking forward to them. There's a lot of interesting things going on there, unfortunately for physicists this is going on more and more in math departments, not physics departments.

You should think more seriously about what "imho" has to say. I think the "I'm on your team" is honest. What do you expect other physicists to think when they see publicity campaigns from the most influential people in HEP theory for multiverse nonsense? People like "imho" are the ones deciding whether or not to hire HEP theorists, and even the most sympathetic ones are getting the idea that HEP theory is a disaster area when they see what is being promoted as the cutting edge of the subject. People who have been working on TeV-scale SUSY for decades are now facing a big challenge of how to deal with failure. If they deal with it by arguing that this shows we're in a multiverse where nothing can be done, they're slitting their own throats as well as taking down the rest of the field with them. I'm not seeing anyone influential other than David Gross willing to stand up to this publicly. Yes, I undoubtedly spend more time arguing about this than is sane, and all it has gotten me is having links from the arXiv to my blog banned for saying unpleasant things about what powerful people are doing. There are a lot of people out there who should be pushing back against Arkani-Hamed et al's multiverse campaign. They're not earning their paychecks.

Personally, I'm spending this summer trying to finish writing up the material I was teaching this past year, including a lot about basic ideas of QFT from the point of view of representation theory. Hopefully by the end of the summer there will be good draft of a 300 page or so book. I've learned a lot, hope to then get back to a list of ideas I find promising, make more progress on them, given what I've learned over the last year.

"But, as you well know, the Standard Model, like all realistic quantum field theories that actually describe practical physics, also predicts that it has a limited regime of validity. So its success and agreement with experiment in that regime of validity does not tell us that it should be valid outside that regime."

A long topic, but I really don't agree with this at all. Asymptotically free gauge theories don't have limited ranges of validity, and I don't understand the point of ignoring this remarkable fact. The LHC Higgs results seem to show a Higgs sector that makes sense to very high energies. There's serious evidence to make one wonder about the whole philosophy that "the SM is just an effective theory, a more fundamental one is some much more complicated mess".

23. **Matt**
May 28, 2013

I suppose I had assumed that given the stridency and longevity of your opposition, there would be more rigorous substance to your position. There is a mismatch between the certainty with which you seem to be manning the barricades and the magnitude of your evidence.

Suffice it to say that whatever is the case for, say, QCD alone, the Standard Model as a whole is not asymptotically free. No one is "ignoring this remarkable fact" — it's just not relevant to the Standard Model. Maybe it'll be true of some as-yet-unconfirmed BSM model. And where people have actually found UV-complete QFTs equivalent to quantum gravity, like AdS/CFT, you've balked.

You write "The LHC Higgs results seem to show a Higgs sector that makes sense to very high energies." How do we know this? What does "very high" mean? Does it mean "arbitrarily high" or not?

You say "There's serious evidence to make one wonder about the whole philosophy that "the SM is just an effective theory, a more fundamental one is some much more complicated mess"." What evidence?

And going from QED to the Standard Model meant adding lots of new parameters, so there's literally no reason to assume that going beyond the Standard Model is going to mean reducing the number of parameters, either. Don't get me wrong — it would be nice! But why should Nature care? The progress of physics thus far doesn't seem to have involved a reduction in parameters, so why should we expect it to?

It is irresponsible for members of the high-energy theory community to be saying outlandish things in public. But that's a different crime, and shouldn't be conflated with the fact of the matter about whether they're working on the "right" things nowadays in their actual research. Like I said, any new idea that jumps through all the hoops would be a major breakthrough, especially for young theorists who'd rather work on something new than models invented decades ago (but that are the only things still standing).

And you still haven't provided a positive agenda here. A positive agenda, not just criticism! Maybe after your textbook is done.

As for everyone else, it doesn't count to say "My pet theory is being ignored by the physics community!" If an idea isn't well-developed, violates trusted principles, is extremely mathematically inaccessible, and/or doesn't seem to jump through all the necessary hoops, then the onus is on the creator to do the legwork of making his or her case to the larger community. Expecting the physics community to do the work for you is naive, to say the least. The vast, vast majority of new ideas are incapable of getting beyond the blueprint stage.

24. **King Ray**
May 28, 2013

Peter,

Your comment

"People who have been working on TeV-scale SUSY for decades are now facing a big challenge of how to deal with failure. If they deal with it by arguing that this shows we're in a multiverse where nothing can be done, they're slitting their own throats as well as taking down the rest of the field with them."

reminds me of this quote by Seneca:

"It is sweet to draw the world down with you when you are perishing."
Lucius Annaeus Seneca, Roman stoic philosopher, 4 BC –AD 65

25. **fuzzy**
May 28, 2013

dear matt,

two remarks:

1) it seems to me a bit preposterous to speak of "crime". could you tell me since when expressing views (possibly critical views) has became a crime?

2) you offer very general remarks to "everyone else". thanks for the consideration, but i urge you to note the fact that, above, i spoke of gauge theories: do you consider it fair labeling the whole class of gauge theories as "my pet theory"?

note that this is exactly what altarelli is trying to revamp, as in the web site pointed out by marcel v.v.. in other words, it looks to me an item worthwhile including in your "positive agenda".

(but maybe you want to discuss only with your Peers, not with some fuzzy guy; in this case i understand your position)

best regards.

26. **ohwilleke**
May 28, 2013

* It is hard not to sympathize with Einstein. How many physicists really think in their heart of hearts that the couple dozen parameters of the Standard Model and its SU(3)*SU(2)*U(1) structure are just arbitrary? I have yet to meet anyone who has thought seriously about the matter who isn't convinced that there is a deeper theory that explains what we know through the SM and GR more elegantly and patches up the remaining holes in fundamental physics. What are we missing that makes a formulation of theoretically consistent GR and SM theories impossible? We have an elephant in the room called dark matter that is tired of living in the Harry Potter room under the stairs that cries out for an explanation. We are so close, and yet so far.
* The "unnaturalness" of the Standard Model is surely a product of the ignorance of the beholder since, of course, it is Nature, however much of a bitch she may be, and decades of meta-theory efforts to define naturalness operationally have clearly missed the point because they are in some way looking at the numbers from a perspective that obscures the missing links that make them natural.
* The new paradigm really ought to be not BSM but "within the Standard Model" theories that seek to think about "why" the parameters take the values that they do and the equations take the form that they do in a more elegant way.
* Efforts to link the "texture" of the mass matrix with the values of the CKM and PMNS matrixes, and phenomenological formulas like Koide's formula and its extensions most directly embrace this WSM approach. But, until we can get a lot more precision in our values for the quark masses is will be hard to distinguish candidate theories; the percentage uncertainties in the lighter quark masses are huge and the theories used to estimate them are still pretty crude so it is too easy to find theories that fit the data. Perhaps improved determination of the Higgs boson Yukawas can move this ball forward by indirectly measuring non-top quark masses via coupling constants that can be discerned with rare decay product production rates.
* While dark energy can be explained as a simple cosmological constant parameter in GR for gravity, we've got to explain dark matter somehow and increasingly it looks like that explanation will be almost completely independent of the Standard Model with the possible exception of a dark matter particle interactions with the Higgs field. (Some recent work on graviweak unification like arxiv 1212.5246 "Gravitational origin of the weak interaction's chirality" Stephon Alexander, Antonino Marciano, Lee Smolin (20 Dec 2012), for example looks promising but simply coming up for air and looking for alternatives completely outside the SUSY paradigm seems like a good place to start.)
* Perhaps what the theoretical physics world needs at this point is one huge "Not SUSY" conference to remind people that there are other approaches out there and to give discourages former career SUSY theorists new research directions to explore.

May 28, 2013

Peter, just want to say I enjoy your blog a lot, and agree with virtually everything you say. Keep it up!

28. **Brathmore**
May 28, 2013

In response to Matt: "If an idea isn't well-developed, violates trusted principles, is extremely mathematically inaccessible, and/or doesn't seem to jump through all the necessary hoops, then the onus is on the creator to do the legwork of making his or her case to the larger community. Expecting the physics community to do the work for you is naive, to say the least. The vast, vast majority of new ideas are incapable of getting beyond the blueprint stage."

While I agree with this statement, Matt, I think you are attacking a straw man and missing a larger point made on this blog over, and over, and over again: sociological constraints/pathologies prevent physicists (especially young, non-tenured ones) from working on otherwise great ideas that are off the beaten track. If I've understood some of Peter's arguments correctly, a big problem is that leaders in the field have created a situation where working on alternatives to string theory/multiverse mania is detrimental to one's career.

The picture you paint of theorists objectively evaluating different approaches solely on their merit is arguably not happening. Instead, the argument is that young theorists pursue string/multiverse ideas due to career pressures and sociological constraints. The refrain you hear from the "leaders" in the field over and over again that strings/multiverse are "the only game in town" exemplifies this. The leaders in the field have devoted their careers to a failed research program, and are unwilling to admit defeat. They're not disinterested observers seeking the "best theory" – they're highly biased towards string theory and have channeled the community toward advancing it, at the expense of other good ideas. Through their positions of influence, they have biased funding, hiring, and promotion critera towards string theory far beyond considerations of merit.

Do you really think that Connes' ideas are being ignored because this fields medalist overlooked something that every 3rd year graduate student recognizes? That the entire community has evaluated his ideas and decided they can't lead anywhere? See Peter Shor's comment about the fact that no one can give him a good explanation for why Connes' ideas aren't being pursued. How come **nobody** at the IAS, Harvard, etc. is working on alternatives to string theory? Why aren't new PhDs at American universities writing dissertations about Connes' ideas?

As a frequent reader of this blog, I cannot agree with your argument that this blog is against all BSM physics. His posts on LQG, Lisi's recent ideas, and Weinstein's latest lecture don't seem outright hostile to me. Quite the contrary – I believe he's argued for a long time that diversity in these ideas should be encouraged.

No, the argument made frequently on this blog is that the theoretical string community has a sickness. It rejects attempts to pursue competing approaches, not based on objective considerations, but on dogma. Further, practioners in the field frequently tout string theory's successes in ways that are misleading or outright false. When string theory doesn't pan out, they argue that the rules of science should be changed, that the accelerator energies aren't quite high enough…or that their ideas DID pan out! Three cheers for all the recent experimental verifications of string theory.

So yes – a person proposing a novel BSM surely has a great responsibility in ensuring that their idea passes various tests, but the community also has a responsibility to evaluate them – not to ignore promising ideas due to dogma or sociological constraints. It is here that the community is failing, and attacking the messenger (Peter) in no way changes that fact.

29. **Peter Woit**
May 28, 2013

Matt,

Maybe best to stick to the main issue here: what progress in HEP has the "SM is just an low energy effective theory for something much more complicated" conjecture led to? Why don't we see anything at all in terms of effects of operators you would expect to see if the SM is just an effective theory? You say the conjecture tells us where the SM breaks down. Where is that? Does this say we will see something non-SM at the LHC? If we see nothing non-SM at the LHC, what does that mean? Do you accept the argument being made that this means the SM is "unnatural" so it is hopeless to explain its features we don't understand? What would falsify the "SM is just an effective theory" conjecture?

30. **Jesper**
May 28, 2013

I agree with those who bring up Connes' work here.

I don't think that its a valid objection that the mathematics Connes is applying/developing is difficult (I think that "extremely mathematically inaccessible" is an exaggeration): isn't it rather conceivable that what theoretical physics needs now is a complete change in perspective and that such a change might very well involve new mathematics? And by way, people like Thomas Schucker have done much work to make the noncommutative framework of Connes' more accessible to physicists.

31. **A.J.**
May 28, 2013

Regarding Connes & Chamseddine's ideas:

The biggest obstacle to attracting more people to work on this stuff is that C&C predicted a Higgs at ~180 GeV. At the time, it was claimed that this was a make-or-break prediction. (Maybe things have changed there; I don't know.)

A secondary problem is that it's difficult for an outsider to tell whether the spectral action principle is actually a deep physical principle or just a clever notation in which nearly any QFT can be expressed. It's an appealing idea and C&C have claimed that the non-commutative geometries which can reduce to the Standard Model are highly constrained. But it takes more expertise than I have to tell what assumptions they are really making. No-go theorems in QFT tend to have loopholes you can drive a bus through.

32. **Matt**
May 28, 2013

Peter,

"What would falsify the "SM is just an effective theory" conjecture?"

I suppose one attitude is just to declare that the Standard Model isn't effective, that it's UV complete, which is essentially the same thing as calling off work on new high-energy physics. Unfortunately, the couplings of the Standard Model run, and there's a Landau pole. On a related point, eventually scattering processes computed using the Standard Model violate unitarity.

As for Brathmore, all I can say is, yes, lots of people who should know better make mistakes that a very good 3rd-year grad student in theoretical physics wouldn't make, including plenty of mathematicians. LQG doesn't work, even at the minimal level of being consistent with everything we know about quantum mechanics and relativity, and Lisi's ideas were obviously inconsistent at the very beginning with lots of what we already know. (See, among other people, Distler's blog on that. But more simply, Lisi just disregards various no-go theorems like Coleman-Mandula without even aknowledging their existence. That's a totally unserious proposal — if you're going to violate a no-go theorem, you have to explain which assumptions you've evaded.)

You claim that top people are pushing faddish ideas on young grad students for sociological rather than practical reasons (the practical reasons being that there aren't any other ideas that don't clearly violate the bounds we know with great certainty).

That's a strong and strident claim, and maligns a lot of people who are working very hard these days. Prove it. Show me some actual, valid, believable directions that are being squashed. Not "pet theories" that the community is ignoring, mind you, or ideas that simply don't work, or are so abstruse and convoluted that their creator has a reasonable duty to make the case with specific details. Actual solid ideas that thread the million-dimensional needle, that have relativistic spacetime and quantum mechanics and can accommodate the chirality and gauge groups of the Standard Model, but extend the Standard Model to higher energy scales. (If at all possible, be sure they somehow also include dark matter and gravity in them. But that's only for bonus points.)

It's easy to declare that it's all sociology, but I claim it's just the nature of the subject itself. A young theorist with a bold idea that actually works and threads the needle would be the hottest thing on the scene, and everyone knows it.

It's also easy just to demand that people working on all this stuff throw everything away they've been working on and stare at a blank sheet of paper, or a sheet of paper with, I don't know, the Standard Model Lagrangian on it. Maybe shout epithets at it and demand a new idea that looks beautiful or something. I don't have to tell you that doesn't work. Coming up with that idea consistent with all the constraints is really, really hard, especially if the demand is to do it from scratch rather than start from BSM models that already thread the needle, which is ultimately the primary reason (not sociology) for why most people take that route.

That's one of those things that people outside high-energy theory tend to underappreciate, just how stringent and manifold the constraints are.

And in the few instances where people have actually been lucky enough to find models that actually work completely and consistently with all the constraints, they've essentially all turned out to be dual to stuff we already had. Not just the five string theories to each other, or 11d supergravity, but even things like string theory to certain QFTs or various QFTs in various dimensions with each other. That only makes things even harder, because the idea has to be not only consistent with all the constraints, but also not secretly dual to models already being worked on.

I think I've made my point, and made my challenge to you all clear — namely, for an actual, concrete, positive agenda, rather than just free-floating negativity from the peanut gallery. What you decide to do with it is entirely up to you. At this point, I think I'll take my answer off the air.

33. **Peter Woit**
May 28, 2013

Matt,

While you've done an excellent job of responding in detail to Brathmore, you answered none of my questions at all.

34. **Jesper**
May 28, 2013

The failed Higgs prediction of Connes' was perhaps sold too hard – if you read his recent papers the Higgs mass is not a problem for his approach.

To me, the interesting point about Connes' work is that the entire SM couple to GR is formulated as a single gravitational theory – with the entire gauge sector arising through inner automorphisms (including the Higgs sector). So probably Einstein would have been thrilled by this. There are challenges, of course, but I think its a very interesting change of perspective that deserves attention. The fact that the SM fits into this framework is not trivial.

35. **Matt**
May 28, 2013

I did answer a couple of your questions already about why we think the Standard Model is only an effective theory, although the deeper reasons are just that the old ways of thinking about the origin of QFTs (magically "quantizing" a given classical field theory and then sticking in some sort of cutoff by hand to hide infinities or something) don't make any physical sense from a fundamental point of view, whereas recognizing that QFTs inevitably describe the low-lying spectrum of states of a relativistic quantum theory with local interactions actually does make physical sense and explains why it all worked to begin with.

I mean, if you discovered that the sound you hear at night isn't actually space aliens but is just crickets, why would you continue to believe it's space aliens, just because that idea seems more elegant to you?

And surely you recognize that effective field theory is a powerful technique. Among countless examples, it works for low-energy nuclear physics very well (see the pion Lagrangian), you can use it to compute low-energy quantum corrections to gravity, it works great for making model-independent predictions in cosmic inflation, and you can even use it for fun stuff like estimating the Rayleigh scattering effect in our atmosphere.

But, most importantly, if your given model doesn't work at arbitrarily high energies (running couplings, Landau poles, unitarity violations, what have you), then it must be an effective theory. QED is the most obvious example. So was the Fermi theory, and also the theory of massive intermediate vector bosons.

But let me answer some more of your questions: "Why don't we see anything at all in terms of effects of operators you would expect to see if the SM is just an effective theory? You say the conjecture tells us where the SM breaks down. Where is that?"

Surely you know the list, which is long, but probably the most obvious pieces of experimental evidence for the insufficiency of the operators already in the Standard Model are neutrino masses and the wrong amount of CP violation.

Now please answer my own questions, concretely and specifically. Again, I'd prefer to take my answers off the air. Thank you for your time.

36. **Brathmore**
May 28, 2013

In response to Matt: "Actual solid ideas that thread the million-dimensional needle, that have relativistic spacetime and quantum mechanics and can accommodate the chirality and gauge groups of the Standard Model, but extend the Standard Model to higher energy scales."

Matt,

You have a lot of points that seem valid to me. However, there certainly are areas where I disagree with you. Beyond the posts we've already exchanged, I would add that you seem to be applying a **much higher and more unrealistic** bar to non-string theory proposals than to string theory itself. It's my understanding that thousands (perhaps ten of thousands) of papers have been written in string theory by perhaps as many researchers – and the theory is still far from complete or finished!

That doesn't bother me, mind you – but now you seem to be saying that to even get a hearing, a person essentially has to provide a final theory that already threads this "million-dimensional needle." Is this standard the same that has been applied to string theory? (Perhaps the needle should have included a few extra dimensions, e.g., 10^500?).

It seems to me that string theory grew as a field as more and more intelligent people thought about the issues in it. To expect a single person such as Lisi or Connes to invent a fully developed, alternative BEFORE receiving input from the lager community is simply preposterous. That there are flaws in their work should be expected, as they haven't had the benefit of having dozens or hundreds of other people helping to refine their ideas. The physics community should exhibit some more openness about pursuing non-stringy ideas.

37. **Anonyrat**
May 28, 2013

IMO, Brathmore is right, super string theory would not have gotten off the ground with the standards Matt seems to be imposing on new ideas for them to be worthy of consideration.

38. **Peter Woit**
May 28, 2013

Matt,
It's been a busy day here and you've written some long comments, hard for me to know where to start in terms of responding to them. Happy to try and discuss specific questions, it would be helpful if you could point me to ones that you feel are important and not getting answered. I'm not understanding your reference to "off the air".

To respond to your latest comment: obviously the SM has problems, I just don't see evidence that this means it needs to be conceptualized as just an effective theory. It seems equally plausible that it's a truly fundamental theory, with some aspects that we don't understand. More precisely, the deep nature of the mathematics of quantized gauge and spinor fields, together with asymptotic freedom in the non-abelian case to me means that a large part of the theory is both fantastic mathematics + rigorously well-defined at all distance scales, with virtually no free parameters. It doesn't get better than that, in particular I can't see a sensible proposal for something "more fundamental" that does better.

Yes, the U(1) gauge field behavior is a problem. The Higgs sector is a big problem: it's both a non-geometric part of the theory, not well-defined at very short distances, and responsible for most of the free parameters. Sure, quite possibly the Higgs field is an effective field describing something much more interesting we don't yet understand. I still haven't given up hope that detailed studies of the Higgs sector in my lifetime will provide some solid evidence of non-SM behavior there.

About the more general issue here though which most concerns me: I'm not arguing that there's no point to BSM studies. To be used effectively, the LHC experiments need guidance about what signals to look for that don't violate everything we already know. But I still think it's a fact that there just aren't BSM models that make one say: "yes, that's a convincing explanation about something mysterious about the SM". Put differently, I don't think there are any models out there that it would make sense to put any money on unless people give you outrageously long odds. About SUSY, it just seems to me to be a very unconvincing class of models that has gotten way, way, way too much attention. Yes, experiments should look for SUSY, along with anything else people can think of, but it should also be acknowledged that this is an unpromising long shot.

About the "Naturalness or Multiverse" campaign, surely I've said enough….

39. **Matt**
May 28, 2013

I simply cannot help myself here. In trying to disprove my point, you've actually picked an example that exemplifies it. I am imposing the same standards on string theory as anything else. I am not imposing "much higher and more unrealistic" bar to non-string proposals.

First of all, it took a long time for string theory to get off the ground. Please read the history books. A small number of people worked on it very hard for a number of years (Schwarz, etc.) despite a lot of skepticism (Feynman hated it, and Murray Gell-Mann kept it alive for a while through his influence). This small group showed that it was consistent with quantum mechanics, relativity, and could accommodate all the known features of the Standard Model — not to mention finally including gravity and unification more generally. And, even then, the larger community basically didn't care until the first superstring revolution in 1984 showed that string theory, beyond all that, also seemed to promise some uniqueness because of anomaly cancellation.

String theory is the very ideal model of how to get a new idea off the ground — work on it, make sure it gets through the hoops, and then the community will be willing to look at it seriously. There are no double-standards here.

The trouble with string theory has never been that it doesn't thread the needle, but that it doesn't uniquely predict the Standard Model. The early hopes (including from all the dualities) that it would give unique predictions didn't work out.

The main trouble is that it doesn't appear to have a unique low-energy solution. (Of course, any theory at the Planck scale is going to suffer from the problem that when you cool things down to present-day energies, there may be a nontrivial spectrum of inequivalent low-energy solutions. The Standard Model is no exception, although the low-energy solutions are molecules and humans, because the overall energy scales are much lower than the Planck scale and don't involve gravity.)

That's the problem with string theory. But string theory has nonetheless served as a huge testing ground for ideas for the simple reason that spin-off ideas generated by string theory are more likely than models plucked from thin air to be consistent with all the necessary constraints. That's why so many BSM ideas originated as spin-offs from string theory, although many do not depend on string theory being the correct theory of Nature.

The same standards apply to all the other ideas, too — uniqueness isn't even one of the conditions, any more than it is for string theory. (Although, like I said, the possible appearance of uniqueness was a big deal in the early days of string theory.)

If you have a better idea, then work on it and show that it goes through all the hoops. There are a zillions potential bad ideas that just don't work, so the onus is on you — don't expect everyone else to drop their work and do your homework for you, and then, when they don't comply, start complaining that your pet theory is being "ignored by the establishment."

40. **Matt**
May 28, 2013

That last comment wasn't to Peter, but to the other two posters before his.

Peter,

I appreciate your taking the time to comment.

You write "I just don't see evidence that this means it needs to be conceptualized as just an effective theory." Being an approximation that doesn't accommodate observed experimental evidence is what it means to say a theory is only an effective theory. Obviously it needs some sort of modification. But there are no renormalizable operators that are allowed by the theory that we can add to accommodate these unexplained experimentally-observed phenomena, so we can either add higher-dimension operators or devise some new high-energy theory for which the Standard Model is only an effective low-energy theory — and both approaches are equivalent, as you surely know.

Then you write "It seems equally plausible that it's a truly fundamental theory, with some aspects that we don't understand. More precisely, the deep nature of the mathematics of quantized gauge and spinor fields, together with asymptotic freedom in the non-abelian case to me means that a large part of the theory is both fantastic mathematics + rigorously well-defined at all distance scales, with virtually no free parameters. It doesn't get better than that, in particular I can't see a sensible proposal for something "more fundamental" that does better."

I'm rather surprised to hear you say that being "fantastic mathematics" is a valid criterion for good physics. And saying that "part" of a theory is rigorously-defined at all distance scales (presumably the parts like QCD that are asymptotically free) doesn't help, because there are also parts of the theory that are not rigorously-defined at all distance scales. And, besides, QCD is rigorously defined at all distance scales for what we now understand are some fairly prosaic reasons — vacuum magnetization wins over vacuum polarization due to the number of colors versus the number of flavors. It's a delicate cancellation between magnetic and electric effects that depends sensitively on the number of gluons. If the number of flavors were slightly higher compared to the number of colors, then all of a sudden the theory isn't rigorously defined at all distance scales.

You write that the Higgs mechanism is bad in part because it is a "non-geometric part of the theory." Again, I'm not sure why we should demand that Nature must be geometric, or require it as part of a valid scientific theory. Principles like quantum mechanics and relativity are known empirically, and to astonishing precision, and they place very strong constraints on valid scientific theories. Imposing geometry is just human prejudice, no better than saying string theory is right because it's mathematics is also beautiful.

There are deeper reasons why geometric (and non-geometric) mathematical structures had to appear in Nature at the levels where they did, reasons that no longer involve simply demanding that Nature be geometric. And, as a proof of concept, we now have lots of extensions like AdS/CFT in which geometry is an emergent property that has no meaning at a fundamental level and can dissolve in certain phases of the theory.

It's nice that many models in physics have a geometric description — that makes it easier to use our intuition and various mathematical techniques, but it's asking a lot to demand that Nature respect our love for geometry as some sort of additional fundamental principle. There's no numerical, high-precision "geometric constraint" provided by experiment.

Next, you say "But I still think it's a fact that there just aren't BSM models that make one say: "yes, that's a convincing explanation about something mysterious about the SM". Put differently, I don't think there are any models out there that it would make sense to put any money on unless people give you outrageously long odds."

I agree. So would most people actually working on this stuff rather than making showy public pronouncements, which I agree with you are not helpful. But these are the models we have now, and people are studying them to learn and are also looking hard for more. My larger point is very simple — models that work are very, very hard to find, and simply yelling at physicists for not finding models that you like is not helpful.

I've noticed that you have only two papers on the arXiv — one on representation theory for QFT, and one on why string theory isn't any good. You would be serving physics far better to start looking for models yourself and putting your own positive ideas and a positive agenda out there than complaining that the rest of physicists aren't doing things the way you want them to or working fast enough for you to find new models that actually thread the needle. Write some papers, give talks, make some contributions. See for yourself how hard it is to make progress given all these constraints. Certainly that would win you some credibility.

41. **Peter Woit**
May 28, 2013

Matt,

Absent better experimental guidance, personally I think mathematics is one of the few available places to look for inspiration. Others may prefer naturalness and effective field theory ideas. Best if different people try different things. My only point is that if pursuing your favorite ideas leads you to a dead end like the multiverse, you should admit it's a dead end and try something else, not go on a campaign to convince everyone else that your dead end is the only possibility.

I'm well aware how difficult progress is at this point, the things that look most promising to me are far from easy. Maybe some day I'll get somewhere with them, maybe not. But if I don't I won't try and convince others to give up because I reached a dead end.

42. **Matt**
May 29, 2013

Peter,

That's a very gracious and reasonable reply. "Best if different people try different things" — I couldn't agree with you more. "But if I don't I won't try and convince others to give up because I reached a dead end." Thank you for that.

For what it's worth, I don't think everyone is saying the multiverse is the only possibility — although some are. But I know a lot who accept it only unwillingly — only through gritted teeth — and would happily jump at the chance for another idea that works. That's not how fads work.

But the multiverse is unfortunately a possibility. Ideally we'll find better ones, but we can't just snap our fingers and make a more palatable idea appear. Nature may well work this way, regardless of human preferences. If that's the case, then at best we can extract some kind of statistical predictions or something. But maybe not. That would be a tremendous tragedy, but Nature doesn't care. We can't just stamp our feet and make demands. Nature doesn't give us guarantees.

Einstein once said, back in 1921, "Raffiniert ist der Herrgott, aber boshaft ist er nicht" — "Subtle is the Lord, but malicious He is not." When he was asked about this remark later in his career, though, he apparently replied "I have second thoughts. Maybe God is malicious."

Ultimately, I think we're all hoping for the same thing. Experimental data is coming in agonizingly slowly, especially anything that's outside the regime of validity of the Standard Model, and people are really doing the best that they can with what's available. As you note, it's not easy, sources of inspiration are valuable wherever we can find them, and people are putting their lives into their work.

I just wish sometimes that we could all tone down the negativity toward each other. It's hard enough struggling to come up with workable ideas, especially for young physicists, without having prominent people (on various sides) bashing people's hard work and impugning their motives in front of a public that doesn't know the difference between one area of physics and another, or even between experiment and theory for that matter, and who frankly think that most physicists are just coming up with crazy ideas without any constraints at all. To a young physicist, I'm sure the impugning of motives and the calls (even if only indirectly) to cut funding comes across as downright mean.

I also fear it's self-defeating to the whole enterprise in the end. Sniping between physicists contributed to the failure to build the SSC, and probably next-generation accelerators in the US that would have come after it, and the result is a lot less experimental data, which hurts everyone in the field. And it also turns off a lot of young people, some of whom might be the ones to find the new ideas we need.

There's a place for criticism, but, ultimately, it's far, far more productive and beneficial in every conceivable way to go out and do the grueling task of finding better ideas that actually work. At the very least, that buys a person a lot of credibility when it's time for more criticism.

It's a big universe, whether it's a multiverse or not. There's room for all of us in it.

43. **amused**
May 29, 2013

Matt:

Most of the issues you raised were already beaten to death during the great string theory punch-up a few years ago – see the ST-related posts on the cosmic variance and asymptotia blogs. But since it seems you are from a younger generation and missed the fun of all that, let me regurgitate a bit of it for you…

"You claim that top people are pushing faddish ideas on young grad students for sociological rather than practical reasons […] That's a strong and strident claim, and maligns a lot of people who are working very hard these days. Prove it. Show me some actual, valid, believable directions that are being squashed."

Well, would you consider the problem of non-perturbative formulation of chiral gauge theories on the lattice to be a worthwhile direction? It would be nice to know if the gauged chiral symmetry of the SM really is spontaneously broken (or, equivalently, if the Higgs field really does have a nonzero expectation value), don't you think? Instead of just assuming that it is and then setting up perturbation theory based on that assumption. But then you will need a nonperturbative formulation of the SM to find out… And it would be nice to know at what temperature (if any) the gauged chiral symmetry is restored too, right? Presumably that would be relevant for models of the evolution of the universe… You will need a nonpertubative formulation for that too.

So here is a question for you: if a young person was naive and foolish enough work on the above, and sought to document his/her progress through single-author publications in PRL, how many such publications would it take for him to balance, in the competition for jobs, one publication in, say, PRD, by a another young person jointly with his famous advisor and a bunch of other more senior and prominent people in the area of string/multiverse/bsm? Don't be wishy-washy now, give us a number.

And since you asked for it, here are a random couple of examples of "being squashed": this guy and this guy.
(Neither of them are me or people I know, just random examples I happened to notice, and there are plenty more.) Check out their impactful (highly cited) and independent research track records, then look up their career outcomes and compare with the outcomes for typical members of the string theory group at this prominent institution (for example). From that it will be clear what things really matter and don't matter for career advancement in this business.

When I was a young person starting out in this business i naively though the situation re career advancement was like this: We all place our bets by what we decide to work on, and then the onus is on each of us to show that our bets are working out. Those who are able to make progress on problems that are considered important (as judged, e.g., by the editors and referees of PRL) will be rewarded, and those who don't won't. Turns out I couldn't have been more wrong about that.

Since you seem to be a newcomer to these debates let me answer in advance the usual protest from the ST/BSM crowd to the points above: "But our topic is so DEEP and DIFFICULT so we need to be given a dispensation and not held to the same standards of documenting important progress as the rest of the community. No one but us is qualified to evaluate our work, and our wonderful results are far too technical to explain in a PRL article." Fine, ok then, instead of PRL you may instead use that prominent string theory journal the Op-Ed Section of the NY Times.

"I've noticed that you have only two papers on the arXiv…"

Disparaging someones publication record behind the veil of anonymity is rather bad form. Is your own research activity and publications impeccable and above any criticism? Any single-author PRLs recently? 😉

I suggest you reflect on why you decided to write a comment here in the first place. If it was just Woit and a bunch of crackpots hanging out here you wouldn't have bothered. But as you know, the readership includes many professional physicists in various areas, including HEP theory, who share to a greater or lesser extent (some of) the views Woit expresses. They are doing positive things in their own work, and yet Woit's negativity on aspects of ST and BSM work resonates with them. So you thought you might be able to change their minds on those views by attacking Woit's research contributions? Ha.

"See for yourself how hard it is to make progress given all these constraints."

Probably I'm just a simpleton but it seems that paths to uncovering new physics beyond the SM are becoming easier these days if you choose good ones, e.g. this one.

Admit it now that when you talk about "BSM" you really mean "BSM topics that are sufficiently grandiose to warrant the attention of myself and my illustrious peers. Any other, e.g. bottom-up type, approaches to BSM physics might as well not exist."

44. **Jesper**
May 29, 2013

"It's a big universe, whether it's a multiverse or not. There's room for all of us in it"

well – thats the point. Its not, and there isn't. Sadly.

Try as a young researcher to work on your own ideas and apply for funding. Then you'll reach the boundary.

45. **Marcel van Velzen**
May 29, 2013

@Mario. Correct, Altarelli many discusses naturalness in the light of supersymmetry.

46. **Anonyrat**
May 29, 2013

http://www.math.columbia.edu/~woit/wordpress/?p=2288

quotes Gell-Mann:

I was a sort of patron of string theory — as a conservationist I set up a nature reserve for endangered superstring theorists at Caltech, and from 1972 to 1984 a lot of the work in string theory was done there.
—

Who are the conservationists/incubators for ideas today, equivalents of Gell-Mann, using their ability to draw funding to support long-shot ideas?

May 29, 2013

A.J. says “A secondary problem is that it’s difficult for an outsider to tell whether the spectral action principle is actually a deep physical principle or just a clever notation in which nearly any QFT can be expressed. ”

As I understand it (which isn’t very well), Connes and Chamseddine’s spectral action construction doesn’t work unless you have Majorana neutrinos, a new sterile neutrino, and a new field that couples to the sterile neutrino. These aren’t radical changes to the Standard Model, and they’ll be hard to see experimentally, but this does seem to demonstrate that not all QFTs can be expressed in non-commutative geometry.

May 29, 2013

amused,

I can only comment on things as I live them now, and today there’s a vibrant community of people in high-energy theory working on all manner of subjects, including non-BSM stuff like collider physics, jets, HQET, and applications of HET to condensed matter, among other things.

As for determining “if the gauged chiral symmetry of the SM really is spontaneously broken (or, equivalently, if the Higgs field really does have a nonzero expectation value), don’t you think?”, or whatever you wanted to work on, all I can say is that demonstrating that roadblocks you suffered were a consequence of sociology rather than the viability and potential of the work itself is still undetermined.

Your list of names brings to mind two favorite SMBC comics, both on the use of anecdotes:
http://www.smbc-comics.com/?id=2159
http://www.smbc-comics.com/?id=2307

For someone who claims not to be impugning people’s motives but just telling things like they are, you do an awful lot of impugning of people’s motives, like mine in particular.

For example, my point in citing Peter’s list of papers on the arXiv was to urge him to go out and work on this stuff rather than simply criticizing it from afar. It matters to his case that he doesn’t show outward signs of working on this stuff himself. It’s not a matter of disparaging him. You were sneaky to truncate my quotation where you did — I encourage people to go read the rest of that paragraph.

But then you turn around and attack my record, for no obvious reason except to disparage me, as though that accomplishes anything other than a fallacious appeal to emotion. None of this is remotely relevant to the argument I’ve been making here.

You write “But as you know, the readership includes many professional physicists in various areas, including HEP theory, who share to a greater or lesser extent (some of) the views Woit expresses.” I have no idea who reads Peter’s blog. I don’t stop by all that often — I just saw a post that I wanted to respond to, because I thought Peter was saying things about his own understanding of the Standard Model and what I viewed as a larger shift toward general antipathy toward all things BSM.

“So you thought you might be able to change their minds on those views by attacking Woit’s research contributions? Ha.” No. It’s rather presumptive of you to declare what my motivations are, don’t you think? I think I made my goals and requests very clear, and none of it involved “chang[ing] their minds” or attacking anyone’s research.

“Admit it now that when you talk about “BSM” you really mean…” I won’t admit anything I don’t believe.

I don’t know you, so I won’t start ascribing beliefs or opinions to you that you don’t possess. But whatever you’re like in real life, you don’t seem like a very pleasant person on the Interwebs. I’m not an apologist for the ways of academia, which has plenty of problems. I was simply commenting on a narrow issue that I thought Peter was incorrect about.

I think that’s about it for me. At the usual risk of not having the last word, I really have to get back to work now.

49. **Peter Woit**
May 29, 2013

Matt/amused,

Enough, please. I’d like people to stick to attacking me here, not each other. For the record, I think Matt is quite right to point out that I should be writing papers, amused is quite right to point out that there is no place in the current HEP job market for those pursuing research programs outside a quite narrow range. Other than that, best for all to attempt to be charitable in considering the motivations of all those making arguments here. I try and delete the really unreasonable ones….

50. **martibal**
May 29, 2013

@Jesper: very nicely said. Of course there is no space for all of us. There is as war for fundings and, as all war, this is pretty dirty and at the end the story is written by the winner. The claim that “scientific excellence is the main criteria of selection” (that would be equivalent to Matt admonition: “stop complaining and show your ideas are the best”) does not survive the analysis: just compare the scientific production of young persons that have been permanently hired because they were supposed to be “the most promising young scientists of the year”, with the scientific production of – say – permanently precarious postdocs. In number of cases (not negligible at all), a couple of years after the hiring and whatever weight you put on the criteria (number of papers, of co-authors, of citations, quality of the reviews) it is hard to get convince that the most- promising-young-scientist always held his promises. I do not think anybody honest would deny that politics is an essential aspect of the hiring process.

–

@Peter: in Connes approach to the SM, the Higgs is completely geometric. It comes out as a component of the connection (in the noncommutative part of the geometry), exactly in the same manner as usual gauge fields come out as connection 1-forms (on the commutative part of the geometry). If one considers the formula of the distance in noncommutative geometry (which generalizes Riemann geodesic distance), one can even see the Higgs field as the component of the metric in some discrete internal dimension. More geometric than that… &#128521

May 29, 2013

What a fascinating debate. If only the professionals in my field were able to debate so eloquently – indeed, I work in a field universally despised by yours: politics. Worse still, I’m a Republican. It’s amusing to hear Matt decry the negativity. You guys sound like choir boys compared to some in my line of work!

Just wanted to drop a note and provide a bit of encouragement from the outside world. Please, keep doing what you all are doing. I have not taken a physics class in my entire life, so it’s hard for me to follow the specifics of your arguments, but I keep my eye on science nonetheless. I believe you and others across so many disciplines are on the verge breathtaking breakthroughs ahead in the next 30 years.

Groupthink is a major problem in politics as well. The journalists who are supposed to hold the powerful accountable attend the same Georgetown parties as the politicians and Joe Biden's water gun fight parties every summer.

If it weren't for the Peter Woits of the political world, the hubris inherent in any political system would go unchecked. I applaud Peter and Matt and anyone else working their butts off to advance science. Peter, continue to question the status quo.

If I ever get to the point in my career where I can sway national policy in any significant way, I will defend science to the hilt. Whether major advancements come from String Theory that Matt is working on, or groundbreaking mathematics Peter is, it doesn't matter from my perspective. All of this work needs to be consistently and concisely explained and defended to policymakers and the public. That's one reason why I think String is succeeding to the extent it is: Green, Hawking, Kaku are fantastic, engaging ambassadors for your profession. The public needs more.

52. **Mark Israelit**
May 30, 2013

I don't understand why the connection is DENIED.
I wanted to see the paper submitted by myself, http://arxiv.org/abs/12122208 , and received even in this case the DENY answer.
Mark

53. **Hugh**
May 30, 2013

@Mark, you're missing a period from the url. It should be http://arxiv.org/abs/1212.2208

54. **Haim**
May 31, 2013

Peter,

This is pseudo-science indeed: "laws are just an arbitrary, messy outcome of random fluctuations in the fabric of space and time".

But this would not be pseudo-science: "The standard model and general relativity are the direct, obvious, and natural outcome of random fluctuations in the fabric of space and time." A number of people are trying this approach, which clearly follows Einstein's dream.

After all we know that space-time is randomly fluctuating. Or do you disagree? Are you implying that there is something wrong in trying to find the correct fabric of space-time? We all know that nobody has found the correct fabric yet. Connes did not succeed. Bilson-Thompson did not succeed. String people did not succeed. Spin network and many more did not. But some day somebody will succeed! Or are you proposing something else? Are you implying that space-time has no "fabric"?

My impression from reading your blog is that you are only arguing against the epithets "arbitrary" and "messy" in the quotation. Or are you arguing something different?

55. **Jack**
May 31, 2013

@haim,

Peter was arguing against the multiverse. To get to your point, there is little hope that some microstructure of space-time will lead to the standard model.

56. **Peter Woit**
May 31, 2013

Haim,

If your ideas are so vague that you can't extract any information about the way nature behaves out of them, then you're in danger of doing pseudo-science. Multiverse theories typically not only don't predict anything, but their who motivation is to construct an excuse for failure, an argument that it is impossible to predict anything. This is true pseudo-science.

The problem with discussing "random fluctuations in the fabric of space and time" is that this is also too vague to be very meaningful. Replace "random fluctuations" by some specific notion of quantization, and "fabric of space and time" by a specific notion of exactly what the fundamental variables describing space-time are and then you start to have something. To have something convincing and testable though, I think you need to do this in a way that unifies with our understanding of quantization and the fundamental fields of the SM.

A Tale of Two Oxford Talks

May 28, 2013
Categories: Multiverse Mania, Uncategorized

Last week (for more, see here) Eric Weinstein gave a talk at Oxford about his ideas about "Geometric Unity", with positive coverage from the Guardian, leading to various critical commentary. I agree completely with the main point of most of the commentary: if he wants to be taken seriously, Eric needs to disseminate the details of his ideas about this, as a paper, slides of a talk, multimedia web-site, or whatever. As AJ put it here succinctly: "Paper, or it didn't happen."

I've only the vaguest notion of what Eric's ideas are, so no way to evaluate them. From this standpoint of ignorance I should comment that I'm quite skeptical he has a viable unified theory, with reports of "very large multiplets of as yet undiscovered particles, and he has no idea of their masses" not confidence inspiring. But on the other hand, the current situation in fundamental theory is one of a serious lack of any new ideas at all. If he has been working on some very different ideas that haven't gotten attention before, he could have something interesting or even important. But, again, until details are available, there's no way to know one way or another. By the way, I should disclose that at one point I remember having a conversation with Eric about his plans to give a talk and make public his ideas. I tried to encourage him to do this, emphasizing though that I thought his main problem would be that he wouldn't be able to get anyone to pay attention. Shows how little I know…

Surprisingly to me, before it was clear what was going on, there was a quick and hostile reaction from some to the Guardian piece about Eric and his work. Yes, it's a bad idea for the press to publish overly optimistic material about grandiose and poorly supported claims from physicists, but this does happen all the time, and usually people (other than me…) don't bother getting worked up about it. Very quickly New Scientist (not known for its general policy of only reporting on carefully vetted research) had a piece from an Oxford cosmologist denouncing Marcus du Sautoy for organizing Weinstein's talk and not inviting any physicists:

> Hosting a lecture in a university physics department without inviting any physicists is, at best, an unforgivable oversight. As my colleague Subir Sarkar put it, "It's surprising that the organisers did not invite the particle physicists to attend – if indeed the intention was to have a discussion."

Soon New Scientist was joined by Jennifer Ouellette at Scientific American and PZ Myers, all outraged at the unprofessional behavior of du Sautoy. Reading the New Scientist piece, for about 5 seconds I thought "wow, that du Sautoy sure is a piece of work", before realizing "wait a minute, how likely is that?" Any experience with academic departments and dissemination of information like this should be enough to make one suspicious that the most likely course of events was that du Sautoy tried to get word out, but this didn't happen very effectively. Yes, departments and groups have mailing lists, but the ones people pay attention to are shielded from use by outsiders. After a couple days, it came out that the true story was that du Sautoy did contact people in the physics department trying to get their help advertising the talk, sent them posters, etc., exactly as one would have expected.

What I find most remarkable about this story though is the contrast to the one that I wrote about the day before here. This involved a Sunday Times report about Laura Mersini-Houghton's "hard evidence" for the multiverse, which she had found by analyzing the latest Planck CMB data. She plans to give a public talk about this at the Hay Festival on Friday, and a talk at Oxford is scheduled for June 11 (this talk is part of a workshop funded by the Templeton Foundation as part of their "establishing the philosophy of cosmology" effort). I assume physicists will get an invitation to the Oxford talk, but, at least at the moment, there's no paper that I'm aware of backing up Mersini-Houghton's claims. There is a 2008 paper about what Planck should have seen, but the Planck team reported nothing of the sort predicted in that paper.

This all leaves me rather curious about the question of why people got outraged about Eric Weinstein getting too much press attention for his undocumented claims and Oxford talk, when the same people as far as I can tell seem to have no problem with Mersini-Houghton and her undocumented claims + Oxford talk. To me it seems a lot more problematic that people have been reading in the press that hard evidence has been found for the multiverse than that they have read that Eric Weinstein has a theory of everything. Others seem to see things the other way around.

Update: Eric will be giving another talk at Oxford, this Friday, see here.

Update: To the extent you can call what's on Twitter "information", there's information about today's Oxford talk there, see for instance here and here.

Update: Denunciations of du Sautoy continue, see for instance here. For a response from him, see here. From the various very fragmentary accounts available online of the Friday talk, it sounds to me like Eric is far from having a viable TOE. Still no paper or details available, which is what is needed to see if he has a promising idea.

Meanwhile, on the BBC, it's multiverse-mania as usual, with Mersini-Houghton,

> a cosmologist at the University of North Carolina in Chapel Hill whose theory of the origin of the visible universe has attracted a lot of attention for its strong observational predictions.

explaining that

> the recently released data from the Planck telescope lend particular support.

As far as I can tell, cosmologists and physicists think this kind of thing is just fine, or maybe they are way too busy being outraged about du Sautoy's attack on the very fundamentals of science.

Update: Laura Mersini-Houghton and Richard Holman sent me the following which I'm adding here so that readers can have their point of view on this.

> As avid readers of your blog, we were a bit dismayed to see your post lumping our work together with Weinstein's. Unlike his case, we HAVE had not just one, but a series of papers where our calculations and predictions are laid out for all too see and argue about.
>
> To recap, we made use of a particular model of the landscape of string theory, the one derived in the Douglas-Denef paper 2004, constructed the effective density matrix for observables in our patch and then used that to derive our predictions. Within the context of this model, we showed that the scale of SUSY breaking would be far above the reach of the LHC and thus no super-partners would be seen. We also calculated how the back reaction from the other parts of the landscape modifies the gravitational perturbations in such a way that the following would be true
>
> a. the cold spot of 10 degrees in the sky at about z~1,
>
> b. another highly underdense/void like region aka a suppression of power at k~1 which would give rise to:
> c. a suppression by 30% of TT spectra of CMB at the lowest l<6 (k=1)
> d. a modification of quadrupole, dipole and octopole (lowest l's) which induces alignment of quadrupole and octopole, (axis of evil)
> e. a preferred direction due to induced dipole power
> f. the power asymmetry between the 2 hemispheres which are determined by the preferred direction (again the k~1 suppression shows as lack of structure at dipole/quadrupole level which suppresses structure in 1 hemisphere)
>
> g. an overall suppression of sigma_8 due to the same correction to Newtonian potential by 30%.

Hints of all of these had been found by WMAP, but PLANCK confirms ALL of these (Paper 13 in the Planck series).

The two papers where predictions were derived are:

http://arxiv.org/pdf/hep-th/0612142

http://arxiv.org/pdf/hep-th/0611223

The full theory in 2005 for which these predictions are made is developed here

http://arxiv.org/pdf/hep-th/0511102

This theory was and remains the only one that uses quantum cosmology to derive the selection criterion from the landscape multiverse and that calculated every single prediction from an underlying fundamental physics formalism, without resorting to anthropics or any other conjectures. Silence does not imply ignorance. While there is certainly room to argue with us (is our model of the landscape truly reflective of its actual behavior? How robust are our results to changes such as in the inflationary potential used?), we have striven to be above board in all we've written and said.

We also made predictions for a bulk flow that was argued for by Kashlinski et al. There has certainly been some dispute about the existence of this flow and a PLANCK paper argued that the flow is not statistically significant in their data but the jury is still out on that. However, the situation is not as clear cut as this. We are aware there was a paper by Pierpaoli et al stating they do not make a significant detection of the dark flow and another paper by Barandela et al., also a Planck team member, stating that the dark flow is definitely there and the filters used by Pierpaoli et al. were incorrect. Our current feeling is that it would be premature to say our theory is incorrect on the basis of a result awaiting conclusion while 8 of its major predictions have just been confirmed. Perhaps you are not aware that a bulk flow always arises when the CMB frame and the expansion frame in the universe do not coincide. On the other hand, should this discussion finally be resolved against us we are ready and willing to acknowledge this and move on. At least we have predictions that COULD be wrong!

It is true that there has been considerable media coverage for the last 7 years around this theory and its predictions but that is not surprising considering we made predictions for a theory of the origins of the universe based on fundamental physics. Don't let the media coverage divert you from the science. The key issue is that we have a theory based on a well known fundamental physics formalism and we made predictions for the anomalies in 2006 that are currently in accord with ALL of the data (modulo the pending dark flow results). That is 8 predictions confirmed and one to go. As we said before, you might want to argue with the underpinnings of our ideas and we are more than willing to enter into such discussions. But we have calculated within our framework, derived physical predictions from these calculations and await further data to fully confirm or refute our model. We think that this how science should be done.

In light of this, we would appreciate it if you could revise your post to reflect these facts.

Best

Laura Mersini-Houghton

Rich Holman

Comments

1. **Shecky R**
   May 28, 2013

   I too was surprised by the level of upset the Guardian piece generated (science "hype" being commonplace in the press), but apparently some folks see the Guardian as more immune to such coverage than other outlets (not always true).
   Hard not to think there's also a bit of jealousy/envy involved when a lone genius type enters the fray without going through normal channels… but someone of Weinstein's caliber certainly deserves a fair, open-minded hearing.

2. **Nameless**
   May 28, 2013

   The obvious difference is that Weinstein has a very high profile subject (the theory of everything), no prior published work in the area, and no clear way of getting where he claims to be getting.

   Mersini-Houghton has a relatively boring subject (multiverse aka Everett's many worlds – known since the 50's and accepted by a large fraction of physicists anyway), prior work (21 papers on arXiv), and at least partly mapped way of getting there (Planck data plus a description of what she'd be looking for in her '05 paper http://arxiv.org/pdf/hep-th/0510101.pdf).

   I'm perfectly willing to believe that Mersini-Houghton found one of the signatures from the '05 paper in Planck data, even in the absence of a new paper. (Whether or not that signature would in fact prove the existence of a multiverse, I have no opinion.) I am much more skeptical about Weinstein's magical leap.

3. **Mitchell Porter**
   May 28, 2013

   Shecky R, there are literally hundreds of similarly hopeful "theories" on the arxiv – theories which are outside of the model-building mainstream, I mean. (The number of mainstream models runs into the thousands.) Should all those people have their 15 minutes of fame too?

4. **Peter Woit**
   May 28, 2013

   Nameless,

   The cosmological multiverse is not Everett's Many-Worlds. The Mersini-Houghton 2005 paper you link to seems to be about something completely different anyway: there's no multiverse in it, it's about string theory inflation. Of course, since the only source for her claims about an analysis of Planck data is a Sunday Times article, with even less detail than the Guardian article, we have even less idea what this "hard evidence of the multiverse" is than what Weinstein's TOE is.

5. **anon**
   May 28, 2013

   Peter—

The biggest difference is that Mersini-Houghton has 43 entries in SPIRES, and over 1000 citations to her work (one paper has 365 cites). Eric Weinstein has zero publications. This should give her work more credibility.

That said, I agree that the Sunday times article, given no paper or arxiv entry, was overly hyped.

6. **Nameless**
   May 28, 2013

   OK, sorry – this paper is more directly relevant http://arxiv.org/pdf/hep-th/0612142.pdf

   I'm picking this up as I go along but Figure 4 seems to be the key. Their theory predicts that the correlation between the spectrum of CMB and cosmic shear (weak gravitational lensing) is substantially different from what's predicted by Lambda-CDM. There's a number of other predictions too (which include cold spots and dark flow as mentioned in the other thread).

7. **Peter Orland**
   May 28, 2013

   I agree with anon (and probably everyone else on this thread) that work which is available in some form should be taken more seriously than unpublished claims. A lot of citations can suggest additional merit.

   Unfortunately, such criteria aren't foolproof. Sometimes heavily-cited papers don't stand up to close inspection (of course, papers which are never cited often have even less value).

8. **Peter Orland**
   May 28, 2013

   Bad construction in parentheses. I meant to say:

   (of course, papers which are never cited ON AVERAGE have even less value).

9. **Kuas**
   May 29, 2013

   The unwritten rules of who is and is not allowed to spin the science press are always a subject of curiosity to me. Clearly the bandwidth for science hype is limited public resource which must be managed responsibly.

   In Weinstein's defense, it's not clear that he actively sought out the Guardian coverage, which was a tad ridiculous. I can see a scenario where he innocently responded to an invitation to talk, and an overzealous reporter somehow got wind "Weinstein, Einstein- it practically writes itself!"

10. **Snm**
    May 29, 2013

    Also, Eric Weinstein will be doing another talk in Oxford this Friday – I don't know if it's the same one, or a follow-up

11. **oxfordanon**
    May 29, 2013

    I think the talk on Friday will be the same as the previous one, except this one has been advertised. I think this is a good faith attempt to address the issues with the previous talk, and I will be attending.

    Just to be clear about what happened and why people were annoyed. Most departments with particle theory groups, anywhere in the world, have a regular weekly seminar on particle theory at a regular fixed time. This is true in Oxford (Thursday 4.15). This Weinstein seminar happened at 4pm on Thursday (ie clashing with the regular seminar), and the first people in the particle theory group heard about it was after it had happened, and in some cases via outlandish claims in the national press.

12. **Anonyrat**
    May 29, 2013

    Shecky R, no one is denying Weinstein a hearing. The problem is that few know what he is saying. There is a paper, as per du Sautoy, but it is not available anywhere. Why is a hype piece so readily available in the newspaper, but the actual work is not?

13. **Shecky R**
    May 29, 2013

    Don't want this to degenerate too far, but worth noting that Marcus du Sautoy has now indicated his umbrage over the issue with several tweets at his Twitter feed:

    https://twitter.com/MarcusduSautoy

    one of which reads as follows:

    > "I spent two years looking at @EricRWeinstein work. @newscientist and @apontzen didn't bother to check their facts. Scientific?"

    (p.s. – he also mentions Peter's post here as a "fair assessment")
    And he mentions the repeated Weinstein talk this Fri. at 2pm at the "Mathematical Institute" (Oxford) …I'm guessing physicists can probably sneak in ;-))

14. **op-ed**
    May 29, 2013

    The tweet itself indicates part of the problem "I spent *two years* looking at @EricRWeinstein work. …" But in all of that time, du Sautoy does not seem to have said to Weinstein "Write this up, post a preprint on the arXiv (or a personal web page) etc. *After* you post a preprint, *then* I shall arrange for you to give a lecture at Oxford." It's only du Sautoy who has seen Weinstein's work. And the Guardian op-ed piece was a clear personal endorsement of Weinstein's work.

    On the other hand, about Laura Mersini-Houghton … the Sunday Times article opens with "SCIENTISTS believe they have found the first evidence that other universes exist." It's a third-party reporting of published material, and one can criticize the 2008 paper by Laura, but at least there's *something* out there for independent researchers to examine dispassionately.

But Weinstein will give a second talk on Friday, physicists will be there (or have been invited), and hopefully a publicly available preprint will follow soon.

15. **A.J.**
May 29, 2013

*It's only du Sautoy who has seen Weinstein's work. *

This is definitely false, and the original Guardian article makes that clear.

16. **Ted**
May 29, 2013

The entire du Sautoy dust up looks like petty office politics to me.

As far as Weinstein goes, his approach is obviously unorthodox, but perhaps not unacceptable. Someone correct me if I am wrong (I wasn't quite born yet so my history might be off!), but didn't Witten present his M-theory argument at Strings 1995 without circulating a paper or publishing prior? Obviously Witten was already a household name at that point and he was working within an already established paradigm at a major conference. And exploring strong coupling limits and playing with dualities of established theories is easier to follow in a lecture setting than proposals of an entirely new framework. But this situation doesn't seem so different that people need to unleash the hounds on Weinstein. Maybe Weinstein wanted feedback before finalizing a paper? I'm very skeptical Weinstein has anything close to a coherent theory of quantum gravity, and when he finally gets a paper out there we'll see (though what I've read about it doesn't sound promising), but some of the rhetoric against him seems undeserved at this point.

As far as the press, I'm all for going against the press hyping scientific claims. I think it pollutes both the scientific process and the dissemination of realized knowledge to the public. Too often the media talks of speculative hypotheses and conjectures as facts, and not just in physics. The Guardian article was obviously inappropriate. That said, I would be more sympathetic to those angry about this if they showed similar outrage about a whole host of speculative claims the media disseminates. To give an idea of what good science journalism would look like, take this Mersini-Houghton case. Before announcing that the multiverse exists, the press should wait until the evidence is formally presented and rigorously examined by her scientific peers – and then disseminate the claim if her colleagues agree.

17. **cormac**
May 29, 2013

I'm not upset, nor am I jealous, and I consider Professor du Sautoy an excellent professor for the public understanding of science. I was just a little surpised that Peter, who has such withering criticisms for the publicity afforded entire fields such as string theory and supersymmetry, seemed to be stay his hand when it comes to the publicizing of work that has yet to be examined by experts in the field.
I could certainly see how an author of ground-breaking advances in theoretical physics who have never received media attention might be miffed at the publicity given by the Guardian to this work, but my real point is that I think this is another example of the media interfering in the normal process of science

18. **Yatima**
May 29, 2013

Implying there is a "normal process of science".

The "advancement of science" is an entirely human affair, indeed.

Papers got to sell copies and fill column space. Writing about as-yet-unproven and unknown ideas does that. Which means there is some interest in these things.

Does it need firing up with ludicrous formulations? Considering that most Guardian readers will run away screaming at the sight of an integral sign, quite possibly. Some showbiz required.

The alternative? No headlines, no-one cares about fundamental science and it dies an underfunded death. Choose your poison.

19. **David Nataf**
May 29, 2013

People give colloquiums about work that is in progress and not yet published on a regular basis. It's quite normal, and those of you arguing against it strike me as likely operating on either the fringes of science or outside of science.

20. **Tammie Lee Sandoval**
May 29, 2013

This idea of expecting the press to do the job that scientific ethics have abandoned is laughable. Its not really their job, but more to the point they wont do it. The press needs to sell papers and hype sells.

Scientists going the press, before having their work independently checked (or even completed) means this: Fame is becoming more important to Scientists than being right.

After all, in the days of book sales, talk shows, and speaking fees, what counts is fame. And even if your stuff is found to be wrong, the fame remains. And if you spin it right, you'll always be known as the scientist with the data on the multiverse. The scientific contraversy, which you can always muddy up for the public, only helps spread your fame.

The Mersini-Houghton case is especially disturbing.

21. **Mitchell Porter**
May 29, 2013

I've just been looking at Mersini-Houghton's work and it's actually somewhat interesting. She throws around the word "multiverse" but her "other universes" are really just other regions of our one universe, beyond the cosmic horizon. The predictions that have been mentioned recently on this blog (dark flow, the cold spot) are imprints of early influences from outside the horizon.

She's also known for some non-anthropic "landscape" predictions. As with "multiverse", the word "landscape" may evoke a negative conditioned response among many readers of this blog, but it just means that there are multiple distinct configurations that the fundamental fields can settle into at low energies. Here she predicted a small cosmological constant and a high supersymmetry scale, but the interesting thing is that she obtained those predictions *not* through anthropic reasoning, but purely from the posited dynamics.

So people who hate parallel worlds and anthropic justifications shouldn't be hostile to her on that account; her style of reasoning does actually fit the old-fashioned method of "make a theory about how physics works in a single universe, and deduce the consequences".

22. **P**
May 29, 2013

David,

You're spot on. I've given talks on work about to be released, as have many of us. I suppose the only difference is that most of us don't claim a brand new theory of everything and don't get it publicized in the Guardian. The latter should be the criticism, not talking on unpublished work.

Cheers,
P

23. **richard**
May 29, 2013

I blogged on the du Sautoy column, and may yet return to it — for me the issue was not someone working outside physics, or Oxford providing them with a venue to share their ideas. The issue was a Professor of the Public Understanding of Science (or whatever his exact title is) hyping work which no-one else had seen in an area full of brave failures — if it had been written by a journalist I doubt it would have prompted the same reaction.

Perhaps a different question here is the extent to which a professional scientist who writes for a wider audience "on the side" is able to avoid being held to the usual standards of "preprint/peer review or it didn't happen" — and in this sense, it is clear that people in the community expected more from du Sautoy. And perhaps fair enough — du Sautoy would have been much less likely to be provided with space in the Guardian if he was not already a serious mathematician.

As far as the Mersini-Houghton issue is concerned, I got asked questions about the same piece at a conference in New Zealand last weekend, on the basis of the press coverage — whether it was read on a website or syndicated by a New Zealand publication is still not clear to me.

As many people have pointed out, very few astrophysicists ever took claims about "dark flow" seriously, and Planck has cast further doubt on the topic — and any extravagant theoretical architecture justified by its ability to explain a non-existent phenomenon is not going to get a lot of attention from scientists. (I work in this general area, and I think it is fair to say that this idea has no real traction in the community.) That said, I don't think it is my job or anyone else's to correct every piece of bad science journalism that comes down the pike — there would not be enough time left for science.

24. **David Nataf**
May 30, 2013

Richard,

It doesn't matter if the idea has no real traction among astrophysicists. Neither did dark matter when Fritz Zwicky first suggested it (in the correct quantity) 40 years before it was found in Galaxy rotation curves, and neither did a cosmological constant when people were suggesting it before the supernovae teams did. Science shouldn't be a popularity contest. The dark flow is still a legitimate scientific hypothesis, that I'm sure a small niche community will continue to work on.

I have no attachment to it myself, and I work on Galaxy-scale astrophysics. However I totally don't get your snarkiness. It seems a lot better motivated to me than some other questions people work on, like looking for variations in the fine structure constant by studying high-redshift AGN, or looking for Lorentz violations by timing of GRBs, or modified newtonian dynamics, or inferring axions from white dwarf cooling curves. These latter questions come off as either similarly or far less well motivated, yet as far as I can tell, more people work on them.

25. **Giotis**
May 30, 2013

There is a correction/apology in New Scientist piece by Andrew Pontzen.

But why this secrecy? Where is the video of the talk? Why it is not available in Oxford page?

Or maybe the talk was so bad and crackpotish and they are embarrassed to publish it in their page:-)

26. **D.G. Perkin**
May 30, 2013

It shouldn't be too hard for physicists in Oxford to find the talk at the Mathematical Institute – the Nuclear Physics Department is just across a very quiet road from the Institute (unless something has been moved since my time).

However, I chance to recollect that the Maths Institute lecture hall is quite small so they might have trouble getting in. Also, physicists tended to ignore mathematical physics events at the Institute. I doubt if things have changed much.

I attended many external seminars and lectures in Oxford but I heard about most of them by word of mouth – I don't think there was an accepted system for informing people. Since this is Oxford, it is not unlikely that nothing has changed.

Regards,

David Perkin.

27. **MathematicianNotPhysicist**
May 30, 2013

Read oxfordanon's post above to see how much effort was made to make the (1st) talk available to the Oxford particle theory group.

Anyway, the second talk must have happened by now. I wonder how it went.

28. **MathematicianNotPhysicist**
May 30, 2013

Oops. Silly me. The 2nd talk is tomorrow. Show how good I would be at scheduling.

29. **Shantanu**
May 31, 2013

Just fyi, in my univ from where I graduated. we usually never got any notices of seminars in math or astronomy
even though many of them were relevant to physics (and probably also vice versa)
However usually all talks used to be advertised on the department websites and that's
how we came to know about it.
and anyhow in this case looks like the notice of seminar was sent to physics department folks.

30. **Richard**
May 31, 2013

David — dark flow and dark matter are not really analogous. Zwicky's point about dark matter was based on cluster peculiar velocities (as I assume you know): if clusters are bound objects the galaxies inside were moving too fast if you assumed galaxy masses based only on their apparent stellar content. In the 1930s this would not imply non-baryonic dark matter, just the presence of a large amount of non-stellar but otherwise normal material, or perhaps a large number of very faint stars. With the benefit of hindsight, Zwicky's point was clearly not given the attention it deserved, but I do not believe it was ever fully addressed or refuted.

By contrast, the claims made by Kashlinsky were not convincingly reproduced, and other results (including the Planck paper) are entirely consistent with the preculiar velocities one expects to see in LCDM models — so the current data suggests that the dark flow simply isn't there, at least in the sense implied by Kashlinsky. Galaxies are moving, including the Milky Way at 627 km/s relative to the rest-frame of the CMB, or whatever the number is — but their velocities do not have a magnitude or long-range correlation beyond that predicted by standard theories.

So yes, you can say that dark flow is a legitimate hypothesis, but it is not a hypothesis that appears to have survived contact with the data. However, the corollary of that is a multiverse theory that can "explain" dark flow is in a similar position to a modified gravity theory that "explains" the Pioneer anomaly: it is not something that needs to be explained, and should probably not be presented as evidence for a multiverse theory.

As to the fine structure constant by studying high-redshift AGN, Lorentz violations via timing of GRBs, or modified newtonian dynamics I completely agree with you — the specific models being tested are simply not that compelling.

31. **Ian Sample**
May 31, 2013

There has been plenty of over-reaction to this, and much it from otherwise sane people. We ran a blog post on a talk at Oxford that we thought was interesting. That's about it. Hardly a reason to reach for the torches and pitchforks. To look at the reactions of some, you'd think the foundations of science had been violated. The piece appeared on the science website's Notes & Theories blog, which we set up as a home for our musings about goings-on in the science community. Nothing appeared in the newspaper, for all the talk of "splashes". The post carried plenty of comments from the author and jobbing physicists on how the idea wouldn't – indeed couldn't – be taken seriously without a paper for others to assess. But take a step back: from an outsider's point of view, this was nonetheless an interesting lecture on a fascinating problem in physics. It was well within the scope of material we want to cover.
There may be a category error afoot. We are journalists, not scientists. We write about issues in science that we find interesting. We make the calls on that. We don't treat our readers as idiots who are too stupid to be exposed to ideas before they appear in a peer reviewed journals. Most can even read without moving their lips. They understand that a talk without a paper is not a paper with a talk. We can and should write about university talks, conference presentations and posters, claims made by government scientists, and of course, peer reviewed studies, and we will of course continue to do so.

32. **Stuart**
May 31, 2013

Du Sautoy isn't a journalist. People are irked by how he went about things, not that a newspaper published a wildly overenthusiastic blog post.

33. **Dom**
May 31, 2013

Ian Sample. I have your excellent book "Massive" but you are wrong here – I'm with Ben Goldacre that Science writing cannot abandon reality and facts in search of a good story accessible to the layperson. I speak as a layperson.

34. **merian**
May 31, 2013

I have no problem with researchers giving talks before publication. This is a completely legitimate way of circulating your ideas. I'm also not unhappy with Weinstein – who I'm unhappy with is first Marcus du Sautoy and second Alok Jah: Science-by-press release and splashy sycophantic reporting of unconfirmed and even unpublished claims has been undermining the public's trust in the scientific process. If du Sautoy, as a professor for the public understanding of science, neglects this, he's not doing his job. I've always liked him a lot when he cooks down mathematical concepts for the lay listener on the radio, so I'm also disappointed. On a personal level, I understand it actually that he may be overly enthralled by some new mathematical physics that he has studied and admires, for sure. I wish he wouldn't forget to step back and assess where this thing stands in the scientific process. Not even a pre-print? Seriously?

In comparison, the Sunday Times article, from the little I can see peeking over the paywall, addresses precisely one of the next steps – comparison with experiment. It reports on new experimental results which are great in their own and quite solid.

To be entirely clear, I'm a geophysicist, cosmology isn't my field, and I tend to be sceptical of new great theories-of-everything, so it'll be a long time until I might be convinced that either of the two has something true to say about what the world's like. And reports about both are a little over the top. But only one I see as actively harmful.

35. **merian**
May 31, 2013

@Ian Sample, an hour earlier: "Roll over Einstein: meet Weinstein" and the harping over trite clichés (the new theory of everything, the hermit [21st century version – an independently wealthy finance guy] working alone in his cave, the upset of established science by the unknown pure brain) — if you really think this is the best science journalism can do I'm not hopeful.

The tendency to uncritical hero worship and the preference for splashy ideas is indeed one of the reason the Guardian science podcast isn't in my top 5 of science podcast even though 3 times of 4 I enjoy it. The fourth it annoys me so much I give up listening for a few months.

36. **Anonyrat**
May 31, 2013

Ian Sample:
One of the problems with what happened is it is not that Weinstein isgiving a talk without a paper. There is a paper.

du Sautoy wrote so in his Guardian piece:

"Weinstein begins the paper in which he explains his proposal with a quote from Einstein: "What really interests me is whether God had any choice in the creation of the world." Weinstein's theory answers this in spades."

Where is this paper? Is it top-secret or something? Or should du Sautoy have written:

"Weinstein begins the private communication in which he explains his proposal….."

You wrote that your readers "understand that a talk without a paper is not a paper with a talk." But du Sautoy wrote that there is a paper. Without Peter Woit's blog how would I have known that there is no paper?

37. **Peter Woit**
May 31, 2013

merian,

The way the Sunday Times article addresses "comparison with experiment" is just by repeating Houghton-Mersini's unsubstantiated claim that her (unpublished) analysis of Planck data provides "hard evidence" for a multiverse. This is despite the (published) analysis by the Planck team showing exactly the opposite. I don't see any good argument for why the Sunday Times should be publishing such claims.

I also don't understand people's complaints about du Sautoy writing about unpublished work. Why shouldn't he (or any academic) write for the public about unpublished work that he finds interesting? If it turns out to be highly significant work, he'll have done very well his job ("Simonyi Professor for the Public Understanding of Science"), if it turns out there's nothing there, he'll have done his job less well. I can easily imagine a circumstance where a mathematician I know had a big result and didn't mind if I wrote about it. If I thought it was probably correct, I'd blog about it. If du Sautoy wrote about Weinstein on his "Finding Moonshine" blog, would that have been a problem?

My suspicion is that people are skeptical of Weinstein's claims (as well one should be of people who claim to have a TOE…), so their problem with du Sautoy is that he was publicly promoting something they think should be treated skeptically. In that case though, they should also have a problem with most of the press coverage of string theory, the multiverse, and any number of other popular speculative ideas about physics.

38. **exscientist**
May 31, 2013

I understand du Sautoy is the successor of Dawkins.
I'm no fan of Dawkins, but I can't imagine him doing something like the Weinstein thing.
"Well, there's this guy Weinstein, who hasn't been active in research in ages, but he has this beautiful biological theory that may solve all the puzzles left by Evolution Theory, so, although he hasn't published anything and no biologist ever saw this theory, I'm going to write an article in The Guardian about it and give him a forum and endorse his theory …" etc.
Or imagine a bunch of physicists who organize a seminar by someone who claims he has solved the Riemann Conjecture – without a decent article, without scrutiny by mathematicians etc.

39. **Peter Woit**
May 31, 2013

exscientist,

Mathematical proofs are a different kettle of fish. In any case my understanding is that Weinstein is not claiming to have a finished TOE, but some important new ideas about such a thing. I think a more accurate analogy would be a physicist deciding to organize a seminar by someone who had a quantum mechanical model which gave new insight into the Riemann hypothesis, and a possible route to a proof (this is not an implausible scenario…). Most mathematicians would be skeptical of such a thing, but I don't think they would get very worked up about an account of it appearing in the Guardian.

40. **André van Delft**
May 31, 2013

I agree with Peter's latest remark. Why set the bar this high for Weinstein and Du Sautoy, and not for String theory? Thousands of scientists have worked for 40 years on String theory; is there any experimental evidence that supports it?

Nobel laureate Martin Veltman wrote a good and readable book: "Facts and Mysteries in Elementary Particle Physics"; he concluded the book with:

The reader may ask why in this book string theory and supersymmetry have not been discussed. (…). The fact is that this book is about physics, and this implies that the theoretical ideas discussed must be supported by experimental facts. Neither supersymmetry nor string theory satisfy this criterion. They are figments of the theoretical mind. To quote Pauli: they are not even wrong. They have no place here."

Half a year ago Veltman was interviewed for the Dutch magazine Elsevier.
A quote in my translation:

He still follows developments in theoretical physics. 'Sometimes they ask if I can keep up. The honest answer is that I do not have to make any effort for that. Since 1973 it stands still'.

41. **book**
May 31, 2013

Actually, Veltman has been on the record (in the past, anyway) that he doesn't believe in the Higgs mechanism either. (Although he did acknowledge that the resulting theory was renormalizable.)

42. **André van Delft**
May 31, 2013

I meant: Peter's latest-but-1 remark, of May 31, 2013 at 3:05 pm

43. **exscientist**
May 31, 2013

Peter,

An even better analogy might be this: Dawkins giving a forum to Weinstein, endorsing his theory as interesting and beautiful, writing a piece in The Guardian etc. People would have wondered if he was out of his mind. Dawkins is a biologist, not a physicist. I haven't read everything he wrote nor heard everything he said, but as far as I know, if Dawkins voiced opinions on the merits of a theory, he stayed close to this subject: biology.

And du Sautoy is a mathematician, not a physicist. If he wants to organise a seminar with Weinstein, that's fine. Perhaps Weinstein did some interesting mathematics. But du Sautoy shouldn't voice opinions about physical TEO's etc.

44. **André van Delft**
May 31, 2013

In this 2003 book Veltman left all options open, but he took the Higgs particle very seriously, and dedicated 1 of the 12 chapters to it. Quote:

So what is the situation? Most likely there is only one Higgs (if any!) and there is a vague prediction for its mass. however, there is trouble brewing and it is not at all sure that the Higgs actually exists. (…)

BTW. A preview of the book is on scripd.

45. **merian**
May 31, 2013

@Peter Woit: The Sunday Times article doesn't reach very high in science journalism either, I agree, and if you asked me which of the two theories is more likely to describe reality, I'd obviously (I hope) opt for Weinstein. Still, as a piece of science writing the du Sautoy/Jah approach makes me increasingly uncomfortable in a way the bubble universe one doesn't. And that's even though I won't believe for a second the multiverse idea is more than an idle thought experiment.

The public understanding of science currently has huge deficits in familiarity with the scientific process. Texts purely concerned with scientific contents, however beautifully written (du Sautoy is extremely admirable in this regard), won't help. We used to have scientists talk about new spekulative ideas, then publish them, then the relevant scientific community hash things out in small committees, then popular though still ambitious articles written, then the press add a gloss of celebrity. Now we get a media machine gobbling up stuff even before an result or proposition has even been examined.

And yes, "most of the press coverage of string theory, the multiverse, and any number of other popular speculative ideas about physics", the way it is currently done (and include some stuff from evolutionary science and microbiology into it) is not something I consider helpful for science in the long run.

46. **Peter Woit**
May 31, 2013

exscientist,

du Sautoy's specialty is the mathematics of symmetry, which is not as far removed from unified field theories as biology is. Yes, he's possibly out of his depth here, but academics commenting out of their depth on speculative physics is not unusual (although mostly it's physicists doing it…)

Funny, but the very little I know about Dawkins does agree with your claim that he is more cautious about this sort of thing than du Sautoy. I picked up a copy of "The Magic of Reality" in a book store, which had a really lurid cover, and looked to see what he said about physics. He had some sort of discussion moving to shorter and shorter distance scales. When he got to the nuclear scale, I was expecting him to go on something like "then there are quarks, then physicists believe there may be strings, etc…". Instead he said something like "I don't understand physics at the nuclear scale or below, so I'll say no more". Admirable. But unusual…

47. **book**
May 31, 2013

Veltman's book: quote from Introduction (opening paragraph):

"The twentieth century has seen an enormous progress in physics.
The fundamental physics of the first half of that century was
dominated by the theory of relativity, Einstein's theory of gravitation,
and the theory of quantum mechanics. The second
half of the century saw the rise of elementary particle physics.
In other branches of physics much progress was made also, but
in a sense developments such as the discovery and theory of
superconductivity are developments in width, not in depth. They
do not affect in any way our understanding of the fundamental
laws of Nature. No one working in low-temperature physics or
statistical mechanics would presume that developments in those
areas, no matter how important, would affect our understanding
of quantum mechanics."

I imagine Anderson will be livid to read the final sentences about the theory of
superconductivity (more accurately, the formulation in terms of spontaneous symmetry breaking) ~ "They do not affect in any way our understanding of the fundamental laws of Nature."

48. **Peter Woit**
May 31, 2013

book/Andre van Delft,
Enough about Veltman please, this has wandered completely off topic.

49. **exscientist**
May 31, 2013

Peter,

Dawkins – love him or hate him. But I think he adhered to the correct academic standards when he refused to judge physical theories.

The correct attitude for someone like du Sautoy – Simonyi Professor for the Public Understanding of Science in Oxford, after all – would be to put question marks around all those outlandish speculative claims by physicists.

But he just seems to add an outlandish claim to the multitude. I agree it's bad that "academics" are "commenting out of their depth on speculative physics" and I agree it's bad that "mostly physicists" are doing it.

But I think it's even worse that people outside of physics are starting to do it. Certainly if they have – or seem to have – some authority, like a Simonyi Professor for the Public Understanding of Science in Oxford. Du Sautoy could have presented the work of Weinstein – which might be very important – as a mathematical exploration, and that's what he should have done.

50. **book**
May 31, 2013

Actually, what I *would* like to see is a post from someone (physicist?) who attended Weinstein's talk, to explain/describe/summarize the main point(s) of the new TOE.

51. **oxfordanon**
May 31, 2013

book: it's more or less what you would expect. He is someone who is not stupid, who is intelligent and has a PhD from Harvard. *But* this is a properly hard subject, and those credentials don't get you anywhere near a theory of everything. He spoke a lot about geometry, and not so much about physics, and the part that was about physics was enough for me to be clear that he does not have a decent enough grip/intuition on what the Standard Model is and what it allows.

I didn't really follow what his geometric construction was, but at the end he predicts a whole bunch of new states (lots and lots and lots) that are both chiral and charged under all three forces of the Standard Model. As chiral matter can't acquire mass above the scale of gauge symmetry breaking (around a 100 GeV), such a prediction is essentially dead in the water – this energy area is all explored and you can't hide this stuff.

This is one of the things that to me rings massive alarm bells at any claims towards a TOE. If someone is not immediately aware – and he wasn't – that there are big problems with predicting new chiral fermions charged under electromagnetism or the strong force, then how much can you trust any other physics claim made?

He's not a crank, he has thought about what he is doing and can put things in the language that professionals use. Cranks don't talk about bundles and know what a representation is. But he's still wrong, and he doesn't really know physics – the way he talked about the Standard Model, the cosmological constant made that clear.

There is a reason professionals in the subject think what they do, and work on the problems they work on. The talk confirmed to me that there are good reasons to this.

52. **Mitchell Porter**
May 31, 2013

"As chiral matter can't acquire mass above the scale of gauge symmetry breaking"

What is the argument for this, exactly? I bet there's a loophole.

53. **Cormac**
May 31, 2013

I'm somewhat surprised by Ian Sample's comments. As a physicist who writes a regular column for a newspaper myself, I pay close attention to feedback from my physics colleagues, rather than dismiss it out of hand.
Also it's worth pointing out that the 'blog post' appeared online as an op-ed article. Many eminent scientists would give their eye-teeth for that sort of publicity.

P.S. I very much enjoyed 'Massive', well done – I sent you a commentary including some suggested minor corrections but you never replied (what would I know, I only teach a course in the history of particle physics for a living)

54. **Brathmore**
May 31, 2013

More news about Weinstein:

http://www.newscientist.com/article/dn23632-how-to-test-weinsteins-provocative-theory-of-everything.html

55. **Mitchell Porter**
May 31, 2013

Another thought on Weinstein's theory… I am waiting for some news that will truly identify what *sort* of construction it is. Such theories of physics don't exist in a mathematical vacuum. An individual theory belongs to a mathematical class of similar possible theories: gauge field theories, string theories, etc. If it's a familiar class of theories, then a lot will be known about what it can and can't do, how unique it is, and so on. If it's an unfamiliar class of theories, then we ought to be interested in other possible theories from that class too, and not just the initial example.

On Quora.com, there is an account of the latest talk, which makes his theory sound like a topological QFT, since it starts from a topological manifold with a bundle and a connection, and then the metric is part of(?) the connection; and all that is a well-explored topic… Hopefully we will soon have enough definitive information to place Weinstein's theory in conceptual and historical context, and see what is new or interesting here.

56. **ab**
May 31, 2013

Mitchell Porter — you have to give mass to charged chiral matter through a Yukawa coupling, so the natural scale will be the symmetry breaking scale.

57. **Mitchell Porter**
May 31, 2013

ab, if that's the argument… It's not even clear whether the mechanism whereby Weinstein's particles obtain mass, conforms to that description; in which case this sort of counterargument is beside the point. He's probably getting mass terms from a geometric effect, and not from anything resembling the Higgs mechanism.

Incidentally, what about radiatively generated masses, or masses from susy-breaking?

58. **Able Lawrence**
June 1, 2013

Here is the link to the discussion at quora that describes the lecture.
Weinstein considers Higgs mechanism as too contrived and has an alternative (more natural mechanism) that is manifest as Higgs mechanism.
http://www.quora.com/University-of-Oxford/What-was-the-reaction-to-Eric-Weinsteins-May-23rd-lecture-at-Oxford-on-the-geometric-prospects-for-unification

Science cannot even begin until we have most of at least the general types of all viable theories.

59. **Shantanu**
June 1, 2013

something OT.
Peter and other : any comments on the SNOMASS conference at KITP?
http://online.kitp.ucsb.edu/online/snowmass-c13

60. **ot**
June 1, 2013

This needs to be a separate post. "Snowmass on the Pacific" … good grief.

61. **Peter Woit**
June 1, 2013

OK, OK, see the next posting

62. **fifth**
June 1, 2013

This all reminds me of the 'fifth force' business from the mid-1980s. The person in that case (Ephraim Fishbach) was a very reasonable physicist, mild-mannered and soft-spoken, not a publicity seeker at all. He pointed out a perfectly reasonable thing, viz. that physics at some length scales was in fact not very precisely tested, and there was room for a fifth force of nature, which coupled to hypercharge with a range of tens of m. There was apparently some experimental evidence for it in those days. It was a reasonable claim, worthy of further investigation, not at all a crank thing. But in the end, it did not work out.

63. **Mitchell Porter**
June 4, 2013

Without a paper, a bootleg video, or any more secondhand reports of the talks, it is impossible to say what Weinstein's theory is, so I will shut up about it after this. But I will record one final guess regarding how it works: maybe it's a 64-dimensional spinor coupled to an SO(14) gauge field that divides a la "graviweak" into SO(10) and SO(3,1).

Circumstantial evidence for this: The 64 has room for 2 generations, and in Jacob Aron's New Scientist article "How to test…", he says "the third generation belongs in a different framework in Weinstein's theory". And, Weinstein just tweeted about SO(10).

Did anyone see Mersini-Houghton talk? 🙂

64. **Terry**
June 4, 2013

This is from the daily galaxy article here: http://www.dailygalaxy.com/my_weblog/2013/06/the-next-einstein-radical-new-theory-answers-unsolved-mysteries-of-physics.html

"Weinstein's theory is also the first major challenge to the validity of Einstein's Field Equations, revealing that "just as Newton's equations were an approximation to nature so too are Einstein's. "

I am going to put a sticky note on my white board about this being "the first major challenge" to Einstein… revealing that Einstein is just an approximation to nature. I am sure the next time I read about an extension of general relativity it will start out "this is the second major challenge…" right?

65. **MarcF**
June 4, 2013

From a distance it looks like yet another group theoretic approach to ToE ala E(8). While one has to admire that the path integral formalism has gotten us so far by basically parachuting terms in Lagrangians and seeing if it agrees with the experiments, the resulting narrow set of symmetries still beg an explanation. Symmetries don't exist in a vacuum. Personally I find the solid state studies of utmost interest in pointing to 'fundamentals of physics'. As a 'gentleman physicist' I relate to the Weinstein story. There is something about getting these ideas in the public domain and getting all of us to argue so violently about 'what makes science'… I have enjoyed reading the thread…

66. **Mike**
June 5, 2013

Here's a Tim Gowers comment on Weinstein's second lecture:

The status of Eric Weinstein's theory of everything has become a bit clearer, because Weinstein gave a repeat of his talk, this time attended by physicists. It is discussed in the article below, of which two key paragraphs are these:

"The trouble is that we should already have seen some of Weinstein's new particles, if they exist, says physicist Joseph Conlon of the University of Oxford. Properties of some of the predicted particles mean that they should be linked to the strong force, one of the four fundamental forces and the one that binds protons and neutrons.

"Experiments at the Large Hadron Collider at CERN near Geneva, Switzerland, have been smashing particles together at high enough energies to overcome the strong force, creating a spray of other more elusive particles, such as the Higgs boson. Weinstein's new particles should therefore have been detected in the resulting particle shower."

So it looks as though Weinstein's theory isn't dead yet, but he clearly has some serious explaining to do.

67. **Mike**
June 5, 2013

Sorry, here is the article link that Gowers was referencing:

http://www.newscientist.com/article/dn23632-how-to-test-weinsteins-provocative-theory-of-everything.html

68. **cormac**
June 7, 2013

Hi Peter, that is a really interesting addendum from Professor Mersini and Professor Holman. For those of us who find the mathematics of theoretical papers quite daunting, a summary of the work by the practitioners themselves is very helpful (as opposed to simplified pieces by science journalists). So blogs can be very useful!

I also agree with the Mersini's and Holman's central point on media hype: it seems unfair to link their case with that of Weinstein. Controversial in the field or not, the recent work of Mersini and Holman is simply one aspect of long careers in the highly competitive field of theoretical cosmology. By contrast, Weinstein is an amateur scientist (in the strict sense of the word, not in a negative sense). I find it reasonable that the predictions of Mersini and Holman would attract attention from the media, as well as the community, given the public's fascination with the multiverse. I don't think this equates with an amateur being granted access to a highly sought-after platform, with consequent publicity.
You may recall that I have some interest in media hype and amateur scientists. In Ireland, a great deal of publicity was given to an amateur scientist who had strong anti-relativity views. 15 years later, we're still trying to clear up the confusion he caused

69. **Peter Woit**
June 7, 2013

Hi Cormac,

Yes, the Weinstein and Mersini-Houghton cases are not quite the same, but I think the issue of the amateur/professional and published/unpublished nature of their work isn't what's really important. In both cases, you have press stories promoting things which have very little support from experts, and this is something to be legitimately concerned about. In these two cases, I think one of the two is far more damaging: it simply is not true that the Planck satellite data gives "hard evidence" for the existence of a multiverse, and the press is being used to mislead the public on a central issue of what we have scientific evidence for and what we don't. That two Guardian blog posts (evidently these didn't appear in the newspaper) describe some theorist as having promising speculative ideas when they may not be that promising just isn't a problem on the same scale. It remains remarkable to me how little anyone in the physics community seems to care about the public being misled about what data says about the origin of the universe, while getting so excited about the fact that a theorist without proper credentials was getting some media attention.

70. **Anonyrat**
June 7, 2013

The way I see it is – is there information available for me to learn more about Weinstein or Mersini-Houghton, and the answer is for Weinstein – No, and for Mersini-Houghton – Yes; and that is the problem.

Snowmass on the Pacific

June 1, 2013
Categories: Uncategorized

Due to popular demand from the comment section, I spent some time this afternoon taking a look at the talks now posted from the KITP Snowmass on the Pacific conference held the past few days. This is part of an ongoing project for a US HEP Community Summer Study that will culminate at a meeting in Minneapolis later this summer. The US HEP community faces serious questions about what priorities for the future should be in an environment of flat-to-declining budgets, no energy frontier projects in the US, and discouraging news from the LHC about no evidence for BSM physics.

The KITP talks cover a wide range of topics, and I haven't had a chance to look at very many of them. For theorists, one interesting session was the Wednesday panel on Structural Issues for Theorists, which featured presentations by and discussions with the people at DOE and NSF responsible for HEP theory grants (Simona Rolli and Keith Dienes). There's a lot of information about the situation of US theory grants there, but I was a bit struck by the impression that despite the large problems faced by HEP in the US, for theorists things look much like they always have:

- Budgets are pretty flat. As salaries go up with inflation, and as new young people come into the system applying for grants, it's harder and harder for people to get the grants and grant amounts they would like.
- The split between DOE and NSF funding of often exactly the same thing doesn't make much sense and leaves people sometimes confused.
- There's always a problem finding grant support for the number of students who want to do theory, leaving theorists trying to justify to their colleagues why their students should get more of the few TA positions available. The situation of funding about 180 theory Ph.D students in an environment where there are maybe 10 tenure track jobs/year in the country isn't deemed even worthy of comment.

Some numbers from the presentations:

- The DOE spends roughly \$25 million/year on positions at government labs, another \$25 million/year on grants to universities (the bulk going to pay grad students/postdocs/summer salary). The NSF spends \$13-14 million/year on grants to universities, another $6 million on Frontier Centers, some of which have an HEP theory component.
- DOE funds 49 PIs at labs, 221 PIs at universities, NSF funds 186 PIs at universities.
  The DOE split by field is 128 Phenomenologists, 73 "Formal" (often "string theory"), 42 Cosmology, 27 Lattice Gauge Theory.
- DOE funds 123 postdocs, NSF funds 50 of them. DOE funds 130 grad students in theory, NSF 50 of them.

This stable system of government funding has been crucial in determining the structure of HEP theory in the US for the past few decades, and the academic system is built around it. I keep wondering what the effect will be as new sources of money come into the system from private sources, on scales approaching that of government funding. As a somewhat extreme example that is likely a one-time thing, last year the string theorists in Princeton got \$15 million in checks from Yuri Milner, a number somewhat larger than the entire NSF $13-14 million/year budget for HEP theory.

   June 1, 2013

   'Snowmass on the Pacific' … a preparation for 'Snowmass on the Mississippi' … I suppose it's an inconvenient truth that one of the consequences of the flat/declining budgets is that 'Snowmass at Snowmass' is now too expensive?

2. **MathematicianNotPhysicist**
   June 1, 2013

   `As salaries go up with inflation, …'
   Is this a prediction, or has this phenomenon actually been observed?

3. **David Nataf**
   June 2, 2013

   In an equilibrium situation where the system was not growing and every PhD got an academic job, professors would have an average of one graduate student over the course of their entire careers.

   In contrast, a typical professor has 2 or 3 graduate students… at any given time.

   Food for thought.

4. **Thomas Larsson**
   June 2, 2013

   That there are 20 times as many PhD students as tenure-track positions is not the problem; that people expect to stay in academia afterwards is. To be given the opportunity to complete a PhD and perhaps a post-doc in theoretical physics is really a wonderful gift from the taxpayers, for which one should be grateful. At least I am.

5. **talks**
   June 2, 2013

   The information on funding by DOE and NSF is interesting but, in principle, it is not something not 'already known'. What is there in these talks that really helps to 'prepare' for SOTM?

6. **Michael**
   June 2, 2013

   180 theory Ph.D students in an environment where there are maybe 10 tenure track jobs/year in the country

   Is that particle theory only?

   I wonder, what eventually happens to 170 – cooking meth can't be really a career choice for theorists, besides, Dr.White already cornered that market…

7. **DTA**
June 2, 2013

If one wants to be hard-nosed about it, the optimum ratio of students to jobs is a balancing act between missing too many potentially top-notch scientists by taking in too few students, and spending unnecessary money on additional students without noticeably increasing the potential of an eventual prize catch. As far the fact that a number of students will have to go into alternative careers is a choice they can make for themselves, if one accepts that people are responsible for the choices they make.

Of course, if a professor only gets to have one student in his or her career, it will be harder to justify even 10 new faculty openings per year in the field, given that universities supposedely teach, but that's a next-order problem. Perhaps a system could with more research positions and fewer faculty ones.

8. **Shantanu**
June 2, 2013

Peter, also interested in yours(and other's opinions) regarding teh talks on supersymmetry and grand unified theories.

9. **Alex**
June 2, 2013

There are probably 10 jobs/year advertised specifically as HEP theory research. However, people who get PhDs in HEP theory will do other things as well. Some will get jobs in teaching-oriented institutions; some of those jobs are advertised as HEP theory but some are advertised more broadly. They still use their training. A few will get various types of staff scientist jobs at government labs. A few will take their big physics brains and pedigrees and go into finance or consulting. A number of them will take their computational and mathematical skills into some sort of applied science work.

All of that is fine, and in my opinion society is well-served by the outcomes of their training. (Well, except maybe the consultants.) I don't consider it a "waste" that they went into "alternative" careers.

The problem is that a non-trivial fraction of them will get stuck in various permadoc/soft-money stints, or adjunct stints. That's fine when you're starting off, but it's a poor foundation for an adult life and career. Maybe this is their fault, because they didn't prepare themselves to branch out. They stayed very narrowly-focused and never prepared themselves to leave. Or maybe it's the fault of some advisors and "mentors" who actively or passively discouraged looking at anything outside of their academic niche. And there's a system that enabled this.

I think that a lot of what NSF talks about with training and broader impact is fuzzy and silly, but I would not fault them if they started requiring that institutions getting funds for trainees in basic research also get some meaningful assistance in preparing for "alternative" careers. NSF should look favorably on departments that have seminar speakers from industry, that encourage their PhD students to take applied classes (e.g. computational methods, some engineering classes, materials science, other applied things related to physics) after finishing their qualifying exams, that have meaningful networking with alumni in industry (beyond something passive like a LinkedIn group), and generally have an atmosphere that says "You are doing fundamental research as a way to train your mind, now pay some attention to what you'll do next."

10. **train your mind**
June 2, 2013

Actually, much of the preceding post applies quite generally across all of physics graduate research, not just HEP theory. It is a valid post, but not restricted to HEP theory.

11. **Amitabha**
June 3, 2013

Regarding the 10 jobs vs 180 students: many of the students are from outside the US, and many return to their home countries after PhD, or after one or two postdocs.

12. **Richard**
June 4, 2013

Re the 180 people and 10 jobs. This year the rumor mill lists 17 "faculty" positions — albeit some in Canada. Moreover, that 180 is presumably a stock, not a flow; given an average of 3 years in the "research phase" of grad school, that suggests supply outstrips demand by a factor of 3 or 4, not 18.

Some of those 180 people will fail to finish, others will finish and go to work for hedgefunds, or Google, or a start-up, or teach in a 4 year college, or take time out for family… I have friends, collaborators and former students who have done all of these things — the HET jobmarket is no bed of roses, the following statement

The situation of funding about 180 theory Ph.D students in an environment where there are maybe 10 tenure track jobs/year in the country isn't deemed even worthy of comment.

is massively wrong; certainly by a factor of 5, and perhaps by a factor of 10.

13. **Peter Woit**
June 4, 2013

Richard,

The statement is accurate, your interpretation of it is wrong: obviously the 180 students on NSF/DOE grants aren't all graduating in one year. Your estimate of "3 or 4" for the ratio of phds/year to jobs I think is quite wrong. Some things to take into account:

1. Final numbers from the rumor mill for the past four years of faculty hires are 9,14,11,11, see here:
http://www.physics.utoronto.ca/~poppitz/Jobs94-08
This is post 2008-recession, and hard to know what the future holds, but I don't see US universities expanding greatly in coming years. Looking at data back to 1994, the 1990s had numbers in the low teens, for a while in the early 2000s the best job market in decades got up to 20, over the last twenty years the average is probably 15 or so, with 11 the most recent number.

The 17 number you give includes not only Canadian universities, but all listed jobs, not all of which get filled, and some of which end up going to non-HEP candidates.

2. The 180 number is just those in the US on DOE or NSF HEP research grants. It doesn't include theory students with some other kind of funding (TAs, other research fellowships). Depending on how you count, I'd guess around 300 Ph.D. theory students. There was a 1997 HEPAP census of US institutions on DOE/NSF grants, now very out of date, which found (with 99/120 institutions responding) 283 theory students (3rd year and above), and 78 theory Ph.Ds /year. See here
http://pdg.lbl.gov/hepap/hepapsurvey97.pdf

I'd be very curious to know if anyone has numbers on what the trends have been since the 1997 census. Speaking of Canada, one thing that didn't exist in 1997 is Perimeter, where it seems that there are about 35 theory Ph.D. students now.

All in all, I think a current estimate of about 10 to 1 for theory Ph.Ds/job is reasonable, with this having been somewhat better during the early 2000s, but prospects for the future not better. Telling students that the ratio is 3 or 4 to one would be really irresponsible.

On the larger issue of whether this is a good thing, that has been debated here often in the past. I'll just point out that with numbers like this it's hard for HEP theorists to legitimately make a case to the NSF/DOE that there is too little theory graduate student funding. I'll also point out that I've seen up close for many years the job market in mathematics (healthy) and in HEP theory (unhealthy), and the difference is huge. Why people in HEP want to defend living with such an unhealthy situation I don't think I'll ever understand.

14. **Dennis**
June 4, 2013

A fair percentage of our graduate students in particle physics are from foreign countries. With US training, they often have good job opportunities in their home countries, which are not included in the 10 per year US jobs. There is also the military-industrial job market as well as the medical market. There is a projected shortage of big data analysts with "deep analytic talent" projected for 2018 of 140,000 to 190,000 people. These jobs currently start at over $100,000 for new graduates. The above discussion of about 80 theory Ph. D.s a year is totally swamped by the number of available positions in the technical job market.
Certainly, we will miss theorists that are highly trained in research directions that should be pursued, but as a training ground for technical people, our field is excellent.

15. **Peter Woit**
June 4, 2013

Dennis,

I'd be wary of promising entering grad students that they'll have no problem getting a $100K+ job data science job when they get their Ph.Ds or their postdocs end 5-10 years down the road, given that every major university is starting up graduate programs specifically in data science right about now.

But the point really isn't that theory Ph.D.s will end up unemployed or working as baristas; these are smart, talented people who will find some sort of better than average employment doing something or other. The point is that there is a big difference in environment between a field where good young people see a future and the senior people working with them see them as future colleagues, and one where they are just cannon fodder, with everyone aware that unless they are both exceptional and lucky, they're on their way out the door at one speed or another. I've seen both environments up close and I think describing one of them as healthy and the other as unhealthy is pretty accurate.

16. **Richard**
June 4, 2013

There are an infinite number of ways to slice this. But comparing the number of people in grad school (or a proxy for it) to the number of faculty slots is misleading.

Looking for some real data, found this

http://www.aip.org/statistics/trends/highlite/edphysgrad/figure7a.htm

which gives "particles and fields" as 208 students graduation / year in 2007 and 2008 (out of 1480). "Particles and fields" casts a fairly broad net and includes experimentalists while the Rumor Mill is incomplete in a variety of ways (people who take jobs internationally, or outside of the rumor mill's scope but still in science) a reasonable guesstimate would be to say that 100 theory students compete for 20 jobs. Which is closer to the my "3 or 4" than it is to your (implicit) 18.

17. **Peter Woit**
June 4, 2013

Richard,

There never was an "implicit" claim by me of a ratio of 18 people/job, that was just your (completely unreasonable) misinterpretation of what I wrote. The only estimate I've given of this ratio is about 10, you've now moved up from "3 or 4" to 5.

We seem to agree on the number of people (100/year). Yes, there are many ways of defining and counting what sort of jobs provide a research career in HEP theory. I still think the 11/year Rumor Mill count is a better estimate than your 20, note that this overcounts permanent positions (some people don't get tenure or leave the field from tenure-track jobs). Yes, US educated students get research jobs outside the US, but students educated outside the US also get US jobs. In any case though, whether it's 90% or 80% of theory Ph.Ds that have no future in the subject, that doesn't much change the picture.

18. **piscator**
June 5, 2013

Just a quick comment on this. The chance of ultimately getting a faculty job also obviously depends a lot from institution to institution: students from Princeton or Harvard or Stanford have far better odds of ending up with a faculty job somewhere than those from Kansas State, and I think people know this from the outset. The former probably have odds a lot better than 1 in 3/4 (provided they are willing to stay in the system and do not self-restrict to top tier research universities), and the latter odds a lot worse than 1 in 10.

I think Erick Weinberg has roughly this data on his faculty jobs page.

19. **David Nataf**
June 5, 2013

Richard,

It is peculiar that you are promoting a rosy view, why? Things are in fact not rosy. Having numerous talented young people get Ph.Ds in HEP, and then sending them to goldman sachs or JP morgan sachs to develop high-frequency trading algorithms is not, in my view, an optimal outcome. I just don't see how you could be stating this to be satisfactory. It's not why people start PhDs in science, and if that was the final goal, there would be better training for it elsewhere than in physics.

I don't think academia would be well-served by transitioning to a medical school model, where it would be virtually impossible to get into graduate school, but there would then be a guaranteed job for every who gets in. However, an intermediate solution, wheresay some ~50 of the 180 graduate student positions across the country are gradually replaced by 15-20 permanent staff scientist positions, should be contemplated as a positive step forward.

20. **Peter Woit**

June 5, 2013

piscator,

I'm guessing you're referring to the data gathered by Erich Poppitz (not Erick Weinberg) that's in

http://www.physics.utoronto.ca/~poppitz/Jobs94-08

It shows most jobs going to people from a small number of places (Berkeley, Princeton, Harvard, Stanford), with those places placing about one person/year. I don't have any numbers, but I'd guess those places produce something like 3 theory Ph.D.s/year. So, if you're a student from such a place, a one in three chance of getting a Rumor Mill type job may be a good estimate.

21. **Mark**
June 5, 2013

I think there are too many PhD students – in my field (experimental HEP) the number of students in the country I come from has been doubled compared to say 10 years ago – yet there are no more faculty jobs than 10 years ago available. Furthermore I don't see that a lot of these students are actually anything more than cannon fodder to do data crunching for PIs – the point of a PhD should be to develop your own idea in my opinion, and this is certainly what I was told to do when I did mine – but nowadays this no longer seems to be the case in a lot of cases.

I would reduce the number of students and instead use the money to provide a better career structure for those who do stay in the field post-PhD. Then you would have a more stable pool of experienced and competent people, and would in principal have a better pool of students coming into the system (I come across students regularly who I can honestly say have no place in a PhD program because they are just not capable – so if we can afford to fund them this is an argument we fund too many places). Furthermore with a better career structure you would be more likely to entice good people to stay on (many very good students in my group left academia straight after their PhD because of the poor career prospects and I don't blame them for doing it).

22. **Richard**
June 6, 2013

I don't think I am "promoting" an overly rosy view; I am genuinely interested in this question, and trying to explore the problem. There are certainly large uncertainties in the data if one can argue for prof:grad ratios that vary by a factor of 2 — and it is equally plausible that some people are motivated to make things look as dire as possible.

Piscator's point that outcome depends very strongly on where you get your PhD is very well made, and it is clear that a handful of PhD programmes are producing a disproportionate fraction of the professoriate in the US. (My own PhD institution is one of the singletons on Poppitz's "PH.D. INSTITUTION OF FIRST-TIME FACULTY HIRES" plot — one faculty member in North America in nearly two decades.)

23. **Dudley**
June 14, 2013

As a passionate student considering a PhD in fundamental theoretical physics, between this and string theory's dominance, it is quite demotivating. From my fairly uninformed point of view, I have a hard time seeing any progress beyond the standard model until our experimental capabilities greatly improve, and an easy time seeing people waffling like they are doing something useful. I hope I am wrong.

Unless you work on a project specified by someone else in a subject you aren't interested in (or even believe in), you aren't going to be able to afford food. Cheap food. Again I am probably wrong, but this is how it feels.

I would agree that taking on less PhD students would be wise. Certainly a lot of my colleagues simply should not be doing physics PhDs, to the point of cringing.

I really have no idea what to do!

24. **Mitchell Porter**
June 14, 2013

Dudley: the standard model has several dozen unexplained features; there are numerous phenomena which require something beyond the standard model; for all these facts, there are numerous ideas about how they might be explained, but the field is still open for anyone with a new idea to voice it as well; and the mathematics and ontology of the subject also still needs work. So there's no shortage of things to do.

25. **Anonymous**
June 24, 2013

Dear Peter,

As a (mathematically inclined) theoretical physics aspirant, I am extremely curious about your comments about the job scene in mathematics. In what way is the mathematics job scene much better ? Is that mainly an artefact of over-supply of particle theory graduates per permanent position available or is there a greater supply of mathematics permanent positions (again, why ?) ? Does it have something to do with the style of work in each community (carefully substantiated and original in mathematics, versus speculative, flashy and "faddish" in high-energy theory) ?

26. **Peter Woit**
June 24, 2013

Anonymous,

The main difference in the math academic job market is just that there is a much better ratio of Ph.Ds to jobs than in particle theory. Just about every higher educational institution does a lot of calculus and other math teaching, so needs a sizable math faculty. In contrast, most places that have physics departments typically have a fairly small number of theorists.

There's a separate issue of faddishness, with the particle theory phenomenon of everyone jumping on the same hot topic and trying to write papers about it pretty much unknown in mathematics. This used to have some justification in particle theory, when experiments were producing unexpected results, pointing to what might be the most fruitful thing to work on. In recent decades, there has been little of this from the experimental side, but the theorist's behavior is deeply ingrained culturally.

All in all, math research is a much healthier community. If you are interested in the boundary of math and physics and trying to decide which area to pursue graduate work in, math has a lot of advantages at this point.

Simons 75th Birthday Conference

June 3, 2013
Categories: Uncategorized

Last week the CUNY Graduate Center hosted a conference in honor of the 75th birthday of Jim Simons. It was organized by Dennis Sullivan as a set of expository "mini-courses" on various topics related to Simons' mathematical work. I was able to attend the morning talks, which were of a uniformly high quality, and focused on the Chern-Simons 3d QFT, as well as the "differential characters" of Cheeger and Simons. Video of most of the talks is available online here. In particular, Witten's talk, which was a very simple physical introduction to use of the Abelian Chern-Simons term in condensed matter, is available here (followed by Deligne on Deligne-Beilinson cohomology). Talks by Robbert Dijkgraaf on Chern-Simons-Witten theory are here and here. The second Dijkgraaf talk was followed (go to 1:05) by some informal comments by Simons himself, explaining the history of how Chern-Simons came about. Mike Hopkins gave two wonderful talks, the first about differential characters in general and about his recent article with Dan Freed, the second about his work with Singer that used generalized differential cohomology.

The talks I missed were likely just as good, I'm starting to catch up on them on video now….

Comments

1. **Robert J Frey**
   June 4, 2013

   I worked with Jim for 15 years, most of it as a Managing Director at Renaissance Technologies. As Chairman and President, he not only guided the overall research program but made many seminal contributions himself. Jim was far more than a brilliant researcher. Renaissance's success can be directly attributed to the environment he created. Jim built a place where integrity, respect, and creativity were nutured and supported. All of us bright boys and girls had pretty healthy egos, but it is hard for anyone to play the prima dona when the boss, who managed to think rings around the best of us, was just so damned decent. Jim taught me that the pursuit of excellence works best when put first the people whom you expect to achieve it.

2. **Lloyd**
   June 7, 2013

   Hi Peter,

   I was asking you about a research paper you were working on way back in 2008:

   http://www.math.columbia.edu/~woit/wordpress/?p=673&cpage=1#comment-36511

   You said you are still working on it, did I miss anything?
   Or is it already posted/published somewhere?

   Best wishes,
   Lloyd

3. **Peter Woit**
   June 7, 2013

   Lloyd,

   See this

   http://www.math.columbia.edu/~woit/brstdirac.pdf

   I've been intending to get back to work on this, for the past year have been working on the notes posted here

   http://www.math.columbia.edu/~woit/QM

   Hope to finish this project this summer, then get back to the BRST/Dirac Cohomology project.

4. **Lloyd**
   June 11, 2013

   Thanks Peter for the links!

   The cohomology project seems very interesting, but the date on the notes is 2009!

   Why not go ahead and publish whatever you have now? You can always submit follow-ups later. I guess this would put to rest the assertion that you do not actually do any fundamental research.

   Best,
   Lloyd

5. **Peter Woit**
   June 11, 2013

   Lloyd,
   The paper is on my web-site, I wrote about it on the blog, it should show up quickly if anyone googles for information on that topic. Honestly, very few people seem to be interested in it. I definitely need to get back to work on the paper, produce a more complete version including what I've learned in recent years, and that I'll likely publish somehow, or certainly make a serious effort to get others interested in.

   For now, I'm working hard on the book, and that actually should be very helpful for the Dirac cohomology/BRST paper when I get back to it. There are a host of tricky technical details I hadn't gone through that writing the book has made me sort out. So, maybe a draft of the book will be done this summer, new and improved paper this fall. We'll see..

Nature at the energy frontier

June 12, 2013
Categories: Uncategorized

Last week a symposium on Nature at the energy frontier was held at the ETH in Zurich, funded by the Latsis foundation. Videos of many of the talks have appeared here.

As part of the symposium, David Gross gave a public talk, available here. Gross is often invited to give such talks, and I've either attended or taken a look at the video for quite a few of them. The first substantive posting on this blog back in 2004 was about one such talk. Back then, Gross was claiming that in 3-4 years there would be a headline in the New York Times about the discovery of supersymmetry at the LHC (he was overly optimistic about how long it would take to get the machine working properly). I wondered at the time:

> What will be interesting to see will be what Gross et. al. do when this doesn't happen. Will they drop string theory?

In all of the talks I've seen since that time, Gross continued to express optimism, including willingness to bet significant sums of money on a discovery of superpartners at 50/50 odds. His talk at the Latsis symposium included a remarkable change of tone, featuring an Einstein quote I hadn't seen him use before:

> The successful attempt to derive delicate laws of nature, along a purely mental path, by following a belief in the formal unity of the structure of reality, encourages continuation in this speculative direction, the dangers of which everyone vividly must keep in sight who dares follow it.

He describes Einstein as both encouraging the kind of speculative path followed by string theory and SUSY, while at the same time warning of its dangers, and noted that Einstein himself devoted the latter part of his life to a speculative path that turned out to be a dead end.

In his explanation of the standard arguments for string theory and SUSY, Gross was much more cautious than in the past, careful to explain that these arguments were based on just speculative "clues". These clues might just be coincidences, but the main reason for not giving up on them was that we don't really have any others.

About the LHC results, Gross described them as having now ruled out the simplest SUSY models, which could be a clue that SUSY does not exist. He said that if SUSY is not seen at the LHC, we will learn for sure that theorists have been on the wrong track for many decades. According to him, this would "change a lot of our way of thinking", since "we have been pursuing these clues for a long time." He didn't discuss how ways of thinking will change, although he is well known to strenuously reject one popular idea about this (anthropics and the multiverse).

Erik Verlinde gave an odd talk with a title that promised to address these issues, String Theory and the Future of Particle Physics. He explained the history of string theory and how the original hope was that it would tell us where the SM parameters came from, something which "looks differently now". According to him, the idea of strings moving in a compactified 10d was the "old view", now made obsolete by branes. The "present view" is all about gauge-gravity duality, which doesn't say anything about those SM parameters. According to him the "future view" of string theory will somehow start from some new basic principles that we don't know yet, providing an underlying microscopic description that will explain holography, and give an "emergent" explanation of space, time, matter, etc. There was no explanation at all of what these new principles were or what the new microphysical description would be. String theory itself would just be an "effective theory", like the Standard Model.

After this introduction, Verlinde than moved on to something that seems to have nothing at all to do with string theory, giving a long explanation of how he thinks there are some new degrees of freedom out there that have dynamics at long time scales. These should be treated by the methods of polymer dynamics, and they will explain dark matter and dark energy. He produced lots of graphs of astrophysical data, and claimed that he has an "extension" of Newtonian gravity, better than MOND, which explains the astrophysical data. At the end of the talk there were a bunch of questions about the cosmological implications of this, I couldn't tell if Verlinde had an answer. He has been talking about this idea in public talks for a couple years now, although as far as I can tell there is no paper. Also, as far as I can tell, no one else besides him takes this seriously.

The last talk of the conference was from Nima Arkani-Hamed, giving basically the same talk I've written about recently here and here. I confess to not listening to the whole thing, since it was quite familiar (although I did notice he addressed the question of the possibility there wasn't really a hierarchy problem, saying people who raised that were "frustrating", since he had thought about it for decades, and "trust me, there's a hierarchy problem"). In the question session, he made the same point I often end up arguing with string theory proponents about, saying (1:14) that if "you can do experiments at the string scale, wouldn't help you at all". The idea that you would see string excitations on a compactified space he characterizes as a misguided old idea from the 1990s. If there's a landscape, the possibilities are so complex for Planck scale behavior that you can't predict what experiments at that scale would see. I'm glad to see that now instead of getting into arguments like this one, I can send people to go argue with Nima.

Comments

   June 12, 2013

   A historical comment: You, and others, have often emphasized that this disconnect between theory and observability, and acceptance of this disconnect, is unprecedented in the history of science.

   In fact, hydrodynamics provides a very relevant historical example: In the 18th century it was realized that ideal hydrodynamics was a very lousy description of the behavior of fluids, even fluids with a very low viscosity ("D'Alambert's paradox", the force on a cylinder undergoing laminar flow, is a textbook example).
   The reaction of the scientific community was pretty much the reaction of supersymmetry and string theory practitioners today:
   ————————-
   http://en.wikipedia.org/wiki/D%27alembert%27s_Paradox
   D'Alembert, working on a 1749 Prize Problem of the Berlin Academy on flow drag, concluded: "It seems to me that the theory (potential flow), developed in all possible rigor, gives, at least in several cases, a strictly vanishing resistance, a singular paradox which I leave to future Geometers [i.e. mathematicians – the two terms were used interchangeably at that time] to elucidate".[4] A physical paradox indicates flaws in the theory.
   Fluid mechanics was thus discredited by engineers from the start, which resulted in an unfortunate split – between the field of hydraulics, observing phenomena which could not be explained, and theoretical fluid mechanics explaining phenomena which could not be observed – in the words of the Chemistry Nobel Laureate Sir Cyril Hinshelwood.[5]
   ———————————
   The best mathematicians in the world continued to study formal, beautiful, and irrelevant solutions of inviscid fluid dynamics, and the reason for the world being grossly different was not paid attention to until the beginning of this century.
   Substitute "supersymmetry" for "ideal fluid dynamics", and you get today's impasse.
   The work on AdS/CFT and amplitudes reflects very well the theorist's response to disappointing experimental results.

   In retrospect, was it a mistake? Certainly we learned a lot of mathematics techniques from these solutions, which are now used elsewhere.
   On the other hand, the _reasons_ the real world is different (which have to do with turbulent regions which form at low viscosity) are equally, if not more, fascinating and rich in mathematical insight. On the "third hand", these reasons are also "hard", we still have not completely understood, so it is difficult to see whether "extra effort" at

that time would have made much difference.

June 12, 2013

lun,

Interesting analogy. One difference though is that here we already have a wonderful mathematical theory that works (the Standard Model).

3. **David Metzler**
June 12, 2013

On an older topic, your more mathematically interested readers may want to go to terrytao.wordpress.com and click on the polymath8 link to see recent progress in improving Zhang's bound on prime gaps (now down to around 250,000 instead of 70,000,000.) You can watch mathematics in action, in almost real time, and participate yourself, if you know your stuff.

4. **Peter Woit**
June 12, 2013

Thanks David,
That is an amazing project, I was thinking of finding some way to write about it. Shows the power of crowd-sourcing in action, when your crowd includes Terry Tao…

5. **A.J.**
June 12, 2013

I'm not sure I'd describe the Standard Model as a wonderful mathematical theory. The computations we can do work nicely, of course, but the Standard Model is not a well-defined mathematical model in the way that hydrodynamics is.

In hydrodynamics, it's very clear the mathematical model is, i.e., what the degrees of freedom and observables are, and what rules govern their dynamics. The big questions mainly concern whether solutions to these dynamical rules exist for various sorts of boundary conditions.

In the Standard Model, on the other hand, it is _not_ clear what the mathematical model is, let alone which boundary conditions play well. We would like the Standard Model to be a continuum quantum field theory. Typically we specify these by either simply just writing down some observables and their OPE coefficients (the "divine inspiration" method) or by showing that some system of regularized Feynman integrals have a well-defined continuum limit.

To the best of my knowledge, we don't have even a physically satisfactory candidate for the set of regularized Feynman integrals. Note that I'm not just complaining we can't take the continuum limit with perfect mathematical rigor. What I'm saying is that every regulator I've ever heard of breaks some crucial feature of the Standard Model: gauge invariance, Lorentz symmetry, locality, or chiral symmetry.

To make matters worse, there's no evidence that any regularization would have a sensible continuum limit, thanks to the running couplings in the Higgs & U(1) sectors. (You can argue that there's no Landau pole if you want, but the burden of proof is on you. And the numerical results aren't exactly encouraging.)

Sorry to be such a downer, but I don't think it's particularly fair of you to take a maximally pessimistic viewpoint on string theory's mathematical structure (in the linked MathOverflow post) while advertising the Standard Model as 'wonderful'. The SM is far more successful as physics, but mathematically, it's in terrible condition. I'm not even sure it's likely that the SM is anything more than a set of recipes for making approximate computations in some unknown model.

6. **Peter Woit**
June 12, 2013

Hi A.J.,

I know basically nothing about hydrodynamics, or the associated mathematical models, other than that there's a million dollar prize for understanding something about the solutions of Navier-Stokes, a situation that doesn't look that different than the million dollar prize for showing there's a mass gap in pure Yang-Mills (which as you know well can be rigorously defined on the lattice).

In what I wrote at mathoverflow, I was trying to give not something maximally pessimistic, but an accurate explanation of what the status is of the attempt to give a definition of "string theory". As far as I know, the statement that no one knows how to define string theory outside of perturbation theory (i.e. M-theory) is completely accurate (other than as a conjectural beast that satisfies certain consistency conditions and has various known limits). People really don't know what the right fundamental variables and laws are for the theory, even at a very formal, conjectural level. I'd be interested to see a good reference if this is not accurate.

The situation with the Standard model, as a mathematical structure is a complex and fascinating one, and I know you're well aware of this. While a rigorous formulation with proven properties is lacking, formally you can write the thing down, and a lot is known about how to make sense of the formal equations. I think there's a glass half-full/half-empty situation here. To me the SM has a huge amount of precise and very deep and powerful mathematical structure and we know in principle how to do accurate calculations with it, although there are fascinating remaining issues about how to get a rigorous definition one can prove things about. To me that's a glass more than half-full, but tastes can differ.

Yes, you can say many similarly precise things about perturbative string theory, but the current lore (see Arkani-Hamed's comment) is that that's not what's relevant to the real world. I don't believe you can produce a realistic (e.g. with the right CC) string theory model purely defined using perturbative string theory. Typical conjectured realistic models use an effective potential for moduli that get stabilized through complex mechanisms, invoking extremely poorly understood and conjectural aspects of non-perturbative string theory. Again, here you don't even know what the right fundamental variables or dynamical laws are, even formally.

7. **cthulhu**
June 12, 2013

I am merely an interested bystander wrt theoretical physics, but I know a fair amount about fluid dynamics (a somewhat more correct name than hydrodynamics). I think that A. J. is off base regarding the well-definedness of fluid dynamics. The overriding problem in fluid dynamics for many, many years has been the modeling of turbulence – there are more degrees of freedom there than you have equations, so the history of accurate solutions (almost all numerical) to the Navier-Stokes equations is the history of turbulence models, and their agreement with experiment is still not that impressive.

Also, for the historical record, the key insight that bridged the gap from D'Alembert's potential flow theory to modern understanding of fluid dynamics was Prandtl's boundary layer approximation. Any analogy between boundary layer theory in fluid dynamics development and quantum electrodynamics in the development of modern physics?…

8. **A.J.**

June 12, 2013

Cthulu,

Thank you for the correction. That's a lot worse than I'd realized.

Peter,

I'm not sure it's a glass half full/half empty situation, as far as the mathematics goes. (I see it as closer to 40/60. 😉 I don't think the situation with the Standard Model vis a viz formal existence is much better than the one in string theory. This is, of course, a subjective opinion, and to do purely with the mathematical merits, not the physical ones.

With the Standard Model, we can write down a classical version and we can write down a free field theory which ought to be the zero coupling limit. This can be done with basically arbitrary amounts of rigor. But when we talk about the Standard Model, we're asserting that there exists a interacting QFT which deforms this things. This is a very sketchy definition, even at a physical level! It's not a completely absurd suggestion, of course. Mathematicians have shown that such deformations can exist in some situations. (But they've also showed that they can't exist in others: There aren't a lot of interacting scalar QFTs in higher dimensions.) And there are subsectors where we can use perturbation theory or monte carlo integrals to make approximate computations.

But this supposed deformation should be regarded with at least a little skepticism. The landau poles suggest it doesn't exist. And the phenomenon of confinement tells us that the deformation is quite singular; the set of observables changes so much that a mass gap appears! It's not really clear precisely what expectation values we're computing; we have to actually write down a set of correctly dressed observables for the IR. Likewise, the troubles we have with regularizing chiral gauge theories (and generally with dealing with fermion determinants) suggests to me that we're missing important parts of the story. We really don't have a completely plausible description of the full dynamics yet. And without a sufficient understanding of the dynamics, we can't _quite_ say what the observables are. (Thus the large cash prize for existence and mass gap in the only interacting subtheory where we think we might have a satisfactory definition.)

The mathetical status of string theory looks analogous to me. They've got a number of quantum mechanical theories (the 5 string theories, free 11d supergravity, large N quantum mechanics, ABJM, AdS/blahblahblah) which they say are degenerate limits of some unknown quantum theory. They can study these theories in infinitesimal neighborhoods, and they assert that bigger deformations exist. They don't have anything as nice as Monte Carlo, but they do have all these BPS & wall crossing computations, which at least suggest that there are paths connecting these limits. (Compare to the SM, where we have pretty good numerical evidence that key parts of the theory, like the field whose interactions give mass to the weak bosons and fermions, can't actually be made to interact in the manner prescribed.)

Analogous but worse actually. I don't intend to minimize the difficulty of the puzzles string theory presents. The degrees of freedom and the dynamics are both generally a mystery. The nonperturbative effects are stronger. And the IR problems that appear when you try to deform the known limits are really gnarly. You thought confinement screwed up your description of observables? Meet black holes.

Lastly, note that I'm not advocating that we not study gauge theokries, especially chiral ones. They're probably my favorite bit of mathematics. I'm just arguing that the Standard Model itself isn't a particularly good example of a gauge theory, chiral or otherwise. The ones that fall out of string theory are far nicer.

9. **Peter Woit**
June 12, 2013

AJ,

The difference as I see it is that in the SM case (modulo problems with chiral gauge couplings to fermions), we have well-defined theories for finite cut-off. We also know a lot about what is likely to happen as we remove the cut-off (for QCD, conjecturally asymptotic freedom tells us this can be done and how to do it, not that we can prove that this works yet…). It may very well be that for some parts of the SM (Higgs, U(1)) there is no way to remove the cutoff and get non-trivial interactions. If so, this tells us something very interesting about physics, that the SM has to fail at some scale (with gravity or some unknown physics coming to the rescue perhaps).

With string theory though, generically non-perturbatively you just don't have anything like this (a well-defined, non-perturbative cut-off theory where you can study the continuum limit). All you've got is some consistency arguments saying maybe something is there.

10. **DimReg**
June 13, 2013

I thought the main difference between the SM and string theory is that we have experimental probes of the SM. That is, we can test the SM against experiments and see if our attempts to make sense of it are at least consistent with reality. With plank scale physics like string theory, we don't have any experiments telling us if it's consistent with reality, so we need more rigor to show that it's at least consistent with itself.

If the SM isn't mathematically consistent in any incarnation, it is at least an effective "rule of thumb" for making predictions about nature. A particle physicist can look at the ill defined nature of the SM and say "at least its predictions are accurate".

11. **Mitchell Porter**
June 13, 2013

AJ said

"Compare to the SM, where we have pretty good numerical evidence that key parts of the theory, like the field whose interactions give mass to the weak bosons and fermions, can't actually be made to interact in the manner prescribed."

What "numerical evidence" are you talking about?

12. **Igor Khavkine**
June 13, 2013

A.J., you've set a very high standard of rigor for the Standard Model (or any QFT) to meet. I would call that a rather pessimistic point of view. However, keeping the same standard, one has to admit that there are no realistic alternatives to the Standard Model that can best it or even match it at its current level of rigor. That is, there is no alternative that is in better shape either. I'm not saying anything that hasn't already been admitted in this discussion. I'm just pointing out that if you choose this reason to feel pessimistic about the Standard Model, then there is no reason to feel any less pessimistic about alternatives.

13. **A.J.**
June 13, 2013

DimReg:

All true, but not relevant. I was talking about the merits of the SM as a particular kind of mathematical model, a continuum QFT. The point is that, while you can do computations and you can say precisely what some of the parts are and vaguely what the whole thing ought to be, you can't write down a completely satisfactory definition, even on the lattice. This is not a problem for the physics, but it's a bit of a nuisance if you want to study the thing as a piece of mathematics. (Compare to the Navier-Stokes model of fluid dynamics, where you can just write down the differential equation and go from there.)

Mitchell Porter:

That comment references the apparent triviality of Phi-4 theory. Wilson conjectured it and it was one of the first things people investigated with computers. What they found generally was a lack of evidence for a continuum limit. The early literature that comes to mind includes Smolensky's thesis and Luscher & Weiss's stuff from ~87. There may be more recent literature contradicting those early studies, but I haven't heard of anything that was universally accepted. Since I'm taking the pessimistic viewpoint here, I'll let others make the argument that phi-4 and U(1) triviality is not a problem.

Peter:

Sure we can define Standard Model-like QFTs, and I'd be happy to bet that they can be made completely rigorous. But the chiral couplings problem and the triviality are real problems for mathematical study of the SM itself.

14. **Peter Woit**
June 13, 2013

DimReg,

As Arkani-Hamed points out, there really is a serious problem with the idea that the problem with string theory is just that you can't do Planck scale experiments to test it. This was only true pre-1995, what Verlinde calls the "old view" of string theory. Once you have decided that you really need to do M-theory, that holography is important, that string theory is going to give you a new idea about what space is, then you no longer have a well-defined, testable framework, at any distance scale. That's the real problem with string theory, not experimental limitations.

15. **lun**
June 13, 2013

Well, the originator of perhaps the leading hope to have a formal understanding of string theory is now working on this:
http://arxiv.org/abs/arXiv:1306.0533
I think its a sign that this particular hope has fizzled

16. **amused**
June 13, 2013

A.J.,

I think your view of the SM is overly pessimistic. The situation is a lot better after the developments in lattice chiral gauge theory in the last 15 years. At the perturbative level everything is fine conceptually and mathematically (I'll explain below), and at the nonperturbative level the thing that remains to be done seems to be "just" a hard technical problem; conceptually there are no apparent problems.

First, regarding what you wrote earlier about the issue of regulators breaking symmetries: This doesn't matter as long as only a finite number of new counterterms (i.e. new terms in the quantum effective action that weren't present in the original bare action) arise due to the broken symmetry. Then you can just include these terms in your bare action to begin with and tune their coefficients to remove them order by order in perturbation theory (and probably also nonperturbatively in a lattice formulation).

Anyway, for gauge theories at the perturbative level with the lattice regularization: this regularization breaks the Euclideanized Lorentz symmetry (after wick rotation to Euclidean spacetime) but preserves a subgroup of it – the hypercubic lattice rotations. Miraculously, this residual symmetry is still enough to ensure that no new counterterms arise. So there is no issue there. E.g. perturbative QCD with lattice regularization is in just as good shape as with dimensional regularization (although in practice computations with the lattice regulator are much more messy).

Now about chiral symmetry: The long-standing problem of formulating chiral fermions on the lattice was solved at the conceptual level 15 years ago. The solution goes under the name "overlap fermions" or "Ginsparg-Wilson fermions" (the name you use depends on whether you would rather be friends with Neuberger or Luscher 😉). This produced a new lattice Dirac operator – the "overlap operator" (hep-lat/9707022, 1000+ citations already) which satisfies the so-called Ginsparg-Wilson relation and therefore has an exact symmetry which can be regarded as a lattice-deformed version of the continuum chiral symmetry (see hep-lat/9802011). Consequently the massless lattice Dirac fermion action decomposes into left- and right-handed parts, giving the chiral fermion actions. Then you can write down the bare action for the SM with the lattice regularization (Yukawa terms coupling the chiral fermions and the Higgs can also be done) and everything is now fine at the classical field theory level.

The remaining issue at the quantum field theory level, in the path integral formulation, is the construction of the integration measure for the chiral fermions. Or equivalently, construction of the chiral fermion determinants. As you know, the massless Dirac operator maps between different vector spaces of chiral fermions (left-handed to right-handed, and vice-versa). So its determinant is only well-defined up to a complex phase factor (which depends on the choice of orthonormal bases for the vector spaces used to compute the determinant). The question then is whether it is possible to find a choice of bases such that the chiral fermion determinant is gauge invariant (this is necessary and sufficient to ensure that gauge symmetry is preserved at the quantum level, which is absolutely essential for renormalizability of any gauge theory). The Dirac operator is coupled to the gauge field, so typically the choice of chiral fermion bases will have to depend on the background gauge field too. More mathematically, the question is whether the determinant line bundle determined by the lattice Dirac operator is trivializable over the gauge orbit space of lattice gauge fields.

The answer should be negative in general due to the well-known "chiral gauge anomaly" – we only expect it to be possible when the chiral fermions live in representations that satisfy the "anomaly cancellation condition". It has been shown that that answer is indeed negative when that condition is not satisfied. (No reference since I don't want to "out" myself ;-).) On the other hand, when the condition *is* satisfied, the situation at present is as follows: (1) Positive answer has been shown for U(1) gauge theory. I.e. we now have a completely satisfactory nonperturbative formulation of U(1) gauge theories with chiral fermions in anomaly-free representations – see hep-lat/9811032. (2) So far a positive answer has not been shown for gauge theories in general, including the SM. It is a hard technical problem, but without any conceptual roadblocks that I can see. Significant progress has been made though – see e.g. arXiv:0709.3658. (3) At the *perturbative* level, a positive answer has been shown for all gauge theories with chiral fermions satisfying the anomaly cancellation condition, including the SM. Specifically, it has been shown that a gauge invariant chiral fermion measure can be constructed order by order in perturbation theory – see hep-lat/0006014. So at the perturbative level the conceptual and mathematical situation for the SM is completely fine.

Finally, regarding the Landau pole issue you mentioned: How would a nonperturbative lattice formulation of the SM deal with this issue? Well, probably the same way that nonperturbative lattice QED deals with it: As the coupling is increased it has a phase transition from a weakly-coupled phase (the physically relevant one) to a strongly coupled "lattice junk" phase. Probably the same thing would happen in a nonperturbative lattice formulation of the SM.

17. **Zathras**

June 13, 2013

A.J.,

You say several times something along the lines that “We would like the Standard Model to be a continuum quantum field theory.” I would suggest that even this premise might be wrong. The scales are always important. The concept of boundary layers can be illustrative here. The physics outside a boundary layer are generally very different than the physics inside a boundary layer. Preliminary findings in quantum gravity suggest a sort of boundary layer in physics at the Planck scale. It is reasonable to keep the regularization condition outside this boundary layer, so that there needs to be no continuum limit. When there exists a boundary layer, perturbative methods do not necessarily need to converge inside the boundary layer, since that is not the area under consideration.

18. **A.J.**
June 13, 2013

Amused:

Thanks for the comments and the references. I hope it’s clear that my pessimism is _partly_ theatrical, as I was criticizing what Peter said on MO about string theory by taking a very grumpy look at the Standard Model. (It’s for example, not really fair of him to say there that nothing is known non-perturbatively. The various matrix theories are … difficult… to make practical use of, but they aren’t totally unreasonable candidates for definition.)

Anyways: I agree that the fermion determinant problems look solvable, but aren’t actually solved. I think the triviality issues are more serious for mathematicians, at least if the game is to construct an example of a particular kind of thing. (Obviously there’s lots of interesting mathematics in just studying Euclidean lattice models.) We have some idea of a continuum QFT is, and what axioms it ought to satisfy. I don’t think we have as clear a picture of what sort of mathematical object an effective QFT is. It’s certainly a much larger class of objects. Even if one can write down a lattice version of the Standard Model, it’s not going to be completely clear what kind of mathematical object you’ve cooked up.

Zathras:

It’s a wrong premise physically, almost certainly. But the point was that the SM doesn’t look likely to fit into any currently known mathematical framework. You’re quite welcome to argue that mathematicians should get to work on finding an attractive definition of ‘non-perturbative effective QFT’. I don’t think that will be a minor undertaking…

19. **amused**
June 13, 2013

A.J.,

Ok, I take it that “not even sure it’s likely that the SM is anything more than a set of recipes…” was theatrical then. 🙂

I do agree though that realistically the lattice formulation (or any other formulation) of the SM will probably never be more than an approximation theory, i.e. will not have a full continuum limit and only able to calculate physical quantities approximately and above some length scale. (I don’t like the term “effective theory” since it implies there is a more fundamental underlying theory, which might not be the case.)
In this regard it’s probably similar to the nonperturbative lattice formulation of QED. But I think such a theory still has “mathematical meaning” though, even though the answers it gives for physics quantities aren’t exact numbers but only approximate. The key thing that the answers, approximate or not, can be derived consistently from an explicit and well-defined starting point. This does look like it will be the case for the lattice formulation of the SM.
And this is already infinitely better than the state of affairs for string theory…although in fairness to the stringers their problem is a bit harder…

20. **Igor Khavkine**
June 13, 2013

Amused,

Any reference for your comments about nonperturbative lattice QED and the “Landau pole”? I’m very curious.

21. **A.J.**
June 13, 2013

Amused:

“I don’t like the term “effective theory” since it implies there is a more fundamental underlying theory, which might not be the case.”

And you think I’m pessimistic… 🙂

22. **amused**
June 13, 2013

Igor,

It was just my expectation/guess. The Landau pole, if it exists, must show up in perturbative QED with lattice reguarization too, so presumably the nonperturbative lattice theory also knows about it and then it will have to deal with it somehow. The simplest (and only?) way I can imagine it dealing with this is by having a phase transition to a nonphysical “lattice junk” phase when the coupling gets large. Such a phase transition certainly exists in lattice QED — existence of a deconfined weak-coupling “physical” phase was shown by Guth in Phys.Rev. D21 (1980) 2291, and existence of a confined, and hence unphysical, phase at strong coupling was shown in Wilson’s initial work on confinement in lattice gauge theories, so there must be at least one phase transition in between. Presumably this has also been verified numerically in lattice QED simulation somewhere… As for whether there has been any work backing up my speculation about the connection between the phase transition and the Landau pole issue, I can’t say… There seems to have been a lot of work on lattice QED in the early days of lattice field theory, but it was long before my time and my knowledge of the literature is very sketchy. Maybe someone else knows about this; I would also be interested to have a reference if one exists..

A.J.,

I also like to indulge in a bit of theatrics sometimes… 😉

23. **Oldster**
June 14, 2013

"He (Gross) describes Einstein as both encouraging the kind of speculative path followed by string theory and SUSY, while at the same time warning of its dangers, and noted that Einstein himself devoted the latter part of his life to a speculative path that turned out to be a dead end."

I suspect Einstein might still reject that verdict of "dead end". He was always inclined to go his own way, and he had a track record such that I certainly wouldn't be the one to try to tell him not to follow his own instincts. On the other hand, his view never dominated physics, or discouraged or crowded out others from following different lines of inquiry. In fact, it was Einstein in the minority, so much so that the "dead end" label was suggested by others even while he lived and rejected that diagnosis (along with Schrodinger). Indeed, after he died, that label of "dead end" was elevated to conventional wisdom so fast, that very few people even tried to follow Einstein's approach to search for a classical unified field theory which can explain quantum phenomena (which Gross correctly notes at 56:30 into his talk, was what Einstein was seeking).

Peter,

Sorry for the off topic update to your "Number Theory News" article published on May 12, but posting in that location is closed. Anyway, New Scientist (on June 4) did an article titled "Game of proofs boosts prime result by millions" containing many interesting links. Apparently, in addition to Terence Tao, most of the recent work on improving the prime gap bound is being done by Scott Morrison and Andrew Sutherland as actively documented on the "Secret Blogging Seminar" both here and, more recently, here. As David as said, you can literally watch mathematics being done in real time. For those wishing to keep abreast of the latest "world record" of the prime gap bound, see the PloyMath Wiki page "Bounded gap between primes". For those trying to work through Zhang's ground breaking proof, the PolyMath page, as linked above, also has a list of frequently updated errata to Zhang's original proof as to be published in a forthcoming issue of "Annals of Mathematics".

Again, sorry for the off topic post.

Amused, A.J., Igor, Zathras, etc.

Forgive a smartass for braying in the middle of your technical discussion.
There are a lot of remarks in your discussion which are important, but need some clarification.

Renormalizability guarantees insensitivity to the ultraviolet cut-off scale or breakdown of the effective theory. As Peter W. points out, in QCD we think the situation is better, and that the cut-off can, in principle, be removed (though we believe that this theory is also cut off in Nature). For this reason, the standard model alone doesn't tell us exactly where it breaks down as a description. Maybe the cut-off is at 100 TeV. Maybe it is at the Planck scale. We can't know any different without experiments.

Forget the one-loop Landau pole. The Landau pole is only suggestive, and should not be taken seriously. The triviality of the S-matrix (as the cut-off is removed) has nothing to do with the Landau pole. Forget the lattice QED phase transition (evidence is strong that this is a 1st order phase transition, hence has nothing to do with continuum field theory).

If you want to understand problems with triviality, etc., the place to start is the Ginzburg criterion from critical phenomena – which gives the physical reason why phi^4 theories need a cut-off in 4D – not the Landau pole. It is in most books on
applications of the renormalization group.

Regards,
P.O.

Peter O.,

"Forgive a smartass for braying in the middle of your technical discussion…"

Well I can't speak for A.J. and the others, but personally I can forgive you. 😉

"Renormalizability guarantees insensitivity to the ultraviolet cut-off scale or breakdown of the effective theory. As Peter W. points out, in QCD we think the situation is better, and that the cut-off can, in principle, be removed (though we believe that this theory is also cut off in Nature). For this reason, the standard model alone doesn't tell us exactly where it breaks down as a description. Maybe the cut-off is at 100 TeV. Maybe it is at the Planck scale. We can't know any different without experiments."

We can certainly agree on that. Hopefully there is no contradiction with anything in the earlier discussion, otherwise there's been a misunderstanding.

"Forget the one-loop Landau pole. The Landau pole is only suggestive, and should not be taken seriously. The triviality of the S-matrix (as the cut-off is removed) has nothing to do with the Landau pole. Forget the lattice QED phase transition (evidence is strong that this is a 1st order phase transition, hence has nothing to do with continuum field theory)."

The meaning of "Landau pole" in the above discussion was perhaps a bit vague. My personal interpretation of it is "the possibility that a renormalized coupling diverges when the energy scale gets sufficiently high (or length scale sufficiently small). *If* this does happen to all orders in continuum perturbation theory (e.g. in QED) then it will also happen in lattice perturbation theory. But then the nonperturbative lattice model must also know about it and deal with it. As I wrote above, the simplest (and only?) way for it to deal with this that I can imagine is to have a phase transition to a nonphysical "lattice junk" phase when the coupling gets large. I agree completely with you that this has nothing to do with trying to take a continuum limit and the associated triviality issue. Never said it did 🙂 Also, my understanding of A.J.'s comments is that the Landau pole and triviality issue were mentioned as separate issues, no implication that they were the same or connected.

Thanks for the suggestion on where to start learning more about the problems with triviality. This is one of many topics I would like to educate myself more about in principle, and would if i had infinite time… But in practice I don't feel an urgent need… My current simple-minded understanding of the triviality issue is that there is some place (presumably at a phase transition) in the bare coupling parameter space of the lattice theory where you can try to take a continuum limit, and when you do it the resulting continuum theory turns out to be trivial (non-interacting). My reaction to that is a shrug. It just means that its not a suitable place to tune the bare parameters when trying to describe Nature.

For example, I read somewhere that nonpertubative lattice QED has (or is believed to have) this same triviality issue. But on the other hand, by suitably tuning the bare parameters in lattice QED it should be possible to calculate, e.g., the energy levels of the hydrogen atom to at least the same high precision as in QM + perturbative QED corrections. So the absence of a continuum limit, or of a physically relevant (nontrivial) continuum limit does not mean inability to calculate/predict physical quantities. It just means the answers are approximate (since the values to tune the bare parameters to aren't uniquely fixed, only approximately), and that there is some length scale below which the lattice theory will not give physically sensible and accurate answers. I expect the situation will also be like this for a nonperturbative lattice formulation of the SM.

Regards,
"amused" (David A.)

29. **amused**
June 16, 2013

Having thought about it a bit more, I don't think there's any reason or need for the Landau pole issue (if there is one) to be connected with a phase transition to a nonphysical phase in lattice QED or lattice SM like I wrote above. So I'd like to withdraw that piece of ill thought out speculation. Once we accept that these lattice models can only describe the physics above some length scale, then that's already enough to "solve" any Landau pole issue and triviality issue. E.g. in lattice QED, perturbation theory indicates that increasing the bare coupling drives the lattice spacing smaller, and a Landau pole would manifest itself through the fact that there is a minimum length that the lattice spacing can't get below, no matter how much we increase the bare coupling. (And at some point, for large enough bare coupling, there is a phase transition to a nonphysical strong-coupled phase, so that also limits how much the lattice spacing can be decreased.)

30. **Peter Woit**
June 16, 2013

Anonyrat/Marcus,

I'm no expert on dark matter, but I can say that this kind of story, based purely on a press release from Vanderbilt
http://news.vanderbilt.edu/2013/06/dark-matter/
is the sort of thing one should be extremely skeptical about. I've now seen a very large number of such press releases ("scientists at our institution have solved one of the great problems of theoretical physics"), and can't think of an instance where the claims being made held up to scrutiny. My guess is that the only question here is whether this will ever make the mainstream science press, leading experts to explain what's wrong with it.

31. **Dom**
June 16, 2013

Not directly following from previous comments but I don't see anywhere to draw attention to things that may be of interest. The Observer (Sunday Guardian effectively) has this article where Jim Baggott and Mike Duff discuss "A theory of everything … has physics gone too far?"
<a href="http://www.guardian.co.uk/science/2013/jun/16/has-physics-gone-too-far" Observer Article

32. **Dom**

Next posting will be about Baggott's book and this debate. Soon…

Nature on the new Nobels

June 12, 2013
Categories: Uncategorized

This week's Nature has an article by Zeeya Merali about various new science mega-prizes, including Yuri Milner's Fundamental Physics Prize. There's also a podcast here, and a Nature editorial here.

I'm quoted in the article, saying about what you'd expect, but in general I was surprised by the extent of the negative reaction to these prizes that she found. Even $3 million winner Sasha Polyakov has concerns, saying

> This new prize is an interesting experiment… Such big prizes could become very influential and they can have a positive impact, or they can be very dangerous.

Frank Wilczek has this to say:

> I don't want to run these awards down, but I find it offensive that people are trying to either borrow the prestige of the Nobel, or buy it…
>
> Prizes are a good thing, but the question is, if your goal is to help science, are large prizes the most efficient way to do that?

Interestingly, Milner counters the criticism that his prizes have heavily gone to string theorists by noting that the award to seven LHC experimentalists this year will shift the balance on the judging panel towards experiment (since awards in the future will be chosen by past winners).

On the whole Merali doesn't seem to have had much luck in getting the winners to reveal what they plan to do with the money. Some of the LHC winners seem to be very aware that they've been given a large check due to the work of others, with Tejinder Virdee of CMS planning to support science in schools in sub-Saharan Africa. I've heard rumors that Maxim Kontsevich is somehow using his award to help others at the IHES, but nothing else about how other theorists will use the money. They are giving public lectures, which are online, see here. After Witten's lecture at Hunter College, the first question was about his plans for the money, but no answer was forthcoming.

The editorial chides scientists for criticizing these new prizes, saying they should "accept such gifts with gratitude and grace". I suppose there would be a lot more of that if the prizes seemed to be helping to support science in general, not just the bank accounts of a few.

Update: At least one wealthy philanthropist has decided to give the millions for theoretical physics to an institution rather than a person. The University of Chicago has announced a $3.5 million gift from an anonymous donor, which will support a new Center for Theoretical Physics to be named after Leo Kadanoff.

   June 12, 2013

   I think that it was Leo Szilard, in the Voice of the Dolphins, who had the protagonist in one of his stories planning to use his vast wealth to retard scientific progress by giving a number of large prizes to scientists. The idea was to get the scientists so busy competing for the awards that they wouldn't have any time to think fundamental thoughts.

2. **David Appell**
   June 12, 2013

   The dilemma seems to me to be that a lot of small prizes, explicitedly for things like sub-Saharan science education, or conference travel subsidies for graduate students, or whatever, do not have the glamour and do not get the attention given to a few big, M$+ prizes, either for science, or (certainly) for whomever is giving out the prizes. That is unfortunate nature of our world. But I think this does put a lot of responsibility on prize recipients to arrange for and distribute the attention and influence given these prizes.

3. **chris**
   June 13, 2013

   our society in general starves the masses to shower the top people with money. why should science be an exception?

4. **Hamish Johnston**
   June 13, 2013

   I agree with Chris, these prizes are another example of the "winner takes all" attitude that was born in the financial sector and now seems to be creeping into the rest of society. I was recently in Waterloo, Ontario where I saw a much more positive example of what one rich person's generosity could do. BlackBerry founder Mike Lazaridis has played an important role in transforming Waterloo from a sleepy university town to a physics powerhouse by establishing the Perimeter Institute and playing leading roles in setting up the Institute for Quantum Computing and a venture capital firm for quantum information technologies. I'd much rather see that sort of investment…but I suppose it's their money.

5. **Chris Oakley**
   June 13, 2013

   There is, of course, a way that those with money to burn, and who want to help fundamental research in science and medicine could make a difference: instead of giving $3m to a handful of burned-out old has-beens, they could give out $30,000 prizes to 100 promising young researchers, much in the spirit of the Gates scholarships to Cambridge, UK, but at post-doctoral level. This also would acknowledge the principle – sadly overlooked by quantum field theorists – that the independent pursuit of different ideas is more likely to get a result than the singleminded focus on one unpromising one.

6. **Ted**
   June 13, 2013

   To answer Frank Wilczek's question, prizes like this are nearly useless in promoting scientific progress. Prizes could be useful if they are awarded for solving specific problems, but the most interesting problems are usually so important that the prestige in solving them is enough to incentivize the profession. For example, did we really need the Clay prizes to get people to work on Riemann's Hypothesis? Further, awarding prizes for past work doesn't incentivize anything. The incentives for producing important work is already so tremendous that the incentives from monetary prizes can only be marginal. Professional prestige is the biggest motivator.

Something like the Milner prize could be useful if given to people with enormous previous success who have experimental ideas and are unable to get funding. Except, this doesn't describe any of these guys – except the LHC team and $3 million is not so different than $0 when it comes to high energy experiments. The only possible use is that these guys can use the $3 million to take a break from teaching, but I doubt what is holding these guys back is a burdensome teaching schedule.

But I don't think these prizes are harmful, I just wish that if Mr. Milner wants to throw away his money, he would gives it to something useful – like a charity.

7. **Bill**
June 13, 2013

I would go a bit further and suggest that all awards and prizes, including Nobel prize and Fields medal, are counterproductive. They upset natural development and natural balance among various areas of research judged purely on their merits by glamorizing some specific accomplishments. This becomes a self-reinforced process since people deciding future awards are often selected among past winners. Some areas become "sexy" while other are perceived as not. This plays a big role in the flow of young talent, for example. Of course, you may say that in the absence of all awards the natural "merits" are rather subjective and political skills will determine the balance of power, but I think this is already factored into reality anyway. I personally would like to see all awards (big and small) disappear and let everyone be judged by the impact of their work.

8. **P**
June 13, 2013

Ted,

Two quick comments:

1) most of the recipients of these prizes aren't teaching that much anyways.

2) your HEP experiment comment is collider biased: dark matter experiments and others that fall under the HEP category according to funding institutions are often on the order of 1-10M. There is continually more push for these experiments at the "intensity" and "cosmic" frontier, and not just the "high energy" frontier, according to the Snowmass distinction. Milner could make a significant dent with his $3M in this regard.

Cheers,
P

9. **Tmark48**
June 13, 2013

Physics prizes should by their very nature be awarded to scientists that have done great scientific accomplishment in physics and I underline physics not pseudo-science, not speculative ideas that have no experimental confirmation.What was good for Einstein should be good also for your physics candidate of the 21st century.

These multimillion dollar prizes are a symptom of "look over there, these experimentalists are getting all the recognition, they are getting all those Nobel prizes (insert curse words for poor Alfred Nobel who wasn't into pseudo-speculative science) we poor theoretical physicists are not recognised for our work. Boooo boooo boooooooo we want a prize. We need a prize." Please, scientific revolutions are not a dime a dozen. So there comes a time when theoretical physicists will be awarded for their theories if they find EXPERIMENTAL confirmation. Otherwise they are just ideas, wrong ideas, nice ideas, leading maybe to new maths but it is not physics.

10. **Pepe**
June 15, 2013

A simple remark. Juan Maldacena donated 200.000 USD to his former institution in Argentina, Instituto Balseiro. This happened some months after receiving the Milner prize, here the info (just in spanish after google it 😉): http://www.lanacion.com.ar/1538630-juan-maldacena-dono-us-200000-al-balseiro

11. **Juan Francisco**
June 15, 2013

Interesting entry! I have always believed, that prizes main values are beyond money:

1) Prestige and influence.
2) Contacts and creation of research groups.

So, really, a prize giving lot of money could not be as good as a low money prize but with "other kind of reward". For instance, I have never seen that, e.g., a very brillian paper or contribution of some unknown person can help him to be selected for certain programme or group. There are "good scientists" that can be "lost" due to "big prize", and equivalently, there are potentially good scientists getting lost for Science due to a lack of (not such a big) cash support.

12. **fuzzy**
June 15, 2013

nobel wanted to apologize for the nitroglycerin, but i wonder what is the psychological motivation of this prize. maybe milner feels that he should have continued studying vague and speculative ideas? gosh, no my friend, please go over! the best physicists can be wrong and you have the right to try your best in the way you like more.

anyhow, in my view chris is right, and i would add the following. the definition of "top people" used in the milner prize is not at all clear, it seems to mix nostalgia and lust for recognizing, rather than caring of true scientific achievements. anyhow, this is a young prize, and we can hope that its target will be improved in the course of the time.

13. **srp**
June 15, 2013

Prizes like the Nobel, where no specific accomplishment is pre-specified, have in principle less power to change the direction of research for good or ill. That means the harm they can do is limited. "Do something that will impress us and we'll give you some money and prestige" is a general encouragement to do impressive things, which seems like an OK thing, and it also calls attention to the work itself and the general character of impressive work which may attract new achievers into areas where they think they can do something impressive.

One problem occurs when people start sussing out in advance what past achievements are going to be rewarded and jockey for credit instead of doing new things. Another is when some anticipated achievement is seen as a shoo-in winner of a future prize and "too many" people crowd into its pursuit. A third is when collective achievements are arbitrarily assigned to a small number of individuals. Milner doesn't seem any worse than Nobel on these criteria.

14. **annamaria**

June 16, 2013

The problem with giving money to Universities is that, unless the money is very well targeted, over half will disappear into paying for the ever burgeoning administrative structures we all suffer from. Much better to pool it in some way and set up a lean research institute(s) focused on providing space and time to think, Perimeter Institute style, and releasing academics from the bureaucracy they are increasingly having to cope with. In many universities, research is something you do in your spare time.

Farewell to Reality

June 16, 2013
Categories: Book Reviews

Jim Baggott has written a very good new book called Farewell to Reality that will soon come out here in the US. It is already out in the UK, where it is stirring up some debate, and perhaps the US will soon see something similar.

In the preface, Baggott explains that he was motivated to write the book by the experience of watching this BBC program, which featured a combination of serious science with revelations about how we're all part of a cosmic hologram, there's an infinity of parallel worlds, and various other examples of what he refers to as "fairy-tale" physics. In the last decade or so there have been a large number of such mass media efforts promoting highly dubious ideas about fundamental physics, and Baggott decided that in his next book he'd try and do something to counter this. I think he's succeeded admirably: the BBC and other such organizations should atone for their sins by sending copies of the book to their viewers.

The book is divided into roughly two halves, with the first half a well-executed overview of the current state of our theories about fundamental physics, from quantum theory through the standard model and cosmology. It ends with a description of the outstanding problems left unsolved by our best theories, and a good summary of the current situation:

> Several centuries of enormously successful physical science have given us a version of reality unsurpassed in the entire history of intellectual endeavour. With a very few exceptions, it explains every observation we have ever made and every experiment we have ever devised.
>
> But the few exceptions happen to be very big ones. And there's enough puzzle and mystery and more than enough of a sense of work in progress for us to be confident that this is not yet the final answer.
>
> I think that's extremely exciting…
>
> … but there is no flashing illuminated sign saying "this way to the answer to all the puzzles". And there is no single observation, no one experimental result, that help to point the way. We are virtually clueless.

With this background he turns to a detailed examination of the speculative ideas that have not worked out, but have dominated the field for the past 30-40 years (SUSY, GUTS, Superstring/M-theory, the multiverse). This is difficult material to do justice to, but Baggott does a good job of giving an explanation of these ideas that includes some understanding of the problems with them. He ends the book with this advice to the reader:

> Next time you pick up the latest best-selling popular science book, or tune into the latest science documentary on the radio or television, keep an open mind and try to maintain a healthy scepticism… What is the nature of the evidence in support of this theory? Does the theory make predictions of quantity or number, of matter of fact and existence? Do the theory's predictions have the capability – even in principle – of being subject to observational or experimental test?
>
> Come to your own conclusions.

The thorniest problems that come up in this sort of discussion are essentially ones about the philosophy of science. What counts as evidence for a scientific theory? At what point does pursuit of speculative ideas that are going nowhere stop being legitimate science? One quickly realizes that naive ideas about the scientific method don't capture how good science really works. Baggott devotes the first chapter of the book to an overview of his take on what the scientific method really is. In the end, this may be the most important issue here: will books and TV programs promoting the views of a narrow part of the scientific community that doesn't want to admit failure end up discrediting the scientific endeavour? Some are all too willing to exploit the subtleties of good science to find a way to defend the indefensible, with the multiverse mania pointing to the all too real dangerous endpoint this can lead to.

For some reviews from the UK of the book see here, here and here.

For a BBC Radio program featuring discussion between Baggott, Jon Butterworth and others, see here. Butterworth has written more today here.

Also today in the Guardian, there's a debate between Baggott and Mike Duff. Duff characterizes the experimental situation of string theory as follows:

> Definitive experimental tests will require that the theory also incorporate and improve upon the standard models of particle physics and cosmology. An impressive body of evidence in favour of this has accumulated, but it is still work in progress.

without giving an example of any sort of conceivable such experimental test. I think Duff is being highly misleading here, since the story of the last thirty years is not one of evidence for string theory unification accumulating, but the opposite: the more we learn about string theory, the less likely it seems that it can predict anything. One can argue that string theorists just need more time (Duff points to the idea of atoms arising back in 400BC, taking more than two millennia to come to fruition), but the problem with string theory is not that progress is slow but that it is negative.

On the question of TV programs like the one that motivated Baggott to write the book, even Duff won't defend them, but blames the situation on journalists:

> As for misrepresentation in the media, there will always be sensationalists and attention-seekers in any field, but in my (admittedly biased) opinion, the worst culprits are the journalists.

This is quite amusing coming from someone who (see here) had his university put out a press release claiming that he had made the first discovery of a way to test string theory. He advertises string theory as having found application in quantum information theory, a claim that I doubt is believed by any other string theorist or quantum information theorist. No, the worst culprits here are not journalists, whose mistake is often just that of taking seriously press releases from people like Mike Duff.

Duff invokes the same criticism made back in 2006 that "Sadly, many critics of string theory, having lost their case in the court of science, try to win it in the court of popular opinion." He's well aware though that string theorists are losing badly in the court of science (with US physics departments now hiring virtually no string theorists). String theory unification is an idea now discredited in the scientific community, but getting propped up by TV programs and prizes from Russian billionaires. I hope when Baggott's book comes out in the US, we'll see a more serious discussion of the issues that it raises.

Update: Duff is unhappy about Butterworth's mild criticism of string theory, so has responded with a comment at the Guardian site that begins

> Dear John
>
> "The concern arises if everyone makes the same wild guess, and the experiments to confirm or deny it are out of reach".
>
> is more-or-less what people said when theorists predicted the Higgs boson in 1964.

According to Duff, I guess, back in 1964 the situation was just like that of string theory, with the field experiencing what people were calling an unhealthy domination by the likes of Peter Higgs and others working on the Higgs mechanism. That's a very odd take on the history, given that the work of Higgs and others was virtually ignored at the time.

Comments

1. **H**
   June 16, 2013

   Can you elaborate the following?

   "String theory unification is an idea now discredited in the scientific community".

   I am not sure what "the scientific community" includes in this context. String theorist will of course disagree, and people outside of HEP will generally not count as experts. So I guess you are referring to the non-string HEP community? Do you know what their general opinion on string theory unification is?

2. **Peter Woit**
   June 16, 2013

   H,

   I actually know many people who work on string theory who have given up on the idea of getting the Standard Model out of it. The most common attitude I hear among string theorists is that the ways people used to hope to connect it to the SM have failed. They say they work on string theory now not because it's a viable idea about unification, but because of things like AdS/CFT.

   For some data points, look at the data on what kind of HEP theorists US physics departments are hiring here
   http://www.physics.utoronto.ca/~poppitz/Jobs94-08.pdf
   One meaning of "scientific community" here is the faculty of US research university physics departments, who now typically want nothing to do with string theory.

3. **Professor Anon**
   June 16, 2013

   Well … I suspect that string theory is not discredited among all the faculty of US research physics departments, but the consensus view of the hiring committees does seem to have soured on string theory.

4. **Peter Woit**
   June 16, 2013

   As another source of data, take a look at the titles of the talks at Strings 2013, here

   http://strings2013.sogang.ac.kr//main/?skin=scientific_talks.htm

   Of the 40 speakers, exactly one (Mirjam Cvetic) is speaking on a topic that has something to do with efforts to do string theory unification (i.e. get the SM out of string theory).

   The other things string theorists are working on are more promising, but the string theory hype and unacknowledged failure of the unification idea have definitely soured their colleagues on doing more string theory hiring of any kind.

5. **Peter Woit**
   June 16, 2013

   By the way, there's an interesting discussion of the current state of things by Mirjam Cvetic here
   http://sciencewatch.com/articles/mirjam-cvetic-string-theory-and-supersymmetry
   which includes the following:

   "If the simplest supersymmetric extension of standard particle physics is valid, the LHC would have found those particles by now. So I think that, as theoretical physicists working on particle-physics models with supersymmetry expected, that supersymmetry would be discovered at the LHC, and it would certainly be disappointing if supersymmetry is not found after the LHC has run for an extended period. In other words, if supersymmetry is pushed to very high energies because we can't find supersymmetric particles at the LHC, it's not going be a very happy situation for us and our theories.

   SW: Should this happen, and nothing beyond the standard model shows up, how do you think theoretical physicists will typically respond?

   I think a typical reaction would be that we can still deal with that, and we just need to adjust the theories. But we have to admit at some point that if our ideas are not being experimentally confirmed, maybe we're just not on the right track. We need experimental feedback, and without it, theoretical research becomes isolated."

6. **Bob Jones**
   June 16, 2013

   "he was motivated to write the book by the experience of watching this BBC program, which featured a combination of serious science with revelations about how we're all part of a cosmic hologram"

   I haven't seen the program, but this Baggott guy needs to wake up if he thinks the holographic principle is some sort of wild speculation. The holographic principle is just about the only thing that is well established about quantum gravity…

   "Of the 40 speakers, exactly one (Mirjam Cvetic) is speaking on a topic that has something to do with efforts to do string theory unification (i.e. get the SM out of string theory)."

   That's why this criticism of string theory is so irrelevant. Hardly anyone is even working on the stuff that you complain about.

7. **Peter Woit**
   June 16, 2013

   Bob Jones,

If “we’re all part of a cosmic hologram” is settled science, what’s the experimental evidence for it?

I’ll stop complaining about string theorists refusing to acknowledge failure when they start publicly acknowledging it. Mike Duff certainly isn’t there yet…

8. **Bob Jones**
June 16, 2013

“If ‘we’re all part of a cosmic hologram’ is settled science, what’s the experimental evidence for it?”

I don’t care for the language being used here, but holography is, whether you like it or not, a well established property of gravity. You can take ordinary general relativity (no strings, supersymmetry, or extra dimensions) and show that the theory has a dual description in terms of a field theory in a lower number of dimensions. There is by now a ton of extremely nontrivial evidence that this correspondence is true on a mathematical level, including experimental evidence.

“I’ll stop complaining about string theorists refusing to acknowledge failure when they start publicly acknowledging it.”

I agree with you that string theory has not convincingly reproduced the standard model, but I’m not sure I would characterize that as failure. The reason is that I’m not sure reproducing the standard model was ever the exclusive goal for string theory. From the very beginning, string theory was related lots of other problems in physics and mathematics, and it led to many important developments in those areas.

9. **Peter Shor**
June 16, 2013

Bob Jones:

Mathematical evidence based on an analogous theory or experimental evidence? Or have string theorists stopped distinguishing between the two?

10. **Bob Jones**
June 16, 2013

Peter Shor,

You would certainly agree that general relativity is a well tested theory, wouldn’t you? What I’m claiming is that general relativity (and its generalizations, such as string theory) is mathematically equivalent to a field theory in a lower number of dimensions. This mathematical equivalence is supported by a lot of evidence, including experiments in nuclear and condensed matter physics.

11. **Peter Woit**
June 16, 2013

Bob Jones,

So, there’s experimental evidence for 4d quantum gravity effects, seen in terms of a 3d conventional qft? Who did that experiment?

12. **Bob Jones**
June 16, 2013

I didn’t say anything about quantum gravity. I’m saying you can take ordinary classical gravity, which is extremely well tested, and by making various field redefinitions, you can show that it’s equivalent to a field theory on the conformal boundary of spacetime, in cases where this boundary is defined.

13. **Peter Woit**
June 16, 2013

Bob Jones,

If you’re referring to 4d gravity, which is what we have experimental data about, and you’re trying to invoke AdS/CFT, one problem is that we don’t live in AdS4

14. **Bob Jones**
June 16, 2013

“one problem is that we don’t live in AdS4”

No, that’s really not a problem. The AdS condition is an asymptotic condition, and the gravitational field is free to do whatever it wants in the bulk spacetime. There are also versions of the correspondence that don’t require AdS space at all, for example

http://arxiv.org/abs/0809.4266

http://arxiv.org/abs/1004.0996

The second of these papers describes black holes with no strings, no extra dimensions, no supersymmetry, no extremality assumption, and no anti-de Sitter space! Is that realistic enough for you?

15. **Mitchell Porter**
June 17, 2013

“Of the 40 speakers, exactly one … is speaking on a topic that has something to do with efforts to … get the SM out of string theory”

They talk about that next month, in Germany: http://stringpheno2013.desy.de/

16. **Roger**
June 17, 2013

I don’t see any testable hypotheses in those holographic duality papers. Is there anything that Popper would consider science? If so what, and why would it be science?

17. **Bob Jones**
June 17, 2013

“I don’t see any testable hypotheses in those holographic duality papers.”

http://arxiv.org/abs/hep-th/0405231

18. **Peter Woit**
June 17, 2013

Bob Jones,

You’re invoking several completely different conjectural ideas about mathematical physics, none of which have been experimentally tested or correspond to evidence that we’re part of a “cosmic hologram”.

19. **chris**
June 17, 2013

Bob Jones,

it might be necessary to remind you, that neither temperature nor entropy of a black hole has ever been measured. Also, there is no experiment about Unruh temperature or just about any quantum effect on a horizon. This is simply due to the fact, that no horizon has ever been observed.

The closest we have is radio and infrared observations of stellar dynamics around Sgr A*. And that’s quite a stretch from there to any horizon dynamics you claim to be experimentally backed.

20. **EDBM**
June 17, 2013

You say, “… the problem with string theory is not that progress is slow but that it is negative.”, which is a claim whose strength rather surprises me – I would have thought that the worst that could be said was that the field has stagnated since it has not produced any theory which could give any predictions, testable or not. Could you elaborate on your point, and maybe provide some references?

21. **Peter Woit**
June 17, 2013

EDBM,

This topic has often been discussed here. The point is that progress in better understanding string theory models has just led to more and more different classes of them. Early on, there was hope that there were a limited number of possibilities, so you had some sort of predictions possible. At this point, it looks like you can get just about anything out of these constructions, so the idea is pretty much empty in terms of any predictive power.

One place I’ve written in detail about this is here
http://mathoverflow.net/questions/133203/explanations-for-mathematicians-about-the-falsifiability-or-not-of-string-theo/133248#133248

22. **Peter Woit**
June 17, 2013

Mitchell Porter,

The Strings 2013 conference is the one that is supposed to not specialize, but survey the whole field, and it’s the one with the most illustrious and influential advisory committee that chooses the speakers. I think one talk out of forty pretty accurately reflects how much interest leading string theorists have in “string phenomenology” these days.

23. **Bob Jones**
June 17, 2013

Peter,

Yes, I’m talking about more than one thing here. The points I’m making are the following:

1. It is reasonable to say that the holography is an established feature of gravity because the holographic principle is implicit in the mathematics of general relativity. It doesn’t depend at all on the validity of string theory or supersymmetry or the existence of extra spatial dimensions. Since this is a statement about the mathematics of an already well tested theory, there’s nothing that needs to be tested experimentally.

2. If you insist on having experimental evidence for the mathematical validity of the AdS/CFT correspondence, you can have that too. AdS/CFT has been used to make successful predictions about nuclear and condensed matter physics.

24. **cormac**
June 17, 2013

As it happens, I chanced upon the Guardian article yesterday. I have to say I thought Professor Duff offered a calm and reasoned pont-by-point defence to Jim Baggot’s criticisms. It seemed to me that Jim made several comments that were rather broadbrush and he conflated distinct issues more than once, as Mike pointed out in his responses.

I was surprised Jim didn’t think to make Peter’s usual criticism, that misgivings about ST are not solely about problems such as compactification, or connecting to experiment, but the sociological problem that a great many researchers have been directed towards a research area with these drawbacks, at the expense of other areas, and whether this is healthy etc. Criticism of the theory itself is more easily deflected since defenders can appeal to the history of science, from the atomic theory to general relativity, just as Mike did.

Overall, I thought Professor Duff a clear winner in that particular debate. I also agree with most of the points he made. It seems to me that a great many ST critics ignore the little word ‘yet’, i.e, do not trouble to acknowledge that problems such as compactification and connection with experiment may, for all we know, one day be resolved (yes, even after 4-5 decades). It always seems a bit one-sided to me to leave this possibilty unsaid….Regards, Cormac

25. **Peter Woit**
June 17, 2013

Bob Jones,

You're conflating several completely different things, and engaging in hype about all of them. As for 1., I just don't see how you get from the conjectures that you link to about a 2d CFT saying something about the horizons of Kerr black holes to the claim that the holographic principle is part of classical GR, other than through an abuse of language.
As for 2, you're just repeating hype, about something completely different than 1.

26. **Peter Woit**
June 17, 2013

cormac,

The problem with Duff's argument is that it applies to any speculative idea that doesn't work out. Anyone whose favorite idea about physics goes nowhere can make the case that it just needs more work, and someday they will be vindicated (and pretty much every crank in the world does make exactly this claim). If you allow people to make this case and give them time-scales longer than their professional careers, no one ever has to admit failure. Everyone can happily come up with a bad idea early in their career (or sign on to someone else's), then get paid for the rest of their careers to work on it, no matter how unpromising it becomes. String theory unification really is an idea that hasn't worked out. Given the lack of other good ideas, you can argue that some people should keep working on it, but I don't think you can argue that most of the people who started on it should keep going. I also don't think you can argue that it's all right not to admit how bad the problems with the idea are. Finally, it's really not at all all right to issue press releases and go on TV promoting your idea that isn't working. It's this last issue that Baggott makes clear is what he sees as the big problem here, and Duff has no answer for that, other than to blame journalists for repeating the hype he and others put out.

27. **Bob Jones**
June 17, 2013

Peter,

In the first paper I cited on the Kerr/CFT correspondence, the authors consider the Kerr solution of classical general relativity, and by analyzing the symmetries of the solution, they conclude that there should be a dual description in two-dimensional conformal field theory.

For an even clearer demonstration of the holographic properties of general relativity, see the paper

http://arxiv.org/abs/gr-qc/9506019

Here the authors study general relativity in 2+1 dimensions and show that the Einstein-Hilbert action is equivalent to the action for Liouville theory on the conformal boundary of spacetime. Of course, the assumption of 2+1 dimensions is a drastic and unphysical simplifying assumption, but it's still interesting because (2+1)-dimensional gravity is one of the few contexts in which we can treat gravity as a quantum field theory.

I don't know what it means to say we're part of a "cosmic hologram", but I would say that the papers cited above give pretty convincing evidence that general relativity has at least some holographic properties.

28. **Peter Woit**
June 17, 2013

Bob Jones,

Now you're introducing yet a different notion of holography, in a different set of (unphysical) dimensions.

Actually, I'm a big fan of the paper you link to, which is part of the amazing story of how 3d Chern-Simons QFT is related to 2d CFT. It's fantastic mathematics and I'm very willing to believe that it has something to do with fundamental 3+1 d physics. Unfortunately I don't know quite what this is, nor do I think does anyone else….

29. **lun**
June 17, 2013

Bob Jones,
———–
AdS/CFT has been used to make successful predictions about nuclear and condensed matter physics.
————
Can you give me an example of a "successful prediction"? I define predictions in a Popperian way "if system X has a gravity dual, we get experimental result Y, if it does not, system X is for sure not described by a gravity dual".

I will make an experimental prediction, "there not a single paper in the AdS/CFT literature that meets the above criteria." I would be very interested in a falsification of this prediction 🙂
Otherwise, String/Gauge is still very very interesting, but claiming it leads to "experimental predictions" is misleading.

30. **Bob Jones**
June 17, 2013

lun,

See the paper

http://arxiv.org/abs/hep-th/0405231

The authors show that if a fluid is described by a gravity dual, then the ratio of shear viscosity to volume density of entropy is equal to a universal constant. If the ratio does not equal this universal value, then the system does not have a gravity dual.

31. **Anonyrat**
June 17, 2013

Duff said, in his conversation with Baggott: "Similarly, string theorists did not assume supersymmetry, extra dimensions, the dualities of M-theory or the myriad possible universes; they discovered them to be consequences of a theory that subsumes empirically well-established features such as general relativity, gauge field theory and chiral quarks and leptons."

While there is a limit to the analogy, the mechanical models of the aether incorporated all the relevant known physics, had counter-intuitive features, and similarly ought to have worked per the best of knowledge that existed at the time.

32. **lun**
June 17, 2013

Bob Jones, see
http://arxiv.org/abs/arXiv:0812.2521
and
http://arxiv.org/abs/1110.6825

With a "classical gravity dual" your statement might have been a bit more precise, but then the assumptions involved (Nc—>infinity) are a bit too naive to really compare to experiment.

33. **GMBH**
June 17, 2013

Bob Jones: I actually work the shear viscosity of strongly correlated fluids. The paper you refer to, 0405231, does not make any experimental prediction whatsoever. It contains a CONJECTURE for a lower bound on the shear viscosity. The conjecture is based on a calculation for a very specific model which is not realized in nature, I.e not in a quark gluon plasma nor in cold atomic gases. If you want to make accurate predictions for the shear viscosity, you have to work much harder using realistic models and not just elevate a result for a very specific model to magically be true universally. The lower bound conjecture can actually be derived from mere dimensional analysis. If this is one of the main examples of an experimentally testable prediction of string theory, then that field is in real trouble.

34. **george ellis**
June 17, 2013

Bob Jones:

"For an even clearer demonstration of the holographic properties of general relativity, see the paper http://arxiv.org/abs/gr-qc/9506019"

This paper relies on a negative cosmological constant. The experimental data is that the cosmological constant is positive. The paper does not apply to the real world.

35. **Bob Jones**
June 17, 2013

GMBH,

I'm mostly interested in the applications of AdS/CFT to gravity, so I don't understand the technicalities of these applications to the quark gluon plasma. I have not heard this claim that the lower bound conjecture can be derived from dimensional analysis. Could you elaborate on that?

36. **Bob Jones**
June 17, 2013

george ellis,

There is a much more obvious reason why that paper does not apply to the real world. I addressed all these issues in my comments to Peter.

37. **imho**
June 17, 2013

I knew this day would come and I fear it's only the beginning. I hope I'm wrong.

Science has flourished over several centuries, not because of our talents for persuasion or our political connections or our eloquence in explaining our points of view. Science has flourished because we produce tangible concrete results that improve the world. Even fundamental Physics research has been able to justify it's existence by claiming some yet unknown future benefit(s). The public trusts us to deliver, because in the past, that's exactly what we've done. This is our bread and butter and it's the fundamental reason the power structure tolerates us instead of taking our lunch money. What do you think happens when we remove Physics from the testable real world and start pontificating about untestable apparitional fairy-tails?… I'll tell you what happens. We lose the public debate to Pat Robinson and Joel Osteen… I promise they are infinitely more persuasive then any of us. Jim Baggot will only the begining.

I know, I know, inside the ivory tower it's pretty easy to become completely convinced that that rest of the world is as thoroughly interested and impressed with our intellect as we are. But trust me… they are not. We exist because we create bombs and magic black boxes. We're funded Billions because we claim that's what is needed to create more bombs and magic boxes. This is the difference between Physics funding and Philosophy funding. Anyone who seriously believes the powers the be will continue to heavily fund a few thousand people to engage in intellectual masterbation is confused about this world and how things work.

38. **Chris W.**
June 17, 2013

From Bob Jones:

> "This mathematical equivalence is supported by a lot of evidence, including experiments in nuclear and condensed matter physics."
>
> "If you insist on having experimental evidence for the mathematical validity of the AdS/CFT correspondence, you can have that too. AdS/CFT has been used to make successful predictions about nuclear and condensed matter physics."

These statements strike me as profoundly muddle-headed at the outset. "Mathematical equivalence" or "mathematical validity" must be established by mathematical arguments, not experimental evidence, *by definition*. By extension, it is not at all clear what "is supported by" is supposed to mean in this context.

Note that by experimental evidence I mean observations on real physical systems, not computational experiments. Regrettably the two are sometimes confused.

39. **Bob Jones**
June 17, 2013

Chris W.,

I actually agree with what you say. Unfortunately, a lot of people don't understand this point, and so we often see demands on this blog for "experimental tests" of

AdS/CFT.

40. **Peter Woit**
June 17, 2013

Bob Jones,

This has long ago stopped making sense, and it's not even really relevant to the topic. Enough.

41. **lun**
June 17, 2013

Bob Jones, have a look at
http://inspirehep.net/record/205584?ln=en
A bound of ~1/12 is "derived" from the uncertainity principle.
I say "derived" because the assumptions used are of course unrealistic (using the Boltzmann equation for a strongly coupled system) ,but then again N=4 Nc=infinity in the UV is also an unrealistic assumption.
I agree that the number coincidence is intriguing.

For the reaction of the heavy ion community to the claims of string theorists, look at the theory summary of the "Quark Matter" conference, the leading conference in the field
http://www.sinap.ac.cn/qm2006/ppt/Nov.20/Plenary-15/Larry-McLerran-QM061.ppt
which if I remember correctly was covered on this blog too.
The talk was provocative, and there are people in the field with a more conciliatory attitude, but it does represent a wide-spread feeling,especially by experimentalists.

42. **amused**
June 18, 2013

Quotes from Duff in the debate:

"Finally, you offer no credible alternative. If you don't like string theory the answer is simple: come up with a better one."

Alternative to what? To a Theory of Quantum Gravity? To a Theory of Everything? Note the sophism here; the implication that these grandiose topics are the only ones worth pursuing in fundamental theoretical physics.

"The battle for the correct theory will not be won on Amazon or on the blogosphere, however. It will be won in the pages of scholarly scientific journals."

What a disgusting lie. If it was true, and if interesting and important physics progress was being made in string theory, then the pages of PRL would be full of string theory papers. Instead there are almost none… In their frustration at having hardly any important progress to report to their physics colleagues in PRL, string theorists of Duff's ilk resort to duping the general public with hype, published, e.g., in that illustrious scientific journal the Op-Ed section of the NY Times.

I wish the public would know how much contempt Duff and string theorists of his ilk (hopefully not all of them) have for the scientific journal system in reality. Scientific output on non-string topics in fundamental theoretical physics is considered to be worthless by them, regardless of which or how many journals it is published in. E.g., when assessing job candidates, single-author PRL publications on a non-string topic by some young person count for flat zero when weighed against string theory publications by another young person in a lesser journal where he/she is joint author with a bunch of senior and illustrious people.

IMHO the problem is not with string theory, which is interesting and worth pursuing as a theoretical model of quantum gravity even if it turns out not to have direct relevance for Nature. (Toy models which exhibit interesting theoretical properties are often studied in theoretical physics, and lessons learned from them are often valuable for "real physics" later.) Instead, the problem is with how string theory has been pursued. In particular the hype to the general public and the sociological insistence that it is the only legitimate topic to work on in fundamental theoretical physics.

43. **Lowell**
June 18, 2013

So why is 2+1 general relativity gravity? I has no gravitons.

44. **GMBH**
June 18, 2013

Bob Jones,

Here is what I meant with my comment on the lower bound and dimensional analysis: Dimensional analysis gives you, that for a strongly correlated system the ratio of the shear viscosity to the entropy density must be some number B times Planck's constant divided by Boltzmann's constant. Now, the hard bit is to calculate B. A proper test for a theory is to predict a value for B which is then experimentally confirmed. What the paper 0405231 does is to show that B=1/4pi for a specific class of systems with a gravity dual. This class of systems is not found in nature. The authors then simply conjecture, that all systems in nature must have B>1/4pi. This is not a proper quantitative prediction – it is simply a postulate.

45. **RF**
June 18, 2013

Nice post. Any chance you could provide a page number for the quotation above which starts "Several centuries…" and ends "… virtually clueless". I wasn't able to retrieve the passage online. Much appreciated!

46. **Jim**
June 18, 2013

Thanks to Peter for his kind review and to all who have troubled themselves to make comments. I thought I might respond to one or two of these.

Bob Jones – please keep going. I think you're helping to prove nearly all my points. I'm afraid parts of the theoretical physics community have developed a misleading interpretation of 'evidence'. In 'Farewell to Reality' I devote some time to talk about the difference between 'coherence truth' and 'correspondence truth'. Coherence truth can be established in terms of mathematical relationships, when something has been shown to be equal or equivalent to something else. These somethings might involve physical concepts, and to establish true relationships between these is obviously a good thing to do. But I argue that the notion of scientific truth is based on a 'correspondence truth' established between theoretical ideas and empirical facts. Something is scientifically true if, and only if, it corresponds to established facts about the real world.

Now, I don't deny the power of imaginative and speculative thinking, and I accept that it can take a very long time to establish the truth of a theory, but it seems to me that some contemporary theorists have retreated into their own, self-referential world, content to 'discover' coherence truths in the math but abandoning entirely any sense of obligation to seek scientific truth. **Peter Shor** – this is the point I think you were making. Actually, I'm really fine with all this – just don't call it science.

cormac – I'm obviously disappointed that I wasn't more convincing in my debate with Mike Duff. I'm very well aware of the sociological issues but other commentators (such as Lee Smolin and Peter, in his book and on this blog) have made these arguments very well in the past and I suspect there's little more to be said. In writing 'Farewell' I wanted simply to point out how very tenuous this structure is – from my perspective it really does look like a theoretical house of cards – yet this hasn't prevented some well-known theorists from publishing popular science books and making radio and TV documentaries which collectively give the rather misleading impression – intended or not – that this is all accepted science. And their efforts to change the way we interpret what science means really scares me. My ambition was to provide something of an antidote to this. Perhaps you could suspend judgement until you've read the book?

imho – I knew that 'Farewell' might be misinterpreted as an attack on science. It's not. I trained as a scientist, taught science at university in the UK and ran my own (experimental) research group for many years. I have even published theoretical papers. I'm not trying to influence science policy or inform debates about funding. I do worry that the rush to string theory has meant that other – possibly equally fertile ideas – have been neglected (which is the point that **amused** has made). I don't offer any solutions in 'Farewell' – a valid criticism. I just wanted to foster the debate.

47. **nemo**
June 18, 2013

imho, I can see what you mean but, as a physicist and a teacher, I slightly disagree. Sadly, bombs and black boxes do play a role. Prestige plays a role too. However, hard sciences, e.g. physics, and mathematics, e.g. operational research, have shown that the various methods they follow have been and are very effective to build solutions to solve problems. That is, also, why funding of physics is much larger than funding of philosophy. Physics, mathematics and engineering have led to much better problem solving than philosophy. That plays a role, too.

48. **Professor Anon**
June 18, 2013

amused:

You say

> "when assessing job candidates, single-author PRL publications on a non-string topic by some young person count for flat zero when weighed against string theory publications by another young person in a lesser journal where he/she is joint author with a bunch of senior and illustrious people."

Do you have any evidence for this? Hiring meetings typically contain both non-string-theorists and string theorists. I can't imagine any string theorists being that openly disrespectful of their colleagues.

49. **imho**
June 18, 2013

AMUSED Says:
"the problem is not with string theory, which is interesting and worth pursuing as a theoretical model of quantum gravity … Instead, the problem is with how string theory has been pursued. In particular the hype to the general public and the sociological insistence that it is the only legitimate topic to work on in fundamental theoretical physics."

IMHO responds:
Yep! Exactly!… and I've stated on other comments, there is nothing wrong with fundamental research at the appropriate scale. The problem is the hype and the massive diversion of funds away from magic boxes. We are signing our own death warrant if we choose to stop playing the game(s) we are good at and enter the debate stage with Huckabee and Gingrich. Only inside the walls of Stanford is it absolutely obvious that those charlatans aren't even worthy to share the same stage with people of our formidable intellect. Outside the walls, Palin is a prophet and we are overly-pampered out-of-touch nerds in an Ivory tower. This will not end well.

to NEMO: So prestige will fund the next collider… it must be an interesting world you've created for yourself?

50. **Anonyrat**
June 18, 2013

lun,
Thanks for that link to the theory summary of the Quark Matter conference.

There is the stern admonition:

"AdsCFT MUST be accountable to the same scientific standards as are other computations, or else it is not science".

and

" Issues must be scientific:
Controlled approximation
A result must be falsifiable."

Other than with the cold fusion fiasco, I've not seen such a strong scolding made in public like this. This is really eye-opening – even though I follow Peter Woit's blog quite regularly.

51. **Peter Woit**
June 18, 2013

RF,

That quote is on page 150-1 of the British edition.

52. **nemo**
June 18, 2013

imho, I do think that prestige has many times played a role, e.g. in funding colliders, space exploration, supercomputers. And I think that it still plays a role, at least here in continental Europe, and elsewhere, e.g. in China and Japan. It seems so. But I am afraid that expanding on this sub – topic would quickly become off – topic. As for the main topic here, I agree fully that the way string theory has been sold to the general public for too many years has been detrimental to theoretical physics and therefore science at large. Also, I agree that the problem with string theory is hype, the insistence to sold it as the theory of everything and the only game in town. String theory itself seems to me a worthy sub – field of mathematics.

53. **cormac**
June 18, 2013

Jim: Many thanks for considered reply, and Peter too. Yes, I'm looking forward to reading your new book, I'm quite sure it will be just as good as your Higgs book, which I very much enjoyed. I also think your insistence on a clear distinction between what is well-established science and what is highly speculative is exactly right, I wish more science journalists would observe this.

Re the Guardian piece,, I think it's reasonable to comment on a newspaper article as a separate entity, since that is what was presented to the public. However, I did wonder about editing – it struck me that several of your points might have been truncated (or omitted) at editing stage. I hope not, I know how that can feel!

In your book, I imagine you address the issue Peter raises in his response to my earlier comment , as it is an interesting problem: that the 'it's simply a matter of time' defense to a lack of predicitve power is weak, because *any* speculative theory can always claim that connection to experiment will be forthcoming one day in the future. This is of course true, but there is a mirror problem, that this statement does not in itself mean that all speculative theories are doomed to failure! Therein lies the rub, I think.

Add to this problem the historical point that in particle physics, the time gap between theory and experiment has tended to widen dramatically from the 1930s onwards, and one has a genuine conundrum….what if we have simply reached the stage where a successful theory really has got that complicated?

54. **lun**
June 18, 2013

This might be a great point to note the passing of, perhaps, the last theoretical physicist who can claim to have Revolutionized our view of reality, Ken Wilson.
I am sure Peter can explain much better than I could why Wilson's contributions to our understanding of the world, in depth and significance, rival any of his more media-savvy fellow Nobel prize winners.

But one thing to say, in view of the current employment situation in physics, is this line from his obituary:
————————————
http://news.cornell.edu/stories/2013/06/physics-nobel-laureate-kenneth-wilson-dies

In 1963 Wilson joined the Cornell physics department and was soon given tenure even though he had hardly published. As he later said in his Nobel autobiography, "my very strong desire to work in quantum field theory did not seem likely to lead to quick publications; but I had already found out that I seemed to be able to get jobs even if I didn't publish anything so I did not worry about publish or perish."
———————————————
I wonder if he could repeat this feat today. Actually I don't wonder, he would not be able to.

55. **Peter Woit**
June 18, 2013

Thanks lun,
I never met Wilson, but of course know some of his work. I'll try and find time soon to write something, but hopefully others who knew him are writing things that will appear soon. I had just this morning been thinking about the question of whether Higgs/1964 was work that would get one a job in the current sort of job market.

56. **Tmark48**
June 18, 2013

@ nemo : The way String Theory has been sold to the public has damaged Theoretical Physics not science at large unless you want to identify theoretical physics with science ? People make fun of theoretical physicists not real scientists. Maybe you haven't noticed, but people are interested in real science. As for those poor theoretical physicists, who cares ? They can't seem to come up with one decent theory thats is confirmed by experiments. Some theoretical physicists even go as far as to put themselves on the same plane as the good old Einstein. Didn't Einstein chase unified theories for a good part of his life ? Of course he did, but what those theoretical physicists conveniently forget is that Einstein before he started chasing speculative ideas had already revolutionized science by establishing special relativity, general relativity and some other things also. So we can certainly excuse the poor fellow in his later years.

57. **David Bailey**
June 18, 2013

I broadly agree with Imho's original comment, and I feel that the problem is far wider than theoretical physics.

For example, it would seem that the UK government is feeling the need to presurise universities to ensure their researchers are behaving responsibly.

http://www.independent.co.uk/news/science/the-bad-science-scandal-how-factfabrication-is-damaging-uks-global-name-for-research-8660929.html

Data fabrication, irreproducible results, and sheer hype are ruining science.

58. **Jim**
June 18, 2013

cormac The debate wasn't edited in any way – what you saw was what we wrote. BUT we were constrained to a very tight word limit for each exchange. So, when Mike rather disingenuously tried to pin the blame for over-selling the promise of string theory on journalists, I found that I couldn't respond to this and still provide a considered reply to his main points. The fact that you were unconvinced by my arguments is entirely attributable to my inability to put them in as succinct and yet powerful way that I felt was really needed. My loss.

I think if you read the book you will – hopefully – see that I am very much in favour of imaginative and speculative ideas. Science is a very forgiving discipline in that it really doesn't matter how a new theoretical approach is contrived – it will succeed so long as it represents a *better* theory. There are many examples from history.

But I've been struck by the simple fact that many of the constructions of contemporary theoretical physics represent major steps in a *backwards* direction. For every attempt to fix a problem in the standard model, it seems we multiply the free parameter space five-fold. Theorists like Mike Duff declare supersymmetry, hidden dimensions and the multiverse to be 'discoveries' of the string theory enterprise, rather than assumptions. I may be rather old-fashioned, but when I was a scientist I had a fairly unequivocal understanding of the meaning of 'evidence'. And this isn't it.

Let's play a game. Let's imagine that I contrive a theory based on the idea that elementary particles can be described theoretically in terms of strands or loops of 'string'. I find that the resulting theory allows me to 'predict' all the things that the standard model of particle physics can predict. It has the added bonus of allowing me to construct a theory of quantum gravity. I know this isn't enough necessarily to replace the standard model, because I haven't yet shown how string theory transcends this. But, in our game, I find that this string theory predicts that the mass of the electro-weak Higgs boson should be something of the order of 120-130 GeV. I make this prediction in 2010. The ATLAS and CMS collaborations subsequently find that the Higgs boson does indeed possess this mass, and we celebrate with champagne.

Of course, string theory doesn't do this, which is why I regard this business of supersymmetry, hidden dimensions and multiverses as assumptions, rather than 'discoveries'. When string theory can make legitimate predictions that can be tested, and when those tests are confirmed, only then can the assumptions be regarded to represent aspects of empirical reality, and so become genuine discoveries.

It could still be argued that string theory will get to this, if only we are sufficiently patient. But I think you might be prepared to admit that the majority of the string theory community gave up on this quite some time ago. Some realized that careers could be built – and, now, highly valuable prizes can be won – by establishing coherence truths, like the ADS/CFT duality, and forgetting that scientific truth is all about establishing a *correspondence* between theoretical ideas and empirical facts.

I find that I still need to tell you that I really don't mind about this. So long as you stop calling is science.

59. **Mitchell Porter**
June 18, 2013

jim:

"I regard this business of supersymmetry, hidden dimensions and multiverses as assumptions, rather than 'discoveries'."

Michael Duff is not arguing that we have discovered these things to be true, he is arguing that we have discovered them to be implications of the string hypothesis.

60. **amused**
June 19, 2013

Professor Anon,

""when assessing job candidates, single-author PRL publications on a non-string topic by some young person count for flat zero when weighed against string theory publications by another young person in a lesser journal where he/she is joint author with a bunch of senior and illustrious people."

Do you have any evidence for this? Hiring meetings typically contain both non-string-theorists and string theorists. I can't imagine any string theorists being that openly disrespectful of their colleagues."

I base it on postdoc job application outcomes. Will provide details if you insist, although I don't think it would be of great interest for the readership here… The real explanation for this situation was simply that the string-dominated particle theory groups had/have a policy of "string theorists only" when hiring postdocs (and presumably also when supporting candidates for faculty positions). Probably there is nothing unusual about that and the situation is often the same in other areas of academic science… If they just admitted it openly, instead of pretending to be noble and altruistic, then I wouldn't get so worked up…

61. **Jim**
June 19, 2013

Mitchell Porter Nice try, but I don't buy it. This is a sloppy use of the word 'discovery', of which we are all guilty (including me). Given what's at stake here, I think we need to be a little more careful in our choice of words.

I respectfully suggest that you can't 'discover' consequences or implications from the math. These implications may emerge from the equations and allow you to make some logical deductions. These implications can be used to construct another layer of theoretical structure. So, string theory *implies* hidden dimensions, and if we compactify these in a Calabi-Yau manifold we can build another layer. We haven't 'discovered' anything – yet.

If and when the implication or assumption of hidden dimensions leads to a firm prediction, and the prediction is upheld by reference to empirical facts (such as the unambiguous observation of KK particles at the LHC), then – and only then – can a consensus form that we have discovered hidden dimensions. Until then, hidden dimensions represent an assumption within a layer of the theoretical structure.

Mike was also constrained to a tight word count, but the words he did choose left no room for doubting his interpretation: 'Yours is a common fallacy… string theorists did not assume supersymmetry, extra dimensions, the dualities of M-theory or the myriad possible universes; they *discovered* them to be consequences of a theory that subsumes empirically well-established features such as general relativity, gauge field theory and chiral quarks and leptons.' (Italics mine). In this kind of language, 'discovery' readily trips over into 'evidence' and, before you know it, we have created the popular misconception that this is all accepted science fact.

62. **piscator**
June 19, 2013

"Some realized that careers could be built……by establishing coherence truths, like the ADS/CFT duality, and forgetting that scientific truth is all about establishing a correspondence between theoretical ideas and empirical facts."

This is a total misunderstanding of what theoretical physics is. While I am not personally attracted to formal work, the discovery of the AdS/CFT correspondence is a deeply important result. Peter, who is no great fan of string theory, will not dispute this. The implication that people like Maldacena should not have careers – you can argue about prizes, but careers!!! – is just dumb and ignorant, to be frank.

amused: I have some sympathy for the points you make, but have never understood why when it comes to hiring the editors of PRL (typically non-practising physicists who are not subject specialists) and its referees (who are just a couple of members of the community) should play some special privileged role.

63. **Jim**
June 19, 2013

piscator I wouldn't wish to deny anyone a career, and I think if you look back you'll find that this is not what I said. I'm very much in favour of academic freedom and speculative ideas. All I ask is that we don't declare this to be accepted scientific fact.

64. **nemo**
June 19, 2013

Tmark48, a very short answer. Of course, I do not identify theoretical physics with science, but there is no physics without theoretical physics, or without mathematics, and think of other hard sciences and engineering without physics. So that is why I think that hype has damaged theoretical physics and therefore science at large.

65. **amused**
June 19, 2013

Piscator,

"I have some sympathy for the points you make, but have never understood why when it comes to hiring the editors of PRL (typically non-practising physicists who are not subject specialists) and its referees (who are just a couple of members of the community) should play some special privileged role."

Well, the editors of Nature are also non-practicing scientists and they have enormous influence on hiring in the bio-sciences…

How useful PRL is as a quality measure depends on how seriously the physics community is willing to take it. At the moment it does seem to be taken seriously by pretty much all of the community. String theorists profess not to, but I've seen firsthand how excited some of them get about sending a paper there when they think they have a shot. 🙂 The quality of judgments on individual papers can fluctuate of course, but I think on a larger scale the level is pretty good.

As for its use in hiring decisions etc, I think it can play a useful role as a kind of minimum criterion. I'm sure that even some string theorists are sick of the phenomenon of the "brilliant young string theorist", whose has been anointed as such by his illustrious advisor/mentor after being joint author on some papers with a bunch of more senior people. IMHO it would be a change for the better if such people first had to publish a few papers on their own in PRL before being anointed as `brilliant' and sent to the front of the job queue. Just to show that they can. Shouldn't take them more than a couple of months 😉

PRL publications are also useful as an indicator of the overall health of a field. If interesting and important developments are happening in the field, it will manifest as a regular flow of PRLs. Absence of such a flow will be seen by the rest of the community as a sign of ill health. And if there is no PRL flow, and at the same time practitioners are seen to be actively hyping their field to the public, it looks really, really bad! And even worse when, on the rare occasion the practitioners do manage to get a PRL, they issue an excited and over-hyped press release…

FWIW I agree completely with what your wrote about the importance of ads/cft. On the other hand, I'm not sure about that 6-dimensional superconformal field theory that Nima is so excited about… If it's really that interesting and important, he should go publish a paper on it in PRL! 🙂

66. **cormac**
June 19, 2013

Jim: those are very interesting comments. I especially take your point on word count, my old enemy. Actually I didn't find your comments in the Guardian unconvincing, it's more that I found Mike *more* convincing, a relative as well as subjective judgement.

Your conversation with Piscador and others is also very interesting because I think the relation between theoretical physics and physics is at the heart of the debate around sting theory, yet this rarely comes to the fore. Peter touched on this quite a bit in his book, I imagine there's quite a lot on it in yours.

As a very ordinary experimentalist who is the son of a well-known theoretician, I've long had a special interest in this debate. Sometimes I think theoretical physics occupies quite a unique position in science; because of its dual role in mathematics and physics (the former is often overlooked) it's not quite clear whether it should be forced to conform with the strict positivism we tend to apply to other areas of science, i.e. should it always be shackled to experiment, or should some theoretical physics be allowed to roam free like mathematics. Perhaps the problem is when the latter is marketed as the former.

For example, SUSY is often portrayed on this blog as an offshoot of string theory. In fact, it was originally a purely mathematical construct that showed one way of cirmcumventing the no-go theorems of gauge theory – to this day, I gather than one cannot construct a unified gauge theory that includes the strong force without SUSY. It may have been adopted by string theorists, but that has nothing to do with the theory itself. You might of course argue that all this has nothing to do with experiment, but the original SUSY theorists never claimed it did – that's my point!

As I understand it, the main motivation for SUSY nowadays comes not from string theory, but from cosmology, simply because it is very hard to see how the interactions were once unified without some sort of bose-fermion symmetry….
Regards, Cormac

67. **MathematicianNotPhysicist**
June 19, 2013

Cormac, I don't understand. Why is there a need for interactions to be (or ever to have been) unified?

68. **Peter Woit**
June 19, 2013

MathematiciannotPhysicist and cormac,

I suppose Cormac is referring to No Go theorems that show that you can't combine space-time and internal symmetries non-trivially, something that SUSY gives new options for. But this is getting way, way off topic, so please anyone who wants to discuss this with Cormac should contact him directly.

69. **piscator**
June 19, 2013

amused,

I take the point that Nature (or more generally CNS of Cell-Nature-Science) plays an important role in bioscience careers – but I don't see that as a good example to be copied. I think PRL plays a similar role in condensed matter, but I agree with you this is not the case in high energy.

I have published in PRL (and on my own), but my best work is not there.

The thing I really don't get though about emphasising PRL publications is that the PRL format is well suited to short papers making a single point. Maybe this works naturally for experimental subjects where there is a single clear result, and what matters is the measurement. But in theory there is an argument to be developed and calculations to be done, and in most cases 4 pages is not adequate to describe this. Such papers – and I think this represents most good work in theoretical physics – should not go to PRL.

My personal experience with papers within my conceptual radius of convergence is that what appears in PRL is disproportionately flashy, and more likely to be making big claims with a small chance of being right than making small claims with a large chance of being right (This is true of my own papers there as well). I don't think there is any intrinsic sin in writing such papers, or that they are intrinsically better or worse than long calculation-heavy papers (which I also do), but to my mind this is the 'PRL type'. So I see PRL more as a style of paper than an indicator of quality.

PRL emphasises general interest, which again affects the type of paper likely to be accepted, without to my mind necessarily implying higher quality.

I do think it is a good journal, and there is an approximate guarantee of quality, but I strongly feel it is suited to a particular type of paper that is not and should not be representative of most work in theoretical physics.

I agree with the comments about the 'hotshot young theorist' issue although I don't think is especially to do with string theory (in recent years I would say this is much more prominent in BSM pheno). Particle theory as a whole, and particularly I think in the United States, has a problem with genetic diversity and inbreeding – look at faculty hires over a substantial period and see how many of these can be traced back to a very small number of advisors at Harvard/IAS. Yes these people are smart, but the history of physics shows how often truly brilliant people completely miss or misunderstand important new ideas, and it is not good if everyone is brought up with the same toolkit and prejudices.

70. **Peter Woit**
June 19, 2013

All,

I think the PRL issue, which had nothing much to do with the book being discussed here, has now been convincingly beaten to death. Enough about that.

71. **Paulibus**
June 20, 2013

Peter: your take, "Not Even Wrong", on the activities of many of today's theoretical physicists looks as if it's been amplified by Jim Baggot's book, which I plan to own soon.

As I see it, there are many human activities which can't be justified on the anthro'centric grounds that they actually sustain our species' survival. But lots, like movie making, sport, art and literature can be justified on the grounds that they are harmless entertainments, mostly free of chicanery, which give spectators much pleasure. They strike a balance between benefit and cost which entertained paying folk happily tolerate . But now and then the balance tips too far towards the cost side for said folk to tolerate happily, and sports players, artists, writers etc. find that they are jobless. Tough: fashions change.

I think that the theoretical physics enterprise is losing this balance, which in its case has long been sustained by human curiosity and the enormous proven utility of new physics in sustaining our species' rise and rise. It looks to me as if theoretical physics, lacking new discoveries, is busy passing its sell-by date. Not that many tears need to be shed over this; its cause includes too great a proportion of hubris. Tough.

72. **Jim**
June 20, 2013

cormac I sense you're coming round, and suspect you will enjoy the book when you've had a chance to study it a bit – please let me know.

It was inevitable that some commentators (who haven't read the book yet or have no intention of doing so) would interpret my position as denying all value in speculative theorizing. At risk of sounding rather pompous, I'd like to quote from my own book (p. 20):

I want to be clear that the demand for testability in the sense that I'm using this term should not be interpreted as a demand for an immediate yes-no, right-wrong evaluation. Theories take time to develop properly, and may even be perceived to fail if subjected to tests before their concepts, limitations and rules of application are fully understood. Think of testability instead as more of a professional judgement than a simple one-time evaluation.

The Testability Principle demands that scientific theories be actually or potentially capable of providing tests against empirical facts. Isn't this rather loose? How can we tell if a novel theoretical structure has the potential *for yielding predictions that can be tested? For sure, it would be a lot easier if this were all black and white. But I honestly don't think it's all that complicated. A theory which, despite considerable effort, shows absolutely no promise of progressing towards testability should not be regarded as a scientific theory. A theory that continually fails repeated tests is a failed theory.*

So, I hope this makes it clear that I have no wish to shackle theory to experiment. My point is that many (the majority?) in the string theory community gave up quite some time ago on the task of progressing the theory towards testability in preference to building ever-more elaborate and abstract structures and seeking coherence truths among these. It is at this point that these theorists cease doing science.

As you know, SUSY is not so much a theory as a theoretical device – there are many different kinds of ways that supersymmetry can be employed. But it looks like the simpler of these (such as the MSSM) is failing the test – there's no evidence of low-mass sparticles from the LHC. I suspect that efforts to salvage it (or 'save the appearances') are driven by the simple fact that SUSY is an important component in superstring theory.

73. **cormac**
June 20, 2013

Jim: Yes, it's hard to disagree with that quote and it's pretty much in tune with Peter's view too. About my only caveat is the business of 'progress towards testability', or, more specifically lack of! This is very much Peter's view too, but I'm not enough of a mathematician to know whether it makes sense. Do good theories always show such progress before they come good? Mightn't they sometimes go dormant, or even backwards for years, before an series of unanticipated breakthroughs happen? For an example, I remember reading that the anti-atomists gained in strength when chemists suddenly started talking about molecules, instead of just atoms! No doubt it seemed a case of a speculative theory becoming ever more contrived, before all became clear years later…
Re SUSY, my point is at least some of the effort in salvaging SUSY is *not* from ST, but from a general need of it for unification (by any means), as Peter points out above

74. **nemo**
June 20, 2013

Paulibus, let's assume that we rename theoretical physics, or part of it, and call it mathematics. Would you stand by your claim ? Now travel back in time two, three or four centuries, and think about the mathematical tools being developed at that time, and contextualize them in relation to the communities at large, at that time, and the technical tools, i.e. engineering, being developed at that time. Would you still stand by your claim ?
The damage that hype has done to theoretical physics and science is exemplified by your extraordinary statement that *"theoretical physics"* […] *"is busy passing its sell-by date."* Does that apply to mathematics as well ?
And another example is this one from The Guardian: *"Scientists working at the Large Hadron Collider have found no evidence that the new particle discovered earlier this year is anything but the simplest – and most **boring** – variety of Higgs boson."*
As for survival: brutally, I ask you whether you suggest we should just pray or else enjoy our time while waiting to be hit by a large enough asteroid. Oh, yes, may be in that case we should just move underground and "survive" down there.

75. **Mitchell Porter**

June 20, 2013

Jim said

“I suspect that efforts to salvage it (or ‘save the appearances’) are driven by the simple fact that SUSY is an important component in superstring theory.”

From what I can see, the principal function of supersymmetry in model-building today is still “naturalness”. It is there to produce cancellations that eliminate the need for finetuning of parameters to enormous orders of magnitude. Even an approach like “split supersymmetry”, which may explicitly tolerate a tuning of the Higgs mass to one part in a thousand or a million, still relies on supersymmetry to explain the rest of the tuning.

76. **Mitchell Porter**
June 20, 2013

more precisely: relies on supersymmetry to explain why the tuning is just one part in a million rather than one part in 10^15.

77. **Paulibus**
June 21, 2013

Captain? N: You have an interesting reaction to my ‘extraordinary statement’, or claim, that theoretical physics is ‘busy passing its sell-by date’. Let me explain: things meant for human consumption (edible or intellectual) get rejected — pass this date — if in time they deviate too
far from a cost-benefit balance acceptable to those that rule the purse. It is obvious to me from academic hiring practice, Peter’s and Lee Smolin’s books, this blog, and what has been said here about Jim Baggot’s book (which I look forward to reading) that the infusion of fairy-tale stuff into theoretical physics is busy tilting its balance towards cost, and away from evident benefits that both you and I acknowledge. Funding won’t go on for ever enlarging rafts of clever people who seem to ignore the essential flavour of physics – a Baconian balance between theory, prediction and verification by experiment and
observation.

Your last comment about big asteroids shows faith in a future way of evading the conservation of momentum. Perhaps there is indeed a need for fairytale physics, failing which: maybe just – Kismet!

78. **Jim**
June 21, 2013

cormac This had better be the last exchange, as we’ve gone on long enough and I don’t want to try Peter’s patience. I buy everything you say. The history of science is full of twists and turns and only a fool would pretend that ‘progress’ (however defined) is something that could be predicted.

I do say repeatedly in the book that I’m not trying to stop the string theory community doing what they’re doing (I’m not that naïve). What irks me is that the assumptions on which the resulting structure is based (call them ‘predictions’ if you really must) have been sold to the wider public as accepted science. To take one example, in his own *Instant Expert* guide to the Theory of Everything (*New Scientist* 4 June 2011), Mike Duff is careful to talk about M-theory being a ‘leading candidate’ for a theory of everything, but I would argue that it’s real hard for anyone with a relatively general understanding of science to read this stuff – with sections on superstrings, supersymmetry, extra dimensions, M-theory, branes, the cosmic landscape and the multiverse, not to be tricked into thinking that this is all accepted, validated science. To be fair, there is a section ‘Answering the Critics’, in which Duff uses the same arguments that he used in his debate with me. Careful reading of this section should convey the impression that this is all speculative theorizing. But, of course, this section is a lot less interesting than the others.

‘Farewell to Reality’ is not necessarily about changing the status quo, it’s aims are to provide something of an antidote, sponsor some healthy skepticism and encourage debate.

79. **nemo**
June 21, 2013

Paulibus, then you are thinking about a really big one … in which case, yes, may be — Viva! And a glass of wine.

No relation to Verne! We agree much more than what I had thought. I look forward too to reading Jim Baggott’s book.
May be, people should just leave what is indeed more mathematics than theoretical physics compete for funding in mathematics? And call it mathematics? And leave what is indeed more metaphysics than physics compete for funding in philosophy? And call it philosophy? I think it is also a matter of science literacy, among the general public and … I wonder … among some scientists, it seems as if too many practitioners, reporters and readers are confusing or misrepresenting assumptions, predictions, (lack of) experimental evidence and how much human effort or ingenuity it often takes to seek reliable (lack of) evidence. As a great teacher of mine had once remarked, some experiments are truly **epic**! And he was a theorist! So I find it inspiring that Kenneth Wilson had found time to support science literacy and education in schools.

80. **Paulibus**
June 22, 2013

nemo: yes, I agree with you; it’s good to call a spade a spade, especially when it’s been a long time since nature sprung a fundamental physics amazement on us. I hope she’s trying, and physics folk are temporarily just looking the wrong way!

81. **Anonyrat**
June 23, 2013

I imagine the mathematician V.I. Arnold’s view would be a distinctly minority position:
http://pauli.uni-muenster.de/~munsteg/arnold.html

“Mathematics is a part of physics. Physics is an experimental science, a part of natural science. Mathematics is the part of physics where experiments are cheap. “

82. **nemo**
June 24, 2013

That’s a quirky view. Thank you. The whole essay is very interesting.

83. **steve newman**
June 26, 2013

Jim Baggott is not alone with his new book-Farewell to Reality: How Modern Physics Has Betrayed the Search for Scientific Truth

A day later, another book with exactly the same theme will be published-
Bankrupting Physics: How Today’s Top Scientists are Gambling Away Their Credibility (Macsci) [Hardcover] by a german theoretical physicist- Alexander Unziker.

It’s becoming common knowledge. The sceptics are getting a strong voice.
Maybe a better day will be coming.

84. **Peter Woit**
June 26, 2013

Steve Newman,

I haven’t seen the Unzicker book yet, will probably write about it here when I do. From what I have seen from him though, it looks like he’s likely to do a lot more to discredit criticism of string theory than discredit string theory.

This Week's Hype

June 18, 2013
Categories: Multiverse Mania, This Week's Hype

In recent years universities have taken to issuing press releases when one of their particle theorists gets a paper on some speculative topic published in a journal like Physical Review Letters. Many examples of such things, often involving bogus claims to have a "test of string theory" have been covered here.

The University of Delaware has now decided to break new ground: they've issued a press release promoting a 1997 paper by some of their faculty that was published in Physical Review D. I gather the argument must be that it's timely because it's about the multiverse and anthropics.

As a bonus topic in the "This Week's Hype" category, there's a new paper out yesterday promoting the idea that string inflationary models have been successfully tested by the Planck data:

> We argue that as a group the predictions made before Planck agree well with what has been seen…

The authors start out by addressing the obvious problem with string cosmology:

> given the complexity of these models it is worth first asking why they are worth scrutinizing in detail at all. After all, if the data is perfectly consistent with much simpler models, Occam's razor suggests we should leave it at that.

It seems that in our new anthropic multiverse-based framework that drops conventional ideas about predictions and testability, Occam's razor has to go too.

Update: I should have mentioned that the Delaware press release links to the article discussed here.

Comments

1. **Tom H**
   June 18, 2013

   The UD press release links to a SciAm article, which in turn states:
   " … If no new particles appear and the Higgs remains astronomically fine-tuned, then the multiverse hypothesis will stride into the limelight. 'It doesn't mean it's right,' said Bousso, a longtime supporter of the multiverse picture, 'but it does mean it's the only game in town.' "

   "only game in town" ? Where have we heard that before?! 😉

   In the past, I don't doubt the prevailing sentiments were
   "epicycles are the only game in town",
   "the aether is the only game in town", etc etc

   Seems to reflect an absence of a breakthrough insight into the real physical world.

2. **M**
   June 19, 2013

   This 1997 paper, despite being largely ignored, is THE important paper where the connection between anthropic selection and the Higgs mass was pointed out. It is the analogous of the Weinberg paper where the connection between the cosmological constant and anthropic selection was pointed out.

3. **Bee**
   June 20, 2013

   I actually found the Burgess et al paper to be a really useful comparison of previously made constraints with existing data. They also give quite frank assessments on the theoretical appeal of the various models. Isn't that the sorting-out of models that we've all been waiting for? Why are you unhappy with that?

4. **Peter Woit**
   June 20, 2013

   Bee,

   I've never really seen the point of constructing this kind of complicated model, and the Planck data consistent with the simplest model would seem to provide experimental evidence against them. The authors I guess are hearing this from their colleagues, the response of an introduction arguing against one of the most fundamental principles of doing science (Occam's razor) is fairly remarkable.

   Coupling this with attempts to mislead like claiming "the predictions made before Planck agree well with what has been seen" doesn't help.

5. **nemo**
   June 20, 2013

   Kenneth G. Wilson here:
   "If your aim is to have an impact on science literacy — in fact, on literacy in all its forms — you need to rivet your attention on the 46 million students in our public schools, not on graduate students in our universities."
   That is also an antidote against hype.

Kenneth Wilson 1936-2013

June 18, 2013
Categories: Obituaries

Kenneth Wilson died this past weekend, in Maine at the age of 77. Some obituaries can be found here, here, here, and here.

Wilson won the Nobel prize in 1982 for his work on critical phenomena and phase transitions, but his influence on particle theory was arguably even greater than on condensed matter physics. Unfortunately I never got a chance to meet him, but a large part of what I was learning about quantum field theory back in my days as a graduate student came either directly or indirectly from him.

Soon after the discovery of asymptotic freedom in 1973, he started work on developing lattice methods for studying gauge theories non-perturbatively with a fixed cut-off. This founded the whole field of lattice gauge theory, which remains a major and active part of HEP theory. Not many people have a whole section of the arXiv they're responsible for. For his story of how this came about, see his 2004 The Origins of Lattice Gauge Theory.

The reason Wilson was well-placed to quickly get lattice gauge theory off the ground in 1973-4 was that he was one of very few theorists who had been thinking hard and fruitfully about the meaning of non-perturbative quantum field theory. After getting an undergraduate degree in math from Harvard in 1956, he did his thesis work under Gell-Mann at Caltech, finishing in 1961 and developing an interest in the renormalization group. From 1963 on he was focusing his research on strong interactions and the high energy behavior of quantum field theory. This was a time when QFT had fallen out of favor, with S-matrix theory considered the cutting edge. One reason others weren't thinking about this was that the problem was very hard. It was also perhaps the deepest problem around: how do you make sense of quantum field theory? What is QFT, really, outside of the approximation method of perturbation theory?

By the early 1970s, Wilson had developed the ideas about the renormalization group and QFT that now form the foundation of how we think about non-perturbative QFTs. The first applications of this actually were to problems about critical phenomena, and it was for this work that he won the Nobel prize. With the arrival of QCD, these ideas became central to the whole field of particle theory, with much of the 1970s and early 80s devoted to investigations that relied heavily on them. If you were a graduate student then, you certainly were reading his papers.

For more from Wilson himself about his life and work, see his 1983 Nobel Prize lecture and a long interview from 2002 here, here and here.

John Preskill has a wonderful posting up about Wilson, with the title We are all Wilsonians now. He ends it by explaining Wilson's early role in the debate about "naturalness". Wilson was well aware of the quadratic sensitivity of elementary scalars to the cut-off and had argued that this meant that you didn't expect to see elementary scalars at low masses. This argument was developed here by Susskind as a motivation for technicolor. Preskill doesn't mention though that Wilson later referred to this as a "blunder". In 2004 he had this to say:

> The final blunder was a claim that scalar elementary particles were unlikely to occur in elementary particle physics at currently measurable energies unless they were associated with some kind of broken symmetry . The claim was that, otherwise, their masses were likely to be far higher than could be detected. The claim was that it would be unnatural for such particles to have masses small enough to be detectable soon. But this claim makes no sense when one becomes familiar with the history of physics. There have been a number of cases where numbers arose that were unexpectedly small or large. An early example was the very large distance to the nearest star as compared to the distance to the Sun, as needed by Copernicus, because otherwise the nearest stars would have exhibited measurable parallax as the Earth moved around the Sun. Within elementary particle physics, one has unexpectedly large ratios of masses, such as the large ratio of the muon mass to the electron mass. There is also the very small value of the weak coupling constant. In the time since my paper was written, another set of unexpectedly small masses was discovered: the neutrino masses. There is also the riddle of dark energy in cosmology, with its implication of possibly an extremely small value for the cosmological constant in Einstein's theory of general relativity.
>
> This blunder was potentially more serious, if it caused any subsequent researchers to dismiss possibilities for very large or very small values for parameters that now must be taken seriously…

He then goes on to argue at length that the lesson of the history of science is that often what seemed like unlikely possibilities turned out to be the right ones, with the argument for unlikeliness just a reflection of the fact that people had been making assumptions that weren't true and/or they didn't understand the possibilities as well as they thought they did.

Wilson may be no longer with us, but his ideas certainly are, and they're very relevant to the biggest controversies of the day.

Comments

1. **Igor Khavkine**
   June 18, 2013

   Peter, that's a great quote from Wilson. It's great to see such a "radically conservative" position from the man himself. I wonder how it would play with the current mainstream opinion, if it were better known. 😉

   Looking at the list of his achievements, it's hard not to find them impressive. However, it is sad to see that part of his legacy is a wide spread conflation of two distinct concepts: perturbative renormalization in QFT and a lift of classical scaling transformations to quantum theory (aka the renormalization group). Moreover, the idea that some (or all) field theories must be defined with an explicit cutoff (in addition to not having any empirical evidence for the existence of any such fundamental cutoff in our world) is tantamount to forsaking the hope of answering the mathematical question of whether renormalized continuum QFTs can be defined on their own terms, independent of any particular choice of regulator. I don't know of any other, similarly important mathematical question, where the widespread opinion is to simply give up looking for an answer.

   I hope that in the future Wilson is remembered more for his important work on the analysis of scaling transformations in QFT (both lattice and continuum), his work on operator product expansions, his work on lattice field theory itself and his work on critical phenomena in condensed matter systems (where explicit cutoffs do actually exist).

2. **Peter Woit**
   June 18, 2013

   Igor,

   I think that the issue of regulators is only one of many where there's a conventional wisdom among particle theorists that keeps people from working in other directions. Unfortunately, we don't know which of these pieces of conventional wisdom are wrong and will someday be seen as what was keeping people from making progress. It does though look like “naturalness” is a good candidate…

4. **meet**
June 19, 2013

Even if you had met Ken Wilson in person, it is unlikely that you would have gotten anything much out of it. He was a brilliant and very nice person but very, very shy. Perhaps if you had been his student or postdoc … but he accepted very few graduate students. Michael Peskin is perhaps his most famous graduate student. Paul Ginsparg was also his student. It is well known that as an assistant professor at Cornell, Wilson published maybe six papers in five years. But when the time came for tenure, Hans Bethe, who was the Grand Old Man of Cornell Physics in those days, protected Wilson (“This man is deep.”) and insisted that Wilson be granted tenure. The next year or so, Wilson’s groundbreaking papers on the renormalization group were published, and the rest is history. At the Cornell press conference for Wilson’s Nobel Prize, Bethe sat next to Wilson at the table and preened himself like a mother hen. Bethe had a smile six inches across from end to end.

5. **gs**
June 19, 2013

RIP.

During roughly the same time frame in which Wilson was doing his scaling-based work, Mandelbrot was formulating (and popularizing) fractals.

In my amateur opinion each was uninfluenced by, and possibly unaware of, the other’s progress. but in a sense they approached the same monolith from very different directions.

6. **King Ray**
June 19, 2013

Lightspeed, Kenneth Wilson.

7. **Blake**
June 20, 2013

Offtopic: Is John Ellis for real saying that the LHC results are actually “encouraging” for SUSY? Are SUSY proponents becoming divorced from reality, or am I missing something.

http://www.youtube.com/watch?v=F8Z1aKyEwNc&feature=player_detailpage#t=767s

8. **Peter Woit**
June 20, 2013

Blake, I had the Google+ hangout thing on in a window for a while, and did hear Ellis going on about the situation of SUSY being encouraging. This is pretty delusional, but it’s also not really news that SUSY proponents aren’t willing to admit the situation they’re in. So, unless there’s something really surprising, best to avoid yet more of the same discussion about SUSY here, where it’s off-topic.

9. **MathPhys**
June 21, 2013

K Wilson was a scientific and an intellectual hero to many of us who learnt quantum field theory in the late 1970’s and early 1980’s. The fact that he wrote one very deep physics paper per year from the late 1960’s to the mid 1970’s, before he eventually turned his attention to computing, set him apart as a great scientist and a profound thinker who did things his own way, and that we looked up to, but had no way to emulate.

I met him in 1982. He was quiet, reticent, reserved but also very polite. For someone who ran the mile in less than 4 minutes as a young man, he was quite out of shape in his 40’s. Listening to his lecture, then asking him questions, I was struck by how he gave very simple arguments that were natural and totally convincing when he said them, but difficult to reproduce after the discussion. His mind worked differently from most other people. RIP.

10. **q&a**
June 21, 2013

The legend was that Ken Wilson didn’t answer the question you asked, but the question you *should* have asked.

11. **Jeff M**
June 21, 2013

OK, if you get far enough into “The Origins of Lattice Gauge Theory” you find Wilson discussing a bizarre episode from the early 70s of someone who read a paper of his and called him to set up a meeting in Ithaca. At the meeting the person gradually explained to Wilson that his work agreed with this person’s idea that the world was a computer simulation (if fact, a chain of computer simulations). Of course, this is now discussed seriously in many circles, but wow, to have come up with that given what computers were like in the early 70s!! No doubt chemicals were involved…

12. **MathPhys**
June 23, 2013

It’s not clear to me why he wrote *“I kept listening. But then he asserted that eventually one comes to a computer simulation run by a Supreme Being. At that point I managed to terminate the conversation.”* My understanding is that Wilson held religious beliefs.

13. **Peter Woit**
June 23, 2013

MathPhys,

Maybe his religious beliefs included a Supreme Being that didn’t do silly things like run computer simulations…

14. **Peter Shor**
June 24, 2013

If a Supreme Being is omnipotent, why would he choose to simulate a world rather than actually creating one? Would you expect your Supreme Being to do shoddy work? (Of course, computer scientists and physicists may disagree about whether simulating a world is the inferior method …)

15. **MathPhys**
June 24, 2013

I personally think that to think of the universe as a computer simulation is just as good as any other image that one can come up with to put metaphysical concepts into words.

More interestingly (to me) is the fact that I have always remembered that Wilson was a Quaker. I'm not so sure how I knew this, but the last time that I have thought of this cannot be long after meeting him in 1982 or 1983, so it may have been Wilson himself who mentioned it, though that seems unlikely.

He was intellectually miles ahead of anyone else around him, but treated everyone from the most pretentious professor (there were many) to the lowliest graduate students (there was only one) on equal footing and equally seriously. When someone mentioned running the mile in 4 minutes, he smiled and said *"That was a long time ago"*.

16. **hari**
June 25, 2013

Is this the last talk delivered by Wilson?
Only abstract seems to be available.
http://www.worldscientific.com/doi/abs/10.1142/9789814335614_0038

17. **Anonyrat**
July 15, 2013

MathPhys, this database of people does list Wilson as a Quaker.

Strings 2013 etc.

June 25, 2013
Categories: Strings 2XXX

These days one can just about attend a wide variety of summer conferences from the comfort of one's home or office, with talks appearing online more or less immediately after they are given. This week some possibilities to consider are:

- The big yearly string theory conference, Strings 2013, is in Seoul this week with about 279 physicists in attendance, talks are available here. As usual for recent string theory conferences, there aren't a lot of strings to be seen. Perhaps these yearly conferences should be renamed something like "Conference on the latest topics popular among people who used to do string theory". No sign at all of the landscape or string theory unification. For some understanding of why, see Life at the Interface of Particle Physics and String Theory, to be published by Reviews of Modern Physics, which makes pretty clear why the organizers of Strings 20XX now want to avoid this topic.
- The 2013 Lepton Photon conference is in San Francisco this week, talks here. To mark the occasion, Gordon Watts and Jacques Distler have thrown in the towel, paying up on their bet with Tommaso Dorigo that the LHC would find SUSY or other "new physics". Tommaso has the full story here.
- For the more philosophically minded, the Templeton Foundation is funding a summer institute on the Philosophy of Cosmology, and you can follow the talks here. If thinking about time is your thing and you've missed out on the free summer amongst the redwoods, there's still time to get in line for Templeton funds, with a few days left to apply for grants here.

Update: To round out the list, I should have included something for the mathematical physicists, this week's Symmetries in Mathematics and Physics conference in Rio. Videos of the talks are appearing here.

Update: Jacques Distler has a posting here (or guest post here) conceding the loss of his bet with Tommaso Dorigo. Unlike some other theorists (e.g. John Ellis) who are arguing that everything's fine, one just has to wait until 2015-6 for the higher energy LHC run, Distler is more of a realist:

> …would I be willing to bet on the 2015 LHC run uncovering new BSM physics?
>
> The answer, I think, is: not unless you were willing to give me some substantial odds (at least 5–1; if I think about it, maybe even higher).
>
> Knowing the mass of the Higgs (~125GeV) rules out huge swaths of BSM ideas. Seeing absolutely nothing in the 7 and 8 TeV data (not even the sort of 2-3σ deviations that, while not sufficient to claim a "discovery," might at least serve as tantalizing hints of things to come) disfavours even more.
>
> The probability (in my Bayesian estimation) that the LHC will discover BSM physics has gone from fairly likely (as witnessed by my previous willingness to take even-odds) to rather unlikely. N.B.: that's not quite the same thing as saying that there's no BSM physics at these energies; rather that, if it's there, the LHC won't be able to see it (at least, not without accumulating many years worth of data).

Comments

1. **P**
   June 25, 2013

   Hi Peter,

   It isn't any more right to say that string theory is just unification than it is to say that QFT is just the standard model. The field has given insight into a broad variety of topics in physics (maths, AdS/CFT, field theory dualities, strongly coupled gauge theories, etc etc).

   In this sense, Strings 2013 absolutely is a conference about string theory. I'd challenge you to find more than 10 talks (other than the ones which seem to be from LHC and Planck experimentalists) which aren't string theory outside the realm of unification or topics in QFT and gravity which owe many of their results to string theory.

   Cheers,
   P

2. **Peter Woit**
   June 25, 2013

   P,
   I don't think there's any point in arguing now about what is "string theory" and what isn't, since the term has become rather meaningless as it has morphed into "stuff that is kind of somehow inspired by something someone once found while working on string theory", which covers all sorts of different things.

   The remarkable thing about string theory unification is not just that it's no longer a central part of string theory research, but that the most influential "string theorists" in the world, those who choose talks for Strings 20XX, now won't touch it with a ten-foot pole.

3. **leptonphoton**
   June 25, 2013

   Lepton Photon used to be 'Electron Photon' in the good old days we all hanker for (when there were no blogs?). Technically I think I wasn't born yet so no hankering for me. Is LP2013 exclusively about leptons and photons?

4. **chris**
   June 26, 2013

   the amazing thing about LP13 is that on monday the new SUSY and BSM search results were presented – the last round of new results before the update of LHC – and nobody seemed to care in the slightest. As the exclusion limits on various stuff inches upward – some of it into the 10 TeV range already – it seems that finally noone expects there to be anything but the SM.

5. **nobsm**
   June 26, 2013

   Therein lies the tragedy. It's one thing to criticize ST/SUSY/etc as hype, and to say 'no evidence for SUSY and BSM search at LHC' but 'no BSM' is a tragedy for HEP.

6. **Peter Woit**
June 26, 2013

leptonphoton,

No, the conference for a long time hasn't just been about leptons and photons. Maybe they should update the name…

7. **Eric**
June 26, 2013

I think it has become very clear that most likely the only superpartners which are light enough to be produced at the LHC are neutralinos and charginos. Unfortunately, the production rate for neutralinos and charginos in hadron colliderss is very low, so there is almost no chance of seeing these particles at the LHC. However, it should be possible to the lightest neutralino in direct dark matter experiments and to produce neutralinos and charginos at the furture ILC. So, I would encourage patience rather than the pessimism which is all too prevalent on this blog.

8. **Bob Jones**
June 26, 2013

I don't think there was ever a time when string theory was just an idea about unification. Back in the late 1960s when string theory first got going, it was a theory of nuclear physics. Applications of string theory to mathematics can be traced all the way back to the days of bosonic string theory. String theory also led to the systematic development of two-dimensional conformal field theory way back in the 1980s.

It's not right to say that the subject has "morphed" into something different. String theory has always been related to lots of mainstream topics in mathematical physics. Critics of string theory typically ignore this fact and focus on the more speculative aspects of the subject.

9. **P**
June 26, 2013

Hi Bob,

I absolutely agree. I think we're in agreement, then, that the talks at Strings 2013 are essentially all about, or at least heavily inspired by, string theory.

Since Peter didn't respond to my challenge: can you (or anyone else) find more than 5-10 of the ~40 talks that aren't actually about or inspired by strings?

10. **David M.**
June 26, 2013

Well using a broad definition of string theory I would say the following weren't exactly stringy talks:
Seibergs talk on 4d gauge theories seemed to me like a pure quantum field theory talk with connections to ST. I enjoyed it though, it highlighted the importance of line, surface, and higher dimensional operators in distinguishing different QFTs.

Komargodski's talk (previous version can be found here:https://sites.google.com/site/zoharswebsite/home/recent-presentations) looks to be on the same topic of SUSY QFTs as does Sunjay Lee's. Then theres Rychkov's talk about bootstrapping conformal field theories. The bootstrap program is obviously related to string theory via ads/cft and in his presentation at the String-Math conference he mentioned the possibility of bootstrapping 6d SCFTs, but direct applications to ST didn't come up this time.

Sara Pasquetti's talk looks like its based on a recent paper where string theory only came up because topological strings were used to derive the partition function of the 5d theory on a product of spheres, but once again seems to fall more under QFT then string theory.

So I would argue that Pasquetti, Komargodski, Seiberg, Lee,and Rychkov all had talks that were more field theory with connections and applications to ST then ST talks. Thats not to say I don't think they should be there, its all fascinating work with connections to string theory, but they do strike me more as QFT talks.

There is definitely a dearth of particle physics related talks. Cvetic is really the only one presenting on that subject. There were definitely more pheno talks last year, but given the lack of any good BSM news its not surprising either.

11. **P**
June 27, 2013

I also have Komargodski, Seiberg, and Rychkov not in the "string theory broadly defined" category, but one could argue for Lee and Pasquetti being within string theory for the reasons you mentioned, i.e. due to the usual ST SUSY gauge theory formal math interplay. But that's a matter of taste, I suppose.

12. **Shantanu**
June 27, 2013

Peter one more conference(although with no slides)
Bruno zumino 90th birthday fest
http://ctp.berkeley.edu/brunofest/Schedule.html

13. **tommaso dorigo**
June 27, 2013

Hello Peter,

thanks for mentioning the bet and its (logical, to me) conclusion. When I offered the wager, in 2006, I believe the large majority of my colleagues would have taken it. Now things have indeed changed dramatically. But let's review critically the situation now and then.

What is it that we did not know then and know now ? That large swaths of the MSSM space are ruled out ? That there are no Z' below a TeV ? That large extra dimensions were not just right there waiting to jump at us ?

The Tevatron had done a pretty decent job at showing that every bit of measurement was in accordance with SM predictions. But what really motivated me to offer the wager was observing the incredible agreement of low-energy observables in B physics, where new particles would have made their effects felt from quantum loops. I think we had all the hints that the LHC would be as successful as its predecessor LEP II in the same tunnel: deliver what it promised, and nothing more.

So if I look at the status of our knowledge then and now, I cannot see a qualitative difference. And indeed, that is why I was already reasonably sure we would not see new physics at the LHC. Of course, ready to be surprised, I put all my research time into sharpening the tools of CMS; but with a good dose of pessimism.

Why others had a different opinion ? Sure, theoretical indicia were important: the energy scale was the right one, if one believes naturalness arguments. But I think it has largely also been a sort of bandwagon effect. The LHC appeared such a beautiful new machine that it just was unthinkable it would fail to deliver what theorists assured us we'd find.

I urge everybody who sits in funding committees to consider quite soberly the new proposals of experiments and facilities. There is a large set of offers on the floor, but I believe it just is not the right time to take a decision now. We said we'd build the ILC with the right design parameters once we knew what SUSY particles we'd study. Now let's hold our horses for a few more years. As beautiful as LEP II was, what do we know from it that we would not know anyway without it today ?

Cheers,
T.

14. **Peter Woit**
June 27, 2013

Hi Tommaso,

Congratulations on your winnings!
I suppose I should have joined you in the bet. My own point of view pre-LHC was that things like SUSY and extra dimensions not only lacked any evidence from places they should have already shown up, directly or indirectly, but that they were (and are) badly motivated ideas. All of such models I've seen introduce large numbers of new parameters and new structure, while not giving any answers to the questions about the SM we don't understand. So, for purely theoretical and aesthetic reasons, besides the lack of indirect evidence, such things seemed highly unlikely to turn up at the LHC.

One reason I didn't join your side of the bet was that it was broader, including any deviation from the SM. In particular, since we had not seen the Higgs, it seemed to me not at all impossible that there was something about the Higgs mechanism we were missing, something that would explain all those parameters that come with the Higgs sector. Maybe once the LHC started seeing evidence of the Higgs sector, something non-SM at 5 sigma would be part of it. So far that hasn't happened, but that's what I wasn't willing to bet against back then (although I liked your argument that doing so would be win-win: either one got new physics, or some money).

I think the HEP community as a whole made a huge mistake allowing the LHC to be partially sold as a machine that would produce new dimensions of space (super or otherwise), black holes, etc. This was never going to happen, guaranteeing a heavy price to be paid in credibility down the road. The Higgs question though was very real, and more than enough to justify the project. If the LHC had been sold as purely a Higgs discovery and initial investigation machine, everyone would now consider it nothing but a huge success and if there's a sensible plan for a follow-on machine, it would be easier to get support for it.

To my mind, the big question about a future machine is whether there's an affordable one that can do a much better job than the LHC in studying the Higgs sector. I gather lots of people are working hard now at trying to figure that out…

"string theory unification is … no longer a central part of string theory research"

http://stringpheno2013.desy.de/e209876/

16. **Peter Woit**
June 27, 2013

division of labor,

Funny how in that division of labor the people not doing string phenomenology get the big yearly conference, the $3 million checks, professorships at Princeton/Harvard and completely freeze out the string phenomenologists, while the string phenomenologists get the small satellite conference.

From 2009, and I don't think the situation has gotten better

" I once heard someone say the shortest joke is "string phenomenology"."
http://resonaances.blogspot.com/2009/06/boston-tea-party.html?showComment=1244898346677#c4807554018314481181

17. **piscator**
June 28, 2013

"I think the HEP community as a whole made a huge mistake allowing the LHC to be partially sold as a machine that would produce new dimensions of space (super or otherwise), black holes, etc. This was never going to happen, guaranteeing a heavy price to be paid in credibility down the road."

I totally agree on this. This is also not the fault of string theory. For all the talk of string theory hype on this blog, over the last fifteen years the area of particle theory most guilty of prolonged and unsubstantiated hype is BSM. You can talk all you like about string unification, but string phenomenology papers do not have five thousand citations for failed models. Likewise, you will not find any speakers at String Phenomenology put forward to the public as great physicists of the age in the way that say Nima Arkani-Hamed or Lisa Randall are.

"Funny how in that division of labor the people not doing string phenomenology get the big yearly conference, the $3 million checks, professorships at Princeton/Harvard…"

Watch the future. The strings conference is declining. Take away the 100 locals from Korea, and it had less than 200 people attending. It used to have 500 people and close registration months in advance. The young have voted with their feet. Few young people do the formal mathematical physics that is represented at Strings, and there are almost no jobs in this area.

18. **billy**
June 28, 2013

Dear peter , Can you explain why are you hostile against string theory ?
I think that The theory is highly constrained mathematically , It claims to be a final theory so why should one expect that we should have results now ? I expect that the human quest for a fundamental theory of nature to take a huge amount of time . Don't you agree ? Second , Are all alternatives as satisfactory and well-developed as string theory is ? Why don't you think that string theory is on the right track ?

19. **Peter Woit**

June 28, 2013

billy,

I wrote a book to answer these questions. It was written ten years ago, but things haven't fundamentally changed.

20. **fuzzy**
July 20, 2013

Nice post, Peter!

In an old joke, a guy was sure he had lost his wallet in some dark street, but he was continuing to look under a lamppost, because it was easier. If we set the duality: HEP COMMUNITY="the guy"; BSM="wallet"; LHC = "lamppost" (and possibly DESPAIR="laughter") we have a picture of the way of proceeding in the last 30 years.

Note that I do not write intentionally what is dual to "dark street", but this is not because I lack valid proposals (e.g., NUCLEAR PHYSICS, QCD, ASTROPARTICLE PHYSICS…) but because I think that anybody, working in high energy physics, should take responsibility in offering the best answer he/she can, rather than following canned responses from somebody else.

Incidentally, I note that you, Peter, have suggested the answer "HIGGS PHYSICS" here above. I respect this proposal but I am not sure that I find it convincing, since I do not see any good theoretical reason that this should lead us to BSM.

Hiking the Appalachian Trail

June 28, 2013
Categories: Uncategorized

I'll be heading North tomorrow, ultimately ending up in backwoods Maine, hiking the Appalachian Trail, then back home after a week or so. The comment section here will likely be closed for the duration.

Progress is being made on my notes on quantum mechanics and representation theory, based on the course I taught this past year. About 3/4 done with the writing at this point, the latest version is available here.

   We know that you will actually be visiting your girlfriend in Argentina.

2. **Peter Woit**
   June 28, 2013

   Maybe, but first I have to pick up this suitcase from a friend of hers…

3. **King Ray**
   June 28, 2013

   Peter, thanks for posting a link to your book, it looks pretty good. You're very far along on it.

4. **Low Math, Meekly Interacting**
   June 28, 2013

   I grew up in Maine, and have hiked pretty much the entire ME AT in bits and pieces over the years. There are still stretches of the 100 Mile Wilderness I've yet to traverse, but it's on The List. If you're up there, don't skimp on the DEET. Hope your trip is enjoyable and the weather cooperates!

5. **El-Coco**
   June 28, 2013

   Please be safe on the trail, Peter.

6. **Peter Woit**
   June 29, 2013

   LMMI,

   Thanks, extra DEET was acquired yesterday. Will be up in the 100 Mile Wilderness, but actually planning more hanging around a lodge than strenuous hiking.

7. **Low Math, Meekly Interacting**
   July 9, 2013

   I was in the vicinity while you were in the Wilderness, with my family on the north end of Schoodic Lake to be precise. Sweltering heat for the region, soup-like humidity, and ravenous deer flies. If I didn't have a lake to jump into every hour to cool off I probably would have left. Hope one of the many beautiful ponds up there provided adequate post-hike relief!

8. **Peter Woit**
   July 9, 2013

   LMMI,

   Yes, I wasn't far away, at an AMC lodge on a lake called Long Pond, spent some time hiking nearby at Gulf Hagas, some time on the AT. Weather wasn't bad the days we were there, and bugs were just at the modest annoyance level. Started out with a few days in New Hampshire, where it rained all the time, and ended up with a couple days on the coast, which was pleasant, but hot for Maine I guess. All in all, a nice break from the city, but I'm glad to be back in bug-free Manhattan enjoying air conditioning…

9. **Vincent**
   July 11, 2013

   As a mathematician, I'm very happy that there is a book now called quantum mechanics for mathematicians! I have a question about the introduction, though.

   You write: `The strangeness inherent in quantum theory that Feynman was referring to has two rather di□fferent sources. One of them is the inherent disjunction and incommensurability between the conceptual framework of the classical physics which governs our everyday experience of the physical world, and the very di□fferent framework which governs physical reality at the atomic scale.'

   My question is: what is the other source? Maybe I misread you, but it seems that you use the rest of section 1.1 to explain what you mean by very different in the second sentence, but all this time I am still waiting for the disclosure of the other of the two rather different sources from the first sentence. Can you tell us what it is?

10. **Peter Woit**
    July 11, 2013

    Vincent,

    Thanks for pointing that out, it is really poorly worded. The material from the second paragraph onwards discusses the "second source" referred to, which is the different kind of mathematics basic to quantum theory as opposed to the classical theory. I’ll try and reword that soon, at some point later I’ll likely be rewriting the introduction more extensively.

No Joking Matter

July 8, 2013
Categories: Uncategorized

Back now from vacation, and while I was away several people sent me links to point out that string theory promoters definitely aren't taking a vacation. Links here with a few quick comments, followed by something about the issue of making fun of string theorists.

- Lenny Susskind has a quite good new book out about classical mechanics (see here), but the Economist doesn't want to talk to him about this, instead it's the usual string theory promotional effort:

  > These extra dimensions can be arranged and put together in many different patterns, in a variety of different ways. Not billions, trillions or quintillions of ways, but many more than that. The ways these dimensions are put together into these tiny little spaces determine how particles will behave, what particles will exist, what the constants of nature are—quantities like dark energy or the electric charge of an electron. In string theory all those things are features of the ways that these tiny dimensions are put together. The tiny dimensions are like the DNA of the universe.

- Last month Cumrun Vafa was in Bangalore, explaining (see here, slides here) among other things about the significance of the web of string dualities that makes up M-theory:

  > String dualities in my opinion perhaps the most fundamental discovery that physicists have made in a century.

  Note that the past century includes General Relativity (barely), quantum mechanics, gauge theory, the Standard Model, as well as quite a few discoveries in other areas of physics.

- The Strings 2013 conference included the usual public talks promoting string theory. Witten's was String Theory and the Universe, which was pretty much unchanged (minus optimism about SUSY at the LHC) from similar talks he has been giving for nearly 20 years (since 1995 and the M-theory proposal). Linde's was Universe or Multiverse?, about the "new scientific paradigm" of Multiverse Mania. He argues that the virtue of this is that it is "impossible to disprove".
- David Gross's public talk on The Frontiers of Particle Physics had nothing to do with string theory, focusing on explaining the standard model and some of the questions it leaves unanswered. Much more interesting was his outlook talk at the conference which included the usual exhortations about string theory being alive and healthy, flourishing with many new and brilliant string theorists, but also included some material unusual in such a venue and much more challenging for his audience. His reference to connections between string theory and condensed matter physics described this as having been "overhyped by our community". About AdS/CFT, he noted that it "does not provide a satisfactory non-perturbative quantum gravity".

  He commented on the lack of connection between the talks and HEP physics, saying that it was "important that string theorists not retreat into quantum gravity". About SUSY, he characterized it as "still alive, but not kicking", and he argued that the LHC results of the past year have made more likely the "Extremely pessimistic scenario" of an SM Higgs, no SUSY, no dark matter, no indication of the next energy threshold. Since "HEP is where string theory connects to reality", he made the point to the audience that "if this scenario materializes we are all going to suffer."

  I'm not sure why he picked this date, but he encouraged those with post-1999 Ph.D.s to realize that it was now quite possible that those who came before them had "somehow got it wrong". This was the first time I've seen an influential member of the string theory community raise this possibility and call for people to consider it seriously.

- Sean Carroll deals here with arguments from the "Popperazi" that the string theory anthropic multiverse is pseudo-science by ignoring the serious arguments being made. He has his own definition of what science is, which looks to me to open far more questions than it answers. About string theory unification itself, the question has never been whether it's science, but whether it's an idea worth pursuing given the ways in which it has so far failed. The best argument for continued pursuit of the idea is of course that there aren't obviously better ones around, but this raises its own issues.

Sabine Hossenfelder has a posting about an introduction to a Lawrence Krauss talk where the joke was made that "String theorists have to sit in the back". The context for this was a controversy about the place of women at a discussion involving Krauss hosted by an Islamic group. Like Sabine, I don't want to discuss here that controversy, just agree there's a good case to be made that it's no joking matter. I think she makes a mistake by interpreting the joke as an attack on string theorists (it's a joke, after all, open to many interpretations), but I was struck by her perception of string theorists as an embattled minority under unfair attack, as well as the claim that it's not all right to in any way make fun of them.

The situation these days is clearly very different than it was back in 2004 when I started this blog, partly because of the past decade of failure of string theory unification to get anywhere, partly because of the negative LHC results, partly because of the multiverse, and partly because of the public behavior of some in the string theory community in reaction to criticism. Given the high profile ongoing promotional campaign exemplified above, I don't think we're yet at the point where criticism of string theorists is "kicking them when they're down", and humor is sometimes the best way to make a point concisely. Probably the most incisive criticism of string theory ever made was made in a cartoon, and personally I've never understood how it is even possible to take arguments like Linde's seriously (and am not even sure he does…), so I see a role for humor in charting the continuing story of the collapse of the heavily influential string theory unification paradigm.

Update: If you noticed more than the usual sloppiness, incompleteness and incoherence, maybe it was because this got published early, while I was in the middle of writing it.

Update: The latest on the philosophy of science from Linde (see here), who is at a workshop in Bad Honnef this week.

> The multiverse is the only known explanation so in a sense it has already been tested

Is it all right to make fun of this, or should one seriously discuss the scientific merits here?

Comments

   July 8, 2013

   Wired Online magazine has a new ST related story you may want to look at http://www.wired.com/wiredscience/2013/07/hidden-particle-world/

2. **Peter Woit**
   July 8, 2013

   Thank Tim,

That's a well-written article, but I'm no condensed matter expert, so will leave the question of what fraction of the claims discussed are over-hyped to the experts (and David Gross…).

A few years ago, there were a lot of similar claims being made about string theory and heavy-ion physics, but those seem to have suffered from a pretty high hype level, with the ideas involved not working out very well (this topic disappeared at String 2013, from what I can see).

3. **David M.**
   July 8, 2013

   The post 1999 Ph.D comment was made because of one slide in Jeff Harvey's talk where he mentions a disconnect between the older and younger generations of string theorists (a year he also admitted to being arbitrary). Harvey's overview was interesting, he also noted that the AdS/CMT work, although not the panacea some people claimed it might be, was making more concrete progress. I don't think Gross or Harvey were happy that more people are working on AdS/CMT rather then AdS/QCD, but it really is a matter of where progress can be made as opposed to where they wish it could be made.

4. **Anonymous coward**
   July 8, 2013

   1997-98 was when the AdS/CFT breakthrough happened. Gross might choose 1999 as the dividing line if he wishes to club AdS/CFT with (stringy) physics of the generation past.

5. **CIP**
   July 8, 2013

   If, however implausibly, string theorists *were* sent to the back of the bus, it wouldn't a prejudice, but an a posteriori judgment on their past sins against modesty and civility.

6. **B.B.**
   July 8, 2013

   I hope that this change in attitudes will also be translated to other things. In his book "Strange Beauty" George Johnson tells an amazing story about the role of James Bjorken in the recognition of quarks as actual particles, so I thought – here is a guy who actually deserves the Fundamental Physics Prize… Did he fall off people's radar for some reason, or does he still have a chance?

7. **Peter Woit**
   July 8, 2013

   B.B.,

   While Gross is changing a bit his tune in response to experimental results from the LHC, he's not an FPP winner, and has no vote there. Linde and Witten are, and they haven't changed their views at all as far as I can tell. The thing which is going to change the FPP choices in the future is the addition of a large number of experimentalists to the group making the choices (due to the LHC special award this year). I have no idea how that will play out.

   Unless there's some news about the FPP, it's kind of off-topic here (as well as the work of Bjorken nearly a half-century ago), so I encourage commenters to stick to comments related to the posting.

8. **nasren**
   July 8, 2013

   Just read Sabine Hossenfelder's blog post and all the comments. At least in the comments she makes it clear that she doesn't approve of string theory hype any more than string theory derogation. It's the interference in the process of rational assessment she is objecting to. But on this I have to say she is alarmingly late to the party: [*irrelevant material about Krauss deleted*]. I have to agree with one of the commentators: string theorists are now reaping what they sowed when for so long they promoted their theory on the back of zero experimental support. That was never going to end well, and now we are seeing that. Reaper, whirlwind…

9. **Anonyrat**
   July 9, 2013

   I am confused by Sean Carroll's statement that the existence of gauge theory is (crude) data that is explained by string theory. Could one not equally well assert that the existence of fermion and bosons are data explained by string theory?

   If the existence of gauge theory QFTs is indeed explained by string theory (but string theory has no Wilsonian definition) then should not string theory also explain why and how the Wilsonian ideas work?

10. **Bee**
    July 9, 2013

    I didn't interpret it as an "attack", this makes it sound way too aggressive and also way too important. I interpret it as a representation of public opinion, basically. The guy is a semi-popular figure and he was trying to make a joke (funny or not) that he thought would appeal to the audience.

    I just don't think ridicule is going to be conductive to scientific inquiry. I would prefer if both the public as well as young students have a chance to get an objective impression of the situation.

    Your blog has added, and still adds, criticism that had been lacking. Of course criticism is always unpleasant for some people which isn't nice, but then nobody says that science has to be nice. This is fine with me, but criticism is only useful though when it has content and I don't want stupid jokes to affect people's opinions. That's all.

11. **Bee**
    July 9, 2013

    Nasren, I've been writing since at least 2006 about the problem that the public opinion affects researcher's decisions, that this problem is becoming larger due to the increased connectivity of our social networks generally and the scientific community specifically, and that I don't think this is good. This isn't a new theme on my blog, if you care to look. But yeah, I'm late to the party, sorry for not having been around to comment on the elan vital.

12. **Peter Woit**
    July 9, 2013

anonyrat,

Sean's argument that "string theory explains gauge theory" is, for good reason, not one that string theorists typically use, and I don't know why he's using it, especially in the context of trying to explain what the scientific method is.

Bee,

I think we're in agreement about the importance of having objective arguments on all sides available, and that's something I've tried to provide, in a situation that, way back when, was dominated by a one-sided public relations campaign. More recently, both sides of arguments about string theory have gotten an airing, and I think the joke you reacted to was just motivated by someone noticing that there was a controversy, which is not a bad thing. About the use of ridicule, I think it's a problem when used to deal with serious arguments, appropriate when used to deal with ridiculous ones. Undoubtedly I make mistakes, but I hope that I mostly get right which is which.

I just saw your posting about Occam's razor, and one thing that struck me about Sean's definition of science is that this plays no part in it. It's true that in some contexts one has to be wary of the principle and it may not be appropriate. But I do think it's a very fundamental part of the scientific method. One thing it does is tell you about a sort of pseudo-science you have to watch out for, theories that don't actually explain anything, bad models where you just add complexity to keep them out of trouble with experiment. Linde's promotion of a new paradigm where you deal with explaining things by saying anything can happen in your theory, (and claim that as a virtue, crossing the line into the ridiculous) is an indication of where you end up if you think Occam's razor is worthless.

13. **John Urbanik**
July 9, 2013

""Extremely pessimistic scenario" of an SM Higgs, no SUSY, no dark matter, no indication of the next energy threshold."

The above sentence really struck me. Especially the part about 'no dark matter'. Does this actually mean that dark matter is not real and therefore the composition of the universe is wrong? Or does it mean something else?

Does MOND or TeVeS now more to the front? Or am I reading way to much into those three words?

14. **Peter Woit**
July 9, 2013

John,
He was just referring to the (all too real) possibility of no heavy WIMP dark matter particle showing up in the LHC data or the direct detection experiments, a possibility that has always been part of the hope for new physics at the LHC scale, SUSY and other wise. One alternative he mentioned was axions. I'd rather not start a discussion of dark matter alternatives here, that's a very different topic.

15. **cormac**
July 9, 2013

On the ST comment, I too thought it was a silly joke of no significance from a non-physicist looking for a quirky comment.
There is another important lesson here – Chairs should leave humour to the speaker, because you don't know what might offend your visiting speaker. It would have been an awkward talk if Larry had reacted the way Bee did!

16. **Bob**
July 9, 2013

Seen this? Apparently SUSY can't be seen at LHC but can at ILC. Now I understand …

http://phys.org/news/2013-07-ou-physicists-rationale-next-generation-particle.html

17. **nasren**
July 9, 2013

Apologies Bee. I suppose it just seemed to me that a mild joke that was mostly against religious irrationality, not string theory, was a strange thing to protest when there is daily a huge amount of hype emanating from multiple sources. It seemed like a strange point to draw the line.

18. **Peter Woit**
July 9, 2013

Bob,
A good candidate for "This Week's Hype" and further evidence that all university press releases about HEP theory are outrageous hype.

It will be interesting to see if anyone seriously tries to convince the Japanese government to spend the many billions an ILC will cost using this kind of argument.

19. **T.G.**
July 9, 2013

Peter, sorry for being off topic. Maybe in one of your future posts you can mention this poll: https://sites.google.com/site/fieldsmedal2014poll

20. **EDBM**
July 10, 2013

> Linde's was Universe or Multiverse?, about the "new scientific paradigm" of Multiverse Mania. He argues that the virtue of this is that it is "impossible to disprove".

I am currently unable to view the talk using the link (very slow loading for some reason), so I have to ask: With such an attitude, what would hinder me to postulate some omnipotent Creator that moves all the particles in the Universe according to his whim, or that he (Linde) is a brain-in-a-vat? I find it difficult to believe that a physicist would make a statement to that effect…

21. **P**
July 10, 2013

Bob,

Baer has been working on supersymmetric theories which are "natural" in the sense of having a very low mu term down between 100 and 200 GeV. This sets the scale of the Higgsino mass; these fermions are vector-like, uncolored, and extremely difficult to find at LHC. There is signficantly better prospect of finding them at a lepton collider like ILC, particularly given that Baer's favorite mass range is below the proposed ILC center of mass energy.

Whether that warrants another collider (which is probably going to happen anyways) is a matter of taste, but the science is solid. Peter is right that university press releases are overhyped, but it's best to get the facts and understand the science before making condescending remarks; sometimes they are warranted, but other times they expose ignorance.

Cheers,
P

22. **anon.**
July 10, 2013

but the science is solid

No, it's disingenuous. Naturalness (at least in the MSSM and simple extensions thereof) does require light Higgsinos, but it *also* requires light stops and light-ish gluinos, and the LHC is doing a depressingly good job of ruling those out without any help from an ILC. This attempt to refocus on tree-level naturalness and handwave away the loop corrections just doesn't make sense. In general, a lot of the Snowmass process involves people distorting physics to reach the conclusions they want about the future of the field.

23. **anonymous**
July 10, 2013

I noticed an upcoming talk entitled "The Standard Model is complete" in the "New directions in Theoretical Physics" part of the linked conference. We'll have to wait and hear what is said…

24. **Peter Woit**
July 10, 2013

T.G.,
Thanks, that's a topic undoubtedly to come up in the next year.

anonymous,
There may not be much meant by this title other than a reference to the fact that the LHC has discovered the last part of the Standard Model (the Higgs).

25. **P**
July 10, 2013

anon,

Large regions of soft-breaking parameter space are better constrained by a lepton collider than LHC, period, end of story. If you're motivated purely by naturalness then yes, the stop mass is the most important quantity, but as you know a theory with a 10 or 50 TeV stop is a heck of a lot more natural than a theory with no cutoff whatsoever.

Bottom line, you're wrong: it is not disingenuous to discuss how certain experiments might be better for ruling out certain parts of parameter space than others. In fact, it's required, and it's science. Baer's scenario is not my cup of tea, personally, but it's easier to probe light Higgsinos at ILC. There is no question here.

P

26. **Chris W.**
July 10, 2013

Maybe somebody should sit Andrei Linde down and point out the similarity of his remarks to the pseudo-scientific apologetics for Marxism under the Soviets throughout much of the 20th century. You would think he would have the sense to steer *way* clear of that crap.

27. **anon.**
July 10, 2013

Bottom line, you're wrong: it is not disingenuous to discuss how certain experiments might be better for ruling out certain parts of parameter space than others.

I agree with your statement, but that's not what's happening here. The point is that the only argument for Higgsinos being light enough to be in ILC range is naturalness, and it's disingenuous to use naturalness as an argument without noting that the LHC is already putting the whole scenario under strain. It's true that the ILC is a great machine for discovering light Higgsinos, but if you give up on naturalness the Higgsinos could be anywhere from 100 GeV to many TeV, and the ILC covers only a fraction of that range. If all that was happening here is that people were noting that the ILC is better for "certain parts of parameter space", I would have no problem with it. The trouble is the argument attached to favoring those parts of parameter space.

28. **Adam Treat**
July 10, 2013

Hi Peter,

I read with interest Sean Carroll's blog post ostensibly in defense of multiverse theory as a sound scientific pursuit. After setting up his own three-part proto-definition of 'science' which is sorely lacking in many key facets, he goes on to lambast those who have other demarcations. Specifically, three:

1) Science assumes naturalism
2) Science requires falsifiable theories
3) Science requires reproducible experiments

He then makes a rather astounding boast, "…each one of these is straightforwardly false."

This is where his blog post became very interesting for me. I was intrigued to hear how he might straightforwardly demonstrate the error with these claims.

He didn't even come close.

In fact, he backed down almost immediately when it came to the falsifiability claim. He said it was a tricky claim and he couldn't/wouldn't do it justice let alone straightforwardly demonstrate it to be false. His argument against the falsifiability criterion seems to be something like – well, String theory and Multiverse theory are just different from other non-falsifiable theories because it is "clearly are saying something concrete about the world." And also because people who are employed as Scientists are studying it so therefore it must be science.

He totally took a copout. As Sean probably well knows, the problem with the landscape is that it isn't falsifiable *even in principle* and not just because we lack the experimental apparatus to test its claims.

Anyways, he offers much much less than his boast of a straightforward refutation of the falsifiability criterion as a limit on the definition of science. The same goes for his supposed refutation of reproducible experiments. The point is that an experiment must at least be reproducible in principle.

I think the multiverse proponents should learn something from the religious apologists. They could teach them a thing or two. This apologia for multiverse theory is not up to snuff.

29. **Chris W.**
July 10, 2013

> I think the multiverse proponents should learn something from the religious apologists. They could teach them a thing or two. This apologia for multiverse theory is not up to snuff.

Adam, the trouble is that they're acting like they have apparently learned something from the religious apologists, namely, that such apologetics are acceptable as well socio-politically expedient—this is what you do to defend what you "know" to be the truth. As I mentioned, many Marxists once upon a time routinely indulged in a similar practice; presumably a few still do. (Apologetics for capitalism are more in vogue these days.)

I share your disillusionment with Sean Carroll's attempt to defend this position. That said, I suppose he has done us all a service by giving it his best shot and coming up so short. That's one way to realize that such a position simply isn't defensible.

30. **CIP**
July 11, 2013

Bee,

I think the notion that ridicule has no place in scientific debate is extremely naive. Ridicule is appropriate when somebody makes ridiculous claims. If you are offended by the kind of sharp elbows debate that can be seen now, you are really lucky that you weren't around for the great quaternions vs vectors debate a bit over a century ago – not to mention almost all of the scientific debates before and since.

As Peter has been mostly very politely pointing out for years, string theory has often been eager to make claims it couldn't back up. These claims influence public opinion, funding, and faculty appointments. When they are false, they deserve to be corrected forcefully.

31. **Fred P**
July 11, 2013

"Is it all right to make fun of this, or should one seriously discuss the scientific merits here?"

In a setting where the presumed reader has some basic knowledge of science (such as this blog), I'd say it's perfectly fine to make fun of this statement. However, were I writing to a more general audience, I probably would bother to write 2-3 sentences explaining why this is a ludicrous statement.

32. **GoletaBeach**
July 11, 2013

You got me to watch Gross' conference summary. I thought he was a bit more balanced than you portray… he presented the optimistic scenario, did say that entire (which heavily leans on low energy breaking of SUSY) package was alive but not kicking.

I thought, did it ever kick? It was always a sleeping princess waiting for an experimental prince to kiss it and animate a kick.

But as he emphasized, there is a continuum all the way to the extreme pessimistic scenario. The data will decide, but he nicely emphasized that creativity in suggesting new experiments is called for. Of course, some of the best experimentalists, from Luis Alvarez to Mel Schwartz to Burt Richter have been saying that for 30 years at least.

33. **Jim Akerlund**
July 12, 2013

Goletabeach,

It is not that Peter portrayed Gross' speech in an unbalanced way. The way I see it, Gross said there might be a door to non-string theory that Peter has been advocating these many years, and Gross has finally admitted it's possible existence. And this speech occurred in "Strings 2013". That is a sign of a change.

Jim Akerlund

34. **anonymous**
July 12, 2013

Though true, I do find a slight bit of irony in how "completeness" could be listed in the "new directions" section. The ambiguity of the title makes it all the more enticing. There are plenty of other post-Higgs talks in the same conference that presumably cover that material.

35. **Bob Jones**
July 12, 2013

"About the use of ridicule, I think it's a problem when used to deal with serious arguments, appropriate when used to deal with ridiculous ones."

The problem is that you usually don't consider any serious arguments on this blog. You find the most ridiculous press releases and act like they describe everyone in string theory. There are good reasons for taking string theory seriously as a theory of everything, and even if it's not a theory of everything, it has proven to be a useful framework for solving lots of other problems. You do your best to ignore this fact on your blog, but it's the main problem with your thesis. It just doesn't make sense to put down an entire field when it has proven successful in so many ways.

36. **Peter Woit**
July 12, 2013

Bob Jones,

In my book and here, I think I address seriously serious arguments for string theory (as well as ridiculing some of the ridiculous ones). I'd be curious to hear of any serious press releases about progress in string theory that I've ignored.

One of the main problems with string theory is that the leadership of the field has pretty much uniformly refused to engage seriously with the issue of the very real and dramatic failures of the string theory unification program, preferring to keep repeating the same hype, trying to pretend they don't have a problem. As long as this goes on, others should point this out.

37. **Shantanu**
July 13, 2013

Peter, interested n your views in yet another LHC related meeting at KITP
http://online.kitp.ucsb.edu/online/lhc-c13/

38. **Thomas**
July 13, 2013

"successful in so many ways" Is this a joke ?

39. **Peter Woit**
July 13, 2013

Shantanu,
Thanks. I did get a chance to look at the Lykken summary talk, which seemed to be quite good.

40. **Bob Jones**
July 13, 2013

Thomas,

You wouldn't know it from reading this blog, but yes, string theory has been successful in many ways.

It doesn't matter whether string theory is a correct fundamental theory because string theory has some general features that are expected to hold in any successful theory of quantum gravity. For example, string theory provides several concrete realizations of the holographic principle. It has taught us conceptually how black hole entropy can be accounted for by microscopic degrees of freedom in a theory of quantum gravity. These results are interesting because they depend only on the general features of string theory, not the specific details.

But even if string theory had nothing to do with gravity, it would still be interesting because of its connections to quantum field theory. For example, string theory has shed light on the mathematical properties of scattering amplitudes in gauge theories. It provides a tool for studying strongly coupled quantum field theories, and there are now probably hundreds of papers which use string theory methods to understand aspects of nuclear and condensed matter physics. More generally, string theory predicts a web of relationships between different quantum field theories, and by understanding these relationships, physicists have developed new ways of computing quantities of physical interest. Again, these results are all true and interesting regardless of whether string theory provides a correct theory of everything.

Finally, even if string theory had nothing to do with physics, it would still be important because of its applications in pure mathematics. The dualities discovered by string theorists imply profound relationships between seemingly different mathematical structures. It was string theorists who first discovered mirror symmetry, a powerful new tool in enumerative algebraic geometry. Methods from string theory were used in Borcherds' proof of the monstrous moonshine conjecture, and string theory has inspired new mathematical ideas, like the notion of a stability structures on triangulated categories.

41. **Yatima**
July 14, 2013

Well, that discussion has already happened at

Farewell To Reality – Comment Section

… Bob Jones vs. The Rest.

42. **DrDave**
July 14, 2013

"You wouldn't know it from reading this blog, but yes, string theory has been successful in many ways."

One interesting thing to do when reading, especially stuff in politics, is turn the sentence around so that it says the opposite, and see if it makes more sense that way. So in this case, "If you read this blog, you will see that string theory is a failure" is actually more true than the original sentence.

"It doesn't matter whether string theory is a correct fundamental theory because….."
In this case, you can supply any word after the "because" but it won't change the meaning of the sentence, which is also cool.

43. **logical mind**
July 14, 2013

So DrDave, applying your principle, that means that the new sentence is actually less true than the original?

44. **P**
July 15, 2013

Dr. Dave,

Very clever! Your silly argument kept you from dealing having to deal with Bob Jones' point.

I’ll give you the benefit of the doubt, though, and assume you have good reasons for your strong statements. Please, explain to us how string insights into AdS/CFT, mirror symmetry, or QFT dualities have been a failure.

45. **Peter Woit**
July 15, 2013

All,
Please, unless someone has something interesting to say about the actual topics in the posting, enough. The only thing in the posting about string dualities was Vafa’s claim that they’re the most fundamental discovery in physics of the past century, I suppose those who want to claim them as the main success of string theory could address the question of whether they agree with Vafa.

46. **William ML Leslie**
July 19, 2013

In flagrant violation of your request that comments be on-topic, may I point out that labelling your links ‘here’ makes them a little more difficult to grab with a keyboard-driven browser or assistive technologies? It’s a minor nit but I’ve been meaning to mention it for a while.

Otherwise, the multiverse is an answer to a philosophical objection, I don’t even think it was supposed to describe any physical effect. It’s neither science, nor useful.

- I confess to mostly finding "philosophy of physics" arguments not very helpful for understanding anything, but for those who feel differently, some new things to look at are a Scientific American article Physicists Debate Whether the World is Made of Particles or Fields or Something Else Entirely, an interview with Jonathan Bain, an interview with Tim Maudlin, a debate between John Ellis, Lawrence Krauss and theologian Don Cupitt about Why is there something rather than nothing?, and the talks at a UCSC Philosophy of Cosmology Summer School. Since the last of these was funded by the Templeton Foundation, it ended with several talks on "Implications of cosmology for the philosophy of religion". These included a detailed argument that the explanation for the laws of nature is "there is a perfect being", contrasting this to another argument favored at the Summer School "the multiverse did it".
- This week the Perimeter Institute will host Loops 13, devoted to loop quantum gravity and other quantum gravity approaches. While it's also funded by Templeton, the organizers seem to have managed to keep God out of this one.
- At CERN, Amplitudes, Strings and Branes is on-going. Philip Gibbs has an amusing argument that this and Loops 13 are The Same Bloody Thing.
- One thing the LQG and Amplitudes people do share is that some of their most important ideas come from the same person: Roger Penrose (who, but the way, would be a good candidate for the Fundamental Physics Prize, although his distaste for string theory might be a disqualifier). There's a long interview with him at The Ideas Roadshow, mainly about his "Cyclic Universe" ideas.
- The Simons Foundation has been publishing some excellent science reporting, and now has an online publication they're calling Quanta Magazine. The latest story there is a very good piece on the search for dark matter from Jennifer Ouellette. The Simons Center at Stony Brook now has a newsletter about their activities.
- Another on-going conference is one of the big yearly HEP conferences, EPS HEP 2013 in Stockholm. CMS and LHCb have impressive new results about rare B decays, timed for this conference. For the details, see Tommaso Dorigo. There are also CMS and CERN press releases.

  Last year similar but less accurate results were advertised as putting SUSY "in the hospital", which some people objected to, on the grounds that it was already in trouble and this kind of result doesn't make things much worse. Resonaances had the details, summarizing this a "another handful of earth upon the coffin". The CERN press office tries to put the best SUSY spin on this that it can:

  > One popular theory is known as supersymmetry, SUSY for short. It postulates the existence of a new type of particle for every Standard Model particle we know, and some of these particles would have just the right properties to make up a large part of the dark universe. There are many SUSY models in circulation, and SUSY is just one of many theoretical routes to physics beyond the Standard Model. Today's measurements allow physicists to sort between them. Many are incompatible with the new measurements, and so must be discarded, allowing the theory community to work on those that are still in the running.

- Finally, for those with mathematical interests who have waded through the above, Terry Tao has a remarkable long expository piece about the Riemann hypothesis, ranging from analytic number theory aspects through the function field case and l-adic cohomology.

Update: For more from Penrose, see this recent talk in Warsaw.

Update: Studies in History and Philosophy of Modern Physics is planning a special issue on the significance of the Higgs discovery, the call for papers is here.

   There was an extra http:// at the end of Peter's link.

5. **Nick M.**
   July 20, 2013

   Terry Tao has more grey matter in the very tip of the nail of his little pinky finger than I have in my entire head! How he finds the energy and time to write with such breath and wherewithal on such a large variety of math related topics is beyond me.

   –Nick

6. **Peter Woit**

July 21, 2013

Tao link fixed.

David,
I was staying near Gulf Hagas, in the 100 mile wilderness in Maine. Only did a few miles of hiking on the Appalachian trail, nothing strenuous. Trail a bit muddy in places, but not too bad. No black flies, a bit late for them, and evidently this year a late frost took care of most of them.

7. **lucretius**
July 21, 2013

The "Perfect Being" should really be "The Best Imaginable Being", i.e. a maximal element in the set of all imaginable beings ordered by the "goodness" of their imaginable properties. One can then easily show that the existence of such a being is equivalent to the Axiom of Choice (this is a mathematical formulation of the so called "ontological argument"). That means that the existence of this "Perfect Being" is undecidable (from the Zermelo-Fraenkel axioms), a fact that was already essentially known to Hume.
PS. This is not meant "seriously". But a lot of serious people have discussed this issue quite seriously http://en.wikipedia.org/wiki/Ontological_argument

Dear Peter,

Many thanks for mentioning the Loops 13 conference. I might mention that the 21 plenary talks and more than 130 parallel session talks will be available on line at http://www.pirsa.org/C13029. This year we saw an increase of registrations for LQG conferences to more than 220, which is evidence for the growing vitality of the field. Indeed the majority of our plenary speakers are young and have not given a plenary talk at a loops conference before, they will report on the strong progress in areas such as black hole entropy and temperature, quantum cosmology, phenomenology and increased understanding of the emergence of general relativity in the classical limit.

Thanks,

Lee

July 21, 2013

Dear Peter,

thanks for mentioning my coverage of the Bs – Bd search in dimuon final states. I have added a discussion of the two Bd measurements (both at 2-sigma, from CMS and LHCb) today. They can be of interest for believers of the SM4 model (four generations).

Personally I don't buy into that stuff much, especially after we found a Higgs-like particle that smells like the Higgs and does couple to photons and has the correct production rate (a fourth generation of fermions would spoil both things). But I have to say that among all extensions of the SM the presence of additional generations of matter is the one which I found the most credible, so I'll keep my eyes open. For the record, both CMS and LHCb measure the Bd rate to μμ pairs to be 3.5 times the SM expectation, albeit with big error bars. A SM4 model would easily fit this in, with a Bs rate equal to the SM one.

Hope you're having a relaxing summer,
T.

July 22, 2013

I think the interview with Jonathan Bain is very interesting, many thanks for the link. Re "philosophy of physics arguments not very helpful for understanding anything", I think philosophy can be useful in understanding and articulating the assumptions one is already making. There are many points in the history of 20th century cosmology where a small examination/attempted justification of underlying assumptions could have been beneficial, from Einstein's static universe to Hoyle's steady-state

14. **Anonyrat**
July 22, 2013

Regarding Tim Maudlin, this is interesting:

> further believe that physicists have been misled by the mathematical language they use to represent the physical world. Temporal structure is part of (maybe all of!) the geometry of space-time, and the standard mathematical description of geometrical structure was developed with purely spatial structure in view. Space, unlike time, has no directionality and the mathematics developed to describe spatial geometry does not easily or naturally represent directionality. The project I have been working on for the past few years involves replacing that mathematical language (standard point-set topology) with a new mathematical language called the Theory of Linear Structures. In the Theory of Linear Structures the possibility of an intrinsically directed geometry arises naturally. If one rewrites Relativistic physics in this mathematical language, the intrinsic directionality of time stands out.

It turns out slated for February 2014, is the first of Maudlin's two planned books on Linear Structures. 'New Foundations for Physical Geometry: The Theory of Linear

Structures',

http://www.amazon.com/New-Foundations-Physical-Geometry-Structures/dp/0198701306

The book description is:

"Topology is the mathematical study of the most basic geometrical structure of a space. Mathematical physics uses topological spaces as the formal means for describing physical space and time. This book proposes a completely new mathematical structure for describing geometrical notions such as continuity, connectedness, boundaries of sets, and so on, in order to provide a better mathematical tool for understanding space-time. This is the initial volume in a two-volume set, the first of which develops the mathematical structure and the second of which applies it to classical and Relativistic physics. The book begins with a brief historical review of the development of mathematics as it relates to geometry, and an overview of standard topology. The new theory, the Theory of Linear Structures, is presented and compared to standard topology. The Theory of Linear Structures replaces the foundational notion of standard topology, the open set, with the notion of a continuous line. Axioms for the Theory of Linear Structures are laid down, and definitions of other geometrical notions developed in those terms. Various novel geometrical properties, such as a space being intrinsically directed, are defined using these resources. Applications of the theory to discrete spaces (where the standard theory of open sets gets little purchase) are particularly noted. The mathematics is developed up through homotopy theory and compactness, along with ways to represent both affine (straight line) and metrical structure."

15. **lucretius**
July 22, 2013

This is the first time I have heard of Tim Maudlin and his "linear structures" so this may be way off the mark but the description above sounds like they could be related to directed algebraic topology, a subject that has been around for a couple of decades.
http://en.wikipedia.org/wiki/Directed_algebraic_topology

16. **lucretius**
July 22, 2013

Actually, I just realised, it was not "the first time" … 😉

17. **Peter Woit**
July 22, 2013

I had noticed that work of Maudlin's, for more, see for instance
http://fqxi.org/data/documents/conferences/2011-talks/maudlin.pdf

Somehow the idea seems to be that replacing the standard mathematical conception of topology (in terms of open sets), by something quite different Maudlin has come up with, he can explain the nature of time. I don't see that he gets anything out of this. Interesting though that one way to get the time and freedom to pursue radically different ideas about mathematics and physics that you'd never get a math or physics department to support, is by becoming a philosophy professor.

Where are we heading?

July 23, 2013
Categories: Multiverse Mania

Every summer the IAS in Princeton runs a program for graduate students and postdocs called "Prospects in Theoretical Physics". It's going on now, with this year's topic LHC Physics. Much of the program is devoted to the important but complex technical issues of extracting physics from LHC data. Things began though with a talk on Where are we heading? from Nati Seiberg designed to explain to students how they should think about the significance of the LHC results and where they were taking the field.

Most of the talk was about the hierarchy problem and "naturalness", with the forward-looking conclusion the same one that Seiberg's colleague Arkani-Hamed has been aggressively pushing: the main significance of LHC results will be telling us that the world is either "natural" (likely by discovering SUSY) or "unnatural" (in which case there's a multiverse and it's hopeless to even try to predict SM parameters). Given the negative results about SUSY so far, this conclusion pretty much means that the students at the IAS are being told that the LHC results mean it's the multiverse, and they shouldn't even think about trying to figure out where the SM comes from since that's a lost cause. The talk ends with the upbeat claim that this is a "win-win situation": reaching the conclusion that the LHC has shown we can't learn more about where the SM came from will be a great scientific advance and "The future will be very exciting!". Seiberg does at one point make an interesting comment that indicates that he's not completely on-board with this conclusion. He notes that there's a "strange coincidence" that theorists are making this theoretical argument about the necessity of giving up at just exactly the same time in our history that we have run out of technological ability to explore shorter distances. A "strange coincidence" indeed…

For more conventional wisdom along these lines, see Naturally Unnatural from Philip Gibbs, which also argues that what we are learning from the LHC is that we must give up and embrace the multiverse.

Frank Wilczek has just made available on his web-site a new paper on Multiversality. It has the usual arguments for the multiverse, although unlikes Seiberg/Arkani-Hamed he doesn't try to claim that this is an exciting positive development, closing with a "lamentation":

> I don't see any realistic prospect that anthropic or statistical selection arguments – applied to a single sample! – will ever lead to anything comparable in intellectual depth or numerical precision to the greatest and most characteristic achievements of theoretical physics and astrophysics…
>
> there will be fewer accessible features of the physical world for fundamental theory to target. One sees these trends, for example, in the almost total disconnect between the subject matter of hep-th and hep-ex.

and a "warning

> There is a danger that selection effects will be invoked prematurely or inappropriately, and choke off the search for deeper more consequential explanations of observed phenomena. To put it crudely, theorists can be tempted to think along the lines "If people as clever as us haven't explained it, that's because it can't be explained – it's just an accident."

He does see possibilities for understanding more about the SM in two places, the SUSY GUT unification of couplings and axions as an explanation of the smallness of the QCD theta parameter. The last part of the paper is about axion cosmology and anthropics. Wilczek has written about the stories of the 1981 origin of the SUSY GUT unification argument and the 1975 birth of the axion. It's striking that we're 32 and 38 years later without any idea whether these ideas explain anything. A depressing possible answer to "Where are we heading?" would be an endless future of multiverse mania, with a short canonical list of ancient, but accepted ideas about fundamental theory (SUSY Guts, string theory, axions) that can never be tested.

Comments

1. **vmarko**
   July 23, 2013

   Given the negative results about SUSY so far, this conclusion pretty much means that the students at the IAS are being told that the LHC results mean it's the multiverse, and they shouldn't even think about trying to figure out where the SM comes from since that's a lost cause.

   This is extremely bad from an educational point of view. This doctrine of giving up on attempts to explain the SM is horrible even for seasoned scientists, let alone students!

   I am just hoping someone outside string theory will get a flash of inspiration and propose a method to predict at least one coupling constant in terms of the others, for example. If this happens, and if that prediction turns out to be numerically correct, it will be a straight slap in the face to all multiverse/anthropic hype. That is, in addition to being a revolutionary theoretical discovery.

   Best, 🙂
   Marko

2. **Zathras**
   July 23, 2013

   I am surprised the "Where are we heading" talk made such short work of dark matter. With the death of SUSY it would seem that the most likely place to see non-SM physics is with dark matter.

3. **weichi**
   July 23, 2013

   The Gibbs article is quite well written; seems like a very clear exposition of the pro-multiverse point-of view. And Lubos has a nice article in response discussing fine-tuning.

4. **Adam Treat**
   July 23, 2013

   Hi Peter,

   I watched the recent talk by Penrose about his Conformal Cyclic Cosmology theory in Warsaw. He ended the talk with new details about the prediction for concentric circles in CMB data. Apparently he now has another independent team saying they've found the circles in the Planck data and the previous claimants have also updated results.

I bring this up here, because it seems that an affirmative finding of such rings would boost Penrose's theory as a serious opponent of multiverse mania. From what I understand CCC would preclude the idea of a multiverse.

So that is one more hope for stemming the tide of these multiverse propenents. If not Penrose's theory, then perhaps other progress will continue and show the way forward.

5. **Adam Treat**
July 23, 2013

Also, I wanted to ask what you thought of this new talk. I know you have been highly skeptical of this theory as you should be, but at least it is science and making predictions.

6. **Peter Woit**
July 23, 2013

Adam,

I'm still pretty skeptical about the Penrose CCC business, haven't seen any reason for more optimism about it. But I'm no cosmologist…

It also really says nothing at all as far as I know about the SM parameters, and from what I remember, one of the biggest problems is that he has to invoke some unknown mechanism to make masses go to zero and get conformal invariance. Even if there were evidence for his picture, I doubt it would be all that difficult to incorporate CCC in some tweaked form of multiverse mania.

7. **Eric**
July 23, 2013

It really troubles me that people seem to so easily accept the statement to the effect that "supersymmetry is dead". This is not even remotely true. At the worst, one might be able to claim that a low-energy supersymmetric solution to the hierarchy problem requires a small amount of fine-tuning at the 1-3 percent level. It is quite possible that all squarks and sleptons have masses in the range 4-10 TeV, and the hierarchy problem can still be solved with fine-tuning at only the 3 percent level. In this case, there would likely not be an observable signal at the LHC. However, in such spectra the lighest neutralinos are Higgsino-like with fairly light masses which might be observed at the ILC. So, it will not be possible to claim that supersymmetry is dead for quite some time. It would be great if people would educate themselves on the actual situation rather than repeating misinformation.

8. **Brian**
July 23, 2013

Adam, the best argument for Penrose's ideas are the low multipole data from Planck2013 – which somewhat disagree with LCDM. One could argue forever about circles.

9. **Chris W.**
July 23, 2013

We seem to be in a true fin de siècle period. The real seeds of what is to come will germinate largely in the dark.

10. **Peter Woit**
July 23, 2013

Chris W.,

Funny, but I remember thinking we were in a fin de siècle period back in the 90s. Maybe these siècles are getting shorter…

11. **Igor Khavkine**
July 23, 2013

I'm sensing that Peter and other readers of this blog (as embodied in vmarko's comment) consider the realization that the parameters of the Standard Model cannot be predicted as "giving up", in a negative, unwarranted sense. Granted, the reasons given by the likes of Seiberg and Arkani-Hamed, namely the cosmological multiverse, are very dubious. However, I'd like to turn this question around. What reason was there to expect that any of the Standard Model parameters could be predicted at all?

My question is not totally rhetorical, but I think the answer is None, at least not in the sense of vmarko (as it appears to me). My reason for saying so has nothing to do with the multiverse or anything similar. Simply, I don't know that, historically, this ambition has ever succeeded and do know that it has notably failed.

Just to clarify my argument, the situation we have with the Standard Model is that all its parameters are already known (with varying precisions) and no empirical reason to suspect that they are not fundamental (in the usual reductionist sense). There's always room to discover a new pattern or symmetry in among the know parameter values, but that is no longer prediction, just observation.

12. **Peter Woit**
July 23, 2013

Igor,
It's not just continuous parameters of the SM, but also the general features one would like some explanation for. Maybe there is no answer to a question like "Why SU(3)xSU(2)xU(1)?" other than "just because", or "the Multiverse did it". I don't see a solid argument explaining why this is something we can't possibly know, so it seems like a good idea to keep thinking about it and seeing what one can learn. Claiming that the failure of one's pet idea means that no one can ever find the answer to such questions, because the universe was constructed to as to make you fail, seems on the other hand like a bad idea. My problem isn't so much with people raising the possibility that such questions can't be answered, rather them doing so to evade having to admit that an idea they promoted heavily just didn't work.

13. **hhoonneeyy**
July 23, 2013

To be honest, the general attitude towards naturalness vs multi-universe among the students is who cares……

14. **Yatima**
July 23, 2013

"What reason was there to expect that any of the Standard Model parameters could be predicted at all?"

None whatsoever, or the same as the reason to expect that the Standard Model had anything to do with group theory.

On the other hand, why aren't there more free parameters? Is there any reason to expect that may be even less free parameters? Where is the [dividing line between numerology and coincidences of some interest?]

How about one might start considering the multiverse idea when a complete description is found with only one free parameter left (under the constraint of not pushing these DOFs into epicycles), and not earlier? That may take some time though.

15. **Lafargue**
July 23, 2013

hhoonneeyy: Are you attending the program? As student or as lecturer? What *do* the students care about?

16. **amused**
July 24, 2013

Well that all sounds very bleak and depressing, but I'd just like to point out that some people in HEP have been, and continue to be, heading in what seems a much more promising direction: finding new physics beyond the SM in quark flavour physics (CKM matrix elements and that kind of stuff) by confronting increasingly high precision theory calculations (involving Lattice QCD) with experimental measurements. Discrepancy between SM theory and experiment at the 3sigma level has already been reported for a few years now – see e.g. [here] for a recent review. A detailed program for uncovering and studying new physics beyond the SM in the quark flavor sector over the next 10 years has been presented [here].

The lack of attention this seems to get from the rest of the HEP community is astonishing (to me at least). You would think people who lament the lack of prospects for finding new physics beyond the SM would at least be mildly interested in existing 3sigma discrepancies with the SM…
On the other hand, it is amusing and not hard to understand sociologically. The university affiliations of the people doing this stuff are all non-elite – no one from Harvard, Princeton, Stanford etc. If such people were the ones to discover new physics beyond the SM it would be a terrible offense against the natural order of things. So the the elites of HEP can't bear to acknowledge this work, and when they don't talk about it then no one else will – such is the sociology.

(Disclaimer: I don't work on that stuff myself and have nothing personal at stake in it. But as someone who works on formal theory/maths aspects of lattice gauge theory I'm vaguely aware of it from following the lattice literature.)

17. **Krzysztof**
July 24, 2013

Gian Giudice has given in Stockholm a great talk on naturalness :
https://indico.cern.ch/getFile.py/access?contribId=870&sessionId=28&resId=0&materialId=slides&confId=218030

Interestingly, though not supported by Templeton, he managed to evoke St. Thomas Aquinas…

18. **MathPhys**
July 24, 2013

This is no good. This is less than professional. No one should teach ideology camouflaged as physics. Definitely not to students.

19. **Krzysztof**
July 24, 2013

MathPhys: Ideology? I was just joking, as was GG I would guess… To ease the tension let me quote Wolfgang Pauli : "Well, our friend Dirac, too, has a religion, and its guiding principle is "God does not exist and Dirac is His prophet."

20. **vmarko**
July 24, 2013

@ Igor Khavkine:

I'd like to turn this question around. What reason was there to expect that any of the Standard Model parameters could be predicted at all?

Let me comment on this just for completeness. The SM features some 20-30 (depending how you count) coupling constants, and cca. 100 elementary particles, with a lot of various structure (gauge groups, finite groups, generations, flavor, lepton/baryon groups, etc.). When you draw it all down on a piece of paper, it looks very similar to the Mendeleev periodic table of chemical elements — they both have periodic, similar structure, and even a comparable number of 100 or so "elementary atoms".

If history is allowed to teach us anything, the whole SM "smells" like having some simpler underlying structure all over the place. This simpler structure is "simpler" in the sense that it has fewer free parameters and fewer elementary particles, while the SM parameters are to be expressed as functions of these. Btw, this is an old idea, look up on [preons] for some historical attempts to address this.

Granted, it might be that SM really does not have any underlying structure of that kind and that all parameters are really fundamental. But students should not be indoctrinated into thinking that way just because string theory has 10^500 vacua and no way to distinguish between them.

Best, 🙂
Marko

21. **MathPhys**
July 24, 2013

Krzysztof,

I had N Seiberg's talk to summer school students in mind. My point is that his is not straight, undiluted science. It's too ideological.

22. **Krzysztof**
July 24, 2013

MathPhys:

OK – but then, only half-joking, I would say that is rather pseudo-religious, in a direct relation to Pauli's quote. Fortunately, Dirac did not mixed up his believes with physics, but it seems now we are facing this problem in fundamental research. In my view, it could be traced back to the idea of the ToE, which from very beginning sounded pretty non-scientific.

23. **Richard**
July 24, 2013

Peter,

This may be a little off-topic, but have you heard "Popsiecles and Icesiecles" by the Murmaids*?
It's a really good song.

— Rich

P.S. I like SUSY and the Banshees, too.

* Siecles are not the only ones with fins!

24. **weichi**
July 24, 2013

Igor:

"Simply, I don't know that, historically, this ambition has ever succeeded and do know that it has notably failed."

I'd love to hear you expand upon this. What episodes in science do you have in mind? As vmarko points out this ambition has succeeded enormously in regards to the periodic table. I suppose one could argue that the ambition failed in regards to explaining the orbital sizes and masses of the planets in our solar system – we now understand that these things are basically random facts.

But the science of newtonian mechanics and astrophysics has explained so many other things, and has lead us to pose so many new and more interesting questions (questions that astrophysics has also been able to answer!) that I don't think anyone really cares about the "random" answers.

25. **srp**
July 24, 2013

The most fascinating thing in this thread is the deafening silence in response to amused's cogent point. I've tried to point out similar things a few times and Peter asked me to stop (so I have). The only non-sociological explanation I have is that the HEP folks have implicitly decided that the proton isn't fundamental enough to be worth their time–it's gotten classed with those messy composite topics like nuclear physics and chemistry.

26. **Peter Woit**
July 24, 2013

srp,

Actually I'm kind of in favor of deafening silence in response to comments that, while reasonable, could easily turn into an attempt to hijack discussion off-topic to something the commenter is more interested in…

That said, the topic of better understanding QCD and flavor physics isn't a completely neglected one, there are many people working on this. It's likely to get more attention in the US in coming years since US experimental HEP has no short-medium term path to a new high energy machine, but is concentrating on a plan for exploiting a new high intensity machine.

Yes, this kind of research isn't popular at high status places like the IAS, but that's only partly because of the domination by topics like SUSY, string theory, and ideas about extra dimensions. HEP theory has always been very faddish, but when healthy the fads were driven by experiment. The problem here is that the size of apparent violations of the SM that have been seen just aren't convincingly large enough. If there were a solid 5 sigma SM violating phenomenon being observed, I think you'd have almost every prominent theorist at Princeton, etc. dropping everything they were doing and working on something related to that. Absent a convincing deviation from the SM, it's not surprising people looking for something high profile and faddish to work on go for black holes instead.

SUSY has been an endlessly popular fad because it's complicated, but can be studied with quite conventional techniques, so there is lots for theorists and experimentalists to do. The failure so far to see anything I suspect will make this a less popular thing to work on, and no SUSY in the next LHC run will seriously damage interest in the subject. Unfortunately, as long as the faddish sociology continues, what this is likely to mean is just that people abandon one fad for an even worse one (e.g. the multiverse), and my fear about talks like Seiberg's is that they are paving the way for that.

27. **amused**
July 25, 2013

I don't want to be a hijacker and start off a discussion about the prospects for flavor physics 🙂 Will just mention that 3 sigma discrepancy with the SM already seems serious to me, and that the prospects for improving on this with higher precision calculations and measurements to reach the 5 sigma discovery level in the coming years look pretty good (although I'm far from an expert on it). Considering all the current doom and gloom about prospects for finding new physics beyond the SM, I just think people should be aware of this (which most people aren't since it's such an unfashionable topic). And it seems not completely off-topic to mention it here in a thread about "where are we heading". The depressing multiverse isn't the only direction.

I guess what we all ultimately want is to discover the next layer of new physics beyond the SM. From a scientific viewpoint the avenue for reaching this shouldn't matter as long as we reach it. But from a sociological viewpoint it matters enormously…

28. **emile**
July 25, 2013

Hi Amused,

For a CMS or ATLAS physicist, a 3-sigma discrepancy is not that significant because the data are sliced and diced thousands of ways. Many distributions will have had strange features that will have disappeared when adding more data. I agree with Peter that when these discrepancies reach 5 sigma, they will get attention from the community. I also agree that, without a machine that goes beyond 13/14 TeV (or a linear collider anytime soon) and assuming no new physics at those energies, we'll have to look in loops to find signs of anomalous contributions.

Back on topic: I think Wilczek's warning is spot on.

29. **amused**
July 25, 2013

Hi Emile,

At the risk of getting my comment deleted for continuing in an off-topic direction (and I will understand if that happens):
The flavor physics stuff is quite different from the stuff done at CMS/ATLAS: high intensity "precision physics" vs high energy "discovery physics". The 3 sigma discrepancy is not occurring in some experimental signal but rather in a mismatch between various experimental and theoretical constraints on CKM matrix elements (and other flavor stuff). From what I understand (and I'm no expert on this!), the experimental measurements are already very precise, and it is on the theory side that precision is lacking. So the goal (as I understand it) is to increase the precision of the theory calculations, with more precise lattice QCD simulations playing an important role for this, so as to push the existing discrepancy from 3 to 5 sigma thus confirming new physics beyong the SM. Looks like this could happen already in the coming years.
(And if I got some or all of that wrong then hopefully someone more knowledgeable will correct it…)

30. **Ravi**
July 25, 2013

It is interesting that Frank Wilczek's article has the Warning "There is a danger that selection effects will be invoked prematurely or inappropriately, and choke off the search for deeper, more consequential explanations of observed phenomena…. I believe there are at least two important regularities among standard model parameters that do have deeper explanations, namely the unification of couplings and the smallness of the QCD θ parameter (for which, see below)…."

While the only solution discussed by Prof. Wilczek for the smallness of QCD theta parameter is the axionic one that has been around for a long time, non-axionic solutions could well be what nature has picked. In recent papers 1009.5651 and 1203.2772 I showed that just discrete space-time symmetries parity (P or left-right symmetry) and CP (equivalent to time-reversal T) can solve the strong CP problem and predict neutron EDMs in experimentally interesting regions. Moreover 1209.3031 shows that spontaneously broken P itself can stabilize dark matter without need for R-parity etc. Leptonic CP phases can vanish in these models for the same reason that strong CP phase vanished at the tree-level.

We may yet discover that nature was left-right symmetric and time-reversal in its fundamental laws.

(There are also non-axionic solutions that include proposals by several researchers that usually involve either P or CP along with other symmetries such as SUSY, Z_2 and with different predictions).

–Ravi

31. **fuzzy**
July 25, 2013

hi igor,

sm does not have to explain anything of course. it is up to each specific model, that aims to extend the sm and to be predictive, to tell us something useful. (btw, even theta is not a issue in sm; if it is small it stays small.)

supersymmetric sm, with its sliding scale and its huge number of free parameters, does not satisfy the criterion of predictivity in my view. concocting naturalness, in order to camouflage this shortcoming, seems to me a rather mean position.

i think high energy physics should care of measurements. there are not so many measurements we have to account for assuming something outside the sm, but these measurements should be considered with more care and less arrogance.

alternatively, the mask should be thrown, admitting of having forgotten the mission of physicists and of preferring to play to the games of the philosophy.

32. **Igor Khavkine**
July 25, 2013

@vmarko, weichi:

Since the example of the periodic table was brought up, consider its history. Mendeleev identified the periodic structure in the properties of elements. The observation of this pattern was extremely useful and its value stands on its own. However, I don't think this observation is an "explanation" in the usual sense. There were multiple theoretical research programs to actually come up with explanations for the periodic structure and the additional spectral line data. These included vortex knots theories, as well as plum pudding models, and I'm sure others that have been forgotten by history. Successful explanation in terms of atomic structure theory came only after crucial experimental breakthroughs: Thompson's discovery of the electron and Rutherford's discovery of the nucleus. These experiments revealed that there actual subatomic constituents and set the challenge of explaining atomic properties in terms of their dynamics.

That challenge was speedily and successfully met. But note the chronological order of the experimental and theoretical input. Those models that preceded the crucial experimental discoveries are now relegated to history, essentially without exception. The apparent pessimism expressed in my earlier post is an expression of my opinion that the existing theoretical research programs aimed at "explaining" the structure of the Standard Model are most likely analogous to the vortex knot and plum pudding models of the past, highly unlikely to succeed. Moreover, without any sharp empirical evidence of compositness (or something similar) of SM particles, the already observed structure and symmetries of the SM are already a great achievement (like that of Mendeleev), which does not necessarily cry out for any kind of "explanation".

33. **Armin Nikkhah Shirazi**
July 25, 2013

Igor,
You make a fairly compelling argument for your position, but I think there is a loophole.
If the foundations and interpretation of QM and, by extension of QFT, were as settled as they seem to be for classical physics and even that additional 'Understanding' failed to provide any addititional clues, then the outlook might be as bleak as you think. But as it stands, the SM is a sophisticated mathematical pattern fitting scheme with little understanding of its deeper meaning. Feynman understood this, recall his analogy with the Mayan Astronomers, who were able to make accurate precision predictions of planetary cycles with essentially zero understanding of planetary dynamics.
The fact that none of the mainstream interpretations of QM has been able to conclusively establish itself may just be another facet of this problem. I for one would not be surprised if we recognized the eventual 'correct' interpretation by noticing that its application to the SM would point to novel approaches for calculating its parameters. It is quite possible in my view that we have already gathered sufficient experimental data to be able to elucidate the deeper meaning if we were only more imaginative. Remember that the technology that led to Newton's laws was essentially available also to the Mayans, since much of the underlying data leading from Kepler to Galileo came from Tycho Brahe who performed naked eye astronomical observations.
So, to answer the question you posed in your first post, as long as we don't understand the deeper meaning of the SM, we have every right to expect that several or perhaps

even all of its parameters can eventually be predicted because, taking an even longer view of the history of science, so far it has been thus.
Your perspective may be just too entrenched in the current zeitgeist.

Armin

34. **pitpstudent**
July 25, 2013

Peter,

I do not know if you are basing your critique of Nati's talk on just the slides which are online. Because I attended Nati's and Nima's talks at the summer school, and both of them made it very clear they do not like the multiverse at all. They would much rather prefer an alternate explanation, and encouraged students to think outside the box and outside current wisdom, for new ideas.
Nima also mentioned that those people in the field who keep updating their "prediction" for masses of various particles as the LHC bounds improve, give the field a bad name. He said you could keep massaging the theory and making it more and more complicated to escape the LHC bounds, but he doesn't believe in that. He gave some very clear numbers for masses, which seem to be already in some trouble after the first run of LHC, and he said that the 14 TeV run will settle the matter once and for all.

35. **Peter Woit**
July 25, 2013

pitpstudent,

Thanks for the report and comments.

I was basing the comments on Nati's talk just on the slides, and I haven't heard him talk about this. The question isn't really whether he "likes" the multiverse, but whether he's following what is becoming the conventional wisdom of "we don't like the multiverse and anthropics, but the LHC results are making it the leading explanation for fundamental physics." As I noted, from one of the slides he seemed to at least be alluding to one argument against anthropics.

I have seen several versions of Nima's talks about this, in person and online. He's been making the "unless the LHC sees new physics below 1 TeV, the multiverse is the leading explanation, even if we don't like it" argument consistently for many years. I know that he's still describing the situation as naturalness not quite yet ruled out, but the discussion is now about how close to death it is, with even David Gross, one of the great SUSY enthusiasts saying the theory may still be alive, but is not kicking. I don't think Nima or anyone else would now bet a dime on the 13 TeV LHC seeing "natural" new physics, even if they're saying it isn't quite ruled out yet.

In his talks for many years, Nima hasn't been one to say that the LHC would definitely see natural SUSY. He is quite fond of his own "split SUSY" from 2004 which is an "unnatural" version of SUSY, with superpartners that can be at masses inaccessible to the LHC.

I'm glad to hear that both Nati and Nima are encouraging others to challenge the current "we don't like it, but the multiverse is the leading explanation" wisdom. I'd be happier though to hear them challenging the current wisdom themselves.

36. **weichi**
July 26, 2013

Igor,

Thank you, that is very clear! I suspect you are correct that any deeper explanation for the SM will not be discovered without further experimental input. The more interesting argument is that without experimental evidence we have no good reason to expect a deeper explanation. I don't think this is right, but I admit that this could certainly just be a pro-reductionist prejudice of mine.

37. **Shantanu**
July 26, 2013

Peter and others,
FYI: See C. Rovelli's comments about susy etc at LOOPS 13 meeting
http://pirsa.org/displayFlash.php?id=13070083

38. **Noah Smith**
July 28, 2013

Peter:

A depressing possible answer to "Where are we heading?" would be an endless future of multiverse mania, with a short canonical list of ancient, but accepted ideas about fundamental theory (SUSY Guts, string theory, axions) that can never be tested.

I don't understand why this is "depressing". We have theories that are very accurate at predicting everything we can observe at the small scale, given our current level of technology. That sounds like an enormous victory to me.

Unless you can derive all of physics from math – and there seems to be no reason to assume you can – you're going to be left with some empirical facts that just seem to come from nowhere. Doesn't seem too worrying to me.

And it seems to me that "multiverse mania" and untestable theories are silly, but not necessarily harmful. If there are no unexplained phenomena at the small scale, why not let our theorists indulge in science fiction and metaphysics and math until technology improves and some new puzzles and anomalies pop up? It doesn't seem likely to actually hurt the progress of science.

Do you disagree?

39. **Yatima**
July 28, 2013

Noah,

Unless you can derive all of physics from math – and there seems to be no reason to assume you can – you're going to be left with some empirical facts that just seem to come from nowhere.

If the history of physics since at least Copernicus "is no reason to assume that all of physics can be derived from math" and that random ad-hocery like the one found in badly written programs is inherent to the thing …

… then I don't know what you need.

('derived from math' should and must be 'constrained by an appropriate mathematical description', as 'derived' is rather meaningless, because it assumes that the description exists as prior – it doesn't, it must be built first)

40. **emile**
July 28, 2013

Noah, you wrote "And it seems to me that "multiverse mania" and untestable theories are silly, but not necessarily harmful. If there are no unexplained phenomena at the small scale, why not let our theorists indulge in science fiction and metaphysics and math until technology improves and some new puzzles and anomalies pop up? It doesn't seem likely to actually hurt the progress of science.".

I think it hurts science when what is really scientific speculation is not clearly labeled as such. The public can get confused about what are our standards in determining what is "true" about the world. It seems there is pressure from some corners to relax those standards.

41. **Peter Woit**
July 28, 2013

Noah,

"why not let our theorists indulge in science fiction and metaphysics and math until technology improves and some new puzzles and anomalies pop up? It doesn't seem likely to actually hurt the progress of science."

I've no problem with the idea of physicists "indulging" in math. Turning to mathematical physics and working on things like better understanding deep questions about the relation of mathematics and QFT might be a good idea absent hints from experiment. Unfortunately physics in recent years has moved in the opposite direction, with physics departments losing interest in mathematical physics. The conventional wisdom now is that the string theory debacle was due to "too much mathematics", a failure to pay attention to experiment (rather than a failed physical idea).

As for indulging in science fiction or metaphysics, the problem is that people are not going to do this honestly. If you announce that you've given up on real physics and you're now doing science fiction/metaphysics, billionaires will stop giving you prizes, the NSF will not renew your grant, your colleagues will not hire your students, etc. So, unable to do this honestly and above-board, it gets done dishonestly, with people refusing to admit what they are doing. Having a whole academic field take up dishonesty as a major operational principle isn't a good idea. The other problem with this is that you drive out of the field people who still think there is progress to me made, even if it is very difficult. Science fiction/metaphysics is easy, and many people find it entertaining. If it becomes a route to professional success, your field is going to be quickly dominated by it, with no motivation for people to keep thinking about hard problems.

42. **Anonyrat**
July 28, 2013

…..when these discrepancies reach 5 sigma, they will get attention from the community.

Should the community be paying attention to supersymmetry before 5 sigma discrepancies are found with the Standard Model? Since the attention to SUSY exists, it is clear there are strong expectations of where the signal of new physics will come from (SUSY – more likely even without 3 sigma discrepancies, lattice QCD discrepancies – less likely, even with 3 sigma discrepancies). The nature of HEP research is that one has to place such career bets; what I'm curious about, and perhaps those in the know can tell us, how much have people in the community hedged their bets? That may help with understanding where we are headed.

43. **Bob Jones**
July 28, 2013

"Turning to mathematical physics and working on things like better understanding deep questions about the relation of mathematics and QFT might be a good idea absent hints from experiment."

The kind of work you describe is practically synonymous with string theory. I guess you'd like to see physics departments hire more string theorists.

44. **Peter Woit**
July 28, 2013

"The kind of work you describe is practically synonymous with string theory"

If only…

45. **Bob Jones**
July 28, 2013

Do you want to elaborate on what's wrong with my statement?

46. **Ravi**
July 28, 2013

I am surprised that Prof Seiberg's talk "Where are we heading" has a basic mistake that should be corrected — Slide 23 says "Strong CP problem … the explanation must involve low-energy physics". This is the case with axionic solutions — in the sense that axions have only a very small mass. It is not in general true for axionless solutions like the ones I mentioned before. All new particles in these models can be at a high scale so that standard model is the effective low energy theory — however they can predict some of the low energy parameters such as neutron edm (or \theta) and leptonic phases as in the papers I mentioned before.

The naturalness of smallness of the Higgs mass (compared to Planck mass) probably needs low energy physics. But naturalness of smallness of the strong CP phase does not need low energy physics.

Ravi

47. **Another Igor**
July 29, 2013

This discussion reminded me that "the difference between theory and practice is much bigger in practice than in theory".

48. **Peter Orland**
July 29, 2013

Bob Jones,

Peter Woit hasn't answered you yet, but I'll offer my response, for what it is worth. Here is what is wrong with your statement:

THE issue in quantum field theory is quark confinement in renormalized asymptotically-free non-Abelian gauge theories. Not supersymmetric N=4 or N=2 theories (though N=1 would help). There is inspiration from (mostly late sixties early seventies) string theory. AdS/QCD models are exactly that – models. They have the same problem that lattice strong-coupled models had in the mid-seventies.

However the confinement problem will be solved, it's clear that 15 years of AdS/QCD has done no better than the 3-4 years of lattice strong-coupling expansions (which the lattice people abandoned once Monte-Carlo methods started to work).

By the way I've spoken many times with people who use AdS/QCD to make claims about entropy, glueball spectra or whatever, in New York, Santa Barbara and Copenhagen. None of them claim to do anything at small bare coupling, where the theory is renormalized.

Maybe some parts of string theory will help. But none of the string theorists I know work on this problem. And they don't plan to either.

49. **Bob Jones**
August 2, 2013

Peter Orland,

Sorry for the late response. I stopped following this thread for a while.

The problem you're talking about is of course very important. I don't know enough about the subject of AdS/QCD to say whether string theory will lead to a complete understanding of quark confinement, but as you say, it's conceivable that some parts of string theory will help.

I think Peter was talking about something else though. It sounds to me like he wants more physicists to study how ideas from quantum field theory can be used to solve problems in pure mathematics. This sort of "physical mathematics" is almost always done by string theorists who are motivated by questions in string theory. Indeed, it's hard to think of many examples of this sort of work which are not directly related to string theory in one way or another.

Bankrupting Physics

July 28, 2013
Categories: Book Reviews

I just spent a depressing and tedious few hours reading through Bankrupting Physics, an English translation of Alexander Unzicker's 2010 Von Urknall zum Durchknall written in German.

When I started reading the thing I wasn't expecting much, but figured it would be some sort of public service to take the time to identify what Unzicker had to say that made sense and what didn't, and then write something distinguishing the two here. After a while though, it became clear that Unzicker is just a garden-variety crank, of a really tedious sort. Best advice about the book would be the usual in this situation, just ignore it, since no good can possibly come from wasting time engaging with this nonsense. I have no idea why any publisher, in Germany or here, thought publishing this was a good idea.

If you must know though, here's a short summary of what's in the book. The first half is about gravitation, cosmology and astrophysical observations. Unzicker's obsessive idea, shared with innumerable other cranks, is that any scientific theory beyond one intuitively clear to them must be nonsense. Similarly, any experimental result beyond one where they can easily understand and analyze the data themselves is also nonsense. He's a fan of Einstein, although thinks general relativity somehow needs to be fixed, something to do with it getting phenomena involving small accelerations wrong. There's endless complaints about how cosmology involves too many parameters, and dark matter/energy shows that physicists really understand nothing.

When he gets to particle physics, we learn that things went wrong back when physicists started invoking a symmetry that wasn't intuitively obvious, isospin symmetry. According to Unzicker, symmetries in particle theory are all a big mistake, "the standard model barely predicts anything", "the standard model can actually accommodate *every* result", and endless other similar nonsense. As for the experimental side of things, he takes a comment from Feynman about renormalization in QED, claims it means that there is no understanding of production of photons at high energy, then uses this to describe as "It's just ridiculous" data analysis at HEP experiments. High energy physics experiments are all just a big scam, with the physicists involved unwilling to admit this, since they've wasted so much money on them.

The last part of the book contains lots of criticism of string theory, etc., much of it parroting my book and blog. According to Unzicker:

> Woit does a great job in debunking the string and SUSY crap. Unfortunately, he has pretty mainstream opinions with respect to the Standard Model.

Well, maybe he does get *something* right… I have to admit that one of the things that every so often makes me wonder if I'm completely misguided, and maybe there is a lot more value to strings/SUSY/branes/extra dimensions etc. than I think, is reading rants like Unzicker's.

So, my strong advice would be to do your best to ignore this. Luckily, there's an infinitely better book coming out here in the US at the same time: Jim Baggott's Farewell to Reality, which I highly recommend. It seems likely that the two books will get reviewed together, giving Unzicker far more attention than he deserves. If so, at least this will provide a real-life experiment indicating whether book reviewers can tell sense from nonsense.

Comments

1. **lun**
   July 29, 2013

   If he says what what you write in the review about the Standard model he is definitely a crank. Cosmological models do have a whole bunch of little understood and somewhat arbitrary parameters through.

   Most importantly, "if you cannot explain something you have not really understood it" is a saying of famous crank Richard Feynman. Who also wrote this from a gravity conference in Warsaw:
   ——————————————
   I am not getting anything out of the meeting. I am learning nothing. Because there are no experiments this field is not an active one, so few of the best men are doing work in it. The result is that there are hosts of dopes here (126) and it is not good for my blood pressure: such inane things are said and seriously discussed that I get into arguments outside the formal sessions (say, at lunch) whenever anyone asks me a question or starts to tell me about his �work.� The �work� is always: (1) completely un-understandable, (2) vague and indefinite, (3) something correct that is obvious and self-evident, but worked out by a long and difficult analysis, and presented as an important discovery, or (4) a claim based on the stupidity of the author that some obvious and correct fact, accepted and checked for years, is, in fact, false (these are the worst: no argument will convince the idiot), (5) an attempt to do something probably impossible, but certainly of no utility, which, it is finally revealed at the end, fails (dessert arrives and is eaten), or (6) just plain wrong. There is a great deal of �activity in the field� these days, but this �activity� is mainly in showing that the {67} previous �activity� of somebody else resulted in an error or in nothing useful or in something promising. It is like a lot of worms trying to get out of a bottle by crawling all over each other. It is not that the subject is hard; it is that the good men are occupied elsewhere. Remind me not to come to any more gravity conferences!
   ——————————————

   Unfortunately, this kind of research activity is most likely a lot more common than in Feynman's time, both in gravity and particle physics.
   The guy might be a crank, but regarding intuition he might have a point.

2. **Ray**
   July 29, 2013

   Now you know how string theorists feel about you.

3. **Mark**
   July 29, 2013

   Peter, why didn't you follow your own advice? Just ignore him….

4. **CFT**
   July 29, 2013

   Mr. Woit,
   When particles are virtually pulled from the void or vacuum (ex nihilo) to allow mathematical models which contain no physical extension to function, yes, my intuition or sense of causality tells me something is wrong, starting with a lack of a logical mechanical explanation of what the heck is actually going on. Your comment about the 'infinitely preferable' "Farewell to Reality" kind of sums up what the very problem itself with physics really is: Physics is no longer even trying to describe reality, It's more interested in trying to describe imaginary internally consistent mathematical spaces that have no overlap with how our reality functions. For the record, Einstein often admitted his work in relativity was unfinished and still had some problems until the day he died. Feynman himself admitted (in his more lucid moments) that

something was wrong with the very heart of QED, and that he thought it wasn't mathematically valid. You yourself have commented at some length about the abandonment of any kind of scientific rigor in string theory. I ask you honestly, do you think you are being fair calling a person a 'crank' because they point out the standard model is a heuristic model that requires many of its parameters to be 'fine tuned' by hand just to get agreement with experiment? Didn't Lee Smolin say just about the same exact thing in his book "The Trouble with Physics" and describe it as a fundamental issue with the standard model?… are you calling him a 'crank' too?
*
Maybe you should be supporting strings/SUSY/branes/extra dimensions, since you seem equally unwilling to critically examine your own mathematical underpinnings and assumptions. Mr. Woit, If you expect others to seriously question their assumptions, you best be ready to do so yourself without complaint and refrain from calling them a name for questioning your beliefs.

5. **Andrew Foland**
   July 29, 2013

   I've never heard of either the author or the book–is there some building buzz around it that needs to be addressed? How did you come to want to write a review on it, if it's purified crankery? (A conclusion that is not disconfirmed by glancing at the author's list of publications.)

   Just curious if there's a backstory here I'm missing.

6. **P**
   July 29, 2013

   CFT,

   As a string enthusiast, this may be the first time I come to the defense of Peter 🙂

   Peter says:
   "symmetries in particle theory are all a big mistake, "the standard model barely predicts anything", "the standard model can actually accommodate every result", and endless other similar nonsense"

   and you say:
   "the standard model is a heuristic model that requires many of its parameters to be 'fine tuned' by hand just to get agreement with experiment."

   but these are very different things indeed. Peter undoubtedly would love to know why the Yukawa couplings are what they are, as would I, but it's just flat wrong to say that the standard model doesn't predict anything, or that it can accommodate every result.

   You want Dr. Woit to examine "his assumptions" about the standard model, etc. But the fact is that this has happened since the early 70's, with experimental confirmation after experimental confirmation. Scientific consensus typically develops for a reason, and in this case it is 40 years of agreement with experiment. The consensus in high energy physics now — string theorists, particle theorists, and experimenters alike — is that the standard model is the correct description of visible sector particle interactions below the weak scale.

   Asking one to "re-evaluate assumptions" about the standard model in the way Unzicker would like (though you are likely being much more fair than Unzicker) is the intellectual equivalent of creationists wanting us to "re-evaluate" 150 years of evolutionary biology.

   Cheers,
   P

7. **Peter Woit**
   July 29, 2013

   CFT,
   Unzicker's claims are quite different than Smolin's and go way beyond your description of them. The quotes about the standard model I included above speak for themselves. Beyond criticizing theorists, he explicitly makes the case that the work of HEP experimentalists is "just ridiculous". His justification for this is the claim, based on his reading of a comment in Feynman's Lectures on Physics, that there is no valid formula for the production of photons by an accelerated charged particle, so HEP experiments can't possibly understand their backgrounds and reliably identify phenomena like the Higgs. I think these claims speak for themselves.

   Mark/Andrew,

   I wrote about this because unfortunately I think it's about to get a lot of public attention and can't be safely ignored. For one thing, a major publication contacted me about their plan to review it, asking if I was available. That one probably won't happen, for some completely unrelated reasons. More amusingly, here's the story of how I got a copy of the book. I was in a Barnes and Noble here in New York, looking at books in the physics section, when one of the book-sellers came up to me, picked up a copy of Lee Smolin's latest book, and asked "aren't you this guy?" I had to explain that this wasn't quite right, luckily there was a copy of "Not Even Wrong" on the shelves I could point to. He then said there was a new book he wanted to ask me about, and brought me over to the new book display, which prominently featured the Unzicker book, which was the one he wanted to know about. I think he and many others like him are curious about the book and deserve an explanation of what's in it.

8. **Zathras**
   July 29, 2013

   Unzicker is listed as a "German theoretical physicist and neuroscientist." Does he do both actively?

   And it is quite ironic to have a neuroscientist complain about hype in theoretical physics.

9. **Low Math, Meekly Interacting**
   July 29, 2013

   To maybe put you in a better mood, there's a very nice (for a change) review of "The Universe in the Rear View Mirror" in New Scientist. Contains a boatload of praise for Noether and her Theorem. Seems like precisely the kind of thing we could use more of in popularizations of science.

10. **Low Math, Meekly Interacting**
    July 29, 2013

    I should clarify I mean the review itself, not necessarily the book, which appears to be merely OK overall, but at least gets some things right. The review at least makes this clear in a very level-headed way, I think.

11. **Oldster**

July 29, 2013

Unzicker's comment about small accelerations and general relativity that you mention, sounds as if he's thinking about some theory such as Milgrom's MOND being incorporated into a modified general relativity. People have attempted to do this, but to the best of my knowledge, nobody's effort has achieved wide acceptance …

12. **Jeff M**
July 29, 2013

@LMMI,

Thanks for the heads up about the review at New Scientist, it is very nicely done. As a mathematician it's hard to imagine that Noether deserves wider fame, in math she's quite famous thank you. Even to an geometric analyst like me, who spent quite a lot of time trying to avoid algebra whenever possible 🙂

13. **David Bailey**
July 29, 2013

I don't normally comment here because as Peter says, this is not meant to be a general physics forum, and my reasonably detailed knowledge only extends as far as non-relativistic QM – as applied to chemical systems, and even that is very stale by now.

However, Unzicker's book is clearly meant to appeal to a much wider audience, that include me, and we have all – even those that never understood algebra at school – contributed to the roughly £7nb cost of the LHC. His book is likely to ring a bell with a lot of people, and maybe help to bring about a reassignment of research priorities and resources – fairly or otherwise!

I think a lot of people have an uneasy feeling about theoretical physics – one that you yourself obviously share when it comes to string theory. It is that if you take an army of mathematicians and set them loose to produce a theory that fits the experimental facts – totally disregarding the physical meaning of most of the variables in the theory – they may well come up with an explanation that fits some of the facts (with a few dozen adjustable parameters), and which is too computationally dense to calculate others. For example, the Standard Model obviously was not able to supply the mass of the Higgs Boson – only an experiment could do that.

Given that thought, it doesn't seem impossible that a whole chunk of the modern edifice of physics is wrong – only appearing to be correct because it was cherry picked from 10000 other theories that could not fit the facts. Even when a theory makes a prediction which is subsequently proven correct there is still the nagging possibility that it has fitted a pattern that was actually produced by a completely different mechanism!

People also see, for example, that a phenomenon such as the speed of rotation of stars in galaxies is interpreted in terms of new concepts – dark matter – rather than daring to suggest that General Relativity might not be correct at galactic-wide distances. In other words, if new evidence arrives that contradicts a reasonably well established theory, the response it to keep the theory and add another epicycle!

The LHC was sold as producing a 'God particle' or mini black holes, and the day may be coming when politicians and public want to see something more impressive than a bump on a graph!

14. **woit**
July 29, 2013

David Bailey,

People should certainly be skeptical about scientific claims with no serious evidence that backs them up. But what Unzicker is doing is something completely different, attacking extremely well understood and extensively tested physics, without showing any signs of understanding anything about it. There is no point in trying to seriously intellectually engage with this kind of critique, it's just nonsense and a waste of everyone's time.

15. **Chris W.**
July 29, 2013

> Given that thought, it doesn't seem impossible that a whole chunk of the modern edifice of physics is wrong – only appearing to be correct because it was cherry picked from 10000 other theories that could not fit the facts. Even when a theory makes a prediction which is subsequently proven correct there is still the nagging possibility that it has fitted a pattern that was actually produced by a completely different mechanism!

David, that has always been the case. What do you think the logic of theory confirmation is about? Physical theories are never proven true, they are only proven successful across some realm of application. That is, they build up a solid track record in research.

The real issue here is that talk is cheap; if one thinks there is a completely different "mechanism", then one should step up to the plate and propose a serious theory that incorporates it, and show how it might be tested—i.e., observationally distinguished from the currently preferred candidate—and then struggle through the process of comparison and confirmation. Doing that has become progressively harder in the last 2oo years. The Standard Model is well-entrenched for many good reasons (and some bad reasons too, perhaps, but that's life).

16. **Yatima**
July 29, 2013

Mr. Bailey,

I am sad to say that your comment is unfortunate proof of exactly the armchair ragefisting of the populace that gets its "science news" from useless TV crud à la BCC or from the sensationalistic headlines and pseudo-scientific dross from the "scientific" press.

I am not a physicist but I am biting through the books when I have the time and by golly…

"I think a lot of people have an uneasy feeling about theoretical physics"

A lot of people have an uneasy feeling when trying to find their own behind with both hands! Most can't make the difference between an integral sign and a random squiggle and they sadly take pride in this. The way things are going Orwell-shaped really fast, their uneasiness is bound to increase. So what. Physics is not the Wellness Studio.

"It is that if you take an army of mathematicians and set them loose to produce a theory that fits the experimental facts – totally disregarding the physical meaning of most of the variables in the theory"

None of this ever occurred. The world does not work as in a Perry Rhodan story. You cannot just "produce a theory" by committee, Nothing is being disregarded. No "fitting (using polynomials?) of experimental facts" occurs. This is exactly why there are problems now – there is not enough fresh data to reasonably know where to go.

“For example, the Standard Model obviously was not able to supply the mass of the Higgs Boson – only an experiment could do that.”

You are crashing open doors. And your statement is in complete contradiction with your previous one. You will probably find that no-one disputes that the mass could not be predicted (although I have recently read about the idea that if the m_higgs is set to 1, then the vector of all the other particles’ masses is of unit length…). That’s why the experiment was done in the first place.

“Given that thought, it doesn’t seem impossible that a whole chunk of the modern edifice of physics is wrong”

Quite likely. If you know how, you know how to post on the arxiv.

“Only appearing to be correct because it was cherry picked from 10000 other theories that could not fit the facts.”

Yet again, you do not understand how these ideas are put together. There were not “10000 other theories”, ready made, to be discarded on a whim by a hidden committe of wise men. The current edifice was constructed from those elements that seemed the most parsimonious description (i.e. no epicycles), that showed a reasonable degree of mathematical consistency and that survived the test of experiments.

Well, maybe there are “10000 other theories” out there but humanity sure isn’t old enough to have explored the first one.

“People also see, for example, that a phenomenon such as the speed of rotation of stars in galaxies is interpreted in terms of new concepts – dark matter – rather than daring to suggest that General Relativity might not be correct at galactic-wide distances. In other words, if new evidence arrives that contradicts a reasonably well established theory, the response it to keep the theory and add another epicycle!”

Completely wrong. GR is the most successful description ever. Modifications of that venerable structure, in minor or major form, is being attempted at regular intervals, but so far nothing of this has proven particularly compelling. Tell you what: why dontcha go to this link and read up on it: [Alternatives to general relativity]. Knock yourself out!

Dark matter is a very simple explanation, not “another epicycle” and until something reasonable comes up that explains all the experimental evidence right down to WMAP data, it will be kept.

“The LHC was sold as producing a ‘God particle’ or mini black holes, and the day may be coming when politicians and public want to see something more impressive than a bump on a graph!”

The LHC was sold as a “Higgs factory”. “God particle” moniker came from some lousy reporter and “Mini black holes” came from very speculative ideas that no-one thought would pan out.

“When politicians and public want to see something more impressive than a bump on a graph!”

Like what? Two bumps good enough? Shall one throw in the DVD collection of American Idol and a Coke for free? Seriously, whaddya want? Cold fusion? A recipe to monetize debt without concomitant price inflation? Eternal happiness? You ain’t gonna get it.

17. **chris**
July 29, 2013

oh my. as if it wasn’t bad enough that this guys second book in German just appeared, this drivel gets translated into english now. i just hope he won’t have such a large audience as he unfortunately has here in Germany.

for those who don’t know: he’s a frustrated high school teacher (frustrated because his scientific career failed) and now grinds his own axe in revenge.

18. **David Bailey**
July 29, 2013

Yatima,

I believe Leon Lederman coined the expression “The God Particle” (at least he used it in the title of his book), not a “lousy reporter”, and my point was that the physics community has allowed hype to run wild, and ultimately people and politicians are likely to start asking what that hype really amounts to, and whether it was worth £7bn!

19. **srp**
July 29, 2013

It seems that our host is taking up my earlier suggestion (in the context of the debate over open-access journals) for “anti-publishing”–effectively eliminating from readers’ purview items that are a waste of time.

The only scruple here is you really have to trust the anti-publisher and you have to have a pretty clear idea about what is a waste of time. For example, there might be sociologically interesting patterns in the things said by “cranks” and dissenters and the ways in which they are kept off stage by actions like Peter’s.

But even as someone with a stronger taste for contrarian views than usual, the quotes and description in this post are sufficient to anti-publish this book for me.

20. **Matt**
July 29, 2013

Hi Peter,

Related to this discussion of deciding when a scientific approach is valid, I have a question that I never thought to actually ask you before now—if you have, in fact, answered it before, I’d appreciate it if you’d please let me know where so I can look it up.

The most familiar way to make progress in science is to be confronted with data, either by accident or because of looking at some new feature of the world, and then trying to find a parsimonious explanation that ends up making new nontrivial testable predictions about data not yet in hand.

But what if we already have several theories that exactly account for a large set of our observations and, while not explaining certain other observations, don’t actual contradict any data we know about. And suppose that these theories we already have don’t agree on their mutual overlap, but that mutual overlap occurs only for data that one can show on general grounds are ridiculously out of reach of conceivable experiments, possibly always out of reach.

In general, one might say we’re stuck and simply should go any further. Just do experiments where we can, far below where these mysterious data are, and just be satisfied.

But suppose that when we look at the theories we know, we find that their mathematics creates a long series of highly nontrivial constraints on any other possible candidate theories that could possible extend them. That is, suppose the theories don't allow arbitrary speculation. And suppose that theorists find a candidate theory that beats the odds and actually makes it through that crazy gauntlet, and despite much work no other approach comes anywhere close to accomplishing the same feat.

By construction, this candidate theory cannot predict any data we have access to, or will have be guaranteed to have access to in the foreseeable future. All those data are explained by the theories we already know and trust.

My first question, and I'm interested to hear your answer: Is it worth provisionally proceeding with this approach?

This is the situation string theorists find themselves in right now. The first quantum corrections to gravity in our solar system are 10^-70 effects. Earth's Bohrian principle quantum number is somewhere around 10^150. There are lots of other examples—when we combine quantum mechanics and gravity, we find that the discrepancies in the resulting data involve crazily inaccessible scales. This isn't the fault of string theory, or LQG, or any particular candidate theory of quantum gravity. It's the nature of the data at which quantum mechanics and gravity become incompatible.

And yet in order to have a quantum theory with classical general relativity in the low-energy limit, one runs into a huge number of highly nontrivial constraints, which one might have doubted could be passed any any conceivable theory. But somehow string theory passes them.

So my second question: Do you have a detailed understanding of all those constraints string theory has passed? To the string theorists, this is by far the biggest deal—this is the absolute fulcrum of their entire case—so I was wondering if you are aware of the full—and I mean full—list and how delicately string theory manages to make it through, and what your answer is to the string theorists who are inspired by this incredibly unlikely ability to pass many highly nontrivial constraints.

I suspect that one reason many string theorists are reluctant to listen to you is that they don't believe you've seen what they've seen, that you are fully aware of the crazy gauntlet string theory has (almost magically) sailed through, so they don't believe you really understand why they keep doing what they're doing. (Third question: Do you believe that this isn't the reason they do what they do?)

It's certainly true that the public, and most science writers who are not trained in theoretical physics, have no idea about all these constraints and what it means to say there's a theory that passes them.

With appreciation, Matt

21. **Adam Treat**
July 29, 2013

Matt, from what I understand it is precisely because String Theory has utterly failed to pass through those highly non-trivial constraints that motivate critics. Despite legions of effort and decades of study no one has demonstrated the Standard Model as a low energy limit of String Theory. And from what I understand, even had we the sufficient technology to probe those energy levels where gravity and quantum theory would both necessarily play a role that String Theory – even in principle – would provide no prediction. So I think your hypothetical does not illustrate the true picture.

22. **Peter Woit**
July 29, 2013

Matt,
This really is off-topic, since it has nothing to do with Unzicker, and I've written a great deal about these questions on the blog and in the book.

I'm well aware of the argument you are making, that the existence of a consistent quantum theory of strings is a very non-trivial fact, and worth investigating. Yes, this is a good argument that there's something there, and people who want to should investigate this. It's also true that everything we have learned (after literally tens of thousands of person-years of work) about this theory, whatever it is, says that it explains nothing at all (nothing, not a single thing, do you understand the significance of that?) about particle physics. The issues surrounding quantum gravity are complicated and murky and have been argued endlessly here. But the bottom line is that no matter what glowing terms you use to describe the situation, we're talking about an idea that has failed completely to accomplish what it was advertised (in equally glowing terms) to do. Yes, there's an interesting structure there, but no, it's not one useful to construct a unified theory, as far as anyone can tell.

Sorry, but I don't want more of this same sort of argument here, it's very tired and off-topic.

23. **eggcrook**
July 30, 2013

Peter,
That may be want you want, but I don't think you're gonna get it. Not Even Wrong may have been an argument to judge string theory based on the claims and predictions for the theory as made by the theory's inventors; and a warning of how and why that record of failures was misrepresented. But sadly most people just see a reduction of the complex problem of "How to pursue Mathematical Extensions to the Standard Model", to simple problems of freshman philosophy: "What is SCIENCE? What is EXPERIMENT?"

And they're gonna invoke your name, and your books name, to grant themselves permission to ignore complicated results, because they can expound on their own understanding of simple and accessible concepts like "experiment".

So I think you're gonna be stuck with cranks like Unzicker claiming to be on team Woit, and even educated opponents like Sean Carrol arguing against you by attacking "Popperian extremism," instead of arguing against your deconstruction of string theory promotion. Cause string theory is a stupid theory by stupid people too stupid to realize science means using experiments! Duh! Peter Woit even wrote a whole book proving it!

Regards.

24. **John Urbanik**
July 30, 2013

Unzicker's book was written for some of the masses, just like other books by Greene and Hawking. So to completely dismiss how the "uneducated" masses take it is wrong. Peter has the right idea in confronting it head on.

Being in the field it is easy to dismiss what he is saying and call him a 'crank'. But if his ideas are planted in the minds of others, especially politicians, you can start to kiss your funding goodbye. The population today is very skeptical about science. Without taking sides look at climate science. Despite huge media backing there are very strong opponents and unless something really proves to the masses that AGW is real it will cause repercussion not only on climate science but all types.

Unfortunately it seems physics today is at a crossroads. You need a Copernicus and a new telescope to advance it. But who knows how long that will take. In the days of smaller budgets and everyday folks questioning why any money should be spent on things like the LHC it falls to those in the field to explain it and defend their field.

25. **Hansl**
August 1, 2013

Maybe the masses should be tought more physics instead of being flooded with wrong analogies (even if this cuts Peter's wealth, sorry) and funding should only be assigned by committees of extremist Popperians in order to avoid that cranks can endanger science. Hmm.
I read Unzicker's book in German and was mostly annoyed by his style of permanently attacking people personally. If the book wasn't just a rant against the physics establishment, I would find on the positive side the list of problems which haven't been settled yet (with the exception of the Higgs particle discovery and the Pioneer anomaly) and not all of which I was aware. But that's not worth to buy the book in times of search engines.
BTW the German title "Vom Urknall zum Durchknall" means "From the Big Bang to madness" and is for the phonetic similarity of "Urknall" and "Durchknall" only, which is more than just a rhyme, a marketing coup.

26. **Hansl**
August 1, 2013

I forgot to mention that I am also puzzled that Springer, one of the most reputable science publishers published the book, which doesn't shed a good light on its current lectorate. Science and money again.

27. **Martin**
August 1, 2013

Unzicker was scheduled to give a colloquium at my university a couple of weeks ago, but for some reason he himself cancelled the talk a week before the scheduled date. (have not idea how he got invited in the first place.) Looking at his website (full of typos) made me curious and suspicious at the same time.

28. **mike**
August 4, 2013

Well, when physics is stuck in a rut like it is right now, the cranks are going to get a lot more attention. Remember, even LQG was considered crankish a few years ago

29. **Stephen Cliffe**
August 7, 2013

Chris
"for those who don't know: he's a frustrated high school teacher (frustrated because his scientific career failed) and now grinds his own axe in revenge."
As a high school teacher whose scientific career took off when I re-entered the classroom, I am jut wondering which axe I should grind.
I enjoyed this book greatly, but was suprised by how personally some people are attacked in the bookand how personally some react to thr book in blogs.
I try to give teenagers meaningful answers to questions about the big-bang, dark matter and genetically altered humans. As a biochemist, the last question is the easiest for me. To help me with the first two, my summer reading over the last few years has included many physics texts, of which the critical ones by Smollin and Laughlin stand out. Unzicker has much less standing and is much more personal in his attacks, but the message for me is the same. Teenagers are right to be sceptical about modern physics -it is no longer a case of just being too difficult but rather the students (and teachers and the public and physicists) have difficulty separating humbug from real science.
Ignore Unzicker at your peril. Read "The Golem- What you should know about Science" for a less emotional discussion.

30. **emile**
August 7, 2013

Stephen:

According to Peter, Unzicker wrote the following: "the standard model barely predicts anything", "the standard model can actually accommodate every result".

This is completely wrong. This means that this individual does not understand the Standard Model at an introductory level, yet writes about it anyway. If he is completely wrong on this issue (we are talking about facts here, not opinion), he's got not credibility left on any other subject as far as I'm concerned.

31. **AndreasK**
August 16, 2013

Possibly one should add here one remark on the political and sociological context that allows books as Unzicker's to enter the laureate lists of Germany's prestigious popular science magazine 'Bild der Wissenschaft'. As some reviews on the german amazon indicate, the book nicely fits into a 'movement', in especially in Germany, which seems to aim at a 're-naturalization' of science in general. That is, one claims to detect a tendency to 'overabstraction', 'lack of intuitiveness', 'dominance of superficial mathematical concepts' and connects this openly or more or less subtly to alleged traits of discourses or methods which are considered as 'non-european', 'pragmatic' or 'american', only avoding to openly claim 'non-german'. The inherent contradictions in those constructions, namely, just one example, to critisize 'pragmatism' and 'over abstraction and non-intuitiveness' at the same time, are quite typical for such lines of argumentation and although I know that Peter would prefer not to read such accusations in his blog here, remind me of the way 'jewish science' was characterized by the antisemtic german discourse in the 1930s and 40s, with known results. That Unzicker claims to be a 'fan of Einstein' is just one of these painful details in this row of all-too-obvious irrational discourses of people who see their culture or their 'peer group' or just themselves 'excluded' from discourses they therefore have to condemn as 'the other'. It wouldn't come as a big surprise to me to learn that Unzicker was, if he was involved at all, into branches of science, that, if 'sufficiently intuitive', lack a certain rigor and entail a certain degree of speculative reasoning by their very foundation (cf. neuroscience).

I have to emphasize, that this book comes in a long row of best-selling books in Germany in which science, or better 'pseudoscientific reasoning' play a very pivotal role in establishing certain political agendas, I only remind on the ramifications of 'genetics' and racism that was established in the realms of the 'Sarrazin-debate' in Germany.

In general, I would critisize one special trait that Unzicker unfortunately has in common with the criticism of Peter, although I am far from equating both. From my perspective this amounts to a certain tendency which can possibly be described as 'overestimating sociology' in science and drawing borders not by means of mathematical or physical content, but by the *perceived* presence of certain sociological boundaries. This is to a good part encoded in modern science itself and reminds me of André Weil criticising the group around Hasse for having lost sight of the 'Riemannian' point of view in their work on p-adic numbers and class field theory. But on a 'meta level', as Peter and Unsicker establish, these reductions to 'schools' and ' sociology' are even more harming since they suggest that for instance there wouldn't be *deep* common principles in theories being described as disparate and even 'rivaling' to the public, which might be deduced even to a certain degree from the personality of the scientists themselves, but bare a deeper truth on the scientific level. For instance once can be surprised that M-theory and the theory of 'spin networks' are regarded as rivaling, while certain 'coincidences' as the 'modularity' of certain partition functions in both theories undoubtedly show there are deep mathematical and physical links between such 'rivaling' approaches. Can someone explain to me here why theta functions appear in Gromov Witten theory as they appear in spin network theories and in DT-invariants? Mathematics and physics are to a high degree 'existant' and independent of the sociology of certain groups and for anyone who is more interested in deep mathematics than in post-adolescent rivalries the boundaries produced in nowadays discourses on physics and mathematics by predominantly sociological means must be understood as highly arbitrary and superficial and tend to deepen the 'crisis', if existent at all, in physics or mathematics more than they help to surmount it.

32. **Fred Bortz**
    August 16, 2013

    I am in complete agreement, Peter.

    Before the month is out, I expect to see my review of *Farewell to Reality* appearing in a major US metropolitan newspaper, after which I will archive it at my Science Shelf web site.

    My editor originally offered me the chance to do a slightly longer comparative review with *Bankrupting Physics*, but it didn't take me long to see that Unzicker's broadside pales beside Baggott's insightful critique. My editor agreed that it made sense to spend our limited word budget on Baggott's book alone.

    I admire your dedication in trying to describe what Unzicker set out to do, but I was grateful to set the book aside before I threw it across the room. 🙂

33. **Fred Bortz**
    August 16, 2013

    Just heard from my editor that the review is delayed a bit by internal priorities, but it will run.

    Stay tuned

34. **J Woods Halley**
    August 18, 2013

    I just read the Unziker book (as quite a few commentators apparently have not). Though I am not knowledgeable about string theory, beyond what could be gleaned from some popular accounts and physics colloquia, it was easy to spot a lot of elementary physics errors in Unziker's book and a lot of resentful personal venom. And I share some commentators' concern that the hostility takes an uncomfortably nationalist tone, somewhat reminiscent of what I have read of what happened in German physics in the 1930's. Nevertheless, I think that Unziker is pointing out some real problems in contemporary physics. Though he clearly doesn't understand gauge theories and their role in the standard model, and though he understates its achievements, practically everyone is uncomfortable with the large number of unexplained parameters which it requires. And it is true that the efforts to do something about this, mostly but not entirely with string theory, seem to have failed despite extensive effort. Perhaps some of the learned participants on this page will disagree, but I am also of the view that renormalization is a way around, but not really a resolution, of the problem of ultraviolet divergences in quantum field theory. In fact, people explained to me in the 80's that a primary virtue of string theory was that it has no such divergences. (Smolin says in one of his recent books that it is not fully established that that is true.) So though Unziker's book is often overstated and incorrect, I think it is pointing to some real problems, not all of which have been emphasized in the recent spate of books criticizing string theory.

Latest from the Stacks Project

July 30, 2013
Categories: Uncategorized

My colleague Johan de Jong for the last few years has been working on an amazing mathematical endeavor he calls the "Stacks Project". As boring 20th century technology, this is a work-in-progress document (now nearly 4000 pages), available here. But from the beginning Johan (known to his friends as "the Linus Torvalds of algebraic geometry") has conceptualized this as an open-source project using 21st century technology, including a blog and a github repository.

As of last night, the Stacks Project has many new features, courtesy of impressive work by Johan's collaborator on this, Pieter Belmans. I was going to write something here describing the new features and how cool they are, but a much better job of this has been done by Cathy O'Neil, aka Mathbabe (by the way, if you're not reading Cathy's blog, you should be…). With her permission, I'm cross-posting her new blog entry about this, so, what follows is from Cathy:

The Stacks Project gets ever awesomer with new viz

Here's a completely biased interview I did with my husband A. Johan de Jong, who has been working with Pieter Belmans on a very cool online math project using d3js. I even made up some of his answers (with his approval).

Q: What is the Stacks Project?

A: It's an open source textbook and reference for my field, which is algebraic geometry. It builds foundations starting from elementary college algebra and going up to algebraic stacks. It's a self-contained exposition of all the material there, which makes it different from a research textbook or the experience you'd have reading a bunch of papers.

We were quite neurotic setting it up – everything has a proof, other results are referenced explicitly, and it's strictly linear, which is to say there's a strict ordering of the text so that all references are always to earlier results.

Of course the field itself has different directions, some of which are represented in the stacks project, but we had to choose a way of presenting it which allowed for this idea of linearity (of course, any mathematician thinks we can do that for all of mathematics).

Q: How has the Stacks Project website changed?

A: It started out as just a place you could download the pdf and tex files, but then Pieter Belmans came on board and he added features such as full text search, tag look-up, and a commenting system. In this latest version, we've added a whole bunch of features, but the most interesting one is the dynamic generation of dependency graphs.

We've had some crude visualizations for a while, and we made t-shirts from those pictures. I even had this deal where, if people found mathematical mistakes in the Stacks Project, they'd get a free t-shirt, and I'm happy to report that I just last week gave away my last t-shirt. Here's an old picture of me with my adorable son (who's now huge).

Q: Talk a little bit about the new viz.

A: First a word about the tags, which we need to understand the viz.

Every mathematical result in the Stacks Project has a "tag", which is a four letter code, and which is a permanent reference for that result, even as other results are added before or after that one (by the way, Cathy O'Neil figured this system out).

The graphs show the logical dependencies between these tags, represented by arrows between nodes. You can see this structure in the above picture already.

So for example, if tag ABCD refers to Zariski's Main Theorem, and tag ADFG refers to Nakayama's Lemma, then since Zariski depends on Nakayama, there's a logical dependency, which means the node labeled ABCD points to the node labeled ADFG in the entire graph.

Of course, we don't really look at the entire graph, we look at the subgraph of results which a given result depends on. And we don't draw all the arrows either, we only draw the arrows corresponding to direct references in the proofs. Which is to say, in the subgraph for Zariski, there will be a path from node ABCD to node ADFG, but not necessarily a direct link.

Q: Can we see an example?

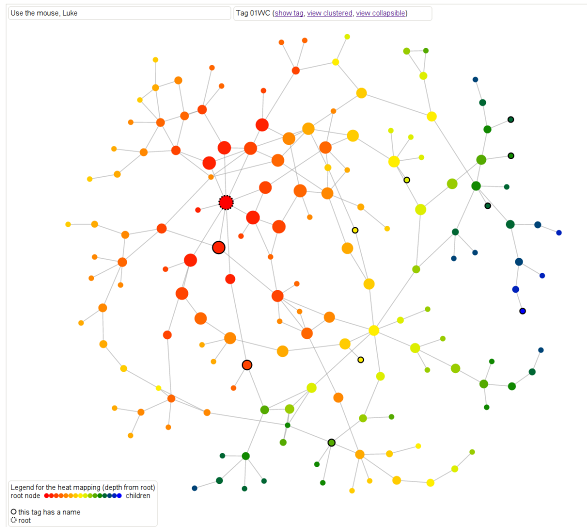
Let's move to an example for result 01WC, which refers to the proof that "a locally projective morphism is proper".

First, there are two kinds of heat maps. Here's one that defines distance as the maximum (directed) distance from the root node. In other words, how far down in the proof is this result needed? In this case the main result 01WC is bright red with a black dotted border, and any result that 01WC depends on is represented as a node. The edges are directed, although the arrows aren't drawn, but you can figure out the direction by how the color changes. The dark blue colors are the leaf nodes that are farthest away from the root.

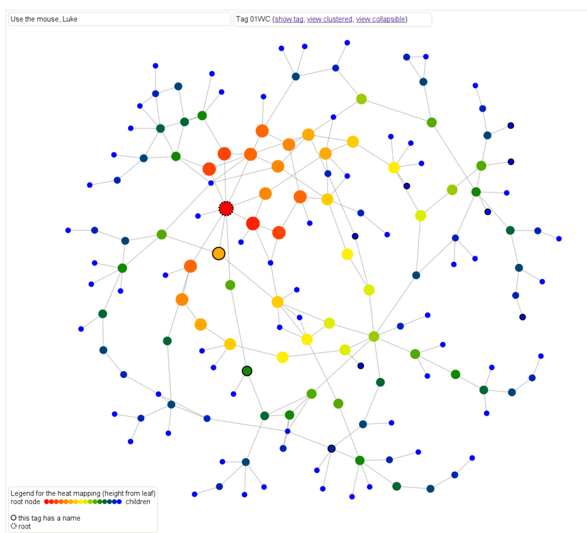
Another way of saying this is that the redder results are the results that are closer to it in meaning and sophistication level.

Note if we had defined the distance as the minimum distance from the root node (to come soon hopefully), then we'd have a slightly different and also meaningful way of thinking about "redness" as "relevance" to the root node.

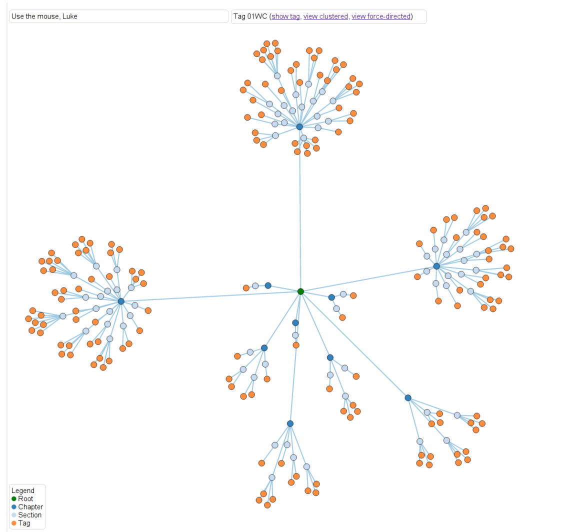
This is a screenshot but feel free to play with it directly here. For all of the graphs, hovering over a result will cause the statement of the result to appear, which is awesome.



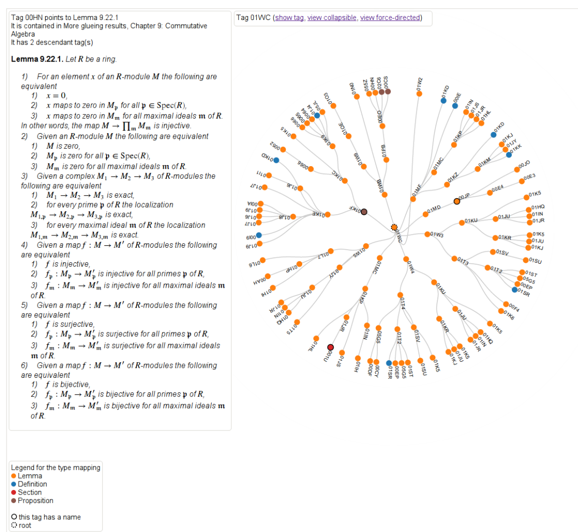
Next, let's look at another kind of heat map where the color is defined as maximum distance from some leaf note in the overall graph. So dark blue nodes are basic results in algebra, sheaves, sites, cohomology, simplicial methods, and other chapters. The link is the same, you can just toggle between the different metric.



Next we delved further into how results depend on those different topics. Here, again for the same result, we can see the extent to which that result depends on the different on results from the various chapters. If you scroll over the nodes you can see more details. This is just a screenshot but you can play with it yourself here and you can collapse it in various ways corresponding to the internal hierarchy of the project.



Finally, we have a way of looking at the logical dependency graph directly, where result node is labeled with a tag and colored by "type": whether it's a lemma, proposition, theorem, or something else, and it also annotates the results which have separate names. Again a screenshot but play with it [here](), it rotates!



Check out the whole project [here](), and feel free to leave comments using the comment feature!

   July 30, 2013

   Great idea, using the proven Open Source methodology to help develop the book. But in this day and age, should we still be restricting ourselves to text?

   I'm a little disappointed in that they haven't gone further with using audio/video lectures to add to the learning experience.

2. **Ben**
   July 30, 2013

   That's a really impressive project, but why aren't they using set theoretical universes? It seems to me that that complicates things a lot, and makes the development less modular.

3. **Peter Woit**
   July 30, 2013

   John McAllison,

   It's probably better to think of this as an attempt to provide a reference work and reliable tool for researchers to work with, rather than an expository work for people to learn the subject from. In this respect it's somewhat like the famous Bourbaki books. Those can be very useful once you know the subject and need a precise result, much less useful if you are just starting and trying to learn what the subject is about. It's not so clear that audio or video are helpful for this kind of thing.

4. **anonymous**
   August 2, 2013

In my, very humble, opinion, a book is not a 21-st century book if it does not explain the motivation behind definitions and tools used, unless by 21-st century one means to write it all down in some formal language and then let finally the computer find out whether there was a gap in the reasoning hidden somewhere. I do not believe that AG definitions and tools cannot be given such motivation. To try to write this motivation down will be probably of bigger value, at least for the "wider public", than the current effort. The best would be also to say clearly for which problems the hypothetical author thinks the machinery is useful, and for which problems he thinks it is not, with interesting examples from both geometry and "arithmetics".

5. **anon**
   August 2, 2013

   @Ben. They explain why they don't use universes. Briefly, they don't need them, and don't want to make an unnecessary assumption (that universes exist).
   @anonymous. Essentially it's a reference work. There are many books on algebraic geometry that attempt to do what you request.

6. **A.J.**
   August 3, 2013

   @anonymous

   To add to anon's comment: Think of it as a technical manual. You don't get your driver's manual out of the glovebox to find out what a car is. Instead, you go to it when you are having a problem with the particular car you are in possession of.

   One problem with this metaphor I'm using: de Jong's book is rather nicely written and seems like an exercise in good taste…

7. **Sebastian Thaler**
   August 5, 2013

   Peter,

   Completely off-topic, but I just wanted to say I'm glad to see you quoted as the voice of healthy skepticism in the article on supersymmetry in the Summer issue of Columbia Magazine: http://www.magazine.columbia.edu/features/summer-2013/heady-collisions

8. **Urs Schreiber**
   August 6, 2013

   @AJ,

   I guess the anonomyous above is a layman in algebraic geometry and secretly asking for help, as in: "Please tell, me, what's the intuition behind algebraic stacks, what are they good for and why should I care" and maybe in addition: "Why should I care, being a person interested and trained (only) in physics?".

   Luckily all such questions are answered in the nLab :-).

9. **Peter Woit**
   August 6, 2013

   If someone wants a 21st century algebraic geometry project of an expository sort, beside Urs' nLab, the mathematically oriented should look at Ravi Vakil's web-site here

   http://math216.wordpress.com/

   Sebastian
   Well, I guess someone was needed for that role….

The Next Machine

August 6, 2013
Categories: Experimental HEP News

For the last week or so US HEP physicists have been meeting in Minneapolis to discuss plans for the future of US HEP. Some of the discussions can be seen by looking through the various slides available here. A few days earlier Fermilab hosted TLEP13, a workshop to discuss plans for a new very large electron-positron machine. There is a plan in place (the HL-LHC) for upgrading the LHC to higher luminosity, with operations planned until about 2030. Other than this though, there are no current definite plans for what the next machine at the energy frontier might be. Some of the considerations in play are as follows:

- The US is pretty much out of the running, with budgets for this kind of research much more likely to get cut than to get the kinds of increases a new energy frontier machine would require. Projects with costs up to around $1 billion could conceivably be financed in coming years, but for the energy frontier, one is likely talking about $10 billion and up.
- Pre-LHC, attention was focused on prospects for electron-positron linear colliders, specifically the ILC and CLIC projects. The general assumption was that LEP, which reached 209 GeV in 2000, was the last circular electron-positron collider. The problem is that, at fixed radius, synchrotron radiation losses grow as the fourth-power of the energy, and LEP was already drawing a sizable fraction of the total power available at Geneva. Linear accelerators don't have this problem, but they do have problems achieving high luminosity since one is not repeatedly colliding the same stored bunches.

  The hope was that the LHC would discover not just the Higgs, but all sorts of new particles. Once the mass of such new particles was known, ILC or CLIC technology would give a design of an appropriate machine to study such new particles in ways that not possible at a proton-proton machine. These hopes have not worked out so far, making it now appear quite unlikely that there are such new particles at ILC/CLIC accessible energies. It remains possible that the Japanese will decide to fund an ILC project, even without the appealing target of a new particle besides the Higgs to study.

- The LHC has told us the Higgs mass, making it now possible to consider what sort of electron-positron collider would be optimal for studying the physics of the Higgs, something one might call a "Higgs factory". It turns out that a center of mass energy of about 240 GeV is optimal for Higgs production. This is easily achievable with the ILC, but since it is not that much higher than LEP, there is now interest in the possibility of a circular collider as a Higgs factory. There is a proposal called LEP3 (discussed on this blog here) for putting such a collider in the LHC tunnel, but it is unclear whether such a machine could coexist with the LHC, and no one wants to shutdown the LHC before a 2030 timescale.
- Protons are much heavier than electrons, so synchrotron radiation losses are not the problem, but the strength of the dipole magnets needed to keep them in a circular orbit is. To get to higher proton-proton collision energies in the same tunnel, one needs higher strength magnets, with energy scaling linearly with field strength. The LHC magnets are about 8 Tesla, current technology limit is about 11 Tesla for appropriate magnets. The possibility of an HE-LHC, operating at 33 TeV with 20 Tesla magnets is under study, but this technology is still quite a ways off. Again, the time-scale for such a machine would be post-2030.
- The other way to get to higher proton-proton energies is to build a larger ring, with energy scaling linearly with the size of the ring (for fixed magnet strength). Long-term thinking at CERN now seems to be focusing on the construction of a much larger ring, of size 80-100 km. One could reach 100 TeV energies with either 20 Tesla magnets and an 80 km ring, or 16 Tesla magnets and a 100 km ring (such a machine is being called a VHE-LHC). If such a tunnel were to be built, one could imagine first populating it with an electron-positron collider, and this proposal is being called TLEP. It would operate at energies up to 350 GeV and would be an ideal machine for precision studies of the Higgs. It could also be used to operate at very high luminosity at lower energies, significantly improving on electroweak measurements made at LEP (the claim is that LEP-size data sets could be reproduced in each 15 minutes of running). Optimistic time-lines would have TLEP operating around 2030, replaced by the VHE-LHC in the 2040s.
- For more about TLEP, see the talks here. The final talk of the TLEP workshop wasn't about TLEP, but Arkani-Hamed on the VHE-LHC (it sounds like maybe he's not very interested in the Higgs factory idea). He ends with

  > EVERY student/post-doc/person with a pulse (esp. under 35) I know is ridiculously excited by even a glimmer of hope for a 100 TeV pp collider. These people don't suffer from SSC PTSD.

  Looking at the possibilites, I do think TLEP/VHE-LHC looks like the currently most promising route for the future for CERN and HEP physics (new technology might change this, i.e. a muon collider). Maybe I don't have a pulse though, since I can't say that I'm ridiculously excited by just a glimmer of VHE-LHC hope for a time-frame past my life-expectancy.

  A 100 km tunnel would be even larger than the planned SSC tunnel (89 km) and one doesn't have to suffer from SSC post-traumatic-stress-disorder to worry about whether a project this large can be successfully funded and built (In very rough numbers I'd guess one is talking about costs on the scale of $20 billion). My knowledge of EU science funding issues is insufficient to have any idea if the money for something on this scale is a possibility. On the other hand, with increasing concentration of all wealth in the hands of an increasingly large number of multi-billionaires, perhaps this just needs the right rich guy for it to happen.

  Someone is going to have to do a better job than Arkani-Hamed in terms of finding an argument that will sell this to rest of the scientific community. His main argument is that such a machine would allow us to improve the ultimate LHC number of "fine-tuning" being at least 10^{-2} to a number like 10^{-4}, or maybe finally see some SUSY particles. I don't think this argument is going to get $20 billion: "we thought we'd see all this stuff at the LHC because we were guessing some number we don't understand was around one. We saw nothing and turns out the number is small, no bigger than one in a hundred. Now we'd like to spend $20 billion to see if it's smaller than one in a hundred, but bigger than one in ten thousand."

Comments

1. **uair01**
   August 6, 2013

   As a normal citizen I'm a bit dismayed by all these plans and amounts. Why spend it on esoteric and far-out theory research? Why not spend it on something that we need more, like nuclear fusion research? I would heartily support that. But this feels more like the weird luxury hobby of a very small elite. We are all in the aftershocks of a financial crisis, people are losing their jobs and you guys are playing with Higgs bosons. What good will that do for the rest of us?

2. **Peter Woit**
   August 6, 2013

   I see that even before I'd finished re-reading this to proof read it, the usual first comment that comes in whenever I write anything about a possible HEP experiment has appeared.

   Enough, all further comments from people who want to argue not about the physics but about the desirability of spending money at all for this purpose will be ruthlessly deleted. This argument has gone on here many times, I don't see any possibility of anything new being said.

3. **Low Math, Meekly Interacting**

August 6, 2013

About muon colliders…I've read a bit about the latest research into hypothetical machine design, but can glean no sense of where the bets are on feasibility. Seems like there's been serious discussion since 2009, so I'm wondering if the HEP community is coming to some consensus on whether or not it's a remotely viable idea.

4. **Peter Woit**
August 6, 2013

LMMI,

There's a long history of work on the muon collider idea, see for instance
http://www.fnal.gov/projects/muon_collider/history.html
As far as I can tell, the current situation is still one of research into determining whether such a thing is truly feasible, with an answer to that question still years in the future.

5. **srp**
August 6, 2013

I wouldn't appropriate money for any of these proposals until some of the ideas here

http://proceedings.aip.org/resource/2/apcpcs/1507/1?isAuthorized=no

had been thoroughly investigated. A billion dollars and five years to figure out whether there isn't a better way (that also may give more-useful spinoffs) would be a very sensible investment. It might even turn out to shorten the time needed to achieve much higher energies.

If it turns out that these concepts are all 20+ years off or are impossible, then OK, it's reasonable to discuss accelerators that would swallow up small countries. Without such a conclusion, these proposals (except maybe the muon collider) all have the air of calling for "more cowbell."

6. **lun**
August 6, 2013

By far the cheapest and fastest option to explore an extra big chunk of as yet unknown parameter space is to put the LEP back in the LHC tunnel, and study ep collisions at much higher space in x-Q^2 than ever before. One can do this with equipment already built.

I cannot help but think that the only reason this is not even mentioned as a main alternative is theoretical prejudice: Theorists are indicating the way, most theorists dont like technicolor and/or substructure theories, therefore such theories (for which an eLHC would be optimized) are not being explored. Note that more often than not the argument against these approaches w.r.t. SUSY is that they are intractable to analytical calculation, something very different from saying they are unlikely to happen.

There is a general point to be made here – experiments and accelerators cost a lot of money, so the pressure is there to go on a road where theorists say youre likely to make a discovery, rather than blindly explore and hope to find something new.
Yet it is the latter road that has often given the big discoveries.
And, more to the point, in this case going off the beaten track (eLHC) would be much cheaper than the standard approach (ILC/VLHCs), and the most quoted theory predictions (SUSY) are being roundly falsified. One needs to invent an experimental strategy that is less risk-averse, which for such expensive toys as those the physicists use is not simple.

7. **M**
August 7, 2013

Theorists too suffer PTSD because LHC did not confirm their theories of the past 30 years. It is great that nature can give such surprises.

A bigger circular collider for a precise study of the Higgs and later an exploration up to 100 TeV would surely the best option. Setting rhetoric aside, exploring is the only way in which we can understand what is the weak scale.

8. **fuzzy**
August 7, 2013

before planning the future, i feel that we should make an effort to remind the discussions before the lhc was built, which arguments have been collected, who had the right to speak and who did not. it is not enough to note the failure of the plans, one should analyze the causes, in order not to repeat it.

personally, i have a strong impression that the lust for machines is larger than the will of discussing what we are searching for. and even when we discuss of physics, the greatest effort is to win the argument or to maintain the position rather than getting to the point. this should change.

finally, i would suggest to invest into gamma and neutrino astronomy, measurements concerning neutrinos, studies about the gravity, understanding astrophysical objects, search for dark matter and alike. these researches gave a lot to physics in the past years and will continue to do so for a long time.

9. **Zathras**
August 7, 2013

This is off-topic for this post, but this article on how science journalists should be skeptical of scientific claims is really fascinating, as well as being quite germane to this blog.

10. **Z**
August 7, 2013

It looks like a muon collider is far off. Results from MICE (e.g. http://arxiv.org/abs/1307.3891) aren't expected until the 2020s, which means it probably won't be ready for a collider planned for the early 2030s. If it does happen though, you could have a 50-70 TeV lepton machine on a 100km ring before you run into synchrotron losses.

11. **Alex**
August 7, 2013

fuzzy's last point is an interesting one. What is the evidence that there must be a theory of fundamental interactions beyond the Standard Model? Well, among other things, there's the existence of dark matter (which we know from astronomical observations), the existence of dark energy (again, known from astronomy), the existence of gravity (something we can study in terrestrial experiments but we understand much better because of astronomical observations), and the existence of neutrino oscillations (something we can study in terrestrial experiments but we first learned about from solar astronomy). For that matter, how did we learn that antiparticles exist? Somebody found positrons in cosmic rays. How did we learn that there's more than one generation of leptons? Somebody found muons in cosmic rays.

I wonder if it might make more sense to invest in understanding neutrinos, looking for dark matter candidates in labs, doing astronomical observations that can constrain particle physics beyond the Standard Model, looking for unexpected things in cosmic rays, and looking for anomalies in dipole moments and whatnot. Those sorts of observations have the potential to either rule out some models or make some models more promising. With that sort of information in hand, one could push for an accelerator with a clearer idea of what it needs to look for.

12. **Peter Woit**
August 7, 2013

Alex,

The things you suggest aren't being ignored, they're more or less exactly the topics that US HEP is now concentrating on, given that an energy frontier machine is not plausible. Even the one main accelerator project (Project X) under discussion is motivated largely by neutrino physics.

13. **Alex**
August 7, 2013

Yeah, I didn't mean to say they're being ignored. I know they aren't. I'm mostly wondering if, given our current lack of knowledge of where to go, these are actually more valuable than a large accelerator.

14. **Sammy**
August 7, 2013

The HEP community might help the case for massive further HEP funding by demonstrating that a by-product could be improved design and analysis of PET scanning, SPECT scanning and Proton Beam Therapy or even the development of Higgs Knives (my second cousin's uncle-in-law's deep brain tumor just got zapped clean away with a Gamma Knife). Then there are smoke alarms and all kinds of industrial probes. Don't forget that the space program gave us nonstick frypans.

15. **Zathras**
August 7, 2013

Sammy,

Pointing to these invention is the conventional response to the cost of science, but I do not think it will be enough. To show this value, the LHC better come up with similar concrete innovations. Otherwise, you're just talking ancient history. There is still time for the LHC to do so, but it is not a given that it will happen.

16. **harryb**
August 7, 2013

I work in the oil industry – and the annual – annual – project capital expenditure globally is now over 1 Trillion dollars (google it). Typically, in any given year, there are 5-15 > $20bn projects underway. I am involved in two currently in this range – one in construction, one in late design. A $20bn project in the oil and gas world – lets call it mature applied physics – is unremarkable at any given moment now. Maybe Peter is right – get these billionaires to invest a proportion in HEP projects rather than largesse to vogue theorists (eg Milner Foundation) and access immortality that way. It would be a refreshing change in perspective to invest heavily in experiment.

17. **Sammy**
August 7, 2013

Zathras: what's ancient history is e.g. the theory (Bethe 1932-33 plus frills) presently used to shape pulses in Proton Beam Therapy. Why not bring it up to the level of modern HEP?

Dirac postulated the positron when my father was a medical student. Now PET scanning is routine clinical imaging. These things take time, and lay people do understand that.

18. **Yatima**
August 8, 2013

Considering the way "western" economies stay mired in inflationism, debt traps and welfare-warfare statism — if China manages to make a soft-ish landing for their overleveraged, bubbling, export-slanted and cheap-labor-from-the-countryside dependent economy (as well as not fall into the trap of internal or external armed conflict), they might be a contender for a projet of a 2030 or later timeframe. They are flush with foreign cash (or rather, US gov'nment IOUs) and looking for national prestige so they could start on design work immediately. Is anyone talking to them?

19. **Loren Petrich**
August 11, 2013

A muon collider seems like a nice idea: the cleanness of a lepton and a high mass. But the muon's mean life is about 2.2 microseconds. That means that there isn't much time to accelerate and collide a muon before it decays. I've seen some discussions of muon colliders, but I haven't found out how they expect to get around that problem.

20. **Peter Woit**
August 11, 2013

Loren Petrich,

See the comment by Z above. The paper linked to has some relevant discussion. The problem isn't so much acceleration but "cooling": the muons you are producing come with a wide spread of momenta, and you need narrow that considerably before you can accelerate and collide. The question is whether you can do this on time scales of less than a microsecond.

Never Give Up

August 7, 2013
Categories: Uncategorized

Alok Jha has a piece in the Guardian yesterday about the failure to find SUSY. His conclusion I think gets the current situation right:

> Or, as many physicists are now beginning to think, it could be that the venerable theory is wrong, and we do not, after all, live in a supersymmetric universe.

An interesting aspect of the article is that Jha asks some SUSY enthusiasts about when they will give up if no evidence for SUSY appears:

> Allanach says he will wait until the LHC has spent a year or so collecting data from its high-energy runs from 2015. And if no particles turn up during that time? "Then what you can say is there's unlikely to be a discovery of supersymmetry at Cern in the foreseeable future," he says.

Allanach has been at this for about 20 years, and here's what he has to say about the prospect of failure:

> If the worst happens, and supersymmetry does not show itself at the LHC, Allanach says it will be a wrench to have to go and work on something else. "I'll feel a sense of loss over the excitement of the discovery. I still feel that excitement and I can imagine it, six months into the running at 14TeV and then some bumps appearing in the data and getting very excited and getting stuck in. It's the loss of that that would affect me, emotionally."

John Ellis has been in the SUSY business even longer, for 30 years or so and he's not giving up:

> Ellis, though confident that he will be vindicated, is philosophical about the potential failure of a theory that he, and thousands of other physicists, have worked on for their entire careers.
>
> "It's better to have loved and lost than not to have loved at all," he says. "Obviously we theorists working on supersymmetry are playing for big stakes. We're talking about dark matter, the origins of mass scales in physics, unifying the fundamental forces. You have to be realistic: if you are playing for big stakes, very possibly you're not going to win."

But, just because you're not going to win, that doesn't mean you have to ever admit that you lost:

> John Ellis, a particle theorist at Cern and King's College London, has been working on supersymmetry for more than 30 years, and is optimistic that the collider will find the evidence he has been waiting for. But when would he give up? "After you've run the LHC for another 10 years or more and explored lots of parameter space and you still haven't found supersymmetry at that stage, I'll probably be retired. It's often said that it's not theories that die, it's theorists that die."

There may be a generational dividing line somewhere in the age distribution of theorists, with those above a certain age likely to make the calculation that, no matter how bad things get for SUSY and string theory unification, it's better to go to the grave without admitting defeat. The LHC will be in operation until 2030 or so, and you can always start arguing that 100 TeV will be needed to see SUSY (see here), ensuring that giving up won't ever be necessary except for those now still wet behind the ears.

For another journalist's take on the state of SUSY, this one Columbia-centric and featuring me as skeptic, see here.

Comments

1. **Giotis**
   August 7, 2013

   SYSY is a fundamental symmetry of Nature. There is no doubt about it. You must be a theoretical physics imbecilic not to acknowledge that.

   Now, how it breaks, at which energy scale breaks and whether it solves some problems of the SM is another issue.

2. **Peter Woit**
   August 7, 2013

   Giotis,
   I suppose another way to deal with losing is by not only refusing to admit that you've lost, but claiming that you've really won. Good luck with that…

3. **Giotis**
   August 7, 2013

   Ok, then I would really like to know your theoretical arguments against SUSY being a Symmetry of Nature. Let me guess, you don't have any. You just sit there crossing your fingers hoping LHC doesn't find anything. That's pathetic…

4. **Urs Schreiber**
   August 7, 2013

   The point hidden in Giotis message is a real issue: people are ever careless about language in what should be exact science, and it leads to endless confusion.

   All mentioning of "supersymmetry" in posts like this is really "low energy supersymmetry". Hence the term "supersymmetric universe" above is quite misleading. Supersymmetry may or may not be a fundamental symmetry of nature, indeedm and what is currently happening at the LHC is quite unrelated to that question. What the LHC sees or does not see is global supersymmetry unbroken at rather low energy. That to exists is — or would be — about as striking as global Lorentz symmetry in the universe, which would be bizarre, even though Lorentz symmetry is a fundamental symmetry of the universe.

   Speaking of universes, that's another example of how careless language damages the scientific discourse: if people had remembered to correctly say "observable universe" instead of just "universe" that awful term "multiverse" would have been neither necessary nor the cause of wasted much bandwidth that it currently is.

5. **Peter Woit**
   August 7, 2013

   Giotis,
   See Chapter 12 of Not Even Wrong, which was written more than ten years ago.

The Columbia Magazine story didn't really quote the arguments I explained to the writer of the article. The simplest is that SUSY explains nothing at all about the SM, since it gives no relations between different objects in the SM, instead relating each SM object to a hypothetical new one. A symmetry argument that explains nothing isn't a very good symmetry argument.

6. **Peter Woit**
   August 7, 2013

   Urs,

   The problem is more your use of language, since if you made it clear to people that when you said "supersymmetry", you meant something that can't ever be tested, they wouldn't take you very seriously. I think you're right that some string theory/SUSY enthusiasts post-LHC will argue that nothing has shown them to be wrong, and nothing in their lifetime ever possibly can, but to the extent that they make this situation clear they will have a serious credibility problem.

7. **fuzzy**
   August 7, 2013

   in my view the problem is worse than pointed out above. even giotis admits that he/she has no idea where this hypothetical symmetry is realized. in this way, he/she is speaking frankly, but i wonder whether this status of affairs was so clearly acknowledged even before lhc—or it was not.

   in particular, i saw that some experts of susy have been mentioned above; let me ask whether, in the past 30 years, they begun their speculative papers by saying "we do not have an idea where susy is broken but let us try 1 tev or so". if they did not (i think they did not) i should conclude that they have misled their field and themselves (which is worse); or, they have believed in some wrong argument. in the last case, i would appreciate very much if they did not rush to tell us what we should think.

8. **emile**
   August 7, 2013

   Giotis: SUSY is a fundamental symmetry of Nature? how do you know this fact about Nature? where is the experimental evidence?

9. **Giotis**
   August 7, 2013

   Emile,

   We live in the 21th century; physicists are in a position now to theoretical deducing properties of Nature. The discovery of Higgs is a great example. They don't have to be guided by experiments, like little kids, to put 2 and 2 together. I'm not in a mood to explain to you why SUSY *has* to be a symmetry of Nature, if you can't figure out why is that just open a text book (indeed SUSY is text book material) and stop wasting your time reading blogs…

10. **Urs Schreiber**
    August 7, 2013

    Indeed, the worldline theory of any spinning particle, such as the electron, is locally supersymmetric. So supersymmetry as such has been experimentally tested since Stern-Gerlach.

    What is under discussion re LHC is some very special aspect of supersymmetry namely "global low energy spacetime supersymmetry". This is the precise term. You may not want to say this each time, but it's good not to forget what you are talking about.

11. **Florin**
    August 7, 2013

    Hi Urs,

    Can you give some more details on "the worldline theory of any spinning particle, such as the electron, is locally supersymmetric" ? I don't follow that.

    As for finding superpartners at LHC.. I don't know but this was never presented as being a "special" aspect of supersymmetry, but the main feature of supersymmetry.

12. **Anonyrat**
    August 7, 2013

    Florin, see http://ncatlab.org/nlab/show/string+theory+FAQ#DoesSTPredictSupersymmetry 4th paragraph.

13. **Peter Woit**
    August 7, 2013

    Florin,

    Urs is just trying to muddy the waters by talking about 0+1 d SUSY when the discussion is actually about 3+1 d SUSY.

    In 0+1 d, you're just doing quantum mechanics, and in cases where your Hamiltonian has a square root, you can call this a supersymmetry. The Dirac operator is an example, so if you want you can say that it generates a supersymmetry, and that SUSY was discovered to work experimentally back in 1928. No need for the LHC! Of course, that's something completely different than what everyone else means when they are discussing supersymmetry (i.e. an extension of the 3+1 d Poincare algebra that mixes fermions and bosons)

    One place that has something about this is a chapter of my book in progress. See chapter 23 of
    http://www.math.columbia.edu/~woit/QM/qmbook.pdf

14. **emile**
    August 7, 2013

    Giotis, you wrote: "The discovery of Higgs is a great example. They don't have to be guided by experiments, like little kids, to put 2 and 2 together. ".

    The Higgs is a great example for not having to run experiments? You knew for sure, that there was a SM-like scalar before it was found? You think we did not need to run the LHC after all? Can you tell me if there are other scalars? an extended sector, 2 HDM? an ewk singlet?

15. **JG**

August 7, 2013

typo in your book link, it should be

http://www.math.columbia.edu/~woit/QM/qmbook.pdf

August 7, 2013

Thanks JG, fixed.

17. **Brian**
August 7, 2013

Ellis: "Obviously we theorists working on supersymmetry are playing for big stakes. We're talking about dark matter, the origins of mass scales in physics, unifying the fundamental forces."

Funny kind of roulette when the barrel is totally empty and you're guaranteed to win. Funnily enough, I heard recently that Ellis was not very interested in the new twistor scattering techniques because it did not fit the priorities of the department … perhaps those senior theorists really should be having a word with department heads.

18. **Seth Goldberg**
August 7, 2013

Somewhat Off topic: Speaking of other physical contexts of supersymmetry, there is also a condensed matter/disorder model. Has anyone here read Supersymmetry in Disorder and Chaos by Konstantin Efetov Cambridge University Press (September 13, 1999)?
See e.g. http://www.amazon.com/Supersymmetry-Disorder-Chaos-Konstantin-Efetov/dp/0521663822/ref=sr_1_1?ie=UTF8&qid=1375921527&sr=8-1&keywords=supersymmetric+solid+state
Anyone willing to comment as to the appropriateness of the mathematical physical analogy (in Maxwell's sense)?

19. **Peter Woit**
August 7, 2013

Seth,
This has nothing at all to do with the topic of this posting, and it's also a topic I know very little about. Fermionic variables have all sorts of interesting uses in stat-mech, and I gather this book is about some of them, but this is a very long ways away from 3+1 d space-time supersymmetry and its uses in particle physics.

20. **Chris W.**
August 7, 2013

> We live in the 21th century; physicists are in a position now to theoretical deducing properties of Nature. The discovery of Higgs is a great example. They don't have to be guided by experiments, like little kids, to put 2 and 2 together.

Giotis, that's just laughable. An undergraduate that made such a statement would deserve to be told they don't belong in physics or any other scientific field in which empirical observations must be accounted for. In such fields, properties of nature are deduced using theories or hypotheses, *and those theories can be wrong*. That is why we test them. If you want a theory that can't be wrong, stick to mathematics or metaphysics and stay the hell out of physics. Period.

21. **Mitchell Porter**
August 7, 2013

Giotis said

"SUSY is a fundamental symmetry of Nature. There is no doubt about it. You must be a theoretical physics imbecilic not to acknowledge that… Ok, then I would really like to know your theoretical arguments against SUSY being a Symmetry of Nature… I'm not in a mood to explain to you why SUSY *has* to be a symmetry of Nature, if you can't figure out why is that just open a text book"

There is no textbook on Earth which explains why supersymmetry "has to be a symmetry of nature". There isn't even a proof that string theory has to be supersymmetric.

22. **Thomas Larsson**
August 8, 2013

Both Michelson and Morley kept looking for the ether wind well into the 1920s. They never, never, never gave up.

23. **Alex**
August 8, 2013

Were Michelson and Morley convinced that there must be an ether wind for them to find, or were they doing their measurements in the spirit of the modern-day physicists who keep doing precision measurements to push the limits on Lorentz violations out another decimal place? I'm pretty sure that these folks will never find anything, but I'm happy to see them trying anyway, and getting published in PRL for their efforts. It's important to the culture of physics that we always have people testing assumptions, and that I can show my students that the people who test assumptions are recognized in prestigious publications for pushing the boundaries out another decimal place.

24. **Bee**
August 8, 2013

Sociologists call it an "escalation of commitment". If I were a sociologist, my next paper would be on "the susy community in the LHC era". Only half joking, it's quite interesting to watch.

25. **N. Nakanishi**
August 8, 2013

Giotis,

Three decades ago, I proved that SUSY cannot be the fundamental symmetry of physics. The reasoning is as follows.
Evidently, SUSY, if it exists, must be spontaneously broken, but there is no Nambu-Goldstone fermion. Hence, one must assume that super-Higgs mechanism works. That

is, supergravity must be encountered. However, quantum supergravity cannot be consistent with SUSY. This is because the global super-charge generators have no space-time index, while the translation generator P_mu does have a space-time index in contradiction with the SUSY anticommutation relation.
The essential problem of Poincare invariance in the framework of gravity is that the general coordinate transformation, which is nothing but the local version of the translation, already contains the Lorentz transformation. The local Lorentz transformation is an internal symmetry; indeed, Dirac field is a scalar field in the framework of gravity. Only after spontaneous breakdown takes place, Dirac field becomes a world spinor. Thus, Poincare invariance is not a fundamental but secondary symmetry. Since SUSY is an extension of Poincare symmetry, it cannot be a fundamental symmetry!

26. **Yatima**
August 8, 2013

The very first post.

1) Fact-free dogmatic statement.
2) Reinforce the fact-free dogmatic statement.
3) Ad hominem attack while claiming the high ground, throw in an argumentum ad populum.
4) Follwup by "I don't know what the hell is going on".

Sure is a formula for success 🙁

27. **LogicFan**
August 8, 2013

I am very pleased that when I was an undergraduate considering the PhD I decided to go into philosophy rather than physics. The intellectual standards of your discipline are abysmal.

You have failed to make any significant theoretical advance in, say, over 30 years. That's pretty bad. Perhaps you will retort that philosophy has failed to make any significant theoretical advance in over 2,000 years, but I do not believe that that is true, and in any case we have maintained our standards when it comes to the pursuit of truth via careful analysis and dispassionate reasoning.

The ad hominem attacks issued from the string theory camp are appalling; its uninterest in the scientific method is baffling; and its emotional attachment to a theory that has virtually zero empirical support is depressing. What has happened to you guys?

28. **gedankentroll**
August 8, 2013

LogicFan said

Whereof one is totally clueless, thereof one should be silent.

29. **Ted Danson**
August 8, 2013

Of course I have no idea who 'Giotis' really is but I have seen this kind of mentality amongst a number of people employed as researches in physics departments (and more than one commenter here). I'm not sure they realize how strange some of their comments seem to those who have (god forbid) been in the business of seriously confronting a model against experiment. Look at this comment for instance:

Giotis:
'Ok, then I would really like to know your theoretical arguments against SUSY being a Symmetry of Nature. Let me guess, you don't have any. You just sit there crossing your fingers hoping LHC doesn't find anything. That's pathetic…'

What a bizarre comment! It would seem to imply that in the mind of 'Giotis', physics beyond the standard model *must* involve supersymmetry. No choice in it. This seems much more like a 'faith-based' statement than something a scientist would write.

30. **LogicFan**
August 8, 2013

gedankentroll:

That is a good paraphrase of Wittgenstein, who in turn is suggesting something important. But what he is not suggesting is that criticism by thoughtful, unbiased, and educated people be ignored.

I have noticed many parallels between string theory advocates and postmodern/Continental "philosophers". Both camps claim special access to profound truths; both camps are highly insular; both camps are resistant to critical inquiry (string theorists disregard calls for empirical verification and postmodern thinkers refuse to subject their "theories" to logical analysis); both camps use ad hominem attacks to defend themselves against calm criticism; both camps write in incomprehensible jibberjabber; both camps have an inflated sense of self-worth; and both camps have utterly, totally failed to add to the sum of human knowledge. The two groups have actually been counterproductive, on my view.

Instead of just working in service of your own ego, don't you want to help figure stuff out about this fascinating universe in which we live?

31. **gedankentroll**
August 8, 2013

Of a long Time I have suspected, that these modern Analytics were not scientifical!

32. **emile**
August 8, 2013

LogicFan: I'm afraid you are being distracted by a relatively small group of people whose notion of science has nothing to do with what 99% of working physicists would accept. To say that the field has low standards is not based on a good knowledge of what is going on. In particle physics, the standards are also high: get educated on what it takes before a paper is even submitted to a journal if you work on CMS or ATLAS. Physics in general is doing great: attend a few colloquia in various subfields and you will be impressed. In particle physics, we just found that the Universe has a scalar field with a non-zero average value. This is significant. The associated particle is a new type of particle never before observed. Not finding anything else at those energies is disappointing to some but it is also an important finding (as you can see from the way many react to this). Just 15 years ago we learned that the Universe is expanding. That's a major, major find. Not too long ago we confirmed that neutrinos oscillate and have now measured the associated mixing matrix which looks very different than its counterpart in the quark sector. I could go on. Lots of progress and lots of questions to answer. A few high profile people and a few bloggers can give the wrong impression. Another thing regarding SUSY: from an experimental point of view, the search will go on for years to come not because experimentalists are necessarily wedded to the idea, but because those searches cast a very wide net in terms of possible final states (these searches can catch many other things from other BSM models) and because you never know what is going to show up in the phase space you have not yet explored.

33. **Mike Mathison**
    August 8, 2013

    Hello Logic Fan – I think emile has more or less just said this already, but here's my take on your comments:

    Earlier, of philosophers, you said "we have maintained our standards when it comes to the pursuit of truth via careful analysis and dispassionate reasoning" but then later you said of your Continental school that they are "[…] resistant to critical inquiry […] refuse to subject their theories to logical analysis […] [and have] totally failed to add to the sum of human knowledge".

    I guess we all have our mad aunties in the attic – perhaps some of ours are string theorists and perhaps some of yours are post-modernists. However, if you're someone who likes big cool machines then I think you probably made the wrong choice going with philosophy rather than physics.

    Earlier, of physicists, you said "you have failed to make any significant theoretical advance in, say, over 30 years". However, as a big fan of physic myself, I don't think that can be entirely correct as I understand there have been many advances in fields such as astrophysics, solid state physics and so forth, as well as a steady stream of speculative big-question theoretical ideas proposed around gravity/quantum-mechanics/Standard-Model-refinement/HEP in general – and at least some of these are/have-been susceptible to falsification either via experiment or observation. Most of us still hold onto the quaint idea that concocting theories that are none the less subsequently shown to be wrong by Nature is *not* actually a waste of time and *does* actually constitute a kind of progress – if only because the knowledge that a plausible/appealing theoretical idea is actually *wrong* is in and of itself very useful knowledge to have gained as it further constrains future theories and is probably telling us something important about our deeper assumptions. I believe such ideas and reasoning are also prevalent in philosophy, though I'm no expert. Anyhow, although it may not be in accordance with the extraordinary rigors of your discipline, I for one would certainly count the failure so far of super-symmetric particles to appear at LHC energies (and the mainstream theories' resulting entry into the arena of the decidedly unwell/coughing-up-blood) as an important advance for physics, both experimental and theoretical.

34. **lucretius**
    August 8, 2013

    Before I ask my question I think I should make a disclosure.

    I am a mathematician with a rather detached attitude to "physical truth" but actually quite excited about the contribution mathematical physics (including the part you refer to in the title of your book and this blog) has made to my own subject. For me the discovery of Witten-Seiberg invariants, Chern-Simons-Witten theory, Gromov-Witten invariants, supermanifolds, superalgebras, Mirror Symmetry etc, more than justifies everything that has gone into the study of the physics. Moreover, I am quite confident that even if the physical theories (like SUSY) do not find experimental confirmation during the next 100 years, the mathematical ideas they have stimulated will find their way into physics via another route. So, quite naturally I think, I am certainly rooting for SUSY physics crowd and hoping that the LHC will bring them some good news. I think it will be good for science, mathematics, almost everyone … which brings me to my question.

    The question is, would you agree that by your public stand on this matter, the success of your book and the reputation it has given you among your readers and journalists, you have inevitably turned yourself into "a partisan of failure" in this matter? Isn't it true that if LHC does find evidence of SUSY you will find yourself in a rather difficult position? Isn't it rather like the situation of an out of power politician who finds himself in the situation where, from his point of view, "the worse is the better"?

35. **Dom**
    August 8, 2013

    Probably going off-topic but aren't you misrepresenting Peter's position which seems essentially to be "Show me the evidence via testable predictions" which then gets hijacked into a meta argument about what science is that we've all heard a million times.

36. **Zathras**
    August 8, 2013

    To answer lucretius, I think one has to recognize a spectrum of theories out there from empirically testable to completely untestable. SUSY is somewhere in the middle, since experiments can confirm or rule out large swaths of the parameter space, but there is still the theoretical possibility of SUSY at energies which cannot be tested. If SUSY is confirmed (looking unlikely, but let's just say…), then there are testable predictions to look at. On the other hand, string theory is something which makes no testable predictions, and has no hope of doing so. And there is no science. Woit's and Smolin's books are not anti-SUSY books; they oppose ideas masquerading as science which make no testable predictions. To the extent SUSY does so, Peter would have no problem with it.

37. **Peter Woit**
    August 8, 2013

    Dom/Zathras,

    The SUSY issue right now isn't so much about testability, but about whether one can get that part of the theory community that for decades has been pushing a specific idea about particle physics to admit that it has been falsified, draw the implications of this, and move on to try and find something more promising. If you know nothing about the scale of SUSY breaking, it's an empty, untestable idea. Pre-LHC, the argument was that SUSY breaking should be at the weak scale, stabilizing it with respect to the Planck scale. This wasn't a very good idea and it didn't explain much, but it got a huge amount of attention and had a great influence on the field. Now the question is whether the fact that it has been experimentally shot down will get acknowledged or evaded.

    About issues raised by lucretius, a separate comment will follow.

38. **Peter Woit**
    August 8, 2013

    lucretius,

    I don't think I'm a "partisan of failure", since I don't think the LHC results ruling out SUSY extensions of the SM broken at the electroweak scale are a "failure". They're actually a huge success of the scientific method. A machine has been built and operated successfully to study nature at distance scales nearly an order or magnitude smaller than ever done before, and one proof of the pudding of this great success is that certain not very good speculative ideas were ruled out. The only possible failure here is if some theorists manage to evade the implications of the LHC results and convince others to keep pursuing the same ideas.

Sure, if the LHC all of a sudden turns up evidence of the kind of SUSY I've been arguing against, then my arguments were misguided and people should take that into account. At this point though, I think if you look at what I had to say in my book (written mostly in 2002), it holds up very well in light of LHC results, especially compared to typical other books of that era which enthused about string theory and SUSY ideas which it's now clear haven't worked out.

It's important to distinguish between the SUSY models that are being shot down and the mathematics that you mention, most of which has nothing at all to do with them. Quantum field theories and superalgebras have all sorts of very interesting mathematics behind them, well worth pursuing (so much so that I included some of this in the course I taught last year), but this doesn't mean that one specific, quite complicated and ugly, example of these is worth much attention. For me the argument against SUSY extensions of the SM has not just been that there's no experimental evidence for them or that they're not as predictive as one would like, but that the ones on sale are hideous and don't really explain anything. I wouldn't be surprised at all if there is some better unified theory that has an interesting super-algebra of symmetries, but just don't think that the ones we know about could possibly work. Hopefully the LHC success at ruling out bad ideas will encourage people to look for better ones. This includes mathematicians, who should pay attention to what the class of theories is that they were often told was of great physical importance, but didn't turn out to be, and decide where to direct their attentions accordingly.

39. **Urs Schreiber**
August 8, 2013

Florin, for an extensive list of references on the local worldline supersymmetry of spinning particles, see here:
http://ncatlab.org/nlab/show/spinning+particle#WorldlineSupersymmtryReferences .

Generally, local supersymmetry is generic in low dimensions, while global supersymmetry is the opposite: non-generic and unlikely.

Historically, people lifted the worldline formalism of spinning particles to the worldsheet formalism of what back then were called "spinning strings", which is 2d gravity coupled to fermions. It turns out that the most natural Lagrangian for this is automatically locally supersymmetric — this is how the concept of supersymmetry was _found_ in the West. People didn't look for it, it jumped at them when they wrote down fermions in 2d gravity. Ever since, the former "spinning string" is known as the "superstring".

The miracle that happens then is that while the second quantization of spinning particles is not itself locally supersymmetric, the second quantization of spinning strings is itself locally supersymmetric. And this is how perturbative string theory implies that if there are fermions at all, then there is local supersymmetry.

As I keep saying, and as our host is now acknowledging too, it is crucial to distinguish local supersymmetry from global supersymmetry. That we don't find global supersymmetry at the LHC says nothing about whether "the universe is supersymmetric". It may or may not be, and it is good to know the difference.

40. **Peter Woit**
August 8, 2013

Urs,
I don't think that global vs. local SUSY is relevant, or that a statement like "the universe is supersymmetric" the way you are trying to use it is meaningful, rather than an empty slogan.

The Dirac operator and spinors show us that there's an interesting superalgebra at work in fundamental physics, but this has nothing to do with SUSY extensions of the SM. One should stop sloganeering, and pay attention to what exactly it is that works as good physics and good mathematics, and what doesn't.

41. **Urs Schreiber**
August 8, 2013

One should stop sloganeering. We can agree on that. A good move is to stick to precise scientific language and avoid imprecise sweeping statements.

There is so much confusion about string theory out there that in all the confused criticism the discussion never gets to what might be good, substantial criticism.

42. **Giotis**
August 8, 2013

The only way to extend Poincare algebra and still respect Lorentz invariance is the super-Poincare algebra. You do that and the existence of fermions is imposed to you by the algebra. SUSY in this sense *explains* fermions which are inherently Quantum mechanical! Similarly in the Superspace formalism you take the ordinary space time and the super-Poincare group forces you to extend it to a Superspace by adding fermionic degrees of freedom to the usual bosonic.

What deeper theoretical reason you want to acknowledge that SUSY is symmetry of Nature? Nature is crying out that it is Supersymmetric at a fundamental level.

43. **Nex**
August 8, 2013

No theoretical reasons ever suffice to prove something is a part of Nature.

44. **CWJ**
August 8, 2013

Seth,
The supersymmetry in Efetov's book is really just a useful tool for carrying out certain Gaussian integrals. Using "normal" numbers, the integral of the Gaussian exp(-ax^2) is proportional to 1/sqrt(a), but if you take the same integral with Grassmannian (fermionic) variables, then it is proportional to sqrt(a). This turns out to be useful in computing Green's functions of random matrices, for example.
(Sorry for being off-topic, Peter–but at least it's on a technical issue and not a rant! And since I happened to laboriously work through the technique some 15 years ago but never published anything…might as well put that knowledge to use.)

45. **Armin Nikkhah Shirazi**
August 8, 2013

Giotis,

I think when one is deeply committed to a particular point of view it can sometimes be very difficult to be aware of the assumptions one makes. In your first sentence " The only way to extend Poincare algebra and still respect Lorentz invariance is the super-Poincare algebra." I could detect at least three.

Assumption 1: One needs to extend Poincare algebra in order to resolve certain issues with the SM that SUSY addresses
Assumption 2: Any approach to understanding these issues potentially conflicts with Lorentz Invariance

Assumption 3: Lorentz Invariance should be respected in a deeper theory

Of course, the assumptions differ in how confident one can be in them, for example I am vastly more confident in the third one than the first two but my point is this: The strength of one's argument depends on the strength of one's assumptions, and if one is either not aware of them or has a quasi-religious belief that they are correct, one is unlikely to recognize the points at which one's argument could break down.
To someone who does not share all of your assumptions it may not necessarily seem that "Nature is crying out that it is Supersymmetric at a fundamental level."

46. **Peter Woit**
August 8, 2013

Armin,

There's another problem, that "The only way to extend Poincare algebra and still respect Lorentz invariance is the super-Poincare algebra." isn't actually true. Presumably Giotis is actually talking about the extension of Coleman-Mandula to include SUSY, so one could figure out what he intended to say, but if you're going to base your argument on a no-go theorem, it would be a good idea to get the theorem right…

47. **lucretius**
August 8, 2013

If you look at section 10.3.3 of Efetov's book you will find that he speculates that there might be a possible relation of the "sigma model" with string theory and quantum gravity. He concludes: "Anyway, the unification of these, at first glance, completely different theories from different branches of physics looks very exciting". Two conclusions:
1. The original question was only about 99% off topic.
2. Some people find "unifications" very exciting even if they do not seem to lead to any now empirical discoveries.

48. **Giotis**
August 8, 2013

Come on, you know what I mean. In fact if you want to be pedantic there are two theorems: Coleman-Mandula and Haag-Lopuszanski –Sohnious.

So you could say the SUSY is the most general symmetry you could have according to these two no-go theorems.

49. **N. Nakanishi**
August 8, 2013

Giotis,

You are wrong. HLS's no-go theorem holds only f0r the physical S-matrix symmetries, that is, for unbroken symmetries. Evidently, SUSY, if it existed, is broken in the actual physical S-matrix. Hence HLS's theorem does not give any priority to SUSY. There is no no-go theorem for the Lagrangian symmetries which we really want to have.

By the way, have you understand my proof of the proposition that SUSY cannot be a fundamental symmetry?

50. **wolfgang**
August 8, 2013

Urs,

your argument is correct, but you have to admit it is a little bit like parents who are proud that their little kid already knows complex numbers – because it can count to three. Yes, 1, 2 and 3 are complex numbers, but …

51. **David M.**
August 9, 2013

Giotis,

It's actually incorrect to say that the only way to extend the Poincare group is through SUSY. For one thing the Coleman Mandula theorem deals with S-Matrices, which assumes the existence of asymptotic states that don't interact with each other. You can do away with this assumption if you consider a conformal field theory. So there are three extensions of the Poincare group: 1)Adding conformal transformations, 2) Adding SUSY generators, or 3)Both.

Another assumption is that we live in flat Minkowski space. If you consider DeSitter or AdS space another exception: Vasiliev theory. There you have an infinite number of higher spin fields.

Although I agree with you that the fact that in flat space, when there is a mass gap and the S matrices are nontrivial the only nontrivial extension of the Poincare group is through SUSY is a compelling argument, you do need to remember the assumptions and other exceptions (besides SUSY) to the Coleman-Mandula theorem.

52. **Giotis**
August 9, 2013

David M,

I'm not sure what you are trying to convey here. Even for massless fields and Conformal field theories the most general symmetries you could have are still Supersymmetric i.e. the Superconformal algebra. And Vasiliev's Higher Spin superalgebras are Supesymmetric ones too.

So what's your point?

53. **David M.**
August 9, 2013

Giotis,

You wrote: The only way to extend Poincare algebra and still respect Lorentz invariance is the super-Poincare algebra.

My point is that this is not true, there are other extensions that work if you relax the assumptions. Yes the maximal extension of the Poincare algebra will include SUSY, but now we've switched from the question of what's the maximal extension of the algebra (which will include SUSY) to a minimal nontrivial extension (which does not necessarily include SUSY). And we know conformal symmetry is not an exact symmetry of nature because we have mass (although at high energies its a good approximate symmetry), so theres no reason to assume SUSY will be an exact symmetry either just because its allowed.

That's not to say these subjects aren't worth studying. CFTs and SUSY gauge theories are important objects to study to understand QFTs and can appear in condensed matter systems (http://arxiv.org/abs/1009.5127 Sung Sik Lee has done work on emergent SUSY), but until its seen an experiment you can't be 100% certain its a symmetry of particle physics.

54. **StevenC**
August 9, 2013

When you think of why someone will never give up an idea or object, you have to step out from the idea or the object, and consider what that idea or object means to that individual. It is more than physics, more than career, but it is psychology. It is completely personal. I don't see SUSY (or string theory) dying in next 10 years.

Sadly, the most successful people who are flexible, accept new information as it is, and understand what that do not understand.

"It is not the strongest species that survive, but the one that is most adaptable to change."
"To know is to know that you know nothing. That is the meaning of true knowledge."
"Facts change, and I change my mind. Will you sir?

55. **Jim Akerlund**
August 9, 2013

I guess a quote from Will Rogers seems appropriate here.

"It ain't what you don't know that counts. It's what you know that ain't so."

Ran across this in the book "A Mathematician Reads the Newspaper" by John Allen Paulos.

56. **Hmunu**
August 10, 2013

Trying to balance the opinions of experts is a rather tricky business, particularly for those of us looking at HEP-EX/TH from outside. I know Bayesian methods are used in the estimation of parameters in particular physics so was hoping that some group had run a model selection test between the SM and a version of SUSY.

With a little digging in the arxiv, I came across this paper with the provocative title *"Should we still believe in constrained supersymmetry?"* The conclusion of **NO** is presented in a rather circumspect and wordy fashion, despite the analysis being pretty definitive.

Has anyone else seen any similar studies testing the SM vs MSSM or some other slice of the SUSY space? I cannot imagine models with a wider range of free parameters would fair any better, their posterior probabilities being dragged down by the increased Occam factors. Is it worth another two decades of work on SUSY, particularly as the models get more contrived as the simplest ones are ruled out? I guess that's for HEP internally to decide.

57. **Marcus**
August 11, 2013

Many former string researchers now seem to have refocused on holographic duality. I wonder if this new article by Don Marolf is relevant to the "never give up" issue:

"A defining feature of holographic dualities is that, along with the bulk equations of motion, boundary correlators at any given time t determine those of observables deep in the bulk. We argue that this property emerges from the bulk gravitational Gauss law together with bulk quantum entanglement as embodied in the Reeh-Schlieder theorem. Stringy bulk degrees of freedom are not required and play little role even when they exist…"
from *Holography without strings?* http://arxiv.org/abs/1308.1977

August 13, 2013

Historical comment:

In your March, 2004 blog you quoted from a talk by David Gross, and said "He then went on to claim that in 3-4 years there will be a headline in the New York Times about the discovery of supersymmetry at the LHC."

Not so.

59. **Visitor**
August 13, 2013

Well you have to give him some credit at least; it was a falsifiable prediction…

Quick Links

August 13, 2013
Categories: Uncategorized

- At HEP blogs you should be reading already, there's Tommaso Dorigo on 5 sigma (with more promised to come), and Jester on the lack of a definite BSM energy scale. Jester puts his finger on the big problem facing HEP physics. In the past new machines could be justified since we could point to new phenomena that pretty much had to turn up in the energy range being opened up by the machine (Ws and Zs at the SPS, the top at the Tevatron, the Higgs at the LHC). Now though, there's nothing definite to point to as likely to show up at the energy scale of a plausible next machine. Jester includes a graphic from a recent Savas Dimopoulos talk characterizing the current situation in terms of chickens running around with their heads cut off, which seems about right.
- The black hole information paradox has been around for nearly forty years, with the story 10 years ago that it supposedly had been resolved by AdS/CFT and string theory. For the past year or so arguments have been raging about "firewalls" and a version 2.0 of the paradox, which evidently now is not resolved by AdS/CFT and string theory. I couldn't tell if there was much to this argument, but the fact that there's a Lubos rant about how it's all nonsense made me think maybe there really is something to it. As usual though, my interest in quantum gravity questions that have nothing to say about unification is limited. For those with more interest in this, I'll just point to today's big article in the New York Times, and next week's workshop at KITP where the latest iterations will get hashed out. For more on the challenge this argument poses to the idea that AdS/CFT gives a consistent picture of quantum gravity, see this recent talk by Polchinski.
- For another challenge to orthodoxy from someone at UCSB, Don Marolf has a new preprint out arguing that strings are not needed to understand holography:

  > Stringy bulk degrees of freedom are not required and play little role even when they exist.

Comments

   August 13, 2013

   Is it just me, or does Leonard Susskind not possess a curious ability to get into the media no matter is the physics topic du jour?

2. **Lun**
   August 13, 2013

   The strong version of ads/Cft must be stringy as you need two expansion parameters, the number of colors and the coupling constant.
   In the planar limit this is however irrelevant, it seems that in that limit (where most on the evidence for holography comes from) such arguments could apply.
   The firewall debate, with neither a sliver or experimental connection nor anything approaching rigor or a coherent picture, is a good example of what's wrong with modern physics.

3. **Oldster**
   August 13, 2013

   David: Leonard Susskind is an outgoing, intelligent, personable guy who has been in the thick of the information paradox and string theory scene for decades, and who likes to write and comment for the public as well. No matter what your views on the physics, it would have been hard to avoid his name in this particular story. I say this as someone who is a hopeless reactionary compared to him on physics too, not as an advocate … 😉

4. **Peter Shor**
   August 14, 2013

   Leonard Susskind gives excellent talks, is a great teacher, and enjoys talking to the public and the media. This is undoubtedly one reason why reporters like him; they find him eager to talk to them, and they can understand him.

   I don't think he's beating on the media's doors and asking them to write stories about him, the way I suspect some other physicists are doing.

5. **Anonyrat**
   August 14, 2013

   Is Don Marolf's argument essentially that a theory with diffeomorphism invariance has an action whose significant terms are boundary terms, and hence has a form of holography?

6. **Mitchell Porter**
   August 15, 2013

   I am still digesting Marolf's paper but it seems a little dodgy. It does not talk about holographic *duality* at all – i.e. the equivalence between a theory in the bulk and another theory on the boundary. Instead, it is (I think) an argument that a general quantum state in the bulk theory can be constructed just using bulk operators from the boundary.

   To understand what that means, we need to distinguish between operators in a separate theory defined on the boundary, as in AdS/CFT, and operators in the bulk theory which pertain to bulk observables near the boundary. In the latter case we are talking only about one theory, called the bulk theory, but we concern ourselves with operators in that theory which are associated with the edge of the bulk.

   Marolf also uses the Reeh-Schlieder theorem, a well-known theorem from algebraic/constructive/axiomatic QFT which says that, because of the entanglement of the vacuum state, any state in the QFT can be approximated arbitrarily closely, by combinations of operators from arbitrarily small spatial regions. He then combines this with special properties of gravitational theories (I haven't decoded that part) to deduce a property he calls "information holography".

   As a non-expert observer, what I notice is that there have been at least two other attempts to apply Haag-like models of QFT to AdS/CFT which have come up wanting. Both were debunked by Jacques Distler: first, years ago, Rehren's "algebraic holography", which Distler dubbed "Rehren duality" to distinguish it from the real thing, and then, much more recently, Gomes et al (arxiv:/1305.6315), who proposed to explain the emergence of gravity from the RG flow on the boundary by using the "shape dynamics" formulation of general relativity. But it will take someone better than me to say exactly what the status of Marolf's paper is.

7. **ohwilleke**
   August 15, 2013

   "Is it just me, or does Leonard Susskind not possess a curious ability to get into the media no matter is the physics topic du jour?"

One of the lessons that I learned in student government as an undergraduate and then a law student (and then again later during a brief stint as a professional journalist), is that the vast majority of people, even prominent people in politics or at the top of their fields, are extremely reluctant to talk to reporters (and not necessarily without good reason, I should add). Despite not having an official PR position, I ended up in the student newspaper almost every week in student government related stories simply because the reporters couldn't find anyone else who would reliably provide them with quotable quotes for their stories. Later, as a reporter, the lazy thing to do was always to call people who I knew would be willing to go on the record for me when I wanted a quote.

If you are among the 5% or so of prominent people in a field who are willing to go on the record with a statement about something on short notice and say something quotable when you do, reporters will flock to your door. Susskind and science reporters have mutually discovered this fact.

8. **Tommaso**
   August 17, 2013

   Hello Peter,

   thanks for the mention of my article on the 5-sigma criterion, of which I issued today the third (out of 4) part. I believe it is an important thing that we realize how that criterion has strong limits and should only be thought of as a guideline, not as a fixed rule.

   Best,
   Tommaso

9. **Peter Woit**
   August 17, 2013

   Tommaso,

   Wonderful series of posts. You're doing a great job of not just explaining the "5 sigma" issue, but more generally giving a lot of insight into the subtleties involved in any search for a bump in an HEP experiment. Very educational.

   My own amateur, much cruder, take on these issues has generally been to not believe discovery claims made by one experiment, no matter how many sigma they say. If their competitor says they also see the same thing, that's the time to start becoming a believer…

Belief in multiverse requires exceptional vision

August 14, 2013
Categories: Multiverse Mania

Tom Siegfried at Science News has a new piece about how Belief in multiverse requires exceptional vision that starts off by accusing critics of multiverse mania of basically being ignoramuses who won't accept the reality of anything they can't see with their own eyes, like those in the past who didn't believe in atoms, or superstrings:

> If you can't see it, it doesn't exist. That's an old philosophy, one that many scientists swallowed whole. But as Ziva David of NCIS would say, it's total salami. After all, you can't see bacteria and viruses, but they can still kill you.
>
> Yet some scientists still invoke that philosophy to deny the scientific status of all sorts of interesting things. Like the theoretical supertiny loops of energy known as superstrings. Or the superhuge collection of parallel universes known as the multiverse.
>
> It's the same attitude that led some 19th century scientists and philosophers to deny the existence of atoms.

The problem with the multiverse of course is not that you can't directly observe it, but that there's no significant evidence of any kind for it: it's functioning not as a testable scientific explanation, but as an excuse for the failure of ideas about unification via superstring theory. Siegfried makes this very clear, with his argument specifically aimed at those who deny the existence of "supertiny loops of energy known as superstrings", putting such a denial in the same category as denying the existence of atoms. Those who deny the existence of superstrings don't do so because they can't see them, but because there's no scientific evidence for them and no testable predictions that would provide any.

Siegfried has been part of the string theory hype industry for a long time now, and was very unhappy with my book, which he attacked in the New York Times (see here) as misguided and flat-out wrong for saying string theory made no predictions. According to him, back in 2006:

> …string theory **does** make predictions — the existence of new supersymmetry particles, for instance, and extra dimensions of space beyond the familiar three of ordinary experience. These predictions are testable: evidence for both could be produced at the Large Hadron Collider, which is scheduled to begin operating next year near Geneva.

We now know how that turned out, but instead of LHC results causing Siegfried to become more skeptical, he's doubling down, with superstring theory now accepted science and the multiverse its intellectual foundation.

The excuse for Siegfried's piece is the Wilczek article about multiverses that I discussed here, where I emphasized only one part of what Wilczek had to say, the part with warnings. Siegfried ignores that part and based on Wilczek's enthusiasm for some multiverse research takes him as a fellow multiverse maniac and his article as a club to beat those without the exceptional vision necessary to believe in superstrings and the multiverse. Besides David Gross, I'm not seeing a lot of prominent theorists standing up to this kind of nonsense, leaving those invested in failed superstring ideology with the road clear to turn fundamental physics into pseudo-science, helped along by writers like Siegfried.

Update: A commenter points to this from Wilczek, noting his lesser multiverse enthusiam than Siegfried's.

Update: Ashutosh Jogalekar at The Curious Wavefunction has a similar reaction to the Siegfried piece.

Update: There's an FQXI podcast up now (see here), with Wilczek discussing the multiverse.

   August 14, 2013

   "Exceptional vision" ??? Siegfried is certainly not at fault for my immediate reaction to his choice of words: that vision required to see N-rays?

3. **paddy**
   August 14, 2013

   Pardon my double post….I tried to ignore Siegfried's choice of the word "belief" in my previous post…but now my gorge is rising..time to have another beer.

4. **Matt**
   August 14, 2013

   Cosmic inflation predicts that the actual universe is much larger than the observable part we can see, and by a truly staggering amount — the observable region is like an atom compared to the rest. The rest is called the multiverse. Other regions can fall out of inflation just like our region did.

   Cosmic inflation is now heavily supported by high-precision observational data. It also neatly resolves the horizon problem, the flatness problem, the relics problem, the structure problem, and what gave the big bang its initial oomph to begin with. And we have direct evidence today that the fundamental mechanism actually works, because of the existence of (much weaker) dark energy.

   So how is there "no significant evidence" for the multiverse? Is the evidence for inflation wrong? Is there some magical principle that prevents any other region of the multiverse from falling out of inflation like our region did, or that nonlocally forces inflation to stop everywhere simultaneously all at once? The name "multiverse" might be the trouble — would it be less controversial if we just called it "the rest-iverse"?

   Note that I'm not talking about string theory or the landscape here — those concepts are logically independent from cosmic inflation, and the enthusiasm of string theorists is not evidence against cosmic inflation. When you say there is no evidence for the multiverse, are you just referring to its fusion with the idea of the string landscape?

   I'm just trying to make sure I understand a little more precisely what you're saying here.

5. **Peter Woit**
   August 14, 2013

Matt,
I think I've discussed this "inflation implies a multiverse" argument many times here. The issue is not whether there's more than the observable universe out there. That may very well be, and maybe someday we'll even understand inflation well enough to have a good model of what that might be. The point though is that there is zero evidence that whatever else there is has different physical laws than ours, and that is what is needed to make the whole anthropic business work. In simple models of inflation, whatever else is out there will have the same laws as ours, so yes, you can get a multiverse, but a pretty boring one. You can use string theory or something else to come up with much more complicated models that give you pretty much any physics you want in different parts of the multiverse, but there's no evidence for these, they are untestable and explain nothing. These models function just as excuses for the failure of string theory to explain anything and that's the pseudo-science problem here.

6. **Daniel TTY**
August 14, 2013

How about other kinds of many-universes theories, such as universes being created in quantum fluctuations, or via black holes?
Do you think that our universe is the only one?

7. **Peter Woit**
August 14, 2013

Daniel,
I have no idea whether there are other universes. If you have a model that produces them via quantum fluctuations or black holes, fine. But if it's untestable and does nothing to explain the things that the SM and GR leave as mysteries, I'm just not interested. If it's untestable and you want to claim it shows why those mysteries can't be explained, and it's hideously complicated, I think you're a pseudo-scientist (and, unfortunately, in illustrious company…)

8. **Matt**
August 14, 2013

Hi Peter,

That's exactly what I wanted to know—thanks.

So I think it's important make this distinction clear. You are okay with the notion of the "boring" version of the cosmic multiverse (which I don't happen to think is very boring! I mean, come on, right!?) necessarily predicted by cosmic inflation, namely, that the actual cosmos is far vaster than our observable region (that's the whole basis for how inflation solves the various problems like flatness, the horizon problem, etc.), and in those other regions inflation can end and produce other observable regions.

Where you draw the line is at the pure speculation that we can attach a string landscape to this cosmic multiverse and use it to start making anthropic claims about what the low-energy physics of our own observe universe looks like—the particle menu, the coupling constants of the Standard Model, etc. So, to be clear, you are okay with the "boring" multiverse, but not okay with the string landscape and the anthropic principle.

Is that a correct appraisal? That may seem like a subtle distinction, but I'm sure it's pretty important to a lot of people! Maybe you could say "anthropic mania" or "string landscape mania" rather than "multiverse mania"? Because even apart from string theory or anthropic reasoning, the "boring" multiverse is a very conceptually amazing consequence of inflation!

9. **Peter Woit**
August 14, 2013

Matt,

Sure, I'm ok with inflationary models that produce lots of unobservable universe with the same laws of physics, but, honestly I do think they're kind of boring. The people out there selling the multiverse as a radical new advance in physics aren't selling this kind, they're selling the one with different physics everywhere, as an explanation for the laws of physics, and that's what I have trouble with.

10. **Anonyrat**
August 14, 2013

I would find it very hard to believe that our cosmos coincides exactly with our observable region- our past light cone. This with or without inflation.

11. **Abbie Hoffman-Tegmark**
August 15, 2013

There are a lot of different multiverses going around these days.

12. **Casey Leedom**
August 15, 2013

So sad that Tom Siegfried is headed this way. Luckily his bias doesn't seem to have overwhelmed Science News' content or I'd have had to cancel my subscription years ago. Interestingly, I was actually turned on to your book via a short review in Science News years ago when it came out (along with Lee Smolin's book in the same issue if I remember right).

13. **Bee**
August 15, 2013

The multiverse is an inevitable consequence of attempting to describe nature by relying exclusively on mathematical consistency. Whatever you do, you'll always have to pick some axioms of your theory and these axioms will either require additional justification or, if you don't have that justification (call it selection), they'll imply a vast number of "universes" that are nothing like our own. That's got nothing to do with string theory in particular, it's a consequence of mathematical "space" being larger than our observed "space".

There are only two ways to deal with that. Either you believe in the multiverse as being real and say we only observe part of it. Or you select the "real" part of the mathematically possible by binding it to observation and disregard the rest.

Which way you prefer depends on whether you believe that mathematics is a language that we use to describe nature (in which case the multiverse is an artifact of the limits of that language) or whether you believe that nature fundamentally is mathematical (in which case you're now missing a criterion that tells you which part of the mathematics is real).

The reason this problem occurs now is that people are attempting to construct theories without observational constraints. (One can plausibly argue that requirements like renormalizability, gauge invariance, and Lorentzian signature are ‘observational’ constraints, though they’re rarely referred to as such. But these are the requirements that dramatically reduce the space of possible theories. Alas, they’re evidently not sufficient.)

I wrote a blogpost on that here.

Personally, I’m in the camp of people who think that mathematics is a language and shouldn’t be confused with reality.

14. **markusm**
August 15, 2013

Maybe there is already evidence for the (“boring” ?) MV:
http://www.youtube.com/embed/OAL1-vzMvmA

15. **imho**
August 15, 2013

There’s evidence for a boring multiverse??? I had no idea. Can some one give me a pointer to a good survey article appropriate for a Cond Matt theorist with a passing interest in these things.

16. **Jim**
August 15, 2013

Matt/Peter,
I thought I might take this opportunity to test my own understanding. Apologies Peter if this is somewhat off-topic.

Although inflation is part of the ‘standard’ lambda-CDM model of big bang cosmology, my understanding is that it is still a bit controversial. In it’s most commonly accepted form, it is based on the idea of supercooling at the end of the Grand Unification epoch, triggered by an ‘inflaton field’ responsible for symmetry-breaking leading to the separation of the strong nuclear force from the electro-weak force. It’s controversial because we don’t have a GUT that everyone can buy into, and so cosmologists have been completely free to choose a shape for the inflaton potential that is consistent with the universe we see today.

So far as I know, there’s nothing in the theory to indicate whether inflation applies to the whole of the post big-bang universe or whether it was just one small bubble of spacetime within this that inflated. If I’m right, then debates about whether or not there’s a larger ‘boring’ universe outside of our bit of inflated spacetime are really rather moot – in any case we’ll never know one way or the other.

Sure, inflation resolves the flatness, horizon, and other problems, but there may be lots of other ways of doing this that do not involve inflation and, if I’m being a tad skeptical, the lambda-CDM model is, for the most part, a best-fit exercise with a good number of variable parameters. It is certainly not wrong (as the fit is quite spectacular), but as we have no theory that can provide *a priori* predictions for these parameters (just as we can’t predict the parameters of the standard model of particle physics) then I’d argue that all bets are off.

Inflation is a great device and it seems to work well, but I think it best that we don’t over-interpret it.

17. **Peter Woit**
August 15, 2013

imho,

I think very few physicist’s believe in the sort of evidence for a multiverse linked to above. For more about this, see here

http://www.math.columbia.edu/~woit/wordpress/?p=5966

18. **Low Math, Meekly Interacting**
August 15, 2013

“Multiverse” seems to me like a fairly meaningless term (i.e. it gets used for so many different things it’s hard to tell if it means anything). However, to the extent it is not completely bereft as noun specifying something, I don’t think it makes much sense to conflate it with “everything beyond our cosmic horizon”. It seems to get used most often as a term for the ensemble of (mostly) isolated vacua with different physical constants, e.g. the string theory landscape.

19. **Chris Oakley**
August 15, 2013

“Belief in multiverse requires exceptional vision” is a very 1960s thing to say, and sounds a lot like “Belief in multiverse requires exceptional amounts of LSD”. It is just more proof – if proof was needed – that the subject has been taken over by hippies.

20. **Harald Kirsch**
August 15, 2013

Can’t help to quote Gemany’s ex chancellor Helmut Schmidt: “People who have visions should go see a doctor.” (http://en.wikipedia.org/wiki/Helmut_Schmidt#Senator)

21. **ED**
August 15, 2013

The most plausible model of the physical world could be a very bad framework for scientific investigation, and in the multiverse wars, it would be nice to see this fact kept in focus. To be worth investigating, a model must be plausible , yet a plausible model may not be worth much attention.

If lost keys might be under a lamp post, might be in the dark beyond, and yet seem most likely to be at the bottom of a river. A wise investigator would neither let inaccessibility discredit the riverbottom-key hypothesis nor jump in the river and drown.

In other words, “X is unobservable, probably true, and worth considering” is entirely compatible with “Assuming that X is true would destroy physics”, and both are compatible with doing experimentally oriented physics and (mostly) ignoring X.

That said, I find Wilczek’s arguments (and lament) persuasive. I recommend the article as an exploration of the limited but non-zero utility of anthropic reasoning.

22. **Peter Woit**
August 15, 2013

ED,

One problem is that "plausibility" is in the eye of the beholder. Those with decades of their lives and their reputations invested in string theory may find the anthropic string landscape a plausible idea, others not so much. They also may feel regrets about putting the torch to physics as a science, that this makes them feel bad, although not as bad as they would feel if they had to admit they had been wrong.

23. **vmarko**
August 15, 2013

Matt said:

"Cosmic inflation predicts that the actual universe is much larger than the observable part we can see, and by a truly staggering amount — the observable region is like an atom compared to the rest. The rest is called the multiverse."

If one is talking about the "boring" version of the multiverse, I think that the terminology is misguided. If there is nothing conceptually different between various inflated bubbles, then it's just more of the same thing, sitting outside our observable space. This does not, and should not, deserve to be called "multiverse". Rather, it is just an extension of what lies beyond our cosmic horizon. It should still be called "universe".

The term "multiverse" makes sense only if those other patches of space are somehow very very different than our own (like having different values for the coupling constants etc.). And *that* is the problem — there is no convincing way to establish that such things actually do exist. This is the failure of string theory that Peter is criticizing all this time.

In this sense Peter is right to push all "multiverse" stuff into the same basket — the inflation-induced boring version of the "multiverse" should not have the "multi" part inside its name in the first place. It's just misguided use of terminology.

Best, 🙂
Marko

24. **Shantanu**
August 15, 2013

Matt,
Despite much hype, I still don't think we can conclusively say for sure inflation happened. The only thing we can say for sure from Planck is that n is different from 1.
We still don't know the energy scale of inflation and GUT based inflation is ruled out from Planck data. Also there are fundamental conceptual problems with single scalar field inflationary models (see http://arxiv.org/abs/1304.2785)

Another thing is that there are so many models of inflation , see for example this 330 paper http://arxiv.org/abs/1303.3787
IF you have so many "models" of inflation, by random chance one of them is probably right. But that defeats the original purpose of inflation.
Also as Peter and other mentioned there is no-observation al evidence for multi-verse and given so many models of inflation, its not obvoious which of them need a multiverse and which ones don't.
and

25. **Matt**
August 15, 2013

That the actual "rest-iverse" is far, far vaster than all that we can directly see all the way out to the earlist galaxies is a fairly robust, model-independent consequence of inflation, regardless of the shape of the potential or the number of scalar fields. In essentially any model, you need enough e-foldings to solve the various problems with the old big bang model, and that leads to a humungous cosmos far bigger than the popular understanding of the term "universe."

It's really a staggering and under-appreciated triumph of science that precision cosmology has advanced to the point at which we can confirm the general validity of cosmic inflation, even if we cannot yet pin down the specific model. And there are lots of people working on that right now, and checking their predicitons against observations carefully. That's most definitely bona fide science, and it would be a real shame if it got lumped into the string wars in the public understanding. And one would have to be really jaded not to realize how awesome this all is.

Some have called it the "megaverse." But the idea that the cosmos is so unimaginably big that there are lots of other pockets just like ours, separated by inflating regions, and with each pocket containing its own galaxies and whatnot—even without the string landscape and any unfounded claims of different low-energy physics in those pockets—certainly fits my picture of what a multiverse is. It's a less exotic notion of a multiverse than given by the string landscape, but as a vast expanse filled with little "island universes" separated by nontraversible inflating regions, it fits the bill for a lot of people when they use the term "multiverse."

26. **Chris W.**
August 15, 2013

Still, Matt, you must admit that there is a certain extravagance in this consequence of inflationary models, insofar as the consequence can never be tested, directly or indirectly. String theory, and perhaps alternative quantum theories of gravity, vastly complicate the picture by introducing enormous scope for variation of low-energy physics in those inflationary pockets, setting the stage for an anthropic trivialization of our understanding of the observed universe.

One might consider how analogous—or not—this situation is to that of the vacuum in quantum field theory. The features of that vacuum play a key role in calculating observable quantities—e.g., the well-known corrections of quantum electrodynamics.

27. **LogicFan**
August 15, 2013

I'm a philosopher, not a scientist, yet I cannot believe that Siegfried doesn't understand the essential difference here; that is, the distinction between being practically unable to observe some phenomenon and that phenomenon being perforce inaccessible to experiment.

I have heard some disparaging things (including, I believe, by the author of this blog) said about philosophers of science (I am not one), but every time I read something like this I am reminded how often even the educated make simple errors of logic, and thus how important our discipline really is.

28. **Low Math, Meekly Interacting**
August 15, 2013

The multiverse does seem to induce a curious form of cognitive dissonance. On the one hand, someone will propose that, say, bubble nucleation will leave an imprint on the CMB. "See? It's testable!" So we see nothing, feel like we've been had yet again, and complain that this whole multiverse business is proving to be utterly unobservable, unfalsifiable, and hence maybe outside of the scope of physics. "Stop being such a positivist!"

29. **Peter Woit**
August 15, 2013

LogicFan,

That's not really the relevant distinction here. What's more at issue is that you can test a theoretical framework not just by directly observing the fundamental entities of that framework, but instead by testing other implications of the framework. The first evidence for atoms was not from seeing atoms, but from seeing their effects on other larger objects (the phenomenon of Brownian motion).

You can imagine a theoretical framework that predicts other universes (which you can't observe), and if this same framework predicts indirect effects of such other universes that you can observe, or it makes new distinctive predictions (say the mass of the electron) that can be verified, you have significant evidence for the parts of the framework you don't have direct experimental access to. This is what the string theory landscape people would like to do. Their problem is that there is no evidence at all that their framework can do this: they can't calculate anything at all in it.

The problem with Siegfried's argument is a very conventional one: it's a straw man argument. He's claiming that the argument of multiverse critics is that the theory can't be directly tested, and that these critics don't understand about indirect tests. But that's not the argument (at least not from this particular very vocal critic). The argument actually is that the string theory multiverse makes no predictions of any kind, either directly or indirectly testable. It's not actually a scientific theory, but a pseudo-scientific construct designed to "explain" why you can't ever predict anything testable, directly or indirectly.

30. **Paulibus**
August 16, 2013

Bee says all that need be said about multiverse mania. Sadly, unless someone trips over a decaying proton while walking in the woods, we're watching the transformation of theoretical physics, sans its Baconian flavour, transform itself into a beached whale. Shades of Mark Twain's Great Nonesuch!

31. **lucretius**
August 16, 2013

I have to admit I am rather new to these "string wars". During the last 25 years or so I have listened to a number of talks by Witten at various mathematics conferences (including at least one at which Peter was present, although I only found it looking at the proceedings last night) and I have never doubted that his inspiration came form "mainstream physics". Well, now it seems, people are claiming it is not physics at all (although nobody seems to know what else it could be). I only realised that something weird was going on behind the scenes by reading Lubos's blog, which I visited for reasons which had nothing to do with "strings".

Anyway, I have decided to sit on the sidelines at least until I am confident I understand the main technical issues involved. This is still going to take time. I am somewhat surprised that not everyone thinks that is the right approach. I am also puzzled buy what exactly we are supposed to worry about. On the one hand I keep reading here alarming messages to the effect that string theorists are "putting the torch to physics as a science" and that "theoretical physics transforming itself into a beached whale" , etc. On the other I remember Peter writing that string theory (and LQG, to which all the same objections seem to apply but which rarely is criticised here) represent only a section of theoretical physics, with apparently decreasing influence. So how can these two things be true at the same time?

On the issue of string theory's lack of experimental predictions own naïve view at the moment is this. If we have two theories (GR and QFT, I think), which have together make a large number of confirmed experimental predictions but are mathematically inconsistent with each other then if we can construct a self-consistent theory (ST) which "in the limit" replicates GR and QM, than that constitutes scientific progress. The theory is "scientific" even if it does not make any confirmable predictions beyond those of GR and QFT since it inherits the predictions that they make and adds self-consistency. Hence the only thing that would worry me as far as ST is concerned are the two questions: 1) is it really fully self-consistent and 2) does it really give GR and QFT in the limits? So I would worry about the kind of criticism that Penrose discusses in "The Road to Reality" (finiteness or the question of stability of 10 dimensional space time) but not about the kind of things that are most often mentioned here.

As for the "multiverse" I would be inclined to follow the method of Sherlock Holmes (as described in "The Sign of the Four"): "when you have eliminated the impossible, whatever remains, however improbable, must be the truth". Of course to some extent this begs the question: what exactly do we mean by "impossible" in this context? Myself I am quite happy with the view that impossible means "mathematically impossible", which means that if it takes hidden extra dimensions and multiverse to construct the unified theory and if all the mathematical problems can be sorted out – than, however improbable, that is maybe not exactly "the truth" but the best we have got.

August 16, 2013

lucretius,
You're leaving the topic of this posting, and trying to start a discussion on a range of topics about string theory and its associated hype which have been discussed ad nauseam here over the years, something I don't want to encourage. If it's not clear though, the on-topic problem being referred to (ok, with imprecise and inflammatory language like "putting the torch to physics", I should try and avoid this as Lubosian) is a straightforward one. As an idea about unification, string theory has been remarkably unsuccessful, and has ended up now forced into the corner of a specific very complex and completely unpredictive and untestable proposal (the string theory "landscape") that I claim is accurately characterized as pseudo-science designed to avoid admitting failure. Siegfried's article is an attempt to justify this, and I'm pointing out the problems with it.

The exact details of what the string landscape proposal is and why it is unpredictive are among the things that have been discussed ad nauseam here over the past 10 years since this proposal first surfaced. If you're skeptical about my claims and want to devote time to this, I'd suggest trying to find a counter-example: a testable prediction, or a plausible proposal for how to get one. Many claims of such things have been discussed here on the blog. You also might want to note that even Lubos doesn't believe in this (he thinks some new insight into string theory will make the landscape unnecessary).

If you're not interested in this, but just want to repeat hype about supposed wonderful properties of string theory and how it's the only way to go to get unification, so it doesn't matter if it's pseudo-science, because we have no choice, then I really can't help you, but do want to point out that you're arguing for giving up on this kind of science, torching it if you will. Maybe better understanding fundamental physics is a lost cause, one could have argued that at anytime in the earlier history of the subject. I don't think it was true then, or that it is true now.

33. **vmarko**
August 16, 2013

Lucretius,

String theory is much more ambitious than just unifying GR with QFT — it aims to be a "theory of everything" — deducing from first principles both GR and all of the Standard Model. As far as incorporating GR into QFT, string theory has been reasonably successful, and that is all good and well (at least up to a point). But as far as reproducing the SM, all string theory attempts have been a disaster — instead of a single version of SM, it "predicts" some 10^500 different versions of it (this is a colloquial way to phrase the so-called “landscape problem”).

So at this point string theorists were supposed to admit that ST simply fails to predict the SM, and that further work is required. Instead, they started arguing that actually all those 10^500 different “Standard Models” actually do exist in nature — the multiverse hypothesis — and that we are seeing this one particular SM in experiments (as opposed to any other) because our universe (our observable patch of the multiverse) hosts a version of the SM that supports life being created in it. This is called the “anthropic principle”.

The issue with this argument is the following — not only that it does not predict anything, but moreover it states that one should give up trying to predict anything. Just like religion (naive interpretations of it) can answer any question with “God did it”, string theory can invoke the anthropic principle to answer any question with “we happen to live in such a patch of the multiverse”. It has 10^500 “vacuua” (or free parameters, simply put), so you can fit basically any experimental data to this set of parameters. No predictions can be made in such a setup, only interpolations and data-fitting.

So, failing to predict the SM free parameters, string theorists should admit that ST is far too general and that further axioms/principles/whatever is needed to reduce the parameter space. But instead of doing that, they simply declare ST to be “correct”, and the SM problem unsolvable, by definition. And they get a lot of positive media attention, saying “string theory, via the multiverse and the anthropic principle, solved one of the biggest puzzles in science”, when in fact they didn’t solve anything — they *gave up* on the problem.

It even goes as far as teaching graduate students not to look for any explanation for the SM free parameters — string theory predicts that they cannot be explained and that no explanation is necessary, so why bother?

From a failed attempt to unify all forces of nature, string theory grew to become a fundamentalist religion of modern physics.

All this has nothing whatsoever to do with combining GR with QFT — that can be done with some level of success in ST, in LQG, and in various other approaches.

Best, 🙂
Marko

34. **Low Math, Meekly Interacting**
August 16, 2013

What strikes me as an incredible irony is that string theory was supposed to solve the problem of having to resort to anthropic reasoning. The multiverse concept (as I prefer to define it) was already quite mature in form eternal inflation. Some people were eyeing the possibility of a non-zero cosmological constant with abject terror. But once we found the principle that selected manifolds that gave us 3+1 extended dimensions, GR, and the Standard Model as a low-energy limit, we could dispense with pseudoscientific anthropic nonsense! Now the ST landscape is the foundation on which eternal inflation can stand. Nothing appears to remain of the notion of selecting anything, except maybe wistful nostalgia among those who don’t regard it now with disdain. What a terrible vision this has turned out to be.

35. **Amos Dettonville**
August 16, 2013

Lucretius, isn’t the landscape/multiverse idea inconsistent with what you described? It says there is no unique “limit” of string theory corresponding to the standard model and general relativity. Instead, there are a bazillion low energy limits, and we don’t actually know (and may never know) if any of them closely resemble the standard model. The hope is that some of them do, but in any case nearly all of them don’t. In this situation, it seems like a stretch to say string theory “inherits the predictions” of the standard model.

If what you described came about, i.e., if there was a unified conceptual framework that uniquely reduced to the standard model and general relativity in some suitable “limits” (as general relativity reduces to Newtonian theory in the weak slow limit), I would agree that it would be very interesting – although if it really makes no new confirmable predictions it might be more accurate to call it an *interpretation* rather than a new theory. If that interpretation sheds light on how the conceptual inconsistencies of the two pre-existing theories can be reconciled, that would be great.

I suppose string theorists believe there are enough qualitative similarities between the generic features of string theory solutions and the facts of the standard model and general relativity that we are warranted in claiming that string theory already constitutes a unified conceptual framework subsuming gravity and the standard model (not withstanding the fact that we don’t actually know – and may never know – if any solution of string theory actually matches the standard model quantitatively). But apparently many have concluded – some reluctantly and some enthusiastically – that a necessary ingredient of this conceptual framework is the landscape/multiverse, i.e., severe under-detemination of the specific attributes. With the landscape/multiverse, we might say the only prediction of string theory is that prediction is impossible – in the sense that there can never be any deeper explanation for the parameters of the standard model, because many different sets of parameters are equally compatible with the principles of string theory.

So in this sense I suppose we could say string theory would be falsified by the discovery of some new constraints or inter-relationships between the parameters of the standard model. On the other hand, maybe any new constraints would simply be taken on board, and the claim updated to say there are no *more* constraints to be discovered. All we’re doing is refining the attributes of one particular solution (the one that corresponds to our universe), while retaining the belief that it is compatible with the principles of string theory (which still seem to be in flux).

36. **DN**
August 16, 2013

“It’s not actually a scientific theory, but a pseudo-scientific construct designed to ‘explain’ why you can’t ever predict anything testable, directly or indirectly.”

Peter, enjoy reading your blog, opinions and the various developments you write about, even though I’m in a different field.

Maybe you’re trying to be funny and serious at the same time up there. I get it. Anyway, help explain “explain” a bit more. Thanks.

37. **Peter Woit**
August 16, 2013

DN,
To really see what’s going on here, you need to get into the very complicated subject of how to construct “string vacua”. At this point I think even most string theorists have given up on working on this, with the subject left in a state where you have so many possible choices that you can get whatever you want, and evade having any testable prediction that might conflict with experiment. The “multiverse” provides the argument that any “string vacuum” might show up. Normally scientific theories explain in one way or another something we observe, this theory explains why we can’t ever test it (too many possible string vacua, we could be in any of them).

38. **lucretius**
August 16, 2013

Indeed I forgot about the ST probably because I am now trying to understand better QFT (for purely mathematical reasons) and the rest of the ST is just physics to me 😉
I agree that the ideas of landscape/multiverse seem contrived and probably unnecessary (although my knowledge of this subject is very limited).

I don't see why anyone should be surprised today by the failure of physicists to arrive at a unique mathematical "theory of everything", particularly in view of the experience of other disciplines.

In mathematics, as everybody knows, Hilbert's naïve hope that a consistent system of axiom for the whole of mathematics could be found (and proved to be such) was destroyed by Goedel's two theorems, after Russel and Whitehead spent years trying to realise it (in volume 2 of Principia Mathematica they managed prove that 1+1 = 2).

In option pricing (in mathematical finance) there was a period when it appeared that Nirvana had been attained: in the Black-Scholes model of stock market prices the assumption of lack of arbitrage implied that there was a unique fair price of every option, and for the simplest ones explicit formulas could be given. In spite of Nobel prizes in economics, this turned out to be an optimistic illusion: we now know that real world markets are incomplete and there are infinitely many "fair" prices of options compatible with the given price of the stock and the non-arbitrage principle. Out of these infinitely many "consistent" prices (or price processes) the market somehow chooses one – but there is no known principle that determines it.

In microeconomics about 100 years of research into general equilibrium run into a brick wall in the form of the Sonnenschein–Mantel–Debreu theorem, which says that equilibrium is neither unique not stable.

In none of these cases the seemingly devastatingly negative result lead to people abandoning the entire field (or even basic directions) of research. In fact, in each case pragmatic reasons were found for continuing.

I don't believe that string theory actually needs the landscape and multiverse to survive. The indeterminacy is disappointing but there are ways to deal with it just as there are in all these cases I have mentioned.

Obviously the landscape and multiverse belong to the realm of speculation, even if dressed up in elegant mathematical form. In fact the title of Sigfried's article suggests this by his use the word "belief". Nothing in science can actually depend on a "belief". "Belief" can be very important in motivating someone to pursue a line or research that seems unpromising to others but to accuse critics of a scientific theory or idea not having enough "belief" makes one sound like an apologist for a religion not a science.
Hoever, I don't see any reason why Sigfried's obvious silliness should be taken as discrediting the rest of string theory and that is really all I wanted to say.

39. **paddy**
August 16, 2013

Lucretius,
Such a comparison of theoretical physics to so-called "economic theory" might (or should) shame those who have monetized the "multiverse".

40. **lucretius**
August 16, 2013

Peter, I am curious what kind of "discussion" you consider to be "on topic" in a thread like this one. I understand that you may not want to return to things that " have been discussed ad nauseam here over the past 10 years" (although I don't think you are seriously expecting new readers of your blog read through 10 years of past discussions before asking a question) but then what is "on topic" except for cries of "whatever next" and "what is the world coming to" and this sort of thing? . I asked one question, which at least had the virtue of being different from what other people wrote. I repeat it: how can string theorists be increasingly irrelevant to physics research and even having difficulties getting hired (both claims I have read on your blog while trying to catch up on the past discussions) and at the same time be "putting the torch to physics"? O.K. you have now disassociated yourself from this "Lubosian" language but you still have not answered my question. If string theory is indeed as unsuccessful as you claim, and in decline then what is the purpose of posting threads in which everybody is clearly expected to express the same "anti-string" view?

41. **vmarko**
August 16, 2013

Lucretius,

"I don't see why anyone should be surprised today by the failure of physicists to arrive at a unique mathematical "theory of everything", particularly in view of the experience of other disciplines."

It is not a surprise, of course. But do remember that (in light of Goedel's incompletelness theorems), a "theory of everything" in physics actually means "theory of everything so far", since every theory in physics can aim to describe only the so-far-known experimental facts. So we are well aware that any proposal for a "theory of everything" is necessarily incomplete from a conceptual point of view, but at the same time it should certainly be able to describe all previous established models in suitable limits.

Also, note that the Goedel's incompleteness theorems and the Sonnenschein–Mantel–Debreu theorem are actually **theorems** (such negative results in physics go by the name "no-go theorems", and there are many examples of such results). In contrast, the multiverse idea in ST and the anthropic principle are **axioms**, that deny one the possibility to give any furher explanation of the SM free parameters.

A lot of people simply refuse to accept such statements as valid axioms, precisely because of the limitations they impose. Even some string theorists are trying to steer clear of them. But there is this group of prominent string theorists who embrace them and advocate them — and they happen to be influential, vocal and widely present in the general media.

"Hoever, I don't see any reason why Sigfried's obvious silliness should be taken as discrediting the rest of string theory and that is really all I wanted to say."

Sigfried is by no means the only one nor the first one to display such "silliness". This "multiverse mania" (as Peter likes to call it) has been going on for quite some time now, and there is quite some amount of propaganda in the media about it. Just take a look at some past posts in Peter's blog, you'll find that this Sigfried's "silliness" is just the latest in a long series.

If other, more sensible string theorists would be as vocal against multiverse as its advocates are, the whole idea would be just one more controversial philosophical idea being debated, like so many others in history of science. But the problem is that those more sensible string theorists are keeping to themselves, while vocal advocates of multiverse are creating the illusion that there is general consensus about the topic.
This situation is what is discrediting string theory in particular, and threatens to discredit the whole theoretical high-energy physics in general, in the eyes of general non-hep public.

Best, 🙂
Marko

42. **Peter Woit**
August 16, 2013

lucretius,
The topic of the posting is the Siegfried piece, which, yes, I claim is arguing for putting a torch to physics by promoting pseudo-science. Some string theorists also argue for this, some don't. The ones who do I personally think are motivated by refusal to admit failure. As for the rest of string theory's problems, that's another topic.

As for insisting on people agreeing with me, I delete large numbers of comments posted here that criticize string theory but have nothing of interest to say. I very rarely delete comments from anyone who wants to disagree with me and argue for string theory. If your comments were arguing against string theory I'd probably have started deleting them on the grounds of off-topic/uninformed. Instead, here you are, admitting that you don't actually understand the issues, but dominating the discussion. Because I'm allowing this, sensible informed people who see this won't write in, just those who like to argue about the same old thing. You are doing everything you can to turn this comment thread into yet another tedious, uninformed and worthless set of string-war arguments, why?

43. **vmarko**
August 16, 2013

Also, while Peter of course has the last word in his blog about what is on/off-topic, I think that this discussion is certainly not off-topic. It certainly is a beating-a-dead-horse-discussion, yes, but off-topic, I'd say no.

🙂
Marko

44. **DrDave**
August 16, 2013

Siegfried:
"If you can't see it, it doesn't exist. That's an old philosophy, one that many scientists swallowed whole….After all, you can't see bacteria and viruses, but they can still kill you.
Yet some scientists still invoke that philosophy to deny the scientific status of all sorts of interesting things."

Actually, you can see bacteria and viruses with a scientific instrument called a microscope, and right there is the logic break: you can't test for a multiverse, or the tests don't show anything.
This is followed by a straw man (straw person, sorry) argument of "some scientists" invoking the philosophy of the unseen. This is not what scientists do; scientists use the scientific method. The whole introduction to the article is to recast any scientists who disagree with SUSY and multiverses as the work of provincial disbelievers, as opposed to the rigorous methods and brilliant experiments developed from years of training.

45. **Chris W.**
August 16, 2013

More succinctly, bacteria and viruses were killing us before we even had any clue they existed, and we now know enough about them to say a lot of testable things about precisely how and when they can kill us, as well as how to produce images of them with appropriately designed equipment.

46. **lucretius**
August 17, 2013

@Peter Woit:

Since you asked me a question I feel obliged to answer it. It was certainly never my intention to take part in the "string wars". As I wrote earlier, I intend to sit on the fence until I understand things well enough to make up my mind for myself. Yes, I freely admit I do not "understand" many of the issues involved, but my standards of what constitutes "understanding" seem to be higher than yours. One of the first things I learned from my supervisor when (a long time ago) I started working on my doctorate was never to claim to understand anything unless I can reproduce all the technical arguments myself, preferably in my own way, and in this sense I certainly do not understand string theory. I noticed, however, that when Matt asked you whether you understood the technical details of string theory in one of the recent threads on this blog you refused to answer and (as you often do) declared his question off topic. I have not read your book but judging by your publications available on the Interent I can't conclude that you apply the same standards to "understanding" as I do.

Your claim that because you are generous enough not to delete my ignorant posts "sensible informed people who see this won't write in" is, in the context of this particular thread, laughable. In fact, except for the replies to my posts by Marko, Amos Dettonville and a couple of other posts, the rest is information-free rhetorics.

So this brings me to your question:
"You are doing everything you can to turn this comment thread into yet another tedious, uninformed and worthless set of string-war arguments, why?"

Purely out of curiosity. I wanted to find out what this blog was: a physics discussion forum or a combat training ground for the "string wars". Lubos' blog, besides his rants (which, in spite of their abrasive language are often witty and entertaining except perhaps to their targets) contains large amounts of technical physics, skilfully elucidated. In spite of its obviously one sided view, it is by a long distance the best place on the web to learn about certain areas of modern physics. Nobody could say this about this blog. To stick to the military metaphor: Lubos is training highly skilled commandos for the string wars while you are training suicide bombers.

With best regards

Lucretius

47. **Jesper**
August 17, 2013

@ Lucretius

what a load of eloquent rubbish. The problem with string theory is not string theory itself but the total dominance in theoretical physics it has had in the past decades. Although it might now face less friendly winds this general problem is still very real. Peter's blog is a much needed vent for dissent. There is nothing suicide bombing about it, rather a forum for discussing what many feel are troubling trends in theoretical physics. I don't see anyone bombing anyone here?

And besides – in my views many of the unattractive sociological aspects of string theory are also found in other research directions in theoretical physics. Only, they are nowhere near as dominating as string theory.

With best regards,

Jesper

48. **Marty**
August 17, 2013

Lucretius,

I have very mixed feelings about commenting on your last post, mostly because I feel like I'm contributing to the drift of the discussion from the primary topic. However, since you've said you haven't followed this blog very long, hearing another perspective may be useful.

I watched the "string wars" play out on several blogs (e.g., this one, Asymptotia and Cosmic Variance) some years ago, and needless to say the discussions turned ugly at times. Unsurprisingly, Peter was usually involved in them in some form or another, primarily because he was unusual among string theory critics in that he had actually spent a fair amount of time learning about some key aspects of string theory. (Lee Smolin was another knowledgeable critic who occasionally took part; almost always he managed to keep his cool in the face of personal attacks.) Although Peter's level of knowledge was/is not at the level of a practicing string theorist, he had/has some technical familiarity with the topics he discussed. I think that earned him at least some respect among non-string-theorists — he didn't post on subjects where he had no knowledge, and didn't pretend to know something he didn't know in responding to others. Moreover, on numerous occasions over the years he has had this blog, when it was brought to his attention that he was wrong he would generally admit it, and when he was justifiably criticized for his demeanor in responding to personal attacks he would often agree that he could have handled it more gently.

Understandably, if you didn't follow those "string wars" discussions, some of which contained *hundreds* of comments, you might not appreciate how tedious it became when a majority of comments were posted by people who were technically uninformed but who didn't like (or did like, as the case might be) string theory for one reason or another, very often doing little more than parroting some point by Peter, Jacques Distler, Lubos or some other well-known critic or partisan — they said nothing new, but still felt that they should say something anyway. Many of the comments were personal and insulting, and for no good reason other than what appeared to be a very personal identification some people had with their own viewpoints. Practicing string theorists could also be insulting, which did nothing to polish the image of said theorists or their favorite theoretical framework.

Returning to your questions and posts, if you keep that history in mind, it is probably obvious that Peter has no interest in repeating that experience with a "fresh crop" of blog readers. It isn't anything personal — I really doubt he knows anything about you, so it *can't* be personal — but in your last post your tone seems pretty defensive as though you took his admonition as a personal attack on you or your questions. In fact, if you compare the change in tone in your last post with some of what transpired in "string wars" discussions, you might recognize a certain commonality: at some point, a string theory partisan would feel like their views weren't given the respect they felt was deserved and then dig in his/her heels, then resort to personal attacks on Peter's (for example) publication record, lack of "string theorist credentials", or other lame attempts to discredit Peter-the-person through bogus rationales, implicitly suggesting that by extension one should disregard the actual content of what he was saying. I'm not saying you are actually heading down that path, but with your most recent change of tone it is a possibility.

(Interestingly, you mentioned Lubos' blog as a training ground for "highly skilled commandos" and Peter's blog as a place for training "suicide bombers." That is such a surprising contrast that I can't help myself in commenting on it. There is no question that Lubos knows a lot of physics; he is definitely gifted that way, certainly in my opinion and undoubtedly in the opinion of many others, say at PhysicsStackExchange. Having said that, on his blog and comments on blogs of others he freely intermixes his own biases and opinions with actual physics knowledge (or at least he did before I stopped reading him much), but often won't tell you that is what he's doing. And my impression/observation, again and again, was that his response when someone pointed out that he had made an error was to argue uncompromisingly, or call the person a moron (or worse) because they obviously didn't know any physics or they would agree with him; but rarely would he admit he made a mistake. Another tactic he uses, or at least used in the past, was to delete posts that criticized the "story" he was trying to present. I stopped reading his stuff because I could no longer stand his frequent insults/intolerance of others who disagreed with him, the general low quality or sycophantic tone of comments readers made to many of his posts, and what often looked like an unwillingness to distinguish his opinions from fact. So in a sense I agree with half of what you said — his blog can act as a training ground for commandos — but only if you mean unquestioning jihadists for the string theory "cause" rather than "warriors" who do battle through rational and open minded discourse. Anyway, you apparently have a lot more patience for the ugly side of blogging than I do.)

49. **Nathalie**
August 17, 2013

Quite a few researchers are dissatisfied with their own (scientific) lives. They didn't manage to dethrone Albert E., as was their original plan when they went to physics. "Everyone" had told them that they are terribly smart. Consequently, these people suffer from internal aggressions. Let them fight over Multiverse and such harmless stuff. Who cares? Nobody gets physically hurt and that is much better than them physically beating their wives and children.

50. **Peter Woit**
August 17, 2013

Lucretius,

Thanks for the advice that I should run this blog more like Lubos's witty and entertaining one that you so much enjoy. The great thing about the internet is that there's a place for everyone. I think you've found your place and I'm sorry but I can't allow you anymore to try and change this one.

Others: please don't feed the troll.

51. **Experimental Physicist**
August 17, 2013

Peter and Lucretius

This is my first comment in any blog. I am SM experimentalist, I consider myself a layperson in BSM physics. Though I came to know about this blog very recently, I have read most of the earlier entries and comments. I read a lot of other blogs on different subjects too. The aspect of this blog I admire the most is the sensible comments from experts from different fields whether their arguments are either for or against Peter's. For instance, though Peter Shor and Matt Strassler may have different opinions, their arguments are worth admiring equally. There are a lot of other regular commentators in this blog whose insights sometimes outweighs than that of the main enetry. Thanks Peter for creating such a wonderful platform. Lucrtius, to me, correct scientific insights are far more important than wits.

Thanks
Exp Physicist

52. **Peter Woit**
August 17, 2013

EP,
Thanks! I should say that among the most rewarding aspects of running this blog is learning new things from and hearing the point of view of some of the commenters here, well-known (not always visible from the name they leave..) and not-so-well-known. It's not always easy though to try and keep this a place that sensible people

would want to participate in…

53. **george ellis**
August 18, 2013

In his previous post at The Curious Wavefunction, Ashutosh Jogalekar (commenting on whether psychology is a science or not) gives the following criteria

" The five basic requirements for a field to be considered scientifically rigorous [are] clearly defined terminology, quantifiability, highly controlled experimental conditions, reproducibility and, finally, predictability and testability."

Sounds good to me.

54. **srp**
August 18, 2013

Don't think you want to rule out the observational sciences–astronomy, meterology, oceanography, structural geology, etc.–because they can't do experiments.

55. **Maynard Handley**
August 18, 2013

"Don't think you want to rule out the observational sciences…"
Oh give that old canard a rest. The cloud chamber was invented precisely to study the phenomena that result in clouds, and then repurposed by physics. The whole point of the diamond anvil is try to get at the actual conditions of matter inside the earth.
And so on, and so on.

If I'm an oceanographer, yes, I observe the existing ocean currents. But I ALSO hypothesize that they are driven by density differences caused by salinity and/or temperature. I do experiments to see how these effects play out. I make predictions about where the ocean water will be above average in salinity or whatever, and test the predictions. I fantasize about what might happen to currents if a mass of fresh water were to hit a particular ocean, and then look in the historical record for any possible such events. etc etc

The issue is not experiments (something like a controlled environment run by the scientist), it is a feedback loop between observations and predictions. The observations can come from experiments, examining "nature", or the historical record; likewise a variety of predictions are possible. What matters is both observation (to keep one tethered to reality) AND predictions (so that one is approaching some sort of understanding, doing more than just stamp collecting).

56. **huhiho**
August 19, 2013

57. **Neil**
August 19, 2013

The multiverse, along with the anthropic principle, in some sense "explains" fine tuning to me, and I like that. It is not traditional science, but it is not religion either. If, someday, fine tuning can be explained without these concepts, I will be happier.

58. **Lee Smolin**
August 20, 2013

Neil,

Cosmological natural selection can explain the fine tunings of the parameters of the standard model of particle physics without the anthropic principle. And it makes falsifiable predictions, for example that the upper mass limit of neutrons stars is at most two solar masses. This is so far consistent with observations but could be falsified at any time. This doesn't mean its right, but it means its a testable scientific hypothesis.

Thanks,

Lee

59. **Giotis**
August 20, 2013

Bottom line is that although other universes cannot be observed, even in principle, it may be indeed the case that there is a Multiverse out there. The thing is, are we clever enough to theoretically deduce its existence even if we can observe it?

I think it is possible if we have a strong belief in the corresponding theoretical framework which predicts it. Besides pure theoretical considerations we may gain confidence on the validity of the corpus of theories supporting the multiverse idea by circumstantial experimental evidence.

In any case the last thing we want to see is wasting decades of research trying to understand the values of parameters which indeed may have a pure environmental explanation. So the sooner we reach conclusions regarding the Multiverse idea the better. In that respect research should continue of course. Don't forget that Nature is full of surprises and you never what you may found just around the corner; either a dead end or a revelation, the only way you could find it out is by walking the path…

60. **Armin Nikkhah Shirazi**
August 20, 2013

Giotis,

I am struck by how the first part of your third paragraph seems to contradict the second part. You seem to consider "trying to understand the values of parameters" at least potentially a waste of time but then say "the only way you could find out is by walking the path". If this is correct then efforts to understand those values cannot be considered a waste of time as long as "walking the path" promises a resolution one way or another.
I think the unspoken assumption behind this incongruence is that you already deem research around the multiverse to be more promising than other approaches (as evidenced by the second paragraph and prior posts).
I think there is nothing inherently wrong with holding that assumption, the problems arise when it is used as a criterion for evaluating and comparing distinct approaches

to solving a problem without making it explicit that it has been used that way. If you are not aware of this, it will make it that much more difficult to understand the point of view of those who do not share your assumptions.

61. **Nathalie**
August 20, 2013

Let us assume that there are billions and billions of universes out there. After all, we already know that there are billions and billions of galaxies. Can any of you explain why humans on our tiny little planet should care about the number of Universes? Don't tell me that it's because we want to understand our own universe better. Such an argument doesn't make sense as our universe need not be a typical one. Of course, you could make further assumptions but who tells you that your assumptions are correct?

62. **Low Math, Meekly Interacting**
August 20, 2013

I'm also utterly confused by the notion that exploring the multiverse deductively could be superior, under any circumstances, to working on alternatives with observable consequences, or even just devoting more effort to increasing our confidence in current theory. I see no way to escape the fact that deductive reasoning about unobservables, no matter how well grounded in established theory, requires belief. And systematic, potentially interminable reliance on belief would be a radical, arguably self-negating paradigm shift in the way science is currently performed, at least at the level of an entire discipline. How can being correct even matter under such circumstances?

63. **fuzzy**
August 20, 2013

hi lee smolin,

i would like to ask you to elaborate your point concerning "falsifiable predictions" based upon "cosmological natural selection".

can you provide me with the proof of the upper bound you have cited? what are the uncertainties in the prediction? moreover, can you recognize or not a quark star with a neutron crust (that can be a rather heavy object) from a "true" neutron star, on observational bases?

thanks

64. **Lee Smolin**
August 20, 2013

Dear Fuzzy,

The argument is in many places beginning with my 1992 paper and my 1997 book. For a recent discussion with references see http://arxiv.org/abs/1202.3373.
The relevant calculations of the UML of a kaon condensate neutron star are not mine, they are discussed in James M. Lattimer, M. Prakash, What a Two Solar Mass Neutron Star Really Means. 4. arXiv:1012.3208 , to appear in Gerry Brown's Festschrift; Editor: Sabine Lee (World Scientific)

I haven't thought about how a quark star might be produced or distinguished observationally. Is there a plausible argument that one might be the remnant of a supernova?

65. **Tmark48**
August 20, 2013

> The multiverse, along with the anthropic principle, in some sense "explains" fine tuning to me, and I like that. It is not traditional science, but it is not religion either. If, someday, fine tuning can be explained without these concepts, I will be happier.

–
It explains jack shit. You say it is not traditional science implying that it is some kind of science. No, it is no science at all. I think scientific faculties should start doing a very heavy selection in terms of students that want to start a scientific career. Start explaining to them what the scientific method is all about. It seems an ever increasing percentage of those students (especially those that go into theoretical high energy physics or theoretical cosmology) suddenly forget this principle. So when are you going to discredit Galileo ?

66. **Neil**
August 20, 2013

Tmark48

I was careful to say that it "explains" it to me. If you think my standards of explanation are too low, fine.

The point is, there are levels of explanation. Dark matter is a good example. We do not know what it is, and have not isolated a single piece of it, yet it provides an "explanation" for things that cannot be explained otherwise.

It may be that the dark matter explanation is completely wrong and a better explanation will be discovered. Actually, I hope so. Likewise, and perhaps more likely, the multiverse will not be needed. For now, they are explanations.

67. **fuzzy**
August 22, 2013

dear lee smolin,

i understand that you have not exhibited a proof but an argument, however, i am sorry, but i fail to find it convincing. when you state: "as low as possible", you mean: "as low as possible compatibly with that we know now". thus, the borderline is set from what we know now, and in fact, it changed in the course of the time. for this reason, i think that the lower bound of 2 solar masses tests the correctness/completeness of our actual ideas of astrophysics and of nuclear physics, rather than fundamental physics.

(incidentally, concerning that, i am not sure that there is a very clear idea of the uncertainties; i do not know whether also rotation might somehow play a role; the role of quark matter remains largely unknown; but this is not the issue under discussion).

thanks for the references and the patience.

68. **CVP**
August 22, 2013

It seems pretty clear that putting large sums of money into terrestrial accelerators is a game that is about over. Let's put that money to work in looking at the rest of our universe and see what we can determine. Many of the puzzles seem to involve gravity in one way or another, and our universe has a lot of gravitational (as well as other) experiments underway. I think the HEP community is having a hard time accepting that their day in the sun, and their method of working, is coming to an end.

In terms of the debates about multiverse pursuits, I think theorists, including many on this blog, have a confusion about what the word "explain" should mean. Claiming that a universe is anthropically selected from an infinite ensemble of randomly produced unobservable universes is not really an explanation of anything. They are "just so" stories. Such a hypothesis can never be true or false in any useful definition of those words. Theorists need to think about those notions. If it turns out the universe has no free-parameter explanation we can determine – OK so be it – don't create a non-explanation explanation and try to shill it for funding.

69. **martibal**
August 22, 2013

A question maybe a bit off topic (I let Peter decide) but I take the occasion of this discussion to ask something I never understood about anthropic principle/multiverses: the anthropic principle states that the value of the fundamental constants are as they are, because otherwise we would not be here to ask why the constants have the value they have, right ? But have the simulations of these universes-with-other-values-of-the-fundamental-constants been pushed so far, that one can claim with certainty that – at no point of their history – no intelligence form (difference than ours) can emerge and wonder why the constants have the value they have ? Said differently: to what extend can one trust simulations of universes with different values of the fundamental constants, based solely on the (very approximative, cf e.g. dark matter) knowledge of our one single universe ?

70. **Peter Woit**
August 22, 2013

martibal,

I don't want to encourage a rehash here now of problems with anthropics, but, yes, one of the well-known problems is that it's not at all clear that if you change fundamental parameters and get very different chemistry and nuclear physics, there won't be some way for "intelligence" to emerge from this.

Then, of course, given pieces like Siegfried's, there's the question of whether intelligence actually did emerge in our particular universe….

71. **martibal**
August 22, 2013

Peter: thanks ! Your last remark sounds like a nice no-go theorem against anthropics 🙂

72. **Evert**
September 6, 2013

I am no scientist, just a very stupid layman interested in understanding "reality" (whatever that may be). While I agree that certain theories posed by the scientific community are questionable (like string theory or multiverses), I would like to think the scientific community could transcend the notion of "war" and create a field of study of its own related to these theories rather than dismiss them to philosophy or (god forbid) theology.
We need something that is at least in part based on scientific thinking which can at some point be either incorporated into science or debunked properly rather than throwing everything in the corner of the opposite of the spectrum of thinking.

Surely there must be some middle ground? If not for the "purity" of science at least for the greater good of human understanding of "reality".
Personally (remember I am no scientist) I always thought that it was a theoretical scientist's job to concoct (forgive the undignified term) theories based on probabilities of possibilities left open by our understanding of the universe, and that it is the practical scientists job to either confirm of debunk those theories. However, based on discussions and arguments on blogs and videos all over the internet I am inclined to think I was wrong and no matter the field of science, it seems to me it is more important trying to convince each other based on arguments long before we are capable of proving or disproving something practically. This whole war seems to me a war of wits rather than a constructive means to come to an answer?
By no means do I mean to insult anyone and I apologise if I offend in any way. But it seems to me it would be preferable to have a lot of silly and contradictory theories in my inbox waiting for a time in which they can be tested, rather than wasting energy in convincing each other to be right. That been said, I understand the need for discussion since it can lead to new insights. But at this point I feel a lot of discussions do not serve this purpose any more and are more subjective than objective.
Again, I do not want to start a war of my own and by no means is this meant as critique, it is simply my observation as an idiot.
In the end, what matters is how we all (the entire human race, intellectuals like you and idiots like me) understand reality and base our lives upon it. And while I accept that certain concepts will remain enigmatic to the greater public (like infinity for example, which deludes me to no end, despite analogies of hotel rooms) in the end we want some sort of straws we can grasp, and I for one would like those straws to be tangible (at least to some extent) rather than magical or biblical.
As such I understand and am a proponent of opposite theories in science, but I fail to see the advantage of them becoming heated arguments to the point of name-calling, rejecting them to the land of theology or worse.
Then again, I may either misunderstand or be a hopeless utopian.

Two Cultures

There are two workshops going on this week that you can follow on video, getting a good idea of the latest discussions going on at two different ends of the spectrum of particle theory in the US today.

At the KITP in Santa Barbara there's Black Holes: Complementarity, Fuzz or Fire?. As far as I can tell, what's being discussed is the black hole information paradox reborn. It all started with Joe Polchinski and others last year arguing that the consensus that AdS/CFT had solved this problem was wrong. See Polchinski's talk for more of this argument from him.

If thinking about and discussing deep conceptual issues in physics without much in the way of mathematics is your cup of tea, this is for you (and so, I fear, not really for me). As a side benefit you get to argue about science-fiction scenarios of whether or not you'd get incinerated falling into a black hole, while throwing around the latest buzz-words: holography, entanglement, and quantum information. If you like trendy, and you don't like either deep mathematics or the nuts and bolts of the experimental side of science, it doesn't get much better than this. One place you can follow along the latest is John Preskill's Twitter feed.

Over on the other coast, at the opposite intellectual extreme of the field, LHC phenomenologists are meeting at the Simons Center this week at a SUSY, Exotics and Reaction to Confronting Higgs workshop. They're discussing very much those nuts and bolts, those of the current state of attempts to analyze LHC data for any signs of something other than the Standard Model. Matt Strassler is there, and he is providing summaries of the talks at his blog (see here and here) At this workshop, still no deep mathematics, but extremely serious engagement with experiment. One thing that's apparent is that this field of phenomenology has become a much more sober business than a few years ago, pre-LHC, and pre-no evidence for SUSY. Back then workshops like this featured enthusiastic presentations about all the wonderful new particles, forces and dimensions the LHC was likely to find, with one of the big problems being discussed the "LHC inverse problem" of how people were going to disentangle all the complex new physics the LHC would discover. Things have definitely changed.

One anomaly at the SEARCH workshop was Arkani-Hamed's talk on naturalness, which started off in a promising way as he said he would give a different talk than his recent ones, discussing various ideas about solving the naturalness problem (though they didn't work, but might be inspirational). An hour later he was deep into the same generalities and historical analogies about naturalness as in other talks, headed into 15 minutes of promotion of anthropics and the multiverse. He ended his trademark 90 minute one-hour talk with a 15 minute or so discussion of a couple failed ideas about naturalness, and for these I'll refer you to Matt here.

Arkani-Hamed and others then went into a panel discussion, with Patrick Meade introducing the panelists as having "different specialties, ranging from what we just heard to actually doing calculations and things like this."

Update: Scott Aaronson now has a blog posting about the KITP workshop here.

Update: A summary of the situation from John Preskill is here.

Comments

1. **MathPhys**
   August 23, 2013

   Who is Arkani-Hamed referring to at 37:50?

   *"And this is why very serious, sober theorists in the late 80's and early 90's were writing papers with super-partners discovered at LEP. They were **not** the people we won't talk about here who for 20 years were saying that supersymmetry is six months around the corner, like a translationally invariant statement. **Not** those people. Much more reasonable people."*

2. **Peter Woit**
   August 23, 2013

   MathPhys,

   I also was wondering who he had in mind. The only thing certain is that he wasn't including Gordon Kane, who surely was part of the "people we won't talk about here."

   Actually, I'm curious if there are any examples at all of theorists who in the 90s argued that naturalness meant SUSY at LEP, and then when it didn't show up, stopped promoting SUSY. All the examples I can think of just translated arguments for SUSY at LEP to arguments for SUSY at the LHC.

3. **CU Phil**
   August 23, 2013

   Hi Peter,

   I'm wondering if there's a reasonable interpretation of the first few split SUSY proposals of the early/mid 2000's that follows that line of thinking — we didn't find superpartners at LEP, so the naturalness argument for SUSY isn't a very good one, but coupling unification and the like are still compelling theoretical reasons to take it seriously.

   Of course, you might think the latter argument isn't very compelling, but I suspect it's people who continued to hang onto naturalness while allowing incrementally more fine-tuning to count as "natural" who are the people he'd be talking about. Allowing a few percent more fine-tuning everytime you don't see anything while continuing to take naturalness seriously would lead to the kind of "every 6 months" predictions he ridicules. The people willing to largely give up the naturalness argument in favor of something like split SUSY would then be the "serious theorists". The fact that he sometimes complains about people having spent far too much time and effort arguing over "how much tuning is acceptable" lends a little credibility to this.

   These wouldn't be people who gave up on SUSY after LEP, but at least people who gave up on the naturalness argument for SUSY after LEP.

4. **Peter Woit**
   August 23, 2013

   CU Phil,

Yes, that’ s one interpretation, with Arkani-Hamed giving himself as a main example. He’s right that nearly ten years ago he was arguing for anthropics, the string Landscape and non-natural split SUSY. For an example, see this talk at a Templeton-funded event on science and religion

http://www.aaas.org/spp/dser/events/archives/lectures/2005/02_Lecture_2005_0428.shtml

However, from what I remember of talks like that, a big emphasis was on his “sharp experimental predictions for physics at the Large Hadron Collider” which were about a very-long lived gluino.

Still, I’m curious if there are any examples of people who not only noticed that LEP killed the main argument for SUSY, but drew the conclusion that SUSY probably wasn’t correct, instead of just moving on to “non-natural” SUSY.

5. **emile**
August 23, 2013

I remember Guido Altarelli being very disappointed about not finding SUSY after the first LEP energy increase.

6. **Jeff McGowan**
August 23, 2013

Must say, never quite appreciated what Peter might mean when he talks about “without much in the way of mathematics.” Checked up on Mark van Raamsdonk’s talk, and as far as I could tell there wasn’t really any math at all. I mean he used some words, drew a few pictures, but wow. I mean 15 minutes into the talk, and he hasn’t even filled up two blackboards, and he’s writing BIG. Actually, that’s true 25 minutes in. At which point he has a couple of arrows indicating maps, and one tensor product sign. Is this typical? Do physicists just not like to waste chalk? Is there any actual content, or is he really just waving his hands and saying “wow, it’s cool, these things look like they might possibly be related and wouldn’t that be neat.”

7. **Scott Aaronson**
August 23, 2013

Hi from Santa Barbara. I’m at the KITP firewall workshop (the only non-physicist participant, I think), where I’m having a very nice time. In my own talk (which dealt with Harlow and Hayden’s work on the computational complexity of decoding the Hawking radiation), I took the opportunity to crack some jokes about the extreme level of handwaving that reigns here, and the airy unreality of some of the discussions.

It’s true that most of the talks have surprisingly little math in them (and, of course, zero input from any recent experiment): it’s mainly just conceptual arguments illustrated by simple cartoons. (Obviously, the cartoons convey vastly more information to Susskind, Maldacena, and the like than they do to me — but they do look funny to an outsider.)

At the same time, you (Peter) have often complained that particle theory has been dominated for ~30 years by a few ideas that haven’t worked out so well. Here, at least, there’s an enormous diversity of ideas on the table, and lots of tolerance (and encouragement) of dissent. And if you think *all* the ideas being discussed are bad ones, then there’s the obvious retort, as John Preskill pointed out in his talk: “OK, let’s hear your better ideas!”

As I understand it, the issue is actually pretty simple. Do you agree that
(1) the Hawking evaporation process should be unitary, and
(2) the laws of physics should describe the experiences of an infalling observer, not just those of an observer who stays outside the horizon?
If so, then you seem forced to accept
(3) the interior degrees of freedom should just be some sort of scrambled re-encoding of the exterior degrees, rather than living in a separate subfactor of Hilbert space (since otherwise we’d violate unitary).
But then we get
(4) by applying some suitable unitary transformation to the Hawking radiation of an old enough black hole *before* you jump into it, you ought to be able, in principle, to completely modify what you experience when you *do* jump in—an apparent gross violation of locality.

So, there are a few options: you could reject either (1) or (2). You could bite the bullet and accept (4). You could say that the “experience of an infalling observer” should just be to die immediately at the horizon (firewalls). You could argue that for some reason (e.g., gravitational backreaction, or computational complexity), the unitary transformations required in (4) are impossible to implement even in principle. Or you could go the “Lubosian route,” and simply assert that the lack of any real difficulty is so obvious that, if you admit to being confused, then that just proves you’re an idiot. (Yes, I did see your comment about Lubos’s dismissal of the issue making you think there might be something to it after all!) AdS/CFT is clearly relevant, but as Polchinski pointed out, it does surprisingly little to solve the problem.

At any rate, thinking about the “Hawking radiation decoding problem” already led me to some very nice questions in quantum computing theory, which remain interesting even if you remove the black hole motivation entirely. And that helped convince me that something new and worthwhile might indeed come out of this business, *despite* how much fun it is. (Hopefully whatever *does* come out won’t be as garbled as Hawking radiation.)

8. **piscator**
August 23, 2013

I find this a bit funny, because Arkani-Hamed is the one person more than anyone else in the field I would pick out as guilty of making regular claims about imminent spectacular signals of new physics – mm-size extra dimensions, stopped gluinos, lepton jets, GeV-scale dark forces…how is split susy not a version of ‘susy is just round the corner’?

9. **wolfgang**
August 23, 2013

@Scott

Since super string theory is indeed the theory of everything, and in particular the only theory which predicted gravity, it will tell us any minute now the correct answer …

Btw I for one would go with “the unitary transformations required in (4) are impossible to implement even in principle” …

10. **Anonyrat**
August 23, 2013

Or a Motl-approved paper (“not self-evidently wrong”)
http://arxiv.org/abs/1308.4121

> “by Nomura, Varela, and Weinberg, three physicists who were previously pointing out that the black hole firewall arguments were flawed because they didn’t treat the superpositions of macroscopically distinct states of black holes correctly, among related “interpretational” flaws.

Today, they present an explicit qualitative model of the black hole microstates that is compatible with the unitarity, the locality at long distances, and the equivalence principle. The firewalls are absent and a smooth horizon is present at all times with the probability 100%."

11. **DimReg**
August 23, 2013

Scott,

What you described seems to be the EPR "paradox" in a fancy setting, unless I'm not understanding something. You could, for example, have two entangled electrons on opposite sides of a lab. You measure the spin of one of them, then walk across the room and measure the spin of the other, (which you already know the result of because you measured the first spin). In this case, your first measurement has "altered" the second, and you did so non-locally. I don't really see how that would be different than what you just described, so my feeling is that there is something important about the event horizon that you haven't mentioned.

(To be fair, the EPR paradox was trying to show that QM implied faster than light influences, not non-local ones, but the resolution seems to be the same: the first measurement only allows you to predict the second measurement, not change it)

12. **Scott Aaronson**
August 23, 2013

DimReg: No, it's completely different from EPR. EPR is about entanglement, which (as you correctly point out) cannot be used for faster-than-light signalling. By contrast, if you believe in black hole complementarity, then you don't believe that the interior degrees of freedom are entangled with the exterior ones: you believe they're the SAME degrees of freedom! So in particular, you should in principle be able to signal "nonlocally" from the interior of the hole to the exterior or vice versa. And that seems to be the source of the problem.

Anonyrat: So, which part of the argument I tried to summarize does that paper reject?

Peter: I can take these discussions to my own blog if you consider them off-topic…

13. **Peter Woit**
August 23, 2013

Scott,

This post wasn't intended as a criticism of the KITP workshop, or this area of research in general, or at all a claim that these are bad ideas being discussed. The world is full of all sorts of interesting and valuable things being done that are "not my cup of tea". All I was doing was explaining part of why personally I haven't been willing to put the time into thinking about such things and being able to comment knowledgeably on them (the other part is the same generic reasons my interest in all QG research is limited). I've seriously got no idea how useful the insights about quantum gravity coming out of thinking along these lines might be. One definite positive thing one can say is it seems to be keeping some of the participants busy who otherwise would be out putting the torch to science (i.e., promoting the multiverse).

Thanks for the very lucid summary of the paradox. I'm happy to have you answer questions from people about this here if you want to, that's on-topic and not something I'm equipped to do. If you find you'd rather use your blog for this, that's fine, will redirect traffic over there.

14. **Igor Khavkine**
August 23, 2013
